The assessment of building safety level, as well as the necessity and the suitability of eventual retrofits, has to be risen from the comparison of the structure capacity, evaluated as the result of qualitative and quantitative knowledge of the building, and the seismic action demand, as a reasonable safety level function. This comparison can be carried out at different accuracy levels, from a territorial seismic analysis (LV1) to the much more complex structural analysis of single buildings (LV3). Restoration policies firstly need the evaluation, in reasonable times, of the safety level (LV1) of the buildings in the most seismic areas. This assessment can be performed by simplified methods that are different from the specific ones used in the strengthening design. The P.C.M. February 9th, 2011 Directive "Cultural heritage seismic risk assessment and reduction with reference to the Italian national building code N.T.C. 2008" [2] identified some simple mechanical models, to be used for performing the territorial seismic safety evaluation (LV1) of the most common buildings types. The adoption of these models, even with uncertainty, has the advantage of providing a reliable and comparable assessment on territorial scale, just significant to the planning purposes. More valid estimates on individual buildings require, however, more sophisticated analysis methods. The seismic safety index I_S can be estimated using a procedure requiring only the building geometry knowledge. I_S greater than 1 indicates the building to be able of withstanding the reference seismic forces, provided by the seismic code; on the contrary if I_S is lesser than unity, the building safety is lower than that prescribed. A building safety level, representing the necessity of interventions, can be computed as the ratio of the structure capacity, assessed as a result of a qualitative and quantitative building knowledge, to the seismic demand, suitably modulated as a function of reasonable levels of protection. Therefore, similarly to the index I_S , it can be defined an acceleration factor f_a , defined as:

$$f_a = \frac{a_{SLV}}{a_{g,SLV}} \quad (1)$$

where a_{SLV} is the ground acceleration leading to the achievement of the building ultimate limit state (SLV), related to the type A subsoil category, computed as a function of the fundamental period of vibration T_1 of the structure, as follows:

$$a_{SLV} = \frac{S_{e,SLV}(T_1)}{S \cdot F_0} \quad T_B \leq T_1 \leq T_C \quad (2)$$

$$a_{SLV} = \frac{S_{e,SLV}(T_1)}{S \cdot F_0} \cdot \frac{T_1}{T_C} \quad T_C \leq T_1 < T_D \quad (3)$$

whereas $a_{g,SLV}$ is the design ground acceleration, corresponding to the assigned return period of the earthquake, still related to subsoil A.

The ordinate value of the elastic response spectrum $S_{e,SLV}$ is calculated as follows:

$$S_{e,SLV} = \frac{q \cdot F_{SLV}}{e^* \cdot M} \quad (4)$$

where q is the behavior factor, F_{SLV} is the lower building shear strength, e^* is the mass fraction participant to the first mode of vibration and M is the total seismic mass.

The shear strength F_{SLV} of the building is computed on the base of the walls shear resistant area at the i -th floor. The masonry walls stiffness and resistant homogeneity, the walls predominant failure type, the masonry spandrel beams strength, and the plan irregularity are taken into account by suitable coefficients. Furthermore, the evaluation of masonry building seismic safety must be performed both with reference to the building behavior, controlling the entire structural system strength capacity, and with reference to local collapse mechanisms, controlling the out-of-plane failure of walls and masonry portions.

2.1 Seismic safety of Liberty buildings

According to the above briefly described procedure, outlined in [2], by considering the geometric features of the Liberty buildings on the Vomero hill, the acceleration factors f_a of nine palaces were computed. These palaces were chosen as the most representative in terms of building geometries and openings; their plans are reported in Tables 1 and 2. Table 3 contains the indexes computed for earthquakes acting on both directions (longitudinal x , and transverse y) and assuming a confidence factor of 1.35 (corresponding to a complete survey of the building geometry and a limited knowledge of the mechanical properties of materials). The acceleration factor f_a is computed through Eqn. (1) according to a seismic safety level corresponding to buildings of limited relevance and class of use normally crowded (Class II); a ground motion acceleration of 0.093 g and a B/C soil class are assumed. The fundamental period of vibration was computed as $T_1 = C \cdot H^{3/4}$ where H is the building height and C was assumed equal to 0.05. In addition, factors in Eqns. from (2) to (4) were assumed as follows: the S coefficient equal to 2.1, the F_0 factor equal to 2.713 and the q behavior factor equal to 3.6. The outlined results show f_a values lower than the unity for all the examined buildings; the lowest values are exhibited by *Palace in via Parco Grifeo* and *Palace in via Lordi* in the y -direction. This is due to the extended development along the x -direction and few resistant walls along the y -direction. On the

| Buildings | Acceleration factor f_a | |
|--------------------------------------|---------------------------|-----------|
| | $f_{a,x}$ | $f_{a,y}$ |
| 1. <i>Villa La Santarella</i> | 0.58 | 0.87 |
| 2. <i>Villa Lorely</i> | 0.62 | 0.72 |
| 3. <i>Palace in via Palizzi</i> | 0.58 | 0.6 |
| 4. <i>Palace Russo Ermolli</i> | 0.63 | 0.55 |
| 5. <i>Villa Catello-Piccoli</i> | 0.58 | 0.65 |
| 6. <i>Palace in via Parco Grifeo</i> | 0.77 | 0.45 |
| 7. <i>Villa Spera</i> | 0.7 | 0.74 |
| 8. <i>Villa Pansini</i> | 1.0 | 0.83 |
| 9. <i>Palace in via Lordi</i> | 0.58 | 0.44 |

Table 3. Acceleration factor f_a of the examined buildings

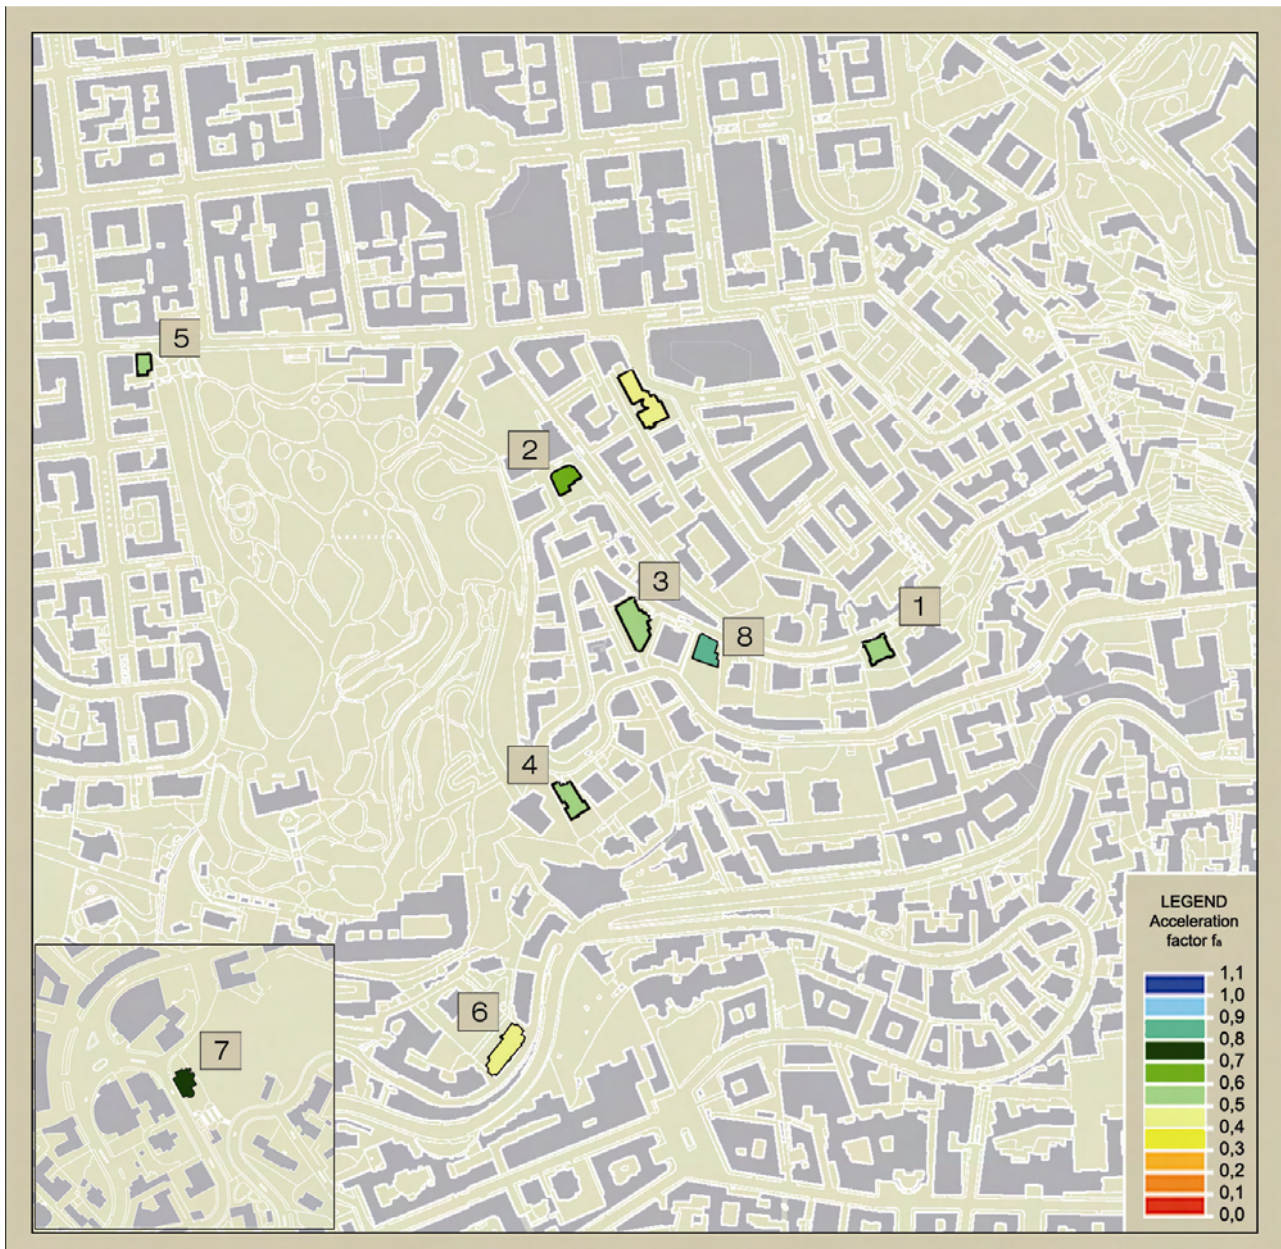

Figure 2. Map showing buildings with colours of their acceleration factor f_a

contrary, *Palace in via Palizzi*, *Palace Russo Ermolli*, *Villa Catello-Piccoli* and *Villa Spera* exhibit the same behavior in both directions. Despite its compact plan, *Villa La Santarella* has a strongly different behavior in the two main directions because the resistant walls along the x-direction disappear completely in the upper stories. *Villa Pansini*, which has an almost squared plan and similar wall distribution along the stories, exhibits an acceleration factor value close to one in both directions. The validation of the results obtained by the above LV1 analysis was previously verified by the authors with respect to the building typology, and in [4] with respect to industrial buildings. Such validation was carried out by comparing the LV1 simplified analysis with more sophisticated methodologies. Result are also shown in the Figure 2, each building is colored according to its acceleration factor.

3. Conclusions

Several roads with liberty palaces built at the beginning of the twentieth century are present on the Vomero hill in Naples. These buildings are representative of the liberty movement, marked by a construction asymmetry and plan freedom. Restoration policies cannot neglect the structural safety, requiring the knowledge of the seismic risk of existing buildings. This paper was aimed at investigating the seismic safety by simplified procedures (LV1). As a matter of fact it has to be highlighted that most of existing buildings were designed and built to resist primarily the vertical loads. Therefore many of them do not appear suitable to resist seismic events, and could undergo damage under earthquakes. The above results also underline that the studied buildings appear more vulnerable to transversal seismic loading, mainly if the plan layout is rather long and transversal walls are widely open or absent.

Cities in translation: the shapes of Earth

Corrado DI DOMENICO

Dipartimento di Architettura, Seconda Università di Napoli, Aversa, Italy
corrado.didomenico@unina2.it

Abstract

A reversal of meaning that translates the idea of the city in a geological and stratified vision, complex and labyrinthine, made by far associations, like forms changed as rocks. From here, the analogy with the metamorphosis of the natural and anthropic elements suggests a *new state of the housing*. So, here will be shown drawings and visions of new cities that demonstrate a city-making compatible with the shapes of the Earth, from the large to the inner landscapes, as a 'metonymic' image of the urban form. It's a kind of discourse that points to the 'sustainability' as a concept related to Art as the higher state of the Nature, before than the matter of environmental preservation. Spaces of the city and shapes in the landscape will be intended as a relationship between masses, exactly like the ancient concept of architectural space, as an 'inside landscape', as well.

The urban form, the clarity of architectural plans, it's now no longer detectable for all the cities, and cities' shape is no longer an „idea“, no longer envelops a vision, except that one interconnected to a grotesque and global media narration. Cannot trace any edges, domains, spatial relationships.

It's from here that we can start a thinking, as if from its ending: by zenithal views from the satellites that are available today in every still-motion trip of a data connection. From there, opens up a new vision, unthinkable combinations of figures, new and clear relations between the city and the forms of the world.

Keywords: City-making, Earth-forming, Space, Ancient traces.

Introduction

«[...] So that world and space seemed the mirror of each other, both minutely adorned with hieroglyphics and ideograms, each of which might be a sign and might not be: a calcareous concretion on basalt, a crest raised by the wind on the clotted sand of the desert [...] In the universe now there was no longer a container and a thing contained, but only a general thickness of signs superimposed and coagulated, occupying the whole volume of space; it was constantly being dotted, minutely, a network of lines and scratches and reliefs and engravings; [...] because it was clear that, independent of signs, space didn't exist and perhaps had never existed». [CALVINO, Italo. *Cosmicomics*, (Translation by William Weaver), Penguin UK, 2009. *Le Cosmicomiche*, 1965]

Developing a theory: from the horizontal view -through the spatial prototype -, to the vertical vision, the plan of the system into the landscape. A so faraway ancient and a so close contemporary view.

City making: projects, models: pieces of cities, clods and islands, horizontal housing units. The landscape as an architectural problem.

Translating Earth Images: satellite views, coordinates and shapes. Landscape and figures: a circular vision.

1.1 Space, three views

A small court crops the essential space of Nature, 'stolen' to the landscape, aligns to the rooms in a perspectives sequence that sights lived places and other courts. Three points of view, which enclose as many visions of Nature, mutated into architectural form: the organised nature, in private courtyard, the nature as a vision outside the space -in glimpses that embrace the landscape- and the changing nature of the zenith view to the sky.

The first view encloses the horizontal plane of the gaze into a basin, in an open sky room; the second allows an escape, a removal, and rotates the head toward the horizon to align, with a detour, the glimpses; the third view breaks at the top and correlates the axes' triad by reconstructing, on the visitor vertical centre, the decomposed spatial cube. Could be an house. The most complex, spatially, but the most simple, architecturally.

From visual crossings of the houses of Pompeii, where the perspective progression breaks visual diaphragms, and alternation of light and shadow, to further sliding of the views in the houses of Mies van der Rohe, the interior space around the court, between the courts, is a labyrinthine path that describes the *intérieur* as the original and transverse prototype in architecture. In Mies, in its houses, the three levels of spatial vision (the nature, the nature stolen to the landscape, the nature crystallized from inside) are simultaneously passed through one perspective that describes the complexity of the horizon as a foreshortening from inside the house that serves as a center (Hubbe house). The Seagram, which is a skyscraper, is positioned to slide horizontally on the platform of the urban basement, creating an unexpected place on Park Avenue and a roof garden on the 51th St.

From the precinct to the thresholds, it's a whole science about the progression of a path through the space that is discovered from architecture by its horizontal planes of penetration and its projection planes. The space disappears in full consistency of transparency. Overlapping and blurring of vision planes.

The studies by Le Corbusier for the plans of the *unlimited growth building*, represent a theorem for axes path stalking, where from the presence of thresholds, hallways and walls, appears a map that defines the scope of the Cartesian approach to the spiral path of the museum. «*Le musée n'a pas de façade, the façade visiteur it will jamais, it will que the l'intérieur du musée*» [1]. A building-threshold: the same conception of space in Egyptian architecture, where the crossing areas, diaphragmed by fences and gates, build an *Interieur*, till its exterior and, like in a time-passage through the space, to arrive unexpectedly in the museum, fully heart of its tortuous and wide place at once, without interruption (fig. 1).

Fig. 1: Le Corbusier, *Musée d'Art contemporain*, Paris 1931

Even the villas by Schinkel are based on the horizontal science of geometry to create buildings that are already architectural systemic space and *inner landscapes*. So, in Charlottenhof (fig. 2), the axial access path is interrupted perpendicularly to the base of the porch, causing the visitor to divert, to turn around the exedra, foreshortening the classical facade of the main building to an higher level - determined by the inclined plane of the garden-, to find themselves, then, at the center of the exedra, in axis with the water canal, already inside the theorem of an *architecture-landscape*.

A space built by points of view (Greek space) on a scientific diagram of the positions and rotations in the horizontal plane of the plan. Everything is designed in the plan and studied by the perspective.

The architecture is the field of spatial behavior on the plane. Emplacements and positions which geometrically relate the points of view, the objects, the parts of the system-building.

Fig. 2: K.F. Shinkel, *Schloss Charlottenhof*, 1829. Sketch plan with paths diagram.

Pathways and labyrinth, forwarding of precincts which breaks thresholds, are like step by step progressive veils that organize an accurate spatial concept and an horizontal view of the space, designed as a map from its rules. Human horizontal vision and vertical look of architecture.

Perfectly Egyptian, exactly Greek, space is at the origin of architecture that is built over time through its prototypes, its heuristics that progressively define the patterns qualities of the forms.

The importance of Greek temples base platforms, that define a relationship of intertwining of the building with the mutability of ground line in the landscape, imposes a horizontal center, which departs from *crepidoma*, from which branches off the visuals through the columns. At Miletus, the *Didymaion* (Temple of Apollo) presents the fluted base of the columns with a myriad of torus moldings, which multiplies the horizontal plane of the column base, in a progression of rising horizon, all contained in a complex order (fig. 3).

Fig. 3: Mileto, column of the *Didymaion*, VI cent.

The temple of Apollo at Delphi, however, already in high position, lying on the floor of a natural *cavea* between the steeped shapes of the sacred hill, represents the culmination of a tortuous path (*climax*), that climbs, and duplicates the natural base in a very elevated platform, that makes the temple jumping directly *in* the landscape of the great plain, like a trampoline, a flattened fold of the rock. The horizon and its goals are literally stuck in the oblique plane of the rocks and the temple becomes center and new hinge threshold.

In this relationship with the natural elements, exactly by the way of changing ground line of the Delphic space, Jörn Utzon's designs for Elviria (*fig. 4*) show a planar geometrizing of the oblique lines of the hills, as if drawing the cut plane of architecture, in the image of an *horizon* embedded into nature. The relationship with the landscape is crucial, in ancient times for symbolic and religious matters, for the construction of architecture as its own spatial interface, as its own system of interpretation and duplication, just like a process consisting of container and contained.

Two horizontal models: the Greek temple as the construction of concentric thresholds that leave the cell spreading to the countryside, which immediately acquires the function of overlooking -or *panorama*- and the Egyptian temple as a linear progression of thresholds in a complex of shadows, where the sky is painted on the ceiling.

It's a space based on the fidelity of the horizontal view, the main breaking direction of the gaze and its routes, and geometric order related to the law of gravity, lead to the vertical, which reconstructs the triad of Cartesian space and places at the center of the world (*megaron, onphalos*, precinct, court) every waiting position between the distance of thresholds.

Fig. 4: Jörn Utzon, Competition scheme for *Elviria*, 1960.

1.2 The ancient vertical view of the plan

In ancient times, the architectural form was, certainly, built as a branch of nucleuses or fences, steps and passages based on discovery and approaching paths, all interpreted as axially and slidings that penetrated the landscape in the system of natural elements, but it was also a symbolic form and diagram built as if it were seen from above. Let's see how the vertical connection between earth and sky, with its cultural values, was a key factor in defining a spatial center and how that was the focus of expansions (visual and functional) of the plastic form.

The zenithal view was a shot of imagination which contained the mental image, or an approximation figure close to the concept, to the symbolic content that the landscape context wanted to get through. Some Leonardo's studies about damming the Arno are exemplary: it's bird's eye perspectives, unbelievable for that period, which organize a conceptual representation of the area (*fig. 5*).

Movement and determination of a privileged position are dynamic and construction of the points of view. Thus, we can imagine, draw perspectives that pass through visual thresholds between courts and walls,

Fig. 5: Leonardo da Vinci, *Bird's Eye Perspective for a Planned Dam on the Arno*, drawing, ca. 1504

intricate spaces of the precincts. The 'one meter and sixty' horizontal cutting plane determines the vision of the eye as movable and compositive centre. As if from the ancient Greek space, from the *Hermes* and *Hestia* spatial dialectic, to now, we can find a contiguity with the aerial views which bring again to our attention the importance of the spatial systems into the landscape.

In the book written with Benno Albrecht, *I confini del paesaggio umano*, Leonardo Benevolo says that in the design practice, what accompanies and guides the thought, are the abstractions that we call *figures*. «Some of them are descriptive and general, as 'environment' or 'landscape' and not prelude to an attitude that faces any problem. Others, will assume, as early as their formulation, more operational values, such as 'scale' or 'border', 'confines'. The mental figure is versatile [...], it's immediate, fast imaginable, and highlights a peculiarity of project thinking: to proceed by images. In design practice, the figure acts as an initial condition. [...] The word 'border' can take these features, and be a mental figure for the project» [2].

The architecture was built by demarcation of boundaries and the plan was the *figure* or the mental diagram of boundary vision from above. This determined the system that was to be automatically interpretation of the site, as each site was designed from its origin, the border, the mental image. The landscape itself was a cultural image linked to the overall vision of the world -the site of the project, the foundation site are always a new center-, and the architecture was the symbolic definition of a precise *nomos*.

So, for Carl Schmitt, «for thousands of years mankind had a mythical image of the earth in its totality, but no scientific experience of it» and, thinking about the old maps, the representations of the known lands, we see that kind of mental and cultural image of terraqueous globe, is a complex vertical view of the sites seen from above. We can add that, perhaps, just the architecture was that scientific experience for the definition of the laws of nature and the worldview, and those passed by the definition of boundaries, areas, enclosures, posts and domains, such as markers seen from the sky or symbols of a taking position of the world. Sighting boundaries crossing thresholds as the expansion of the circles in the water. Spatial domain based on the vertical axis of the mental vision from above. Archaeological Plans of a timeless vision of the space.

1.3 Earth-forming

«The border is independent from the concept of scale and does not fall in the statement what Gulliver tells, commenting on the size of the kitchens of Brobdingnag: Undoubtedly philosophers are right when they say that nothing is great or small in itself, but comparatively. They are so similar to each other, the border of a state, that of a city or a small private space» [3]. The urban form, the clarity of architectural plans, it's now no longer detectable for all the cities, and cities' shape is no longer an „idea“, no longer envelops a vision, except that one interconnected to a grotesque and global media narration. Cannot trace any edges, domains, spatial relationships.

The ancient cultures land art, disappears by the meshes of the city. «In the Neolithic period, the signs of human presence are multiplied on large areas of natural empty landscape, and form a very extended range, up to a geographic scale, which seems huge to us, and in fact remains unsurpassed throughout the subsequent history» [4].

It's from here that we can start a thinking, as if from its ending: by zenithal views from the satellites that are available today in every still-motion trip of a data connection.

From there, opens up a new vision, unthinkable combinations of figures, new and clear relations between the city and the forms of the world.

Perfect shapes appear through the deserts and the formless reveals itself between the areas of the city. The relations with the large-scale, that in ancient times were symbolic, re-open, and now can reveal a new 'mantic' of places to translate and to trace shapes and geometries. As if through archaeological plans and sacral marked places.

The idea of an *informal and abstract poetic* allows us to consider the architecture as it appears objectively in its formal mutations. The zenith view of the space will clarify the presence of the architecture in the same way as the anthropic environment that extends between the cities by its geometric rules, and will start a thinking to redefine an *architecture of the earth*, a new way to see the geography, like a system of architectural forms, spaces converted into geography, like cities translated into landscape.

Fig. 6: Paul Rudolph, *Orange Government Center*, NY 1963-70, axonometric view.

Fig. 7: Candilis-Josic-Woods, *Freie Universität*, Berlin, 1963. View of the model.

It's as if, since then, the visual perspectives were concentrated in a single focal point that overturns the traditional view in any asymptotic perspective that will definitely change the perception of space. Many design experiments, from the satellite architecture of Paolo Soleri, to the city that are related to large scale landscape of Candilis and Woods (*fig. 6*), or to architectural geminations of Paul Roudolph (*fig. 7*), introduce a conscious desire to work on large territorial systems or tilt the balance of size that architecture had with the world.

It was as if everything was visible from a distance. As a metonymic process, in a close relationship between container and content, the various landscapes intersect each other at different scales, like an image inside another which describes a process of generation of the shape. An earlier record for this kind of forms behavior was investigated in a study of the couple Charles and Ray Eames, in the film *Powers of Ten* (1968), whose circular vision from large to small and vice versa, seems to confirm the discovery of vision vertically acquired from Earth seen from the Moon. A sort of theory that develops a concept related to scale relationships that exist between the landscape and the things, at all levels, where the «*Scale is the new geography*».

Here we can find a circular discourse from the Earth-shapes to the landscape as a spatial system, from the cultural presences which innervate the system of colours and objects to the architecture. So, for instance, in Le Corbusier's *Carnets*, it's clearly defined that the colours of Chandigarh are derived from the nuances of tone traced by the aerial views, and the city plan is related to the texture of an Indian bed. This is the circular view of the architecture. You can call it 'landscape' or 'plan', but the matter is how deep is the vision of the content.

As if from a distance we were able to recognize a shape to everything. A general beauty, a unit of work to the scale of satellites. At a certain point, latent forms and marks appear on the surface of the earth, which, together with other tracks, become synopsis. A world of signs, interrupted tracks, forms in composition and disaggregated figures, that show us, unbelievably, a marked space, a talking space more than spoken, a manifold and iridescent set, from place to space. That's the zenithal vision, this new gained view, which plays the small and the big in a perspective asymptote, not in "*bigness*". That's a call to collection of forms.

We can recognize forms by association, aggregations or repetitions, similarities with other forms or with objects, seems to be faced to a formal tautology, between life and nature, architecture and the earth's crust, you can find a continuity. *Translating the forms in cities* were a "primitive future" can aggregate the archaic and the contemporary in a syncretic image drawn by present peaks and past folds.

The forms of involuntary shapes of the world, as if from a far landscape, seem similar to voluntary forms of art, and the anthropic traces design a clear map of a mental and cultural city. There is a metamorphosis of natural elements which is important to trace because suggests us the state of the form.

So, what is the image of the world that, today, the Architecture can contain?

Abstract

The preservative restoration of the great work of Pericle Fazzini (1913-1987), entitled *La Resurrezione* in the Aula Paolo VI at the Vatican, has involved the workers of the Fonderia Del Giudice (Nola), and (for free) the authors of this paper, as researchers of the Faculty Architecture "Luigi Vanvitelli" and of the Benecon Research Center, for over seventy days.

The University contribution was orientated towards the scientific project of its conservation and restoration, as well as providing a repertoire of diagnostic tests that have supported the intervention protocol, appropriately designed, applied by the Foundry and confirmed by the Directorate of the Vatican Museums and Laboratories.

The essays describe the multidisciplinary methodology, analytical operations as well as techniques that have marked all the development and implementation phases of the preservative restoration, from concept to project, from shipyard to communication. At the same time, particular attention was given to the spectacular architectural space designed by Pier Luigi Nervi.

In line with the Tenth Forum topics, the work was inspired by the minimal intervention – remote analysis and non-invasive interventions – accurately planned, for the best expected result, that has returned the dazzling image to the statue as Pericle Fazzini has realized in a mixed alloy of bronze and brass. The work has also provided material and structural integrity of the articulated metallic mass.

Keywords: Contemporary Architecture, Multicriteri@, Conservation, Remote sensing, Bronze

1. Foreword

The site of the restoration of the masterpiece by Pericle Fazzini entitled "The Resurrection", opened on Wednesday, September 28, 1977 by His Holiness Pope Paul VI, started work on Monday, October 3, 2011 and ended on Tuesday, December 13, 2011. Promoted by the "Fonderia d'Arte 2000 s.r.l.", represented by Giuseppe Farina and Dr. Antonio Del Giudice, approved by the Directorate of the Vatican Museums Director, Professor. Antonio Paolucci, in conjunction with the bronze restoration laboratory of the Museums headed by Dr Flavia Callori, in collaboration with restorers from the Istituto Centrale per il Restauro, coordinated by Dr. Emiliano Africano, graduated from the same Institute in the specific sector, as well as with the scientific direction of profs. arch. Saverio Carillo and Danila Jacazzi of the Faculty of Architecture "Luigi Vanvitelli" of the Second University of Naples, using the instruments of the Centre of Competence Benecon at the Second

University of Naples directed by prof. arch. Carmine Gambardella with the technical coordination of the architects Pasquale Petillo and Pasquale Argenziano, the technical collaboration of Eduardo Fiorillo and Donato Marcantonio of Topcon Italy and the external help of prof. Engineer. Vincenzo Sepe of the University “Gabriele d’Annunzio” of Chieti-Pescara. The particular of condition the work of art, its location and use have influenced and even defined the time required for the interventions to be carried out, in relation to both the specific conservation needs of the monument as well as to the use of ergonomic resources. Thus, many of the tasks that should have been carried out in advance, due to the amount of time available and commitments of the Aula, were carried out, in part, simultaneously and synchronously with the other interventions on the monument. In many ways, therefore, the work carried out, and could not be otherwise, was a privileged opportunity to study the precious relic considering that a *proper restoration* would have taken much longer with a series of preliminary investigations that would have compromised, at least partially, the use of the Aula, obviously creating a series of complications.

2. Representing Knowledge in the Restoration and Protection of Cultural Heritage

Carmine Gambardella

The restoration work on the masterpiece by Pericle Fazzini, "*The Resurrection*", one of the most significant works of art of the papacy of His Holiness Paul VI, lasted more than seventy days, ending on December 13, 2011 and with several professors from the Faculty of Architecture as well as the Competence for Excellence, Benecon contributing to this essay.

The research was carried out with the support of innovative technologies and is based on the concept that any action for the protection, maintenance and improvement cannot be separated from a preparatory activity of multidimensional knowledge based on the discretization and extent of the heritage. Even in this case, widening the traditional notions of geometry and measurement, a complex representation was produced, with every element of the subject, material and immaterial, defining a dimension that contributes as a whole of the competencies as given to the state of the art always detectable and, similarly, is a reference for future maintenance and restoration activities.

The dimensions are the disciplines that contribute to the understanding of the complex phenomena of decay that, interacting, re-establish a model for understanding the integrity of the object under examination. The scientific corpus has as reference a discipline that is the basis of our investigations, "Echogeometry", intended as a technological echo of reality, a model where it is possible to measure all the tangible and intangible relationships between the elements, in order to return, the objects or parts of them, the architecture as constantly evolving dynamic entities in light of the safety and transmittability of the works themselves in the future.

Fig. 2: La Resurrezione. Orthographic projection by point cloud model (Benecon).

With this approach, the results of the studies are not given though the summation of individual, monothematic knowledge, but rather a complete understanding of the data, in which all the information is qualitatively and quantitatively, integrating the complex knowledge of the object or part of it. Each point is no longer described only by the Cartesian coordinates that define its position in the space, but rather by multiple information obtained from the studies carried out in several disciplines that contribute to the capitalization of the data. Thus, the echogeometric approach makes it possible to "measure the whole", i.e. to recognize the basic characteristics of the identity of objects, architecture and landscape through the reading of the signs

translated into experience that, on different scales of investigation, not only concern objects and buildings, but also environmental systems, ecological networks, watersheds, coastal systems, historical landscapes, types of settlement and production, as well as agricultural fabrics, all the characteristics whose loss or degradation may affect the protection. Multidimensional representation is a fuzzy boundary between what has already been done and what there is to do, including all the dimensions that are useful for the knowledge of an object on both a small and large scale. It already contains the prediction of possible changes, proposing scenarios for reliable scheduled maintenance, monitoring, protection and regeneration. The innovation of this approach is based on the production of a complex and dynamic system of knowledge, articulated so as to allow for the production of a wide series of discretizable information. The method has a general validity, having been tested and applied in different contexts as well as at different scales, from individual products to the territory, from Pompeii to the Nativity Church in Bethlehem, the Pio Monte della Misericordia in Naples to Michelangelo's David statue and the statue of Pan and a goat in Ercolano, and now, the Resurrection by Pericle Fazzini. The integration of multidisciplinary knowledge and skills (restoration, representation, history of architecture, chemistry of materials), were applied as an essential prerequisite for the managing of the planned restoration. The activities that were conducted in constant synergy with the research groups, related to the subject areas involved set up a field laboratory, producing a fully-integrated, multidimensional and multi-scale digital representation.

Furthermore, the investigation has also had a strong educational value. In fact, PhD students of the Faculty of Architecture, with the associated Center of Excellence Benecon, were involved in research alongside professors and senior researchers and were able to have a significant learning experience. When research orientates teaching, the University produces a higher quality of human capital, with cultural assets of our territories requiring skilled operators who can draw from the humus of our identity the talent they need to create the job with Art.

In conclusion, I hope that our research can be placed within the limits between a broadly Cartesian view of an object and the intense one of Leibnitz. on the limit as a place, as a topos of the research project, the development of knowledge has been entrusted to a dynamic concept that, in order to overcome metaphysical obstacles, proposes spiritual and patrimonial scenarios based on our roots.

Fig. 3: Christ contour lines model, detail.

3. Conservation project, cleaning interventions and restoration protocols

Saverio Carillo

A first definition of the time required to carry out the cleaning of the sculpture was calculated on the basis of its size, with it being about 7.60 metres high, 16.60 metres long and 2.60 m wide. The visual investigation revealed that it is made of a copper alloy with brass fittings as well as the use of the of lost wax casting technique.

The visual investigation initially defined the state of conservation a generally satisfactory condition of the monument and upon which the first approach was based, which did not include the most beneficial and precise feedback, that was subsequently obtained after having mounted the scaffolding. The state of preservation, therefore, as a result of an detailed visual investigation led to a series of general considerations according to which the sculpture could be evaluated to be in good condition. The proposed evaluation orientated the intervention project by referring to the location and function that the monument has, due to its expressive meaning as well as complex media figure that its *image* represents.

In addition to the above considerations, there is also the principal aspect of the conservation intervention that the role of the operational tool carries out in the development of the complex modern sculpture that, due to it being so close, physically, to the focal figure of one of the oldest and most authoritative human institutions, and certainly the most charismatic figure in the Christian West, must condense the valuable contemporary decor that recognizes the role of the Petrine Throne when dealing with the uninterrupted secular continuity of over two millennia of existence.

Fig. 4: Sculpture detail.

The scientific responsibility for the direction of the restoration has therefore evaluated the coherent relationship between the technical equipment and diagnostic and operating protocols in agreement with the findings of the Laboratories of the Vatican Museums Directorate not only because of the application methods but also the anticipated results, as well as those while the work is being carried out.

On the other hand, the experience of Fazzini at the Vatican is almost at the end of a long very significant period for the Catholic Church of the twentieth century that, through one of the most archaic materials of human culture, tried to incorporate into their environment contemporary artistic expression that had previously been strongly. Similarly, the royalty and continuity value of the historical dignity of the ecclesial reality places were highlighted by the “adding” of numerous bronze valve “Doors” that were open to the advent of modernity, even at the cost of cultural controversy with the State Administration. The case of the Doors by Emilio Greco for the Cathedral of Orvieto, put in place on 11 August 1970, after eight years of waiting in the aisles, which subsequently occurred after the decisive intervention of Paul VI, explains the cultural climate a work like *The Resurrection* summarizes.

Fig. 5-6: Rome, Saints Peter and Paul Church, main bronze door details.

The complex bronze sculpture was, therefore, shown by the Holy Father on the day of its inauguration: “But we will not talk unless about the monumental and unique figure, that of Jesus Christ the risen, living and blessing, which dominates this room, and that we are inaugurating today, the work of the sculptor Pericle Fazzini: it says what the testimony entrusted to the apostolic ministry is, to be that of Jesus, who is crucified, made Man and Christ evidence that here the successor of Peter and with certainty humility of faith want to proclaim. Yes, we want to entrust this to our voice, in simple and clear enunciation of words and image that he wants to express, but almost suffocated by their exuberant real meaning (cf. THOMAE *Summa Theologiae*, Ia, 2 ad 2). Jesus is the Way, the Truth and the Life (*Io.* 14, 6). Jesus is the light of the world (*ibid.* 8, 12, 9, 5). Jesus is the Bread of life (*ibid.* 6, 48). Jesus is the Good Shepherd (*ibid.* 10, 11-14). Jesus is the Son of Man (*Mt* 16.13 *Mt* 25.31 *Mt* 26:24), is the son of Mary (*ibid.* 13, 55), is the son of God (*ibid.* 14, 33, 26, 64 *Io.* 9, 35 etc.) Jesus is the alpha and omega (*Revelation* 22:13)” (Paul VI, General Audience of Wednesday, September 28, 1977). The references and citations of the papal text are the explicit meanings that are recognized and “used”, in a functional way, of the *media machine* that the sculpture itself is jointly conceived to the immense Hall, for which the values to be specified in the restoration intervention must aim precisely to *facilitate the reading* of such peculiarities of expression.

The profound significant meaning of the work, also represented by the reading of Paul VI during its inauguration, is itself, in terms of the expressive analysis that the restoration work helps to guide and enhance, a binding trace in the direction of the entire research, including the restoration itself, cannot fail to make explicit. Specifically, the homogenous and coherent cleaning of the entire bronze surface, regardless of location or image of the single portion, should contribute, in the restoration, to the preparation of lighting that is able to fully satisfy the requirements for the use of the complex sculpture, especially in relation to it

Fig. 7-8: The bronze Christ sculpture.

Fig. 9: The bronze Christ sculpture.

being the *scene* and *crown* of the papal Throne in the action of the Magisterium exercised as a place of acceptance of the Christian Synaxis.

The sculpture, made in the Michelucci Art Foundry in Pistoia between 1972 and 1977, overall, is in a condition that can be called good. The environment in which it is located has helped to delay the oxidation/corrosion processes, thus, avoiding any consistent changes to the entire sculpture, which also has less detailed parts, over time, that could have led to irreversible superficial changes. Prior to the conservative intervention, it was entirely covered by a layer of dust and atmospheric particles with various deposits, concentrated in substantial quantities where the sculpture has horizontal planes or less inclined pronounced parts. This also occurs near the horizontal planes and in the recesses creating a “visual haze” that compromises a correct reading of the whole, rendering the “polychrome” lighting of the different tonal accents of the elaborate construction ineffective. The overall colour scheme of the entire sculpture retains the restrained golden yellow hues, sometimes with strong tendencies towards the other range, with added red-brownish nuances from the manganese on the less pronounced surfaces. The variations in lighting are, in part attributed to the different nature of the surface materials, which will be subsequently referred to, as well as to some of the treatments chosen, evidently by Fazzini to have the desired end effect. The overall image of the metal surface is affected, however, by the widespread oxidation that is, in several parts, certainly due to the composition of the alloy mixture used, various shades of white or light green.

Fig. 10: Christ's left hand, meshing 3D model processed by point cloud.

The chromatic alterations may also be an expression of an oxidation process that is still in progress, probably caused by the variations in the amount of moisture present inside the large hall that, due to its function, with it containing a large amount of people, could lead to the transformation, sometimes, of the temperature conditions, as well as the condensation effects which may induce reactive conditions in the materials of the metallic layer. Further degradation processes can be noticed in other parts, such as those of high “flashes”, caused by the casting, with the “cooking” effect or “deformed” conditions of the metal for more “serial” production. There are widespread cracks and lesions in the discretized parts of the monument that may be due to the “composition” and “assembling” operations. There are numerous untreated welds, especially at the back, that have led, from an aesthetic point of view, to unsatisfactory solutions, giving the

impression of a rather rush mounting, leaving parts of it pending that were never completely finished or deliberately left so.

The restoration involves an initial phase of documentation and diagnostics, useful for the characterization of the alloy, the present degradation phenomena as well as the planning of the intervention. The processes of the mechanical removal of the deposits and the washing of the metallic layer, illustrated in the scientific literature of protocols to be adopted, are the operating terms also on the basis of the choices considered *to orientate* the intervention. Specifically, for example, it is priority to maintain the *status quo* of sculpture, even if some of its conditions could led to specific assessments of the scientific purpose of the restoration. The case of the earth used in the casting to produce it and, in part, still present in the bronze could be an dialectic opportunity of confrontation. Similarly, the welding at the back or other aspects documented video-endoscopy which has prevailed on the basis of the logic of minimum intervention aimed at preserving the given absolute testimony represented by the work itself.

Upon concluding the intervention, between the sculpture and the surrounding environment, there will be a series of layers with barrier functions and sacrifice, upon it will be possible to intervene in order to carry out planned routine maintenance.

4. The reasons for restoration: reflections on the methodological approach

Danila Jacazzi

Why restore the Risen Christ by Pericle Fazzini just 40 years after its creation? And, consequently, why a book on the Resurrection?

This is probably the question that many will ask given the popularity of the sculpture that dominates the background of the Hall Paul VI.

As is often the case, there was no preordained reason, nor programme with a deadline or precise aims, but rather, a project resulting from the meeting and cooperation of different professionals who wanted to record in a book their thoughts and experiences during the restoration.

However, there were various reasons behind the decision to submit the well-known sculpture to a skilful restoration, which, without entering into specific details, requires some more general, critical considerations.

Over the last three decades, the debate on the arts and restoration has been variously traversed by a problem that has imposed a critical reading of traditional history in the search for intervention principles and methods: the issue of the restoration of contemporary art.

Fig. 11: Sculpture details.

Fig. 12-13: The shipyard upper level, the comparison between the picture and the point cloud model.

Art produced in the 1900s has, in fact, often used “unusual” materials, often perishable, as well as new techniques that preclude the concept of long-duration and transmissibility. The restoration intervention model was, therefore, inevitably the subject of a critical review that significantly developed the types of application. There are no doubts that the great masterpieces and artistic heritage of the modern world are an asset to keep and preserve, but the historiographical basis upon which they are compared through the studies by historians, art critics and theorists is constituted by the recognition of a methodological identity of the restoration of contemporary art with respect to the canonical theory of Brandi, elaborated in relation to the experience of the old. The *unity of methodology* principle – in which the theoretical assumptions of the restoration should universally apply to all artistic disciplines – established by Brandi, has influenced the Italian debate on the restoration of contemporary art. Although this principle has recently been questioned, the theoretical background established by Brandi in relation to the concept of restoration and its applicability is still valid:

“restoration is the methodological moment of recognition of the work of art, in its physical consistency and its dual aesthetic and historical polarity, in view of its transmission to the future”.

“As a product of human activity – continues Brandi – the work of art poses a twofold instance: the aesthetic artistic value that corresponds to the basic fact of artistic for which the work is a work of art; the historical case that implements it as a human product carried out in a certain time and place and that it is in a certain time and place”.

The theory summarized in these brief quotations can easily refer to the contemporary arts, which, like the artistic production of the past, require historical contextualization and critical evaluation. These include both the aesthetic, in the case of works of art being recognized as such, as well as the historical, as a “unique and singular” product of a “historic present that has become the past”, as well as of a given cultural-historical moment.

Fig. 14: Sculpture details during the restoration.

Reviewing the assumptions made by Brandi, therefore, any doubt of the adaptability of his theory to contemporary art seems to disappear, even if he theoretical principles in the field of restoration – citing Carbonara – are “intended as guidelines and methods of thought and not as a rigid or prescriptive recipe. Theoretical propositions to be filtered through a personal commitment, encouraged by the demanding, prudent and experimental attitude which Foucault talks about”.

An indispensable prerequisite of any restoration, whatever the nature of the work in question may be, is, the evaluation of the specificity of the work and the appropriate weighting of the intervention project, assuming a “demanding prudent and experimental attitude”.

It is in the complexity of practice, rather than in the methodological reference framework, that the restoration of contemporary art differs from that of the old.

The restoration, albeit limited to a deep cleaning of the work, always involves a choice, “postulates – as highlighted by Carbonara with reference to architectural heritage – a design and aesthetics solution” that cannot be entirely neutral.

In the case of the restoration of the *Risen Christ*, with an appropriate scientific and philological methodology, the state of conservation of the material which the sculpture is made was carefully examined and only after this investigation, were specific restoration strategies developed. Diagnosis of its conditions was carried out with the aid of digital equipment that made it possible to gather scientific data in order to understand the degradation factors and, consequently, the planning of the restoration and prevention of further degradation.

Therefore, a restoration in which science, technology, research and craftsmanship have interacted to ensure a correct and adequate aesthetic appreciation of one of the most beautiful bronze works of the contemporary world.

Fig. 15: Bronze plaque Michelucci's Foundry.

5. For a structural reading: a work of apparent lightness

Vincenzo Sepe

The cleaning of the sculpture by Pericle Fazzini, carried out from October to December of 2011, was an opportunity to observe closely, with scaffolding installed by the technicians of the Vatican Governorate, an extraordinary work of art from many different points of view.

Innovative from an iconographic point of view, it redefines the classic theme of Christianity, placing it within the anguish of twentieth century man overwhelmed by the nuclear threat, as well as in terms of size, due to the large scale required in order for it to fulfill its role of scene of the Audience Hall and the material used, a copper/bronze alloy. Even from a technical point of view, the work of art is, a considerably interesting structural challenge.

It is approximately 16.40 m in length, about 6.30 m high and approximately 2.40 m wide, with it being the background of the terminal part of the Paul VI Audience Hall, where there is the Papal Throne.

Its transverse dimensions are less obvious, but equally impressive, reported in Figures 2 and 3, which are about 2.40 m, and then go up with parts projecting towards both the back and the room. These include the figure of Christ who is reaching out, with it starting at a height of about 3.00 m and the entire figure being at least another 3.30 m tall along with a vertical projection of about 1.25 m,. Thus, exceeding the base upon which the whole bronze structure is placed, resulting in an extraordinarily dynamic effect.

Fig. 16: Structural scheme of the sculpture (front).

A first reading of the work from a point of view of the overall balance – with more detailed considerations being made in the future – that has not been adequately studied due to the short space of time allowed for the cleaning – has a total weight that varies between 280 - 300 quintals according to the testimony of the heir of the Renzo Michelucci Foundry, Mauro Patrizio, son of Renzo, who worked directly on its creation. On the basis of his testimony, it was also possible to reconstruct the five sections in which the sculpture was divided for transport as well as obtain information about its assembly.

Despite the absence of detailed quantitative information, the wise balance between the weights of the various parts of the work becomes clearer by subtracting the eye from the “upward” effect wanted by the artist. In fact, on closer examination, it is worth noting that the work is characterized by a mass of material towards the base and a relationship between the full and empty decreasing from bottom to top or, if preferred by a thickening of the material towards the base of the sculpture. The “branch” elements in the bottom part gradually thin out as they go up, with the scenic effect of a dispersion – as if evaporating – of the material heading towards the sky on one side, while on the other contributing – without seeing – to the overall

stability, with the barycentre – while not determinable with the information available so far – being below where it might appear to be upon first sight. On the other hand, the base is extended by the curvature of the contact surface between the metal sculpture and the base, so as to obtain a maximum distance between the most extreme points greater than the average thickness of the contact surface.

Fig. 17: The restoration shipyard.

Fig. 18: Structural scheme of the sculpture (plant).

According to Patrizio Michelucci, for each of the four base sections, anchorages had been planned berths, reflecting an “engineering” of the work of art that goes far beyond the typical aspects (welding between parts, metal core inside hollow surfaces) of a foundry piece, more obvious than relevant.

The restricted cleaning time and the need to not impede it, did not allow for any studies to evaluate the nature and characteristics of the anchoring system to be planned, and more generally of the transmission system of loads to the base. This issue will be dealt with in detail in the future, with it not only being relevant to the maintenance and conservation of the work over time but also of considerable scientific interest, from the point of view, of the area that is never fully explored in which a work of art “embodies” the subject, especially if characterized – as in this case – by volumes and weights of unprecedented importance, whose apparent lightness or evanescence is “only” the result of a comprehensive technological culture, which seems to almost evade the laws of gravity.

6. The restoration of contemporary art by sacred multi-disciplinary dimensions

Maria Carolina Campone

The study aims to highlight how the *Resurrection* by Fazzini is able to effectively express the binding characteristics of twentieth century religion, marked by a strong intimacy, with the image of the *logos* for the faithful gathered in the Audience Hall. In doing so, it reasserts the iconic value of the work of art as such, admirably summarized by Lotman as the synthesis of finite and infinite, “the whole in the episode”, which assigns to the piece of art a totally unrestricted space of the whole, physical and not.

The theme, central to Christian iconography, is solved with the figure of a Christ rising above a formless chaos, image of death and destruction. As the author admitted, it admirably summarizes one of the fears of the last century, that of nuclear power, defeated and dominated by the divine figure that rises with outstretched arms and opening to enclose the whole of humanity. The artist uniquely re-interprets a theme dear to the Christian tradition, recoding the classical image in light of the considerations of his time, of which he was an authoritative interpreter.

Fig. 19: The bronze Christ head in Michelucci's Foundry (1975).

Fig. 20: The bronze Christ sculpture in Michelucci's Foundry (1975).

Fig. 21-22: Restoration shipyard setup (2011 October).

In the sculpture in the Vatican, the Christ stands emerging from a primordial chaos without any other figures, according to an individual concept of faith and religious experience which distinguishes the twentieth century. Simultaneously, the presence of an amorphous mass, which surrounds the divine form and accompanies the upward motion, transcribes in the material, synthesizing it, the “powerlessness” that, according to Hobsbawm, characterized the last century and which consists not only in the depth and complexity of world crises, but also in the apparent failure of all programs, old and new, to maintain or improve the condition of mankind.

In this failure, the only salvation for the believer is faith in the event of Redemption, of which the resurrection is the essential moment, expressed by the upward – moving metaphor of absolute spiritual freedom – with which Christ frees himself from the material, while still remaining bound to it. Fazzini immortalizes the Risen Christ in an eternal moment: the Son is already potentially in the Father, but is still being held back. He intercedes, inter-comes, remains present, and of this presence, the sculptor is able create the essence through a figure that is the bridge between two worlds, Intermediate Passage, an open dialogue, involving the nature involved in its upward movement.

The renewed iconography of the event of the *re-rise* that the sculptor from Grottammare suggests, assumes a search for dialogue, openness to others, which is rooted in a deeply “mystical” experience in its etymological origin of the term, which the study highlights.

The “sculptor of the wind” reaches the climax of his dynamic search, returning, with his formal choices, to the ontological origins of the revelation. Not surprisingly, the artist says that, while making the work of art, he felt that he was almost “forced, dragged” to its conclusion. The force of the wind blowing everything visually overwhelms the intensity of the religiousness of the Maestro, strongly felt and directly engaged in the majesty of God entered into the very force of nature.

Fig. 23: Rome, Saint Eugene Church. Via Crucis (XII) by Giacomo Manzù (1950).

The study highlights how the crisis between the considerations present in the formation of Fazzini, coupled with an intense spiritual participation, are united in the Resurrection in the Vatican, in order to express through images the implicit awareness of the dynamic nature of the Divine present in everyday life and history, particularly relevant in a social context, such as that of the late twentieth century, that tends to see the dignity of the human person as an essential foundation of social life.

The aim – the divine figure caught in a central moment in the history of Christianity – is overcome by the poetry of the invention, the attitude to graft the form in space or the wisdom to root in the soul, the movement, but not reject the painting experience, repeating the chiaroscuro effect in the material.

The objective is to provide a universal model of the human and divine, offering a visual language that is incredibly simple and spontaneous, inspired by a poetry inspired by the sense of being lost that takes hold of man before the mysteries of life and the universe.

7. For a reading and diagnosis of the material

Pasquale Petillo

Maurizio Marabelli, a renowned expert in the restoration of metals, when republishing his 1995 study in 2007, complained about the significant absence of a unified and shared approach to how to approach the problem of conservation of these specific pieces: “In a certain sense, to date there is still a methodological uncertainty, arising from the fact that the Charter of restoration by Cesare Brandi lacks a Protocol, at least, in the sector of metal products”. The guidelines for interventions in this matter are an interesting dialectic aspect to resolve particular issues such as, in general, the treatment of surfaces, the resulting aspect of the restoration and above all the environmental conditions in which the artefact is left upon completion of the work. The general conditions of the piece are, therefore, the determinant of a positive outcome: it is clear that the behaviour of a metal surface in the open will be quite different from that of one such as the sculpture in the Audience Hall.

Fig. 24: Pistoia, Michelucci's Foundry. Sculpture tour to Rome (1977).

However, even for this specific creation and the particular function it has, the structure shows different exposure times to microclimatic mutations, therefore, capable of providing surface variations on the metallic layers with consequent switching of the reagent states and alteration of the chemical-physical balance. A leading scholar in the conservation of metals and pioneer of modern restoration techniques –although, later, invariably the subject of distinguished observations and distinctions – noted, particularly in the nature of the bronze statue, of its multiple component *alloy*, to be a complexity of effects that were created with inevitable consequences for the final aesthetic appearance of it being the skin of the work. In relation to a historian fixated about St. Paul Outside the Walls recalled: “The remaining door thus presents very serious damage and are far from those commonly observed in excavated bronzes (Etruscan and Roman) or those which have suffered the influence of environmental conditions such as monuments exposed to the elements (horses of Venice, Donatello's bronzes in Padua, St. Peter's Filarete Gate, etc.). Damage of this type is always determined by electrochemical changes, favoured by damp environments as well as the presence of particular substances (carbon dioxide, ferrous oxides, organic acids, etc.), which, in the soil and prolonged action of rain water, creates an favourable environment for an ion exchange of the various elements, thus, the formation of salts and oxides of the metals constituting the bronze alloy. Where there is copper in greater abundance, there is a larger amount of incrustation. It has various aspects: smooth, spongy and mineraloide as well as different colors ranging from emerald green to malachite green, red to brown and even white. Upon chemical examination, this salification reveals the presence of copper oxides, copper chlorides, basic copper carbonates, as well as the salts of iron and tin. The first result from the ferrous metals and the soil at the excavation, while the second are part of the alloy. Due to the electrochemical process previously mentioned, there is a considerable increase of volume in the salification poorly soluble in those recesses of easy solubility such as chlorides and basic carbonates.

Fig. 25: Pistoia, Michelucci's Foundry. Sculpture tour to Rome (1977).

Complex atacamite and nantokite mineralizations are formed in the excavation minerals, over centuries. In fact, the electrolysis that is carried out between the buried objects and the salts and acids of the soil occurs through the charge of the same metals that form electrolytic cells and transport the metal ions.

On St. Paul's Gate, even if there is the briefly described damage caused by time, it is not as extensive as to cause concern because, among other things, its action is shallow". The Director of the Materials Analysis Laboratory of the Vatican Museums, Vittorio Federici, thus, commented on the complex nature of the bronze statute, due to the very fact that the material is a result of different elements, mixed in varying percentages, that could result in substantially different figural and formal definitions. In this case, by exploiting the information of Mauro Patrizio Michelucci – of the well-known and prestigious company of Pistoia where great historical and artistic masterpieces have been made as well as pretext of furious historical controversy and criticism triggered by the doors of the cathedral of Orvieto by Emilio Greco, nephew, among other things well-known architect of the Church of the Autostrada del Sole in Florence, Tuscany, Giovanni – this is red bronze statue, made according to the canonical proportions of 5% tin, 5% zinc, of 5% lead and 85% copper. However, there is a substantial percentage of brass, at least with regard to the dermis in view of the sculpture – more widespread in the lower part (on the left as viewed in the Audience Hall) – probably requested by the artist in order to obtain special light effects in the light of the general consideration of the manufacturing plant that a bronze statue with brass in it is considered to be of lesser quality.

The preciousness effects, however, achieved with the use of brass are also enhanced by the presence quite large parts of the statue being untreated, where the different roughness of its fusion with tones of blacks on the newly cast statue. For example, in the numerous "intertwined branches" of the two convex caverns of the lower part of the sculpture which, like chains of DNA, there are large quantities of material extensively stacked in a rotary motion. In the plastic masses parts that seem to summon, especially in the dome-like form with of legs, there is a sort of mass of birds, – evocative, in other respects, of skulls and portions of upper limbs in human survivors scarified in the ulna and radius with only carpal and metacarpal remaining – the affixing of nitric acid, occurred in the bronze mould, made it possible to obtain greater detail in the colouring process precisely where the sculpture tends as a whole. The opportunity to use, visually of a greater quantity of reflections for the roughness of the "skulls" or "bodies!" of the birds is without doubt a visual counterpoint of considerable formal interest, obtained through the "philological" and "canonic" treatment of foundry techniques. The removal of the fusion crust and valourisation of the gold hues of the copper or reddish of the brass through the reactions with the chemical preparations are salient features of the piece, because of the realization of the imagined and planned intentions of Pericle Fazzini.

Fig. 26-27: Exam of outside/inside details during the restoration shipyard.

It is not by chance that many welds have been left unfinished. Among the reasons to be assumed for the other parts and, especially for the "flashes", it is believed that this is an additional safety feature, mainly motivated by the strong projection of the individual parts and the easy with which the entire work will be affected by vibrations. Refining the amount of deposits created by welding with acetylene could weaken the overall bronze statue. The blackish streaks of the welds have been left at the back, leading to the image of an effective use of the welding. This very feature presents a series of signs that create quite a few interesting technical problems for the restoration as well as the possibility of a "tout-court" or "heavier" restoration.

The topics upon which the dialectic discussion is based, deal with issues of self-reflection in light of operational choices. The presence, for example, of substantial traces of casting soil within the individual bronze elements of the sculpture – as highlighted in detail through the video-endoscopy, need particular consideration in view of the weight and more extended structural behaviour component of the individual lugs. The longitudinal hollow elements show, through the many “windows” left to realise it, not only for the lute for the casting of the monument, but also the tools that made up the “soul” of the lute itself. The lute, which is nothing more than a mixture of powdered clay with scagliola, held together according to the shape desired by the artist through the metal, made it possible for the wax to configure the product formed and finished by the forms, so as to assume, as soon as the bronze entered the mould, the appearance given to it through the modelling. In this case, the general shape of the sculpture, as is known, was made by using polystyrene elements.

The “investigation of the inside” also highlighted the fusion nails as well as the distance metres between the walls of the individual “bars” of the quadrilateral section in a fascinating path and the creative point of view and, perhaps, even more, from the interpretative point of view.

8. The religion of concrete

Riccardo Serraglio

Commenting on a masterpiece like the Hall of Audience by Pier Luigi Nervi would be difficult. The Nervian building – subject to both authoritative approval and disapproval – has been, of course, accurately described and historically contextualised, by contemporary reviews from its realisation up to the recent monograph by Conny Cossa and recent essay by Carillo and Petillo during the restoration of *The Resurrection* by Pericle Fazzini. This is a masterpiece of contemporary art as well as one of the most famous buildings of the twentieth century that, like the extraordinary sculpture that defines the scene, has become part of our everyday life through the countless television appearances. However, as an inattentive spectator, I never paused to reflect *sub species architecturae* on this unique building before having the opportunity to visit it with due circumspection of the ceremony on the occasion of the completion of the restoration of *The Resurrection*. Nevertheless, I am a great admirer of Nervi, and I personally include in the select group of elected representatives of architecture – he was an engineer – considering him to be the best interpreter of the expressive potential of concrete in the twentieth century.

Fig. 28: The 'Aula Paolo IV' point cloud model, perspective projection (P. Argenziano, Benecon 2011).

Fig. 29-30: Aula Paolo VI and Fazzini's sculpture.

I will try to describe some of the feelings, perhaps trivial but certainly sincere, perceived from this piece:
Firstly: the courage of Nervi. Upon accepting the invitation of Pope Montini, he accepted the inevitable comparison with Michelangelo and Bernini. A courage that, mind you, was not presumptuous but contemplated and weighed. In my opinion, the papal auditorium is proof of the extraordinary maturity of the designer, because he does not want to the contrast, in terms of a challenge, his creation to the masterpieces of the past, but with the modesty of the strong, assigning it a supporting role, while at the same time, full of meaning and personality.

Secondly: the greatness of Fazzini. I cannot imagine the Audience Hall without The Resurrection in the background just as I cannot imagine the Stanza della Signatura without the School of Athens or the Sistine Chapel without the Universal Judgement. The dialectical relationship between Nervi and Fazzini, contextual and following the completion of the building, could not generate a more stable balance between the sculptural and architectural masterpieces.

Third and finally: The educational significance of the building. Finally overcoming “[...] the climate of ecclesiastical distrust to more recent materials especially in the specific approach of explicit powers of expression”, the Audience Hall represented a pass for a genuine use of reinforced concrete, which would have allowed many other designers freedom of expression, definitively marked by the concealment of this material by some who unjustly considered it to be suitable only for structural elements, or concessions to a fashionable decorative style of bad taste.

The enormous amount of concrete poured in the period after World War II at the end of the twentieth century for the postwar reconstruction and subsequent housing boom is associated to a generally poor level of built environment. In fact, the daily living of Italian cities clearly shows the serious imbalance between the quantity and quality of buildings made from concrete. It is precisely due to this uncontrolled use that this unique material has become a common negative perception and has become synonymous with ugliness.

Fig. 31: Sculpture detail in concrete architectural space.

However, we cannot blame the concrete, it was nothing more than an instrument in the hands of constructors. We should, rather, report those who have used it inappropriately. On the other hand, the construction research in the twentieth century cannot be limited to reporting negative data, which may seem to be overwhelming, but must also include recognizing noteworthy elements, both for the individual connotations as well as the improvement of the environment in which they are inserted.

In this sense, the religious architecture represented – and still is – an environment congenial to the appropriate use of concrete and it would be possible to compile a long catalogue of ecclesiastical buildings worthy of consideration, made from this material in subsequent periods of the twentieth century. I hope, therefore, to be able to develop in the near future this issue along with Carillo and other colleagues of this assorted group of scholars who participated in the research prior to the restoration of *The Resurrection* by Fazzini, considering not only the best-known works, but also the many buildings constructed by ordinary actors of the profession, which in many cases were able to interpret this theme with appreciable results.

Fig. 32: Monographic magazine cover on 'Aula Paolo VI' by Pier Luigi Nervi (1973).

9. Examination of the sculpture: high-tech aids as configuration and representation diagnostic knowledge

Pasquale Argenziano

The multicriteri@/Multidisciplinary approach to the knowledge of a cultural asset – as experienced over the years – at the Benecon Research Centre has in its design or rather in the three-dimensional geometric characterization, the first and strategic methodological step, regardless of size, the space or material consistency. This is the definition of the *geometry layer*, fundamental action due to it ordering all the subsequent scientific-disciplinary characterizations that relate to it, with this layer being the backbone of the larger multi-dimensional model.

In the digital era, the *design* retains its epistemological roots based on the interaction eye-mind-hand, extractable with graphic signs on two-dimensional media. Their potential for control by recording more accurate geometrical dimensions increases and affirms the inherent handling characteristics of the broader process of knowledge of the asset. The eyes, mind and hands are the human tools for the sensitive knowledge of *The Resurrection* by Pericle Fazzini and make it possible to appreciate the size, the proportions in the architectural context, the spatial complexity as well as the textural quality of the materials. They are fundamental aspects for the planning of the technical and scientific characterization of the complete work of art and, in particular, the geometric and morphological investigation.

According to a previously tested technical-operational protocol the geometrical and morphological investigation of the Resurrection was planned focussing on two specific issues: the choice of digital instruments that are more powerful than the reality of the place and the chronological development of data acquisition as a function of the conservation interventions and restoration site.

The most advanced three-dimensional geometric surveying techniques and technologies of detection include 3D laser scanning and digital photogrammetry. Upon comparison, the first was chosen, given the exceptional spatial organization as well as the particular texture and colours of the bronze surface. The scanning laser is, in fact, more precise in the presence of irregular morphologies, with alternating full-empty and concave-convex elements with significant undercuts as well as in the presence of darker-coloured and opaque metal surfaces.

Fig. 33: Point cloud post-processing model, graphical colour representation (P. Argenziano, Benecon 2011).

Given the historical and artistic value of *the Resurrection* by Fazzini, the Benecon team planned to carry out the study in three sessions related to restorative activities; prior to the restoration site being set up in order to “crystallize” the condition of the premises, during the restoration to monitor the progress of the work as well as reach the apical areas of the sculpture using the scaffolding; at the end of the work to record the work and determine a delta with ex-ante conditions.

This laser scanning survey is in line with the most reliable methods and practices in the preservation and maintenance of archaeological, artistic and architectural assets. As stated by Luigia Melillo, crystallizing the three-dimensional geometry of an object – scaled to different sizes in accordance to the current regulations (DM 04.20.2005) – creates an everlasting digital data-based analysis that can be “used for the making of copies” and as an “objective reference to verify over time the state of preservation” of the cultural asset. Moreover, such a database would be “a sort of “memory”, a store of information in the event of the loss of the work itself. Imagine, for example, what if a natural disaster or a terrorist event caused the destruction of an old masterpiece. There would be the photographs, scientific descriptions, maybe even a few copies, but the three-dimensional object would be lost for along with all the details that characterize it. The 3D relief could be used to realise a perfect copy to perpetuate the memory and knowledge of the object itself. If the work were badly damaged, the three-dimensional relief could be very useful in restoring it.

Returning to the geometric analysis of the *Resurrection*, in the three data acquisition sessions, several instrumental detection processes were iterated using two different integrated laser scanner-phase time-triangulation sensors through the overall geometric control of a topographical sensor with millimetric accuracy. The instrumental approach was inductive: After having placed the statue in a single Cartesian reference system, the complete geometry of the work station from multiple points – placed at a set distance and with a resolution of 10 dots/cm² on the metal surface, was recorded with the sensor phase time, while the triangulation sensor measured the most interesting and peculiar sections of the sculpture, at a resolution of at least 100 points/cm². The accuracy of the data was increased tenfold due to the particular hardware used and triangulation sensor the acquisition technique used, which operated by human hand can follow any plastic form freely set in a space.

The 3D laser scanning of the *Resurrection* was performed with a sensor in phase time in order to fully take advantage of the technological characteristics. Each point on the bronze surface was “touched” and “measured” by the laser scanner, resulting in 4 numeric values, the three Cartesian coordinates and the reflectivity value – the fraction of incident laser radiation reflected from the surface at that point. This dimensionless value is comparable to a reading of the object in the spectrum of near-infrared (NIR) and therefore is particularly interesting and a forerunner of specific experiments in the restoration field.

Fig. 34: Photorealistic architectural 3D model, perspective projection (P. Argenziano, Benecon 2011).

The integration of the two sensors led to the definition of a variable-resolution geometric model, textured with photo-realistic images – also at different pixel resolutions – classified at during the different stages of the restoration, in relation to the various and multiple morphological specificities of the masterpiece by Fazzini.

The “multi-resolution three-dimensional model” to scale (point cloud) of the entire Resurrection has more than 70 million points that apparently reproduce its morphological continuity, but in reality, is discontinuous due to it consisting of all the points read by the laser sensors and integrated into a single Cartesian system. This model is the “geometric layer” upon which to incardinate the larger multi-dimensional model. All the information on the sculpture by Fazzini, the chemical, structural, colour and morphological aspects, are related to each point in digital form.

The colours and morphology, in particular, are two types of scientific and technical information that can be obtained from the laser scanning analysis. The surface shape (DSM) was determined by the autonomous and semi-automatic processing of the point cloud, with overall colour being returned by the time series and ordered by the RGB images acquired by the sensor in different scanning sessions.

In the area of DSM modelling, current scientific literature defines two different approaches: the *meshing* or construction of surfaces through the triangulation of the points constituting the discrete model or the discretization of operated rational geometries by means of coordinated plane sections of the points cloud model and the relative geometric extrusion. The first approach, used in this case study, is ideal for processing DSM non-rational geometries, with obvious applications of the areas of marked plastic forms to any scale. However, the second approach is particularly good in the modelling of volumes that can be related to Euclidean samples, for example urban fabrics, the structure or construction elements.

The work carried out on the sculpture and the more accurate modelling of plastic figure of Christ suggest a parallel example of the relationship (not just figurative) between the structure of human skin and that of the 3D digital laser scan model. The points cloud represents the “dermis” upon which the DSM mesh lies, comparable to the epidermis that is divided into layers according to the colour information, colorimetric or thematic issues (curvature index, contour lines, chemical characterisation etc.), which gives the larger model the interpretative image of the various scientific assumptions.

As previously mentioned, this comparison is not only figurative: the 3D laser scanning like photogrammetry gives the morphology of the object which can be textured with photorealistic images, with derived geometric themes as well as with the various characterizations of the surface layers obtained with non destructive digital sensors that read and analyse the surface of the object. It is worth considering the spectrophotometer, the thermal camera, the covermeter, the video-endoscope, to mention only the sensors used in this study.

Fig. 35-36: 3D laser scanning action and mesh 3D model by point cloud model (P. Argenziano, Benecon 2011).

The multidimensional analysis considers the “body” of the cultural asset so as to study it “live” and “in vitro”, with, the team, therefore going beyond the metal surface. With the aid of digital video-endoscopy, the eye of the researcher was taken inside the sculpture, recording new images and valuable information on the structure, as well as technical solutions during melting and the thicknesses of the different sections. The concrete base upon which the bronze mass stands was analysed with the digital covermeter, highlighting the main anchorage areas on ground for the structural analysis of the statue within the larger architectural machine by Pier Luigi Nervi.

Fig. 37-38: Snapshots of mesh 3D modelling (P. Argenziano, Benecon 2011).

By making this information system, the DSM model acquired a “physicality” not only because the framework under the “skin” of the sculpture is described but also because a step by step multidimensional model was created .

The multi-dimensional attributes, organized in an analytical and discrete way, are related to the points cloud and visually manifest themselves in thematic projections on the DSM. If the point cloud is the geometrical database of the object investigated, each discrete element is identified with a unique code and the multiple coordinates (Cartesian, spectral, colorimetric, chemical potential, etc..) are attributes of a table structure to be implemented in order to increase the scientific investigations on the object under study.

The definition of the geometric layer of the Resurrection in the Audience Hall, already characterised by various and coordinated investigations presented in this volume, would be the first step towards the definition of a multidimensional model that integrates “detailed” knowledge of the bronze artefact.

The Social Housing for a new ethic of architectural Project

Lorenzo CAPOBIANCO

ARV, Architettura "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Aversa, Italy
lorenzo.capobianco@unina2.it

Abstract

If, on the one hand, the condition of widespread deterioration that seems to omologate our cities from the center to the periphery is the declaration of a contemporary inability to retrieve the ancient relationship between nature and built that presided over the founding of the city, on the other hand, the global crisis presents us a impressive generational data: entire sections of society are, at the same time, excluded from the target of popular houses and private of the economic capacity to access the market. The project of architecture should regain that sense of ethics and social that can represent, today, a proper and necessary disciplinary contribution attempt to the solution of a much more complex question. Precisely because in a time of deep crisis, any construction, from small urban design element until recovery or the construction of a new neighborhood, sees grow its value exponentially. Not a case that we record the progressive growth of interest in a new form of housing: the social housing. A "sustainable" alternative to the popular houses, the Social Housing combines the low environmental impact at the high energy performance and content of construction's cost, permeating of a logic ethics and a strong social connotation an increasing number of financial transactions that involve collaboration of public and private operators. In the same line it is also places the initiative of european competition "Housing contest" which was attended, with success, by this project.

Parole chiave: Social Housing, widespread deterioration, ethics of architecture

1. The contemporary scene

The conditions of widespread deterioration declined in terms of waste of resources and energy dispersion that today seem to homologate in the same uniasiness the appearance of our city from the center to the periphery, declare their structural and systemic character.

They, in fact, are the inevitable consequence of the difficulty of managing the existing built heritage and the processes of construction of new volumes. These conditions, on the other hand, returns the immediate perception of the depth of a crisis related to the contemporary inability of recuperate the relationship between nature and built that presided over the founding of the city in history. These are conditions of degradation that is possible to measure in comparison with similar European experiences, and that lead to the apparent inability of management and interpretation of new forms of public space, to the rarefaction of the quality in the new buildings both from a purely technological point of view and in reference to the idea of architectural project, in the difficulty of the authorities in processing widely shared designing development strategies, into the uncertainty of shared cultural references, in the absence of a clear system of values and performance requirements (and with it the ability to distinguish) for contemporary interventions, and, last but not least, the growing difficulty of architects to interpret and communicate the instances and the sentiments of urban communities. Not all aware of the social problems connected to this process of progressive deterioration of the habitat, especially when the goals of environmental sustainability are forced to confront whit an unfavorable and dramatic economic downturn in global scale that projects the future in the insecurity. The city offers to the new generations of citizens the complexity of the urban fabric and an organization of

services that are distant, impractical because it is put into question the ability to meet one of the primary needs of the human being: the house.

It is a impressive generational fact that large parts of the social body, in particular the young, intended to compete with a twofold difficulty: on the one hand the exclusion from the target of popular houses, on the other hand the deprivation of economic capacity to access the market. It is a generation handed over to a sort of limbo, for which does not seem to be approaching another way out if not the expectation to the "protection" of the family of origin.

In confirmation of this scenario are the 2011 Istat data which, compared to an increase in the cost of the house that goes from 50 to 100% for the purchase and from 130 to 145% in the hiring market in the last ten years, has suffered a decline of 3.2 % on an annual basis of contracts of sale and a literal collapse, at the same time, of the 8.1 % in signature of loans for the purchase of the first house.

Occasional workers, insecure, temporary employees, young families, pensioners, a veritable army in numbers, substantiates the population of our country.

Fig. 1: The "Pignasecca", a historical district of Naples

1.1 The role of architecture

The only architectural project can not provide the solution to these complex problems, but a reflection on its statute, and the available tools and its priorities, it is still required. Therefore the architectural project should find, without rhetoric, its civical original vocation, that social and ethic sense, its civilians reasons that seemed to have lost in the contemporary season but that can represent, today, a proper and necessary attempt to disciplinary contribution to the solution of a much more complicated question. More of a clue to the spread of this need for moral renewal is offered by the theories of the decrease which is inspired by a growing number of experiments in historical and degraded fabric of the contemporary city.

In England, for example, the streets abandoned by trade, victim of the crisis, the "slack space", escape to a destiny of dangerousness and re-populate itself thanks to artists and local communities that transform the free spaces in cultural centers and handicraft production.

The studies of Ivan Illich and Richard Semmet, tell about a new way of feeling, free from killer instinct of economical capitalism, that makes it possible to find the ability to do together beautiful and useful things and that becomes the engine of the relaunching of entire communities. However, in this direction, are the concepts of 'sustainability' and architectural experimentation which, probably, would deserve a deeper reflection. One renewed look is that what exceeds, in the exercise, the "artificial" specializations and the disciplinary distinctions, conditions which proved to be as less unproductive if measured respect our urban landscape. Precisely because we live in a time of deep crisis, any achievement, from small urban desing until the recovery or the construction of new neighborhood, sees grow its value exponentially; for this the consciousness and the architectural quality may no longer be understood as autonomous characteristics of the project, but they assume characters of necessity in an organic and integrated generative process from the definition of the type of construction up to the study of architectural detail.

Fig. 2: A more and more frequent image of the contemporary city: abandoned shops

1.2 The Social Housing: some experiences

Not by chance that in the current architectural debate, we record a progressive growth of interest for a new formula of the residential building: the social housing. Closed the season of the reconstruction of state and, fortunately, also the one of the wild speculation due to which, still today, our cities are paying the consequences, the changed economic conditions and the dramatic growth prospects, bring to the attention of the market the social housing as "sustainable" alternative to the popular houses. The attempt to combine the low environmental impact to the high energy performance and low cost of building, permeates of a logic

ethics and of a strong social connotation an increasing number of financial transactions that involve collaboration of public and private operators. An applicant formula provides for the granting in gratuitous bailment of the ground fromrt of the Municipality, which thus becomes co-sponsor of the operation of construction, in return of the guarantee of a controlled discounted price for rent or sale. In this direction the Municipality of Parma has approved, in 2010, the construction of 852 social housing, in Turin, in 2011, has been inaugurated "Sharing", the largest Italian project of temporary social housing that move from the conversion of a former Post's building and, for the next few years, the investments dedicated to quality homes at low cost are quantifiable in 10 billion of euros.

Fig. 3: "Sharing", Turin 2011

2. The "Housing Contest"

In the same line it is also places the initiative of european competition "Housing contest" which was attended, with success, by this project. The design team, formed by Lorenzo Capobianco, Antonella Violano and Francesca Capobianco, has responded to a request for a residential building on 5 levels which extends for about 5000 square meters of residential surface at a low cost and high energy performance. The choice of the project has been entrusted not so much to the design of a single building as far as rather to the organization of a flexible modular system to accommodate the different functional and dimensional requirements.

The starting point of the composition has been in the definition of a structural system with a constant pitch (3.60 mt.) that will make it possible a free association of the five required housing typologies. All the houses, in this way, may be variously determined in the constitution of individual building blocks, which are distributed by a line system, and their amount and size is function of specific needs. In this case, in our opinion, the

proposal solution suggest a limit size for the building (20 meters in height, and 120 in length) beyond which it would be preferable not to go.

Fig. 4: Housing contest, East Elevation whit hanging gardens

The required five residential levels are distributed, starting from the first floor, in eight separate blocks using the ground floor of the building to accommodate warehouses and common services, among which, a fitness room for the exclusive use of residents. Access to homes is imagined through a system of stairs and elevators, outside from the area occupied by residential blocks and in the open air. This physical separation between vertical links and residences makes it possible to define a real further "urban scene" (the eastern front of the building) characterized by the presence of seven hanging gardens for the exclusive use that can also be used as "condominium garden" (planting in a pot), and by a system of internal green terraces that define a privileged and protected habitat to the sleeping area of houses that all overlook on this space. In addition, the system of pedestrian access located in correspondence of the stairs blocks and of the warehouses draw the perimeter of a long private green dedicated to the children's play.

Fig. 5: Housing contest, Plan of the Third level

The type of accommodation, to the vary of the size, is declined while maintaining constant the division between living area and sleeping area through a functional area of central services. The living areas are facing to the west, by defining the front of the building through the alternation of horizontal cuts and bow-window, while the bedrooms facing to the east, above the internal square and on the green terraces, placing himself in relation with a controlled space protected from the street. The building choice of a constant structural step allows, to equality of sqm., to configure a wide range of solutions of prospectus of east front for each individual types: solutions with loggia, solutions with bow-window, ribbon windows or solutions with small terrace are available for a free design and constantly changed front of the building. To reduce the effort the and maintenance's cost related to the considerable presence of green condominium's spaces, has been formulated the hypothesis of an automatic watering system that exploits the recovery and reuse of rainwater adhering to the principle of resource saving that presides over the project.

ARCHITECTURE AND URBAN PLACES

Ottavia GAMBARDELLA

Dipartimento di progettazione urbana e urbanistica, Università degli studi di Napoli Federico II, Napoli, Italia
E-mail: ottavia_gambardella@hotmail.it

Abstract

The contemporary city is characterized by deindustrialization, tertiarisation of the economy and growing process of relocation; the disposal of places, buildings, artifacts belong to its history. "Indicator of an impossibility, disposal often involves changes in scale and spatial relationships" [1]
"The contemporary city is by its nature unstable, the site of ongoing changes that give rise to the formation of critical situations and temporary solutions of problems." [2]
The biggest problems of our territory concern the use of land, the lack of public spaces, the bad condition of the housing built after the war, the energy consumption and the related pollution, the issue of waste and non-recyclable materials. The theme proposed concerns the design of a settlement of Social Housing inside an area of Bagnoli previously occupied by Italsider. Starting from the analysis of the territory and its genius loci, the indications of the PUA and of the urban transformation society Bagnolifutura, the project is a tool of regeneration for the abandoned area, in a sustainable way. I chose this topic for my contribution because the method pursues a growth based on less land consumption, less energy consumption, less waste of resources; and it pursues the research of a possible solution to the problems of our time.

Keywords: regeneration, abandoned area, sustainability.

1. The study area

Fig. 1: Picture of the study area.

Fig. 2: Orthophotos of the study area

"The European city has rediscovered in recent decades, a new porosity. It is related to the phenomena of the disposal of large areas, or of a myriad of small lots within the tissue." [3] The theme that I propose concerns the design inside an abandoned area, and more specifically of a settlement of Social Housing in Bagnoli on a site previously occupied by Italsider. The project is seen as a tool for regeneration of the disposal area in a sustainable way. The study area is a lot putted on sale by the urban transformation society, Bagnolifutura.

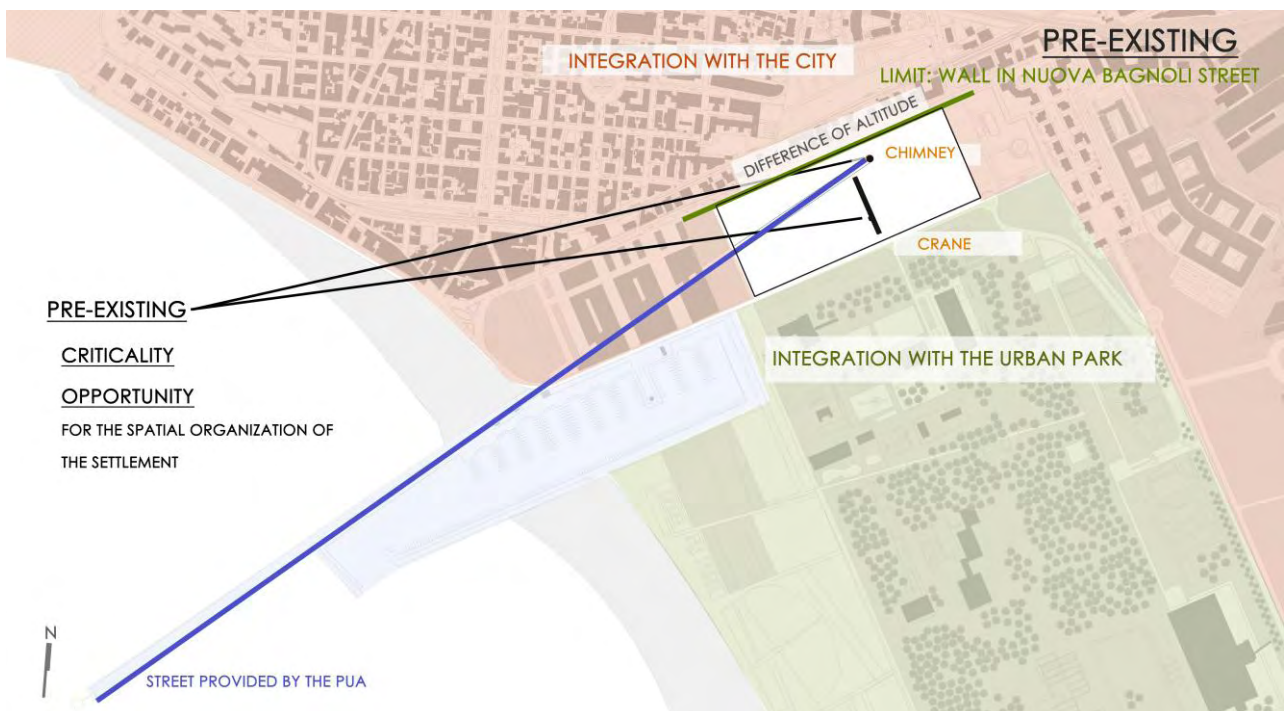

Fig. 3: Creator principles of the project.

The lot borders to the north with Nuova Bagnoli street, to north-east with the auditorium “La Porta del Parco”, to the south with the large disposed area, site of the urban park planned by Francesco Cellini and provided by the PUA, and finally to south-west with an area in which are provided accommodation and commercial activities.

"The quality of the relationship between the new and the existing is complex and can not be reduced to the addition of something that was not there before to a system of fabrics that already formed a part of the physical world. The new is contaminated with the existing, and this becomes different in contact with the new. "[4] For this reason, the definition of the project was based on the analysis of the territory and its genius loci. The lot is characterized by several critical issues, such as the difference in level with Via Nuova Bagnoli and the related wall that goes along the street; the presence of two elements of industrial archeology: the crane and the chimney; the road that goes through the lot provided by the PUA.

2.The project

The project aims to transform the existing structures from criticality into opportunity for the spatial organization of the settlement and it develops from a grid and several streets that cut the grid and allow the connection to the city and the physical and perceptive connection to the pier and the sea. Elements such as the crane and the chimney become points of orientation for the new settlement. "The points of orientation are essential for a healthy life in any environment, whether urban or rural. Without them, the citizen can not read his country, nor even understand it. "[5] "A characteristic and legible environment, not only provides security, but makes the human experience potentially more intense and profound."[6] The project aims to create an union between the district and the urban park designed by F. Cellini, through the recovery of its guidelines for plan development; it creates physical connection with via Nuova Bagnoli through pedestrian access to the lot; perceptive connection between the project area and the residential area through the partial elimination of the wall on the Nuova Bagnoli street. The project of the settlement also provides the creation of two levels of usability placed at different heights: 0 level dedicated to commercial activities and functions of the district, level 1 social activities and semi-public space of interaction.

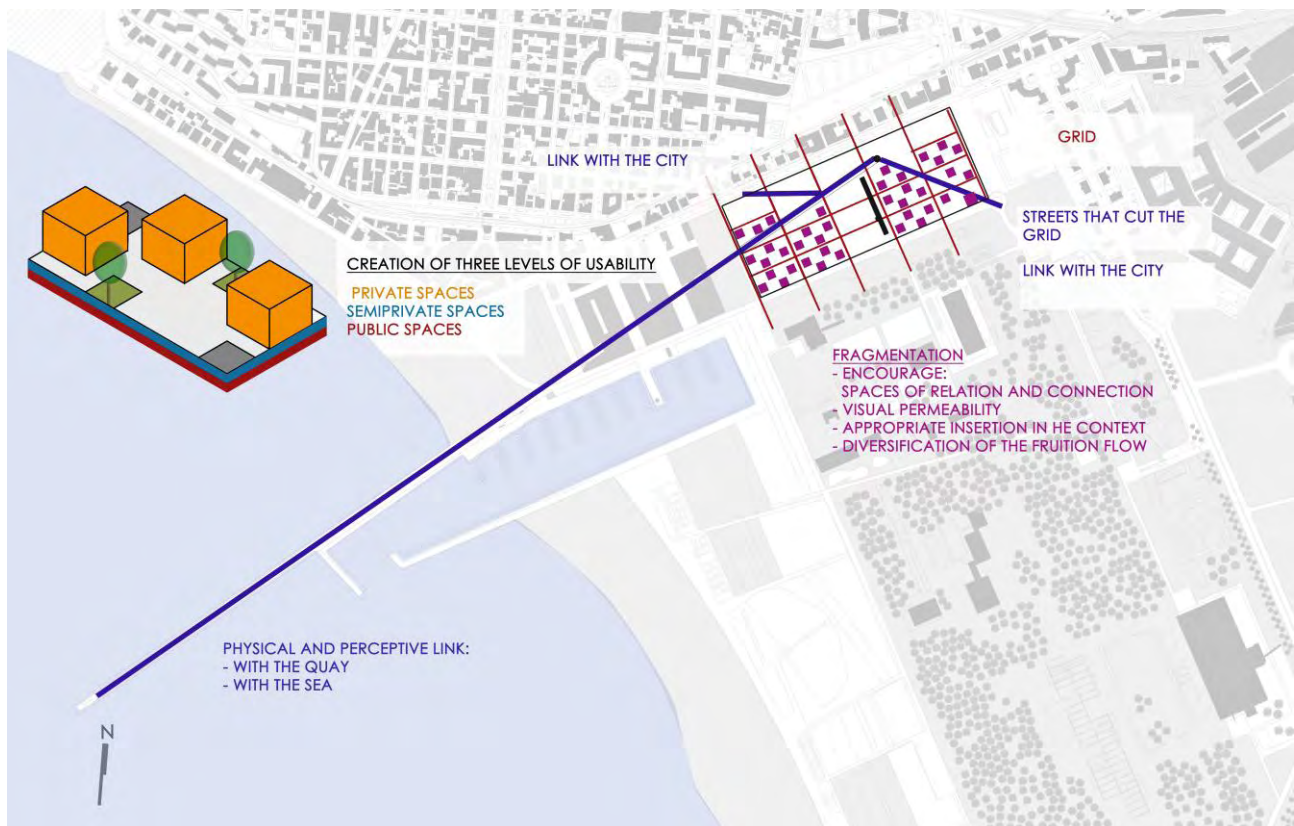

Fig. 4: Creator principles of the project

Fig. 4: Masterplan

"The emerging of environmental issues, their severity and their potential for conflict, has enlarged the debate to the global arena, in the form of scenarios, of the future planet." According to Viganò there is a "close relationship between the awareness of the conclusion of the experience of the modern city, the emerging of new forms of settlement, and the need to analyze their consequences in the future, to imagine alternative scenarios." [7] Considering the problems of our country and our time, more attention has been paid to the climatic analysis of the area and consequently to the optimization of the sun exposure and of the wind exposure of housing. The fragmentation allows the summer winds to penetrate inside the settlement while the winter winds from the north-east are blocked thanks to taller buildings and a green barrier. The project involves the surface modeling of the ground with recovery of the excavation soil, the creation of a linear park, social spaces and urban gardens belonging to the Social Housing.

Fig. 5: Masterplan and profile

Fig. 6: Volumetric

At the building scale the design strategies are the use of a dry constructive system and the distribution of interior spaces depending to the solar gains during the day and in relation to the activities that take place inside the building. The control of the internal ventilation is implemented favoring the creation of windows located on opposite sides. The control of solar radiation is implemented on the west through vertical screening for transparent windows and on the south through front horizontal screening. The ventilated wall to the west allows the reduction of heat in summer while the coat wall to the north allows the control of heat loss. The project involves the use of renewable energy sources like the photovoltaic panels integrated into the roofing system and the recovery of rainwater for irrigation of green spaces and common services, using external paved surfaces and roofs of buildings as collecting surfaces.

Fig. 7: Perspective view

The central theme of the project are the public and semipublic spaces of relationship. "Space is not designed as a simple negative or empty, but as places available to accommodate the many facets of an idea of community." [8] The project method pursues a growth based on less land consumption, less energy consumption, less waste of resources, and pursues the search for a possible solution to the problems of our time. It promotes the idea of a project as "a continuous reading of history, founded on the recognition of the landscape's structuring character, of the historical/testimonial values, to undertake alternative design paths, to establish a "synergic interaction" between diffusion and recovery of "historic territory", interpreting the effects of new settlement trends. [9]

Complex of San Lorenzo ad Septimum. Architectural contribution to sustain energy

Efisio PITZALIS

Dipartimento Cultura del Progetto, Facoltà di Architettura Luigi Vanvitelli, Seconda Università di Napoli, Aversa, Italia

E-mail efisio.pitzalis@gmail.com

Abstract

Within a collaboration and communication among different subject areas, the garden of the complex of San Lorenzo ad Septimum - Faculty of Architecture of Aversa - is the place chosen to prepare the architectural prototype of a solar energy system. The floor plan consists of the newly formed multi-cellular matrix combination wrench. This matrix unfolds in a process of slippage along the sides of the hexagon base and second alternating between full and empty. The formal nature honeycomb then a warrant for land for small samples, necessary to the custody of the parts and the housing of various seeds. This focus is in full agreement with the vocation of planting woodland and rural dwelling newly refurbished function on the example of the ancient convent of the orchard. This genetic parentage is able of establishing a dialogue between interventions distant thunderstorms. A dialogue laced with references and allusions to memories that emerge in the thick perimeter planted with greenery. The resulting texture reminds "viti maritate". These are the hallmark of the agricultural system of Aversa, but also the reference cards with festoons that adorn the city center during religious festivals. The colored glass held in the dense network perimeter recall the statements of votive lights, and weld in this way, the religious origin of the ancient building complex of the current scientific university. Faith and science together in a common root of knowledge.

Key words: prototype, energy, multi-cellular, memory, knowledge

1. Architectural contribution to sustain energy

On the inside of a sinergetic collaboration between different areas of discipline, the garden of Saint Lorenzo's complex ad Spetimum-center of the Faculty of Architecture of Aversa, is a prechosen place to prepare the architectonic prototype of a energetic solar panel system. In particular, the useful system for autosustainment of the eight century body is placed in the posterior part of the courtyard, in the intermediate portion between the existing garden of the rectangular planimetric sods and the grove with quadrangular mesh. The planimetric system of the new formation is constituted of a multicellular aggregation from a hexagonal matrix that is developed second after a process of slidings along the sides of the hexagon of the base and second, an alternation between full and empty adaption that intercept visually the pieces of the pre-existing historic building. The whole project is constructed in a way to not occlude or to minor in an excessive manner the sight of the ancient complex of the building, and at this end the texture of the handmade ex-novo, everything imprinted on the transparency, is guaranteed for total permeable vision. The natural form of the beehive then guarantees an occupation of the ground for a little sampling, necessary for the custody of the area's parts for lodging of the seabeds and mushroom farms, in full accordance with the vocation of woodland planting an rural dwellings newly refurbished functioning on the example of the ancient convent of the orchard. This provides genetic parentage, so to speak, a reciprocal relationship between ancient and modern that can establish dialogue between the intervention of distant thunderstorms . A dialogue laced with references and allusions to memories that emerge, decanted from excessive historicists, in the thick brushwood perimeter

that contains vertically the volumes of the hexagonal base. This texture recalled the screws (intertwined?) : It is the Aversa hallmark of the agricultural system, but also an architecture of minors that can be safeguarded, that of the congratulatory festoons that adorn the historic center of the old town Aversa in religious festivals. The colored glass held in the thick boughs of the perimital perspectives return in a match of veiled allusion, the votive lights, welching in this way, the religious origin of the complex of the ancient building of the current science university. Faith and science together in a common root of knowledge. The single element with a hexagonal plant consists of a wooden platform resting on the punctual perimeter supports that are anchored, by means of anchor bolts, and a cement block buried 40 cm into the ground. In this way the soil is stripped in singular points to a minimum depth in order not to affect anything. A system of support surface springs, ajustable in function of soil compaction the suspension ensures the ground and the wooden base perimeter groove, while an umbrella device, with a central pillar cable for the watershed of water, cooperates statically with the flat metal perimeter system. These are anchored to the flat base and cover by screwing the ajustable galvanization and enamelling. The coloring of the metal are ivory white in contrast with the colorful pieces mounted on the metal cabinet behind. The cover housing in its thickness holds the solar panels, which in this ways are completely hidden from view, from below. Around the aggregate system, there are 8 cell lodge activities related to the function/agricultural rural orchard, 1 cell repair and a small trench for stratigraphic studies of soil and 1 final planimetric deformed cell matrix that contains the technical elements for the collection and branch energy produced by solar panels. The height of the cells is 3.00 meters with a suspension volume of 10 cm, around the base slab. Having regards to the conformation of the ex-novo article, of particular importance is the nature of the removable architectural complex thus obtained, easily removable, replicable and reassembled in different points depending on the changing needs of use. This possibility, within the system is modular and combinable and ensures the correct installation in particular of the historic building of merit. This is the easy maintenance of components useful for commisioning of solar panels for energy self sufficiency.

Abstract

To reach Segezia needs, as it remembers Pennacchi, to pass under a double row of eucalyptus ' trees that connect them toward the center; the tall bell tower, well visible also from far, guide like a lighthouse in the countryside.

Segezia is born in the strategic sketch performed by the Onc driven by Araldo Di Crollanza and technically submitted, with the Urbanistic Plan of the Tavoliere, to the architect of foggiana's origin Concezio Petrucci. The objective of the intervention is to put in evidence the system of division of land of farmhouses spread that have in the town centers and suburbs the points of reference of the gravitating polycentric constellation around Foggia.

In the project for Segezia, certainly a point of arrival for Petrucci, it is clearly visible the stylistic jump made in the elaboration of the plan and in the built restitution; it is a clean, dry and centrifugal system, a feature proper of the systems theorized by the leader teacher of the organic movement, Frank Lloyd Wright.

From the point of view stylistic reports clearly a planning evolution, the architect's architectural will, (prematurely disappeared), the point of arrival of a search who often engaged him with the theme of the rural city - theme that has been often ignored by the great architects of the time focused more on the architectural object - and that it stays, in every way, his last realized work.

Keyword: chief town of country

Segezia, the conclusion of the experience

To reach Segezia needs, as it remembers Pennacchi, to pass under a double row of eucalyptus ' trees that connect them toward the center; the tall bell tower, well visible also from far, guide like a lighthouse in the countryside. The city enjoys the same color, the same bright atmosphere of the small and large urban centers of the Puglia's and particularly in the regions of Gargano; atmosphere which resents also in the architectural composition of Segezia, in its entirety, so varied and picturesque. [1]

Posta Tuoro (former name of Segezia) is the first of the towns and villages, built with the " Plan for the Tavoliere" designed by Petrucci, then there is the town and villages of Incoronata, Cervaro and Giardinetto which are, however, partially completed during war (1943), while others never get started. Segezia is born in the strategic

sketch performed by the Onc driven by Araldo Di Crollanza and technically submitted, with the Urbanistic Plan of the Tavoliere, to the architect of Foggiana's origin Concezio Petrucci. The objective of the intervention is to put in evidence the system of division of land of farmhouses spread that have in the town centers and suburbs the points of reference of the gravitating polycentric constellation around Foggia. This project adds to previous attempts by the Consortium for the remediation of Capitana, producing, however, poor results, detectable in the two interventions Mezzanone suburb (La Serpe) and Siponto. The project is made by Concezio Petrucci and, only this time, he continuing the research on the new city began and continued for Aprilia and Pomezia. The Regional Plan, first outlined by the Opera, was developed in consultation with the architect Concezio Petrucci, who prepared the completion of the system subsidiary tracked, formed by the arrangement of some "tratturi" direct to Foggia, with the primary intention to relieve the roads, real backbone of the drainage areas, the slow and bulky agricultural traffic aimed to the chief town. Other tracks planned are designed to connect with each other [...] the six new major towns designed in the region and [...] create a new, much larger ring of bypasses around Foggia [...]. The ONC, in order to provide the people scattered in rural homes, has crafted the construction of six new villages [...] to fulfill administrative, political and religious needs [...]. Of these centers, three are new municipalities of chief towns (Segezia, Incoronata and Daunilia). [2]

The experience of the city is part of a period of great ideological turmoil on the question of how to design cities. The work seems to prefer a monocentric city scheme and sees in the group headed by Petrucci an effective interpreter, in fact, they are able to apply the best indications of the ONC. The substance of a rural town is that it is not a city, in practice the characteristic that should be their own is to be anti-city, point of reference for people all over the country and not stable population in it. Therefore, since the permanent population is about three thousand inhabitants, it is not clear how this proves a problem for traffic or congestion. The original idea is not to found a city that must expand continuously, but only be a symbolic place where you join and identify with the community for those who are scattered over the country, the place, therefore, where to find the public institution and religious, in this connection is easily noticeable how, the early works built are always public buildings, and then residential buildings, precisely because that is not the primary purpose for which they were born, these buildings are the true essence of the foundation and the part on which the designers attention is focused. The contrasts are reflected also in the academic power clashes that see opposing the two great barons of the time: Piacentini and Giovannoni. Piacentini on several occasions criticized the plans of his rival's protege, Concezio Petrucci, who in a letter he assumed the responsibility to reply to the lines: "V.E. he forgot, instantaneously, that until yesterday he preached in his lectures at the School of Architecture to avoid the roads North-South and East-West. Today, transalpine fashion is back on checkerboard patterns with those guidelines. This will be fine for the northern regions where people trying the sun frantically, in homes, with large windows, in the streets with the NS orientation or almost. But in Italy, Sir, do not you walk the streets without the risk of sunstroke and in fact, VE recommended a few years ago to avoid that orientation. Do not you remember? Climate conditions have changed or have changed his views?" [4] Segezia surely is influenced by the historical local Romanesque as evidenced De Angelis [5] who speaks of St. Nicholas of Bari, the cathedral of Ruvo, or Troia. For George Mason, Segezia represents a stylistic gap compared to the rationalism that has characterized the way of designing cities by groups involved in the various competitions, sees the influence of neo-classical Scandinavian, from Aalto to Asplund, for sure how much importance the designer admits he held "... the simplicity and purity of Tuscan architecture." [6]

In the project for Segezia, certainly a point of arrival for Petrucci, it is clearly visible the stylistic jump made in the elaboration of the plan and in the built restitution; it is a clean, dry and centrifugal system, a feature proper of the systems theorized by the leader teacher of the organic movement, Frank Lloyd Wright. The strong element is the square with public buildings, a single square, the Wright 's fireplace, the compositive core from which to start the arms of the cross, the main axes which are inserted in the square and extend the campaign, the artificiality of the offset allows to have public buildings as a backdrop, according to the known signs of Gustavo Giovannoni, teacher of Petrucci and sponsors in various contests. By the urbanistic analysis is known as the "Fascio's home" is lower in tone and in the lateral position compared to previous compositions, it is in contradiction to the fascist's rhetoric who wants the symbol of the power system as a predominant feature and the Fascist tower with the Arengario fully obscured by the steeple of the church. The square is, therefore, characterized by the strong presence of the bell tower that polls sleek and slender on the extended composition of the buildings; along the staggered arms is prepared in a very simple composition the houses for the residents in the city: on the axle north-south the houses binate and on the perpendicular to it, east-west, houses to team with garden. "The plan assumes a stellar form, to Greek cross, favoring the modern criterion that extends to articulated and open formations I pour the country, also not opposing itself to the Italian urban planning tradition of origin "castrense", founded on the orthogonality of a thistle and a decumanus." [7]

The sketch of the plan for Segezia loses, therefore, also that rigidity and allusion to the regime contained in the Roman castrum, the intersection stays only thistle-decumanus, but it loses him the idea of a city rigidly circumscribed within an enclosure; it is a city open shutters factum it hears again some inevitable epilogue. Petrucci strives him to reach a modern and reassuring project, turned to a population for him country, not gotten used to radical and sudden changes, to reach the purpose, is submitted to elements proper of the classical and popular architecture even if in some cases it shows to know how to also plan well to the international way, as in the case of villa Cernò. "The central plaza is of measure suitable to the greatness of the town center (m. 40 xes 100) and introduces the greatest side toward the National Street, to do yes that the new building nucleus can introduce to whom passes long such road a great architectural consistence, also in the first period of its formation." [8]

As already seen to Pomezia, also to Segezia the bell tower detaches him from the surrounding volumes to rise him isolated as element of territorial reference and compositive piece organizer of the urban sketch; Petrucci is a careful architect to the traditions and the spirit of the place, he often succeeds in getting a good result filtered by a mixture of traditional constructive techniques and modern languages; for all the public buildings of Segezia, it uses a constructive system in carrying masonry with bricks of the caves of Lucera, only exception is made for the loom in cement armed with the bell tower that, however, as it makes to probably notice Cucciolla is not thought so in initial phase, "The bell tower that dominates isolated on the angle of the church square will have the central nucleus, within which the staircase unties him to helix, in bricks masonry. Around such nucleus nine orders of loggias are prepared overlapped that they lean on a plinth dressed again of stone of Trani. The loggias are formed from a peristyle of plates in ingot of stone of Trani on which leans the pure lintels in stone of Trani and the insoles of armed cement that form the various ledges of it. To the summit it is the bell cell surmounted by the conic cusp" [9], and Cucciolla adds "you can be thought that for the architect this detail of the general composition dresses again particular importance to mark a change in its language and in the hierarchy of its universe of symbols: rarely, in fact, in his preceding production, Petrucci has used and, above all exhibited, so the "modern" loom in armed cement, if not in the project "private" of the villa Cernò to Bari and in some details of the work St. Michael of Foggia. Perhaps now, in the case of Segezia, built while everything one world of values and certainties goes to splinters, Petrucci wants to signal the to mature of one critical afterthought of his, using a language anti-rhetorical, in no conventional comparison with the tradition really to give form to the tower, that is to the symbol for excellence of the "new city"; this comes besides fact, you are noticed, for the bell tower of the church, and not in the "littoria" tower that, straight it misses in the general setup. [10]

Compositionally the carrying structure of the bell tower is to square base, every side is quadripartite from openings and repeats him overlapping itself for nine orders; the covering is in stone of Trani seized to the loom with metallic pivots; the structure to loom leans on a solid cubic plinth, from the monolithic aspect, also dressed again it in limestone, from here part the staircase that is screwed inside the tower that is dressed again in facing bricks, with I get off on landings of rest protected by balusters to tubular metallic horizontal, draws stylistic of a modernity rationalist of nautical derivation; the ascension concludes him in the bell cell surmounted by conic steeple, dressed again in green enameled ceramics of Vietri. The bell tower is thought as an autonomous element in comparison to the church, it stretches out ahead him in toward the plaza; . isolated in front of the Church, tall and slender, it dominates the whole urban aggregate, and it is the compositive focus of the Plaza, around which all the other constructions are gathered and tied up according to an unitary urban planning and architectural order. On the backdrop of the street coming from the sour one, visible from very distant, it will serve from call and reference to the farmers of the distant agricultural houses, [11] it is slender and balanced compositionally; it succeeds in conjugating well tradition and innovation so that to observe the Duce's indications.

It is certainly an important element of the project that illuminates of itself the whole urban composition and it gives measure and sense to the buildings; it can be considered, perhaps, excessive for quality, in relationship to the around but, surely it is an anti- rhetorical object, elegant and secular, realized as a small miracle, in the eccentric lowland of the Tavoliere, in dialogue with the endless line of horizon, Maria Luisa Madonna defines it as "a sort of squared tower of Pisa with echoes of the Apulian cathedral " [12], it represents a fundamental point for the project, testified by the weight that it assumes in the numerous sketches that Petrucci makes about Center. The church is evidently thought of continuity with the bell tower, the two buildings certainly represent the most important pieces of the whole composition; they are tied up among them from the before church square the façade of the church. "The church is situated to side of the central plaza of Segezia on an ample church square that stretches him before the façade and to one of the sides that it looks out upon on the plaza. Such location allows the maximum exploitation of the view of the architectural masses of the temple the plaza. Insofar

on the side open three doors that will serve to the ordinary entry in the unique aisle have been, while the principal door will be open only in the great occasions of religious parties. In correspondence of the three side doors, they open on the wall opposite three chapels votive, while in front of the principal entry the presbytery introduces him with the greatest altar, the pulpit and the choir." [13]

The plant is to unique aisle with the three chapels that are extended northwestern, the three accesses on the southeast plaza and the apse rectangular turning to barrel. "Wide it is the presence of interventions taken care of by artists as Amedeo Vecchi for the majolicas of the Crucis Street; Thomas Bertolino for the Baptismal source; Giovanni Cavalieri for the Easter candle; Conrad Corelli for you furnish him sacred; Gisberto Ceracchini, exponent of the "Roman school", for the fresco apsidal that doesn't come, however, performed". [14]

As already happened in other cases, also for Segezia it is visible a release of modernity in the realization of the buildings in comparison to the elaborate ones of project, more traditional, perhaps also to gratify the superior organs of the party, it stays that it is practical enough diffused for many projects compiled in the two decades, you are enough to think about the enormous release modernist of the mails of Vaccaro in comparison to the elaborate ones of project. " Near the pulpit, in the aisle, it is the Easter candle; the baptismal source is to the side of the principal entry. The confessional ones are situated in special places, sideways prepared to the chapels votive, easily visible from the central aisle. In direct communication with the presbytery, it is the sacristy and the parish office, that have access independent from the plaza, through an ample place with side closets, from which it is also accessed the pulpit. The coverage of the aisle of the church is to roof with the nervous systems to sight; the side chapels and the presbytery are covered at times to barrel; all the other environments have attics in armed cement; the sacristy is crowned by a conic little dome of armed cement that it remembers the ancient Apulian "Trullo." [15] The church, therefore, for some admission of the author, it hears again some influence of the local architectural repertoire, but revisited anew and with the graft of some heterodox lines, as for instance the inserts polychrome majolica of Vietri "like a jeweled fabric." [16]

Anthony Pennacchi [17] he/she sees in the continuous centrality of the church with the bell tower, this last underlined to landscape staircase as lighthouse and point of reference for all the farmers on the territory, a clear message of the victory of the faith on the fascist military power; it believes that Segezia, built to the peak of the parable of the two decades, signs the end of that historical period and the beginning of a new aware antifascist conception. The public buildings, that complete the central part of the Center, are prepared as to curtain of defense of the bell tower, almost positioned in barycentric way, and they seem to play a perspective role in the study of the views; in fact, they are prepared in way progressive altimetrically up to the lowest volumes in the houses not realized for always guaranteeing a good view of the bell tower. The precise goal of the architect is the to want to stretch the more possible the volumes on the line of horizon, making then to emerge, with vertical rush, the only bell tower. The road of access to the Center conducts us to the town building, that has of side the buildings of the firm (residences and offices) and the mails. On the west side there are other residences with the cafe-inn and a side of the church, that from which you/they open the doors of access, since the principal entry usually stays closed; in nearness in the church they are situated the scholastic buildings: church and kindergarten, close then the buildings Onc, the policemen's barracks, the clinic and the covered market. The town building is dressed again in facing bricks of Lucera on triplex order porch of seven arcs to all sixth that forms some deep shades in façade that oppose the covering in stone of Trani of the church and the bell tower of the strong banging of shades and light, it effectively detaches him from the whites and calms houses that surround it sensitively accenting its important civic function. [18] Petrucci speaking of the triplex order of overlapped loggias says that they are thought, according to the traditional type of the southern architecture. [19]

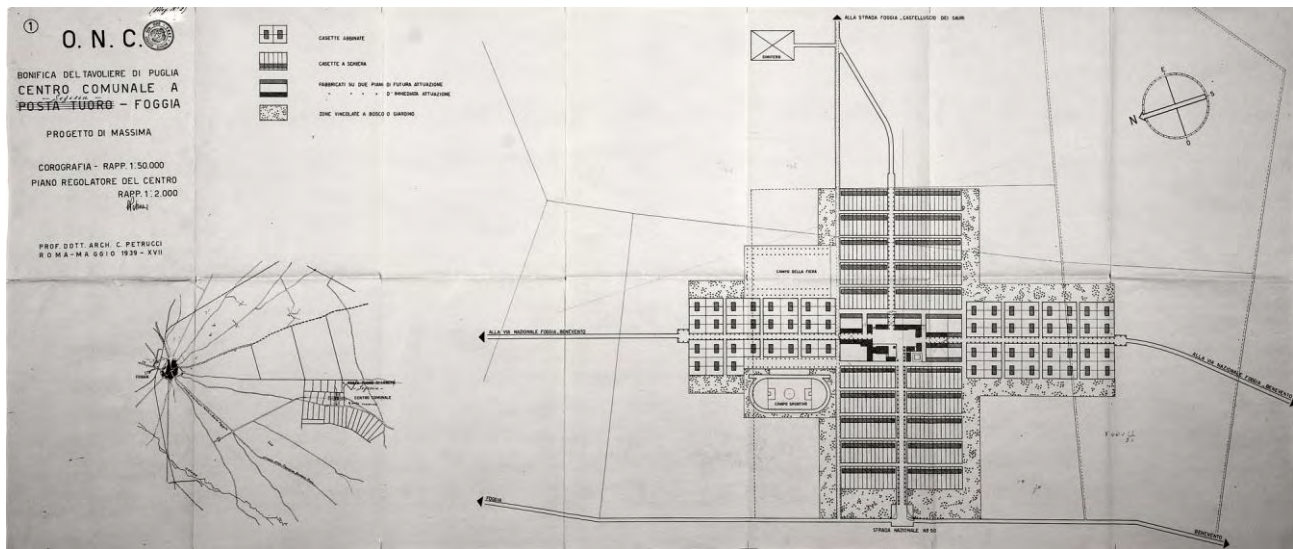

The House of the bundle is evidently under tone in comparison to the precedents examples; the "littoria" tower is timidly reported above the atrium, the covering is in mighty ashlar of stone of the near Apricena, the Arengario and richly decorated by sculptures of Francis Magni; it is connected to the municipality through the postal office that is prepared to the plain earth, while to the superior plan there is an apartment from lease. The architect specifies that" [the] anticipated constructive systems for all the above described built they are those Apulian traditional that corresponds to the necessities of the autarchy." [20]

The barracks and the clinic constitute a body to if the opposite side of the building for residences and shops, the barracks on two plain allocate to the plain earth offices, dormitories and kitchens, to the plan superior two lodgings for military. Residences and shops are prepared on buildings to two floors some of which "connected from underpasses they contain the covered market."; IV I lot. This last is formed from a quadrangular porch covered with a light platform in armed cement with the accesses allowed by the above underpasses; making

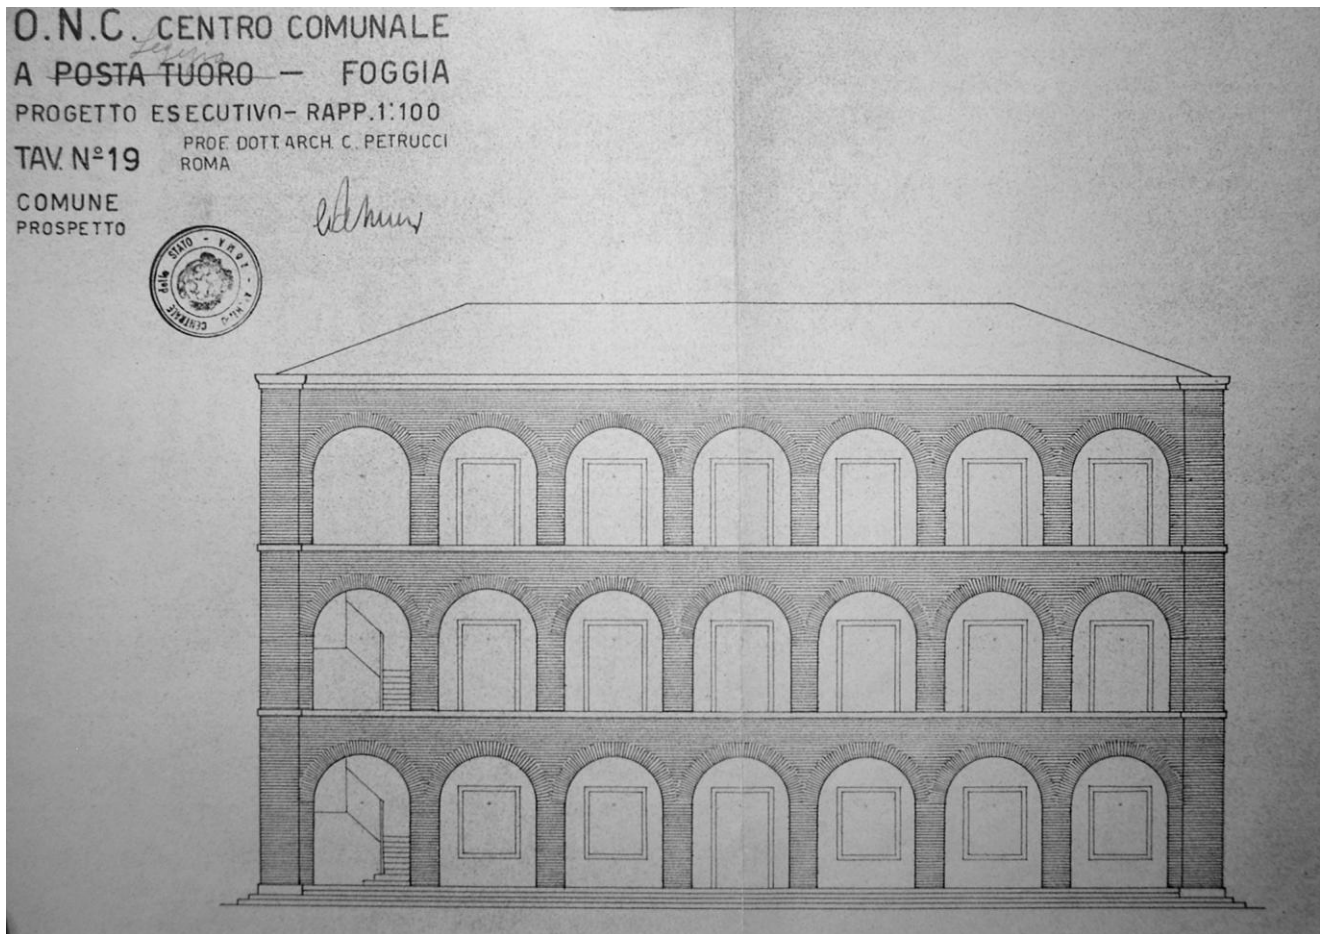

exclusion for the building destined for the coffee restaurant and inn, it substantially concerns a least aggregate constituted from shop and back office to the plain earth and residence to the superior plan, the sense it is that to recreate an intimate relationship between house and shop as custom in the small suburbs. Segezia as other cities been born in the imminence of the burst of the second world conflict, are alone partly completed and, as already happened in precedence, only in the share of the public buildings, this because they are such buildings to constitute the part most important, the least nucleus of existence, being these cities to service of the population disseminated in the country. From the point of view stylistic reports clearly a planning evolution, the architect's architectural will, (prematurely disappeared), the point of arrival of a search who often engaged him with the theme of the rural city - theme that has been often ignored by the great architects of the time focused more on the architectural object - and that it stays, in every way, his last realized work.

The church in the theatre: the relation with the old age in the architecture of Benevento in XVIII century.

Patrizia MOSCHESE
Facoltà di Architettura, SUN, Aversa, Italia
E-mail patriziamoschese@yahoo.it

Abstract

The church of Santa Maria della Verità is a really interesting example in the architecture of Benevento in XVIII century. It has been built on the ruins of the roman theatre in Benevento. It is a monument that hasn't been recognized yet as a symbol of the urban decoration.

This work was built at the end of the XVIII century, on Saverio Casselli's project who was an ecclesiastic architect as a professional polyhedron, and who worked in Benevento between the second half of XVIII century and the beginning of the XIX.

The studies of the documentary founds, preserved in the Record Office in Benevento, have given the possibility to establish the steps of the plan, the choices and the reference models used by the architect. Moreover, these studies have marked the relation with the old age in the architectural culture of Benevento in XVIII century.

Parole chiave: Benevento - XVIII century - architecture – old age

A particular interest has been found on the church of Santa Maria della Verità in Benevento, built on the ruins of the roman theatre by the architect Saverio Casselli [1].

Its setting was required after the earthquake in 1702, that destroyed the native church built thanks to Cardinal Orsini in a different place from the current one [2].

The former church with an octagonal plan, dedicated to Santa Maria della Verità, was built by the architect Giacomo Manerba in 1693. Its project has been preserved and attests the planimetric configuration of the building [3].

As the documents preserved in the Record Office of Benevento, the project of the new church of Santa Maria della Verità, wished by the archbishop Banditi, is assigned to Saverio Caselli in 1779, who supervised the works too [4]. The architect wanted that the building of the new church would be based on the ruins of the roman theatre in the area called Triggio [5].

The strange position close to a roman structure is advised by technicians who are charged by the bishop Banditi, to find an ideal site for the new foundation. Casselli takes care of these advices after a wise strategic choice which was shared by his main customer coming from the order of Theatines [6].

The choice of the area of Triggio could be linked to the habit of Theatines to create their churches in strategic points of the city, where the presence of people was higher [7]. Moreover, by starting again the settlement of the area of Triggio, begun by Orsini after the earthquake in 1702 with the cleaning of the area, Casselli plans to transform this area in gardens, maybe as hanging ones; this idea is well shown in the detailed project found in his *Topografia della Pontificia Città di Benevento* in 1781 [8].

Many sources between the XVIII and the XIX century, show the condition of the theatre in a urban stratified context, by attesting the presence of little houses got from the ruins of the old structures [9], which will be completely reemerged only in 1985 [10].

The roman theatre, wrongly called amphitheatre, wasn't considered as symbol of the urban ornament in XVIII century because of the presence of houses whose bricks barred to distinguish the ruins of the arcade [11].

Fig. 1: Giacomo Manerba, plant of the old church S. Maria della Verità, ASBn, Notai, certificates of the notary Giuseppe de Pompeis, b. 2490, f. 488.

Fig. 2: *Pianta della Pontificia Città di Benevento* printed in 1764 - draftsman L. Pizzella, engraver V. Alojja. (in the area of roman theatre in particular).

Casselli is the first architect to recognize the real shape of the old roman area, and to make a survey in 1779 linked to the project of the church of Santa Maria della Verità [12].

The ruins of the theatre hidden by modern buildings, and the Banditi's wish to create, there, a new church, let Casselli not to respect the former structures on which he plans to put the bricks of the new church.

In the second half of the XVIII century, the attitude towards the old cities wasn't established on modern principles of protection for monumental buildings, even if the architectural culture recognizes the value of the classic areas. Susanna Pasquali writes: "If Bernini, in occasion of the Holy Year in 1650, and Carlo Fontana at the end of the XVII century could plan the settlement of a church in the Colosseum, during the jubilee in 1750, such a project that come out again, found the unfavorable opinion of who wrote that a modern building distorts the old open air-theatre" [13]. A similar opinion – Pasquali continues - comes from Paolo Posi about the replacement of the old penthouse in the Pantheon with a new one with modern shapes. Giovanni Gaetano Bottari too, says that the new settlement of Santa Maria degli Angeli with its further transformation of the central hall, made by Luigi Vanvitelli in 1750, takes the areas near the *tepidarium* away from the old *thermae* [14].

The choice of Casselli – as his drawings attest in the past – to create a new church on the ruins of a roman monument can be justified by the consideration of the old things in the XVIII century. Studying the old era in the XVIII century, represents a good means to become an architect, to enrich his culture and to find ideas to put into his own works.

As educational aims, the survey of old monuments is really useful, made during *Gran Tour* and proposed by the Academy of San Luca either as practice than as topics in academic competition of the third stage [15].

So, the documents about the steps of the settlement of the church are important to explain the cultural opinion about the old age.

Fig. 7: Facade of the church of Santa Maria della Verità in the roman theatre. (Photo taken from the convention *L'Acustica dei teatri antichi*).

While the carrying out of the works – drew up by Giacomo Farotti who was the representative of the Cardinal archbishop Francesco Maria Banditi, and Ignatio de Juliis who was the master bricklayer, in 1779 – plans to demolish some original structures of the roman theatre together with the demolition of the former buildings, on the other hand in *Piano e Dettaglio* Casselli affirms that all the valuable things found during the excavation as inscriptions, coins, gold, silver had to be considered a property of the cardinal Banditi [17].

So, we can affirm that documents recognized these valuable finds as important, which could enrich the old collecting, but the structural parts of the old architecture weren't appreciated with the same value.

The plans of the church, preserved in the Record Office in Benevento and published in 1976 in *Benevento Sacro* by Gaetana Intorcchia, reproduce the plan, the facade and the area of the church and of the parish church [18].

The first table - *Piantato della chiesa Parrocchiale di San Giacomo e l'Elevato della Facciata della Parrocchia* - presents the drawings of the plan and of the facade.

The church, with a rectangular plant, has only a nave with two chapels on the side.

It is covered by a big elliptical vault divided at the end by a marble balustrade which defines the presbytery area.

The high altar formed by an elegant decoration with polychromatic intarsia, ends with angels as support corbels, is still today present [19]. Differently, the two side altars had been demolished during the works repair made in the 60th of XX century [20]. Maybe the balustrade that defined the high altar had been demolished too [21].

In the second table, Casselli plans the area of the church, where we can find geometric spans of ionic pilasters, triumphal arches and simple painted cornices which are the only ornamental elements. In the longitudinal area there are ionic pilasters and artificial doors that defined the nave.

Thanks to the three lunette windows and the central big window of the façade, the inside area is lighted. The section shows a strict relation that links together the formal composition of the façade with the inside area. In fact the composition of the spans-reproduces the motif of the pilasters with ionic capitals, lightly over hanged, and with cornice in entablature for the façade.

In the 1933 De Lucia gave to Casselli not only the role of Architect but also that of manager about the painting works of the church, attributed to the scholar in 1786. The new documents can date the wall decorations between 1781 and 1782.

De Lucia attests the bad state of the painting decorations which had been spoilt by the dampness, and covered by the plaster [22]. Today what it is left of the pictorial work created by Casselli is only a minimum part on the right side of the apse. Where it makes out the remnant of the original scenery with the shaft of fluted column and the ruins of a feigned marble decorations that frames the door.

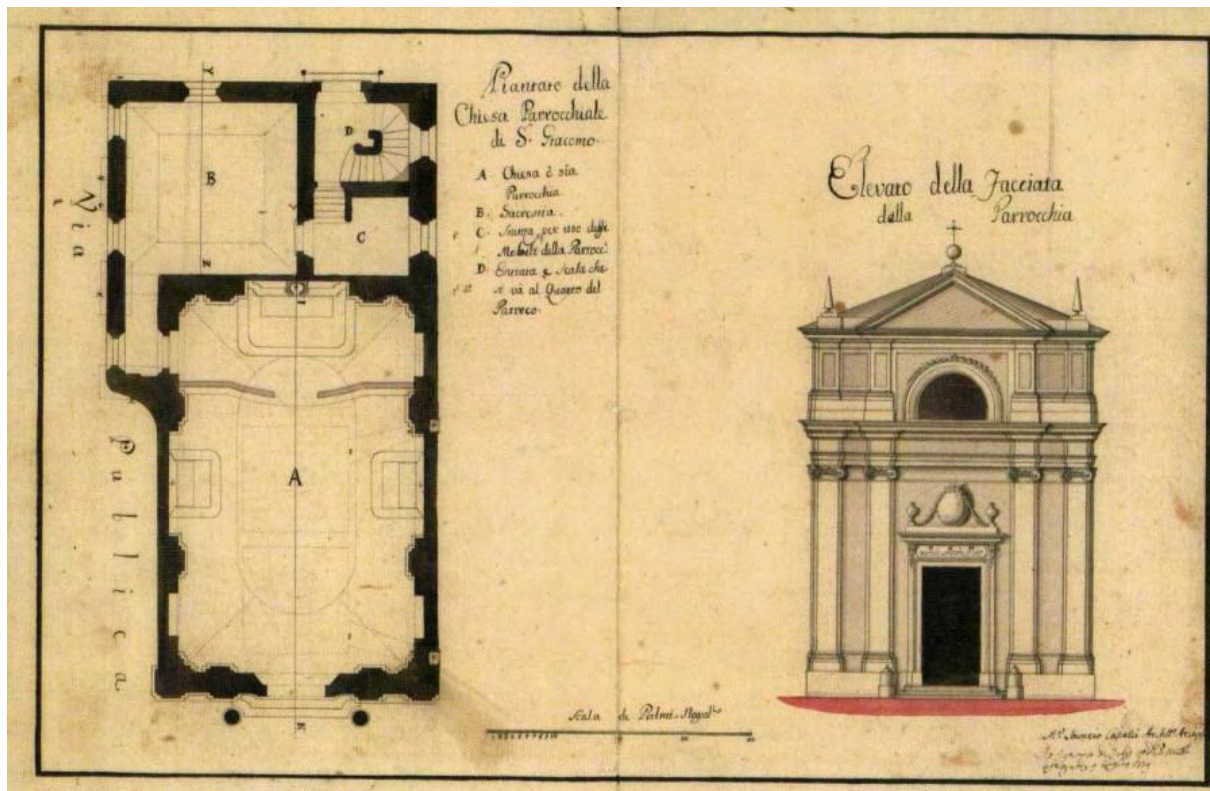

Fig. 8: Saverio Casselli, plan and facade of the church of S. Maria della Verità, ASBn, *Notai*, 8456, f. 137. 1779.

The ornamental intervention envisaged by the architect is in line with a taste for the spectacular widespread in the cultural climate of the XVIII century, both in Papal Rome and Bourbon Naples, the idea of Casselli to interrupt with an optical illusion the space through the architecture as an ornamental decoration comes out in the work of Bramante for Santa Maria near San Satiro in Milan.

The architect to extend the space of the church that is too little uses the drawing of trompe-l'oeil on the outside wall of the high altar Bramante creates in perspective with the effect of *trompe-l'oeil*, a barrel vault and lacunar as an ideal prosecution of the nave.

Casselli too has to intervene in a very little space limited in the plan from the structures of roman theatre where it is joined. The nave takes up the whole planimetric composition of the church sacristy and additional environments are situated, behind, the presbyteral area. The illusory trompe-l'oeil becomes, so, a necessary device to extend the perception of an architectonic space that is too limited. The introduction of artificial doors in the walls of the nave and the spatial expansion made by the use of scenery painted, indicate a particular sensibility of the architect for the pictorial decoration perceived as an instrument of spatial composition.

Casselli considers as models the scenery architectures built on San Feliciano theme of the staving in of the wall and the variety of the visual directions of bibienasca tradition that we can often find them not only in Fuga, Vanvitelli and Gioffredo, but also in the use of vaults and artificial doors used by painters that work in the vanvitelline equipe such as Gaetano Magri and Giacinto Diano [23].

The church of Santa Maria della Verità was realized during the initial stage activity of the architect, that even if he was only 30 years old, he was able to express his simple and elegant style, however he was influenced too by the neoclassical culture.

His first ten years of activity represent for Casselli a period of an hard professional engagement during which the architect uses a simple style and at the same time perfectly harmonious following the formal and proportional system inherited by the sixteenth century. Casselli suggests, indeed, for the composition of the façade a component solution very used in Rome academic environment where his formation may be done.

Fig. 9: Saverio Casselli, section of the church of S. Maria della Verità, ASBn, *Notai*, 8456, f. 138. 1779.

It is interesting to notice the presence of the thermal big window that was used by Palladio and Vignola and of the tympan placed on the top that were morphological solutions visible in different examples of the second eighteenth century; as in the plan for the church of Sant'Aniello in Piano di Sorrento, work of the architect Gaetano Barba, elaborate around 1787 [24]. The project is compared with the solutions proposed by Valadier in Santa Maria del Popolo and in San Pantaleo in Rome; the reason is the presence of the thermal big window and of the tympan [25].

But we can find relevant similarities of formal dictionary link together to the church of Casselli also the solution suggested at the beginning of XVIII century by Valadier for the façade of the church of Scolopi in Frascati.

From the study of the drawings, it is clear that for the architect of Benevento the plant is the main element that creates the architectural space. The ornaments are avoided according to a refined geometric definition and a simple composition expressed both on plant and on the structure.

The decoration of the principle façade constituted by pilasters, the only formal elements, results simple and essential. The façade of the church of Santa Maria della Verità presents indeed a podium on which is based on four pilasters with ionic capitals that flank and frame together to the trabeation, the portal of entrance with the marble armorial theatins, the group one belongs to the customer.

The final stage of the façade is made by a crowing dominated by a semicircular central big window and by a double triangular tympan where a cross in the middle and two pinnacles on its sides are placed. The present configuration shows, instead, a circular opening in the double tympan that is not present in the plan of Casselli. Even in the composition of the prospect, the ornamental structure is reduced to few elements extremely efficient, such as a huge order of pilasters, the final window and the double tympan. The formal solution realized for the façade could be linked to the theatin customer Francesco Banditi, as similar to typologies used in the second half of XVIII century from theatin order that relates to the armorial bearings [26].

The church of Benevento presents, indeed, a similar layout to many churches dedicated to San Gaetano, the founder of Theatin order in particular with the oratory of San Gaetano in Vicenza, realized for the theatins between the 1708 and 1709 that presents a different window up to the portal. It is also similar to the church of San Gaetano di Thiene in Siena, built between 1683 and 1700 at the end enriched on the portal by a big niche with filler with the *Madonna con il Bambino e Santi* at the centre.

The plan for Santa Maria della Verità represents so, the practical realization of a precise dictionary based on geometry, proportion and on harmony defined since the beginning of the architect, the themes that marked his professional activity: the relation with the old things, the geometric definition of spaces and the integration between the arts.

Abstract

The opening of the Mexican economy and globalization bring new opportunities for Mexican companies to expand their markets and get their products around the world. The internationalization process requires a sound strategy for the consolidation in foreign markets. The aim of this study is to analyze the different internationalization strategies followed by three Mexican companies with a global presence: Grupo Modelo, Grupo Bimbo and Cemex. We conclude that the differences in their strategies arise from the characteristics of each of these companies.

Keywords: Mexican companies, strategy, expansion, internationalization.

INTRODUCTION

The landscape of this century requires companies to be increasingly competitive, and that not only have to compete with domestic rivals but new players come in search of a single market. Today's competitive advantages and are no guarantee of success without a solid strategy that will ward.

The decision made at the time a local company to expand its market to new countries, must be supported by an internationalization strategy appropriate to the characteristics of the company. It also has a wide range of options for entering new markets, exports, licensing, and joint ventures with foreign partners, strategic alliances, acquisitions, establish subsidiaries, among others. However the best choice will be consistent with its objectives and characteristics.

BACKGROUND

Globalization is a phenomenon that accelerated in the late twentieth century, in the last three decades, increased international economic transactions, thus expanding economic relations between countries.

The world economy entered a process of numerous scientific and technological advances that changed production patterns worldwide. The deregulation aimed at removing trade barriers between countries was a consequence of globalization, which for some companies has been a growth opportunity, while for others a latent threat to the entry of new competitors.

In the mid-eighties with the entrance to the General Agreement on Tariffs and Trade (GATT), the Mexican economy began a process of trade liberalization which is consolidated with the entry into force of The Free North American Free Trade Agreement (NAFTA). Thus our country adapts a new economic model: the neoliberal model, which encouraged external competitiveness from trade liberalization (Branches, 2005).

The new economic policies of this new model involve change and restructuring of Mexican companies. The Mexican economy opened to international trade and financial markets, gave a strong boost to exports and foreign investment was allowed in more sectors of the economy. All these actions benefited large Mexican companies in their growth and expansion, while allowed to integrate into international production and exports through acquisition of companies abroad (De Gortari, 2005).

Grupo Modelo, Bimbo and Cemex were three large Mexican companies that were consolidated in the country and sought to internationalize through different positioning strategies in international markets. A common denominator among these companies was the use of acquisitions and alliances with foreign partners, but the strategies followed by each were different.

DEFINITION OF THE PROBLEM

According to De los Rios (2005) among Mexican multinational companies successfully in the internationalization process are: America Movil, Bimbo, Gruma and Cemex. Clarifying the process of internationalization beyond imports and exports, i.e. involves the establishment of subsidiaries or the acquisition of companies is elsewhere.

This research focuses on the analysis of internationalization strategies followed by three of Mexico's most important companies of our country with a presence in international markets: Bimbo, Cemex and Grupo Modelo were chosen because these three companies have been recognized by national and international magazines as successful businesses in foreign markets. According to the ranking made by the group and published on its website CNN Expansion, these companies are among the 500 most important companies in Mexico. Cemex is in the number 6 in the place Grupo Bimbo and Grupo Modelo 11 at number 22 (see Attachment A).

Moreover these companies to analyze different strategies to position it clearly in foreign markets.

Hypothesis:

The characteristics of each of these three Mexican companies are a major determinant of the choice of different strategies and ways of entering foreign markets.

OBJECTIVE

To analyze the internationalization strategies and positioning in international markets of three Mexican companies with a worldwide presence: Grupo Bimbo, Cemex and Model and demonstrate that these three companies have expanded their market by using mergers and acquisitions as growth strategy.

- Analyze the trajectory of each of the three companies in the global context.
- Establish the most important factors influencing the success of each of the companies chosen.

FRAMEWORK

Cortes de los Rios (2005) says that many of Mexico's most important economic groups were created and managed its expansion, consolidation and development thanks to the acquirers and mergers took place. It analyzes the behavior of the acquisitions in Mexico in the period 1986-2005, concluding that this type of operation shows a cyclical and economic fluctuation coincide with the country, increasing in the late eighties and early nineties.

On the other hand shows that mergers and acquisitions for our country are concentrated in banking, finance and telecommunications. In the study period prevailed horizontal acquisitions, followed by vertical and finally concludes that the process of mergers and acquisitions is indeed, as she defines a "vehicle" for the internationalization of Mexican companies.

Moreover, Celso Garrido (2001) a study on cross-border operations during the nineties in Mexico, distinguishing foreign acquisitions made by companies established in Mexico, Mexican takeovers by foreign companies. This study shows results that say the process undertaken grades Mexican companies and groups to internationalize their production activity. Garrido ranks results of acquisitions fleshed out by Mexican companies at three levels: macro, meso and micro.

This work is a case study of the different strategies for entering international markets and show that despite the existence of a common denominator among these strategies, as is the case of acquisitions, the company's own resources play a key role to allow them to take different paths to achieve their goal.

CONCEPTUAL-THEORETICAL

When a company decides to expand into new markets is essential to plan a strategy to reduce the risk of failure, for this is to consider the advantages and disadvantages of different forms that have to enter these

markets and also to consider its position market and the characteristics of your company. In this context we say that an international strategy is one used by a company to sell its products outside its national territory. Internationalization is a process by which a domestic company can extend their productive activities to other countries, according to Peng (2006), is a process where a multinational organization is responsible for any commercial or production of an enterprise located in different parts the world.

The reasons that lead companies to make the decision to internationalize your business are the benefits they can acquire if they implement the strategy succeed. These expected benefits are:

1. Increased market size. Expand their productive activities to another country gives them the opportunity to captivate new customers, new markets to sell their products.
2. Better returns on their investments. It is expected that investments in other countries generate above average returns.
3. Better economies of scale, scope or learning. Producing under economies of scale production reduces costs and produces the same internationalization synergies, which shares knowledge and learning.
4. A competitive advantage of location. When a company decides to settle in another country with the intention of reducing costs many times companies are looking for markets where they can get cheap labor, natural resources or cheaper energy or potential new customers in that country (Hitt, Ireland & Hoskisson, 2008).

There are two ways of entering foreign markets, on one hand the non-property, as its name suggests involve entering new markets without the need to use part of its assets or capital. Examples of these: Exports and contractual agreements.

Moreover there are still properties, which involve the establishment of subsidiaries in new markets; investment is needed to begin operations. Some examples of these: Joint ventures (joint adventure) and partially owned subsidiaries. This approach gives rise to multinational corporations (MNCs) which are companies that operate with foreign direct investment, its function is the control and management of value-generating activities in foreign countries (Peng, 2006).

If a company decides to export has two possibilities: Direct export is the direct sale of goods to foreign customers or where the indirect export sales to foreign markets is through intermediaries.

Contractual agreements are classified as:

A. Licenses / franchises. When a foreign company buys the rights to manufacture and / or sell products in the domestic business. This in exchange for a royalty per unit produced or sold (Hitt, et al., 2008).

B. Projects ready to operate. Projects are paid for certain activities for a business (construction of facilities or personnel training, etc.).

C. Research and development contracts. Agreements between companies to assist in research and development one can work for another.

D. Joint marketing. A set of companies agree to jointly market their products.

Property forms Returning to internationalize. a company defines what is a joint venture (EC) which is understood as a company originated and owned by two or more companies This new company can be a minority (when one of the generating company has less than 50% ownership), 50/50 (partners have the same percentage of ownership) or majority (a company has more than 50% of CD) .

For their part, wholly owned subsidiaries (SPT) are subsidiaries of the multinational company, located in different countries. In turn, these can be of two types: operations on a blank field, when companies begin operations from the construction of these. Moreover mergers or acquisitions are the most popular form of entering foreign markets. Involve the transfer of assets, knowledge, and control operations between companies.

Because the latter is the most sought after by companies wishing to establish themselves in other markets then we pause this for a better understanding.

A merger is defined as the combination of assets, operations and management of two companies to establish a new legal entity (Peng, 2006). Meanwhile an acquisition is the transfer of control of the assets, operations and management of a company (object) to another (purchaser), making the object in a unit of the purchaser (Wright, 2002). In reality the acquisitions are more common than mergers. These operations can be carried out in three directions:

A. Horizontal. Are acquisitions between competitors within the same industry? This is the most common type, as it increases the market power of the synergies obtained by exploiting the costs and revenues.

B. Vertical. This type involves the relationships between companies which makes them focus their suppliers (up) or its buyers (up). With this acquisition the company is vertically integrated, controlling additional parts of the value chain

C. Conglomerate. These are transactions where companies interact unrelated products.

Hitt et al. (2008) adds the related acquisitions occur within an industry closely related and transborder acquisitions are those which as its name says, transcend territorial boundaries.

Moreover, this type of transaction may be hostile or friendly, the first concern when management of a target company is against the acquisition, this company is not seeking a takeover bid. Such events increases during downturns in the economies, as it is easier to detect companies that are undervalued mismanaged in relation to its assets (Thornton, Keesnan, Palmeri & Himelsten, 2002). The acquisitions are friendly when both companies are in agreement to carry out the transaction.

The table in Annex A summarizes the advantages and disadvantages of each of the modes of entry to foreign markets.

A complete model of foreign market entry described in Peng (2006), which considers the tripod base of the strategy as a sound strategy. Considerations based on the industry through the diamond of Porter's five forces suggests a review of the industry environment it belongs to the company, this analysis can uncover opportunities to open new markets.

For their part, resource-based considerations, led by the model VRIO (value, rareness, imitation and organization) are a factor to be taken into consideration the managers of a company when deciding to enter international markets. Many times the value of the assets of a company are key factor to compete abroad, likewise if a company with resources much rare and difficult to imitate, has assets that can exploit an opportunity in other markets.

Finally considerations institutions are perhaps one of the key firms in search of new markets should consider when embarking on new markets. Knowledge of the rules are vital for easier entry to markets unknown. Although globalization seeks the integration of countries, institutions and culture rules are factors that have not yet unified.

After the theoretical review that supports the internationalization of companies in the next section proceeds with the individual analysis of each selected Mexican firms to conclude this section with a comparison of the various factors that influenced the success of internationalization of each company.

METHODOLOGY

The methodology for the preparation of this work was the revision of the paths that have these three companies since its inception to the present, past and putting special emphasis on internationalization. It also is evident through its success through the search and tracking of recognition has been given to these companies. The information collected for this analysis comes from the official website of each company, as well as annual reports and additional sources such as empirical studies for these companies.

The next section will be the case study of each selected Mexican firms: Grupo Bimbo, Cemex and Grupo Modelo.

ANALYSIS OF MEXICAN COMPANIES

GRUPO BIMBO

Founded in 1945, today this company is one of the largest bakery companies in the world and a leader in the Americas has earned recognition for their production and sales volumes. According to its annual report 2010 (Grupo Bimbo, 2010) has 103 plants and over 1000 strategically located distribution centers in 17 countries in America and Asia. One of its most valuable assets is the possession of one of the most extensive distribution networks in the world with over 41,000 routes.

Starting operations on December 2, 1945 the first production plant in Mexico, under the direction of Jaime Sendra and Lorenzo Servitje, Bimbo is placed on consumer preferences through the presentation and quality of their products. In 1946 this plant is expanded and begins structuring the area of vehicles, which later became his strategic asset for the growth of the company. The Bimbo distribution network began with an agreement to distribute its products with carriers who distributed newspapers in the province. However this was not enough and had to open routes and outside agencies, the first in Puebla in 1949.

The distribution of products of this company took from town to town, following the paths, roads and railways, so vendors were opening up the market.

The growth of this company in our country was the result of knowledge of the needs of its consumers (building products) and vision of its managers to take advantage of opportunities offered by the market, spread around the country through establishment of new silver and the acquisition of some of its competitors. In search of closer integration in 1973, Bimbo began making jam in order to supply one of its lines (Marineo dedicated to making cakes and cookies) of raw material. Also in the late seventies Bimbo executives found themselves in the market for sweets and chocolates retailer an opportunity, as this was poorly attended, and decided to put a small candy manufacturing plant (Ricolino). Thus began a diversification outside the bakery and confectionery.

After consolidating the domestic market, leaving Mexico in 1984 the first trailer with Marinela products, bound for Houston, Texas. And in 1989 began international expansion with the creation of Bimbo Bimbo Central America and Guatemala with the construction of the first plant outside the country.

In 1991 created the Latin America Division (OLA) to operate the expansion south of the country. In this decade the company acquired Alesa (Chile) and Holsum, bakery leader in Venezuela. Bimbo is created El Salvador, Costa Rica, Argentina and Peru in Colombia, established a partnership with Noel, the largest biscuit company in the country In 1998, the purchase of American bakery Mrs. Baird's, a leader in Texas that had 11 floors.

In 2001 he made the purchase of Plus Vita from Brazil, which confirmed its leadership Bimbo Latin America and in 2002 acquired the Canadian company George Weston Ltd. Bimbo In this decade, began its presence in Europe with the purchase of the company confectionery Park Lane, located in the Czech Republic.

This decade also acquired in Mexico: Bakeries El Globo, La Corona, Gabi Cookies and Joyce. Bought outside the country: Pan Europe (Guatemala), Los Sorchantes (Uruguay), South Lakes (Chile), Lalo's Bakery (Colombia), and finally Laura, and Plus Vita Nutrella LTDA, the latter one of the bakery companies more large and important in Brazil.

In 2010, specifically three strategic acquisitions: Dulces Vero in Jalisco, Mexico, Hong Jin Wei in China and the U.S. Foods Bimar Finally in November of that year announced the purchase of the bakery division of Sara Lee bakery largest U.S., which as a group Grupo Bimbo Baker worldwide.

In short today Grupo Bimbo has 103 plants worldwide, 42 plants in Mexico, 34 in the United States, 25 in Central and South America and 2 in China. The first quarter reported sales of \$ 29.312 million pesos, an increase of 3.5% over the previous year.

Currently this group has more than 150 brands, the best known are: Bimbo, Marinela, Milpa Real, Aunt Rosa, Oroweat, Entenmann's, Thomas', Boboli, Mrs. Baird's, Barcel, Ricolino, Coronado, La Corona, El Globo bakeries, Suandy, among many others.

All group companies are located in four divisions: Bimbo SA, brings together companies bakers and confectioners in Mexico and Central America, Barcel SA, which integrates the business of snacks and Ricolino, Bimbo Bakeries USA (BBU), serving the U.S. market and Organization finally Latin America (OLA), responsible for operations in Latin America.

ANALYSIS: GRUPO BIMBO

As we can see, the expansion of Grupo Bimbo is the result of significant investments it has made to establish new production plants, strategic alliances and acquisition of companies. His strategy was to acquire or ally with local companies that will offer something in terms of technology or distribution capacity, choosing only those companies that share their values; if the companies did not meet the latter requirement would enter the market from scratch.

One of the key factors that have influenced the success of Grupo Bimbo in the national and international market, innovation is not only their products but to organize the company as the coordination of their plants requires the use computing platforms that support business processes. On the other hand is a company that knows its customers, the distribution network has created allows a more direct and frequent contact with customers, allowing you to identify new growth opportunities and product innovation based on consumer preferences.

In this sense Bimbo has a very important competitive advantage: its ability to reach more distant outlets. Bimbo in our country has to sell their products to an average of less than a mile from each consumer (Grupo Bimbo, 2011). This distribution network is one of the intangibles of the company, which tried to establish the same way in other countries, without a clutch that has found cultural differences that have led to the need to adapt to each country based on their conditions individuals. Finally Grupo Bimbo is a company that just look to expand geographically, also seeks to be a profitable company, which has managed to increase the efficiency of each of its processes. For that seeks to optimize its resources by using technology.

CEMEX

It is a Mexican company initially dedicated to the production and distribution of cement and concrete, but is now a global company that offers products for the construction industry. It began operations in 1906 with Cementos Hidalgo plant in the north. After significant growth for six years, the operation of this company is affected by the Mexican Revolution forced to suspend operations. In 1919, partially resume their operations and not until two years later when the market comes back completely.

Cementos Hidalgo in 1931 merged with its competitor Cementos Portland Monterrey, giving rise to what is now known as Cementos Mexicanos SA (CEMEX). For about thirty-five years, this company has a steady growth backed by the expansion of its plants in the northern region.

Until 1966, decided to venture into the southern part of the Mexican Republic, acquiring in that year the plant Cementos Maya, Mérida. With this acquisition continues to meet demand in this part of the country through Portland Cement brand Maya. That same year the new plant starts operation Valles, in order to meet the Huasteca region in Mexico.

In order to expand across the country in 1967 opened a plant in Torreon through brands pozzolanic Portland cement Portland Cement Monterrey and Monterrey; the plant is responsible for meeting growing demand in the Northeast. Plants installed in all regions continue to grow by increasing its production capacity.

In 1973 Cemex acquired Portland cement plant in the Bajío region of central Mexico. 1976 was a watershed for the company as a part begins trading on the Mexican Stock Exchange and on the other side becomes the leading Mexican producer of cement to its acquisition of Cementos Guadalajara.

In 1986 starts joint venture with U.S. cement companies, in order to enter that market. In 1987 acquires Cementos Anahuac. And this year it created a solid team of professionals who are in charge of the integration of acquired companies. It also implements a satellite system that allows you to connect all the facilities of the company (CEMEXNET).

When purchasing your competition, Cementos Tolteca Cement Company in Mexico second in 1989, Cemex became even without significant presence in other countries, one of the ten largest cement companies worldwide.

It was not until 1992, when he decides to start its internationalization process, which starts on the European market by acquiring the two largest cements in Spain: Valenciana and Sanson. Two years later ventures into Central and South America, buying Cemento Bayano in Panama and the company expires, Venezuela's largest cement. Also, the purchase of Balcones cements plant in the United States.

In 1995 Cemex continues its international expansion this time to acquire Cementos Nacionales, the leading company in the Dominican Republic. A year later became the third largest cement company in the world to be part of your company Cementos Diamante and Samper in Colombia.

Not content with its spectacular growth in such a short time in 1997 the largest cement company in Mexico comes to Asia with the purchase of Rizal Cement and APO Cement in the Philippines two years later. That same year, Cemex ventures into Africa by acquiring Assiut Cement Company, one of the leading cement producers in Egypt also buying Cementos del Pacifico, Costa Rica.

Mexican Cement century starts with the determination to consolidate the already developed markets in 2000 purchase Southdown, Inc. in the United States in 2001 and acquired Nicaragua enters Saraburi Cement Company in Thailand. The operation performed in 2005, doubling its size and expanding its market to more than twenty countries, mainly in Europe. This transaction is the acquisition of the British building materials RMC, which according to a press release on September 27, 2004 posted on the website of the Mexican company and meant a great synergy that will allow the centralization administrative functions, optimization of network marketing, logistics and process standardization.

Far from purchases made by the Mexican company in 2000, implemented an initiative to identify, incorporate and implement standardized best practices within the entire organization (CEMEXway). This initiative consolidates the group that was responsible for the integration of acquired companies.

Finally the integration of the Australian company Rinker Group Limited, the Mexican company consolidates its position as a leader in the cement industry.

ANALYSIS: CEMEX

As we see in the above description Cemex in less than twenty years the company extended global territory through the use of acquisitions, it is surprising success of this instrument through which although not clearly mentioned in its path also has been due to the economic and financial company that manages the.

Cementos de Mexico took advantage of the benefits it gives its sector to grow, among them is the oligopolistic power that exists in the cement industry worldwide and on the other hand the technology needed to get started in this industry.

It is also important to highlight the use of information technology as a key tool for coordination and smooth running of all its businesses. In addition to this we believe that one of the intangibles that this company has is the group of professionals responsible for integrating each of the acquired companies, which we believe has been a fundamental part of their success in geographic expansion.

Finally for this company innovation is also one of its strategies on the one hand to stay ahead in terms of the needs of the construction industry. On the other hand has also allowed it to innovate the production process which has gained efficiency by getting competitive production costs and has remained a profitable company. For the first quarter of 2011, record gross profit by 963 million dollars and a profit margin of 28.5 percent. Your total debt to 17,059 million dollars estate

Finally, to confirm the success of global expansion strategy we can summarize that has followed it, one of Mexico's most important companies of our country and worldwide presence, has been placed today in 35 countries.

In Central and South America is in Argentina, Colombia, Costa Rica, Dominican Republic, Guatemala, Jamaica, Nicaragua, Panama and Puerto Rico and our trading operations in the Caribbean. In Europe in Austria, Croatia, Czech Republic, Denmark, Spain, Finland, France, Germany, Hungary, Ireland, Latvia, Norway, Poland, Sweden and the UK.

In Africa and the Middle East with operations in Egypt, Israel and the United Arab Emirates Finally in Asia is found in Bangladesh, Malaysia, Philippines, Taiwan and Thailand.

This company has continued growth by taking advantage offered by your industry and geographic expansion strategy. The cement industry has a short chain which facilitates the vertical integration (Torres, 2006). In this sense the location of subsidiaries in places where you can extract the raw material, was one of the strategies for geographic expansion.

Cemex has a presence in other countries by building or acquiring complementary businesses in these markets, this has been done without the need to accept foreign capital. This type of strategy was successful thanks to the short chain of cement, and innovations necessary minimum the oligopolistic structure of this market (Pozas 2002).

According to de Gortari (2005) when Cemex acquisition takes place, first make a review of the country's culture and the target company after that his team, made up of trained professionals in the area of systems, resources human, financial, acquisitions, business relationship management, conducts a comprehensive analysis of the company. If the transaction takes place beginning a process of integration with the aim of unifying the levels of productivity and culture will be outcome. In addition, this company takes advantage of regional economic activity and consumption capacity.

GRUPO MODELO.

Today, Grupo Modelo is the leader in developing, distributing and selling beer in Mexico Founded in Mexico City in the year by 1925.

Since its founding the basis of growth of this company took in two ways, firstly the acquisition of breweries in the country thus acquired new brands and on the other hand the construction of new plants will allow increasing production capacity. In addition to these two pathways, exports have been the tool that this group has chosen to internationalize in markets around the world, which has contributed significantly to its growth.

I make the first acquisition was the purchase of Brewing Company in Toluca and Mexico, Victoria Marks and Pilsener in 1935. By 1954 the brewery acquired the Pacific, Mazatlán, Sinaloa and Brewery Star in Guadalajara, Jalisco. In 1960 he joined the group Northwest Cervecería Modelo, Ciudad Obregon, Sonora.

Exports of beer of Grupo Modelo in 1933 started albeit sporadically, with the first American foreign market.

In 1964 he established the Cervecería Modelo de Guadalajara in 1964 and in 1967 opened the Cerveceria Modelo Torreon. For the year 1979 built the Tropical Brewing Company, located in Tuxtepec, Oaxaca, but starts to operate until 1984.

A strength of this group is the vertical integration that have since not only focused on building new breweries but also worried about the creation of companies that produce the inputs required by the brewer. That is why in 1979 he founded the company Cebadas and Malta Calpulalpan, Tlaxcala and in 1981 the company Inamex Beer and Malta, in Texcoco, Mexico State. In the same year acquired Cervecería Yucatan.

We can say that the internationalization of the Mexican company gains importance from 1985 when Grupo Modelo beer exports start to new foreign markets, this time the beer the company heads to Japan, Australia, New Zealand and some European countries. In 1990 Corona beer is exported to Hong Kong, Singapore, Greece, Holland, Germany and Belgium.

Zacatecas Brewing Company began operations in 1997. That same year, Corona beer stands as the first imported beer in the United States.

In 2006 Grupo Modelo set up an alliance (Joint Venture) with Constellation Brands, a leading international wine and spirits. This alliance creates Crown Import LLC, headquartered in Chicago. Began operations in 2007 and the main reason being is that Grupo Modelo has a single importer in the North American market. That same year he started building another brewery in Nava, Coahuila.

Grupo Modelo currently exports about 6 brands of beer in 156 countries around the world, these brands include: Corona Extra, Corona Light, Negra Modelo, Modelo Especial, and the Pacific.

ANALYSIS: GROUP MODEL

According to the trajectory described by this company, its expansion into territory was through the acquisition of breweries from other companies and the construction of plants characteristic of the group. One of its

strengths is its vertical integration which allowed him to strategically integrate companies that provide their own raw materials and packaging. In this sense also has a strategic partnership that gives it mainly American machinery of high technology, which guarantees the efficiency of their processes.

With regard to international expansion, as it says Hitt et al. (2007) companies engaged in the production and marketing of beers have few growth opportunities in its home market, which urges them to offer their products abroad. This was the case of the Mexican company, however as some firms internationalize by acquiring companies in other countries, this Mexican company has achieved its goal of placing their products in different countries of the world only through exports.

Although exports have certain constraints such as less control of the marketing and distribution, this group has dispelled this disadvantage by establishing offices in strategic locations in order to respond in a timely fashion importers, distributors and customers, it also meets the goal of placing products in a strategic model.

When Grupo Modelo decided to venture into new markets, makes a study of the target market considering their economic and cultural conditions, likewise due to their experience have learned to look after intellectual property issues and laws. Finally enter the market with adequate infrastructure in sales, promotion and marketing.

CONCLUSIONS

We conclude that a common denominator in its internationalization strategy between the three companies chosen for this work was to use acquisitions to expand its market. But while two of them, Grupo Bimbo and Cemex, these types of transactions conducted in foreign markets, Grupo Modelo now consolidated its position by acquiring companies in the same business only in the country.

Cemex was the three most dynamic in terms of foreign companies compare in terms of time and quantity.

Among these companies there are common elements that have been present in their internationalization strategies such as innovation not only in products but in new systems of organization. All three make use of information technology for better coordination of all group companies or company.

Despite having a similar strategy, each of these companies differentiates your strategy based on characteristics of the company. On the one hand Cemex has advantages given the sector where, as it is an industry with few producers of cement. On the other hand Grupo Modelo by the type of good it produces, allows you to use exports, it does not require the installation of plants in each market again.

In this study we recognize intangible assets of two companies, which have been a tool that has helped the success of your business. Cemex has a group of professionals responsible for integrating each of the acquired companies, allowing them to be integrated resources, knowledge and learning specific to the company obtained in each market.

One of the intangible assets was recognized of Grupo Bimbo's distribution network which has enabled it to reach a large number of consumers and be at the forefront in meeting the needs of its consumers. Examples of these needs have been a wide range of products more healthy.

Grupo Modelo because it only makes its internationalization through exports, has expanded to a large number of countries through the establishment of offices in foreign markets not only engaged in the marketing and distribution of their products, but also is responsible for positioning your product in strategic locations.

THE DEVELOPMENT OF THE PRINTING DIVISION OF THE KOREAN GOVERNMENT (1880- 1910): - JAPAN INTRODUCED MODERN PRINTING TECHNOLOGY TO KOREA -

Dr. Hyun-Guk RYU

Professor, Visual Communication Design Program, Tsukuba University of Technology, Japan

E-mail h-ryu@a.tsukuba-tech.ac.jp

Abstract

The purpose of this research is to discover the missing factors in Modern design history of Korea and to investigate the introduction of modern printing technology and historical development of the Government Printing Division. Korean modern printing technology was introduced not by the westerners but China and Japan. "Chosunsinbo" which introduced the printing press and letter types for the first time in Korea (1881) was a newspaper for the Japanese merchants' organization living in Busan, Korea. "Korea Imperial Government Printing Division" so called "Yongsan Printing Office" in particular, it reformed types and distributed the standard letter types to the public. In this regard, this paper has been focused on reconstituting history based on research data explored to clarify the historical development of the Korean Government Printing Office.

(1) The historic development of the Korean Government Printing Office is clarified from the perspectives of typeprinting history.

(2) The significance of the first Korean newspapers, stamps and banknotes, the employment of Korean and Japanese editors and printing technicians, their roles and activities and the characteristics of typographic design are clarified.

(3) The introduction, development and trends of Korean typeprinting, printers and press machinery are examined based on verified research data.

(4) The roles of the Architectural Bureau of the Branch Printing Office (Takjibu), the architects' activities and the characteristics of architectural buildings are clarified.

Keywords: Korea Government Printing Office, Newspapers, Japanese, Typographic, Architectural

1. Introduction

This study aims to examine the historical development of the Korean Government Printing Office, the process of introduction and development of modern printing technology and related activities and restore some history omitted from the modern history of design.

Due to a long-held closed-door policy espoused by the Joseon Dynasty, the introduction and dissemination of modern printing technology were closely related to the expansion of western influence and missionary work by Christianity. The Japanese forced the Joseon Dynasty to sign the unfair Ganghwado Treaty (1875) with them in order to advance into the market and secure their control over the Joseon Dynasty while coercing the Joseon Dynasty to open its port. In this regard, Japan recognized the importance of newspapers as political tools. Bakmunguk, the first Korean Government Printing Office, was founded in 1883, and Hanseongsunbo published the first issue with the help of the Japanese. In the meantime, Hanseongjubo (1885), a newspaper, was published by Koreans, but it was closed down in 1888. In 1900, the Agriculture, Commerce and Industry Department Printing Office was revived as Government Printing Office after 12 years later. With the installation of the Post Office (Woojeongguk) in 1884, a modern postal system was introduced, and stamps were printed for the first time, but they were not distributed. After that, it was converted into the Mint Authority, and the Branch Printing Office (Takjibu) was installed as part of a governmental currency reform in 1895 introduced printing and casting facilities. As it became necessary to introduce independent printing facilities for the post and for currency in March 1895, the government offices were reorganized, and the Agriculture, Commerce and Industry Department was absorbed and abolished by the Mint Authority of the Branch Printing Office (Takjibu).

In so doing, the Government Printing Office that started as Bakmunguk went through the Agriculture, Commerce and Industry Department and Mint Authority of Branch Printing Office (Takjibu) before its abolition. After that, it was known as the Printing Bureau of Branch Printing Office (Takjibu), Printing Office of Korean Empire or Yongsan Printing Office. With the Japanese annexation of Korea in 1910, the government offices were reorganized, and it was renamed as the Printing Office of Joseon Government-General. In so doing, public printing and paper manufacture were controlled by the colonial government that combined a printing factory and printing administration.

Although the Korean Government Printing Office played an important role, few studies of it have been conducted until now.

2. Bak-Mun-Guk

2.1, Background of Establishment

The first modern printing office was installed as the Government of the Joseon Dynasty found it necessary to adopt the products of a new modern civilization. As Young-hyo Park’s argument for the necessity of newspapers was suggested to Emperor Gojong in 1882, ‘Hanseongbu (Seoul City Hall)’ was ordered to take charge of publishing newspapers. As a result, ‘Bakmunguk’ was installed on August 17, 1883, and Young-mok Min, from an extremely conservative group, was designated as the governor, and Man-sik Kim was appointed as vice-governor. Inoue Kakugoro (Editing and Translation Officer), a Japanese advisor equipped with vast amounts of ability in Japanese, English and Chinese, was invited, and Ushiba Takuzou, Tkahashi Masanobu (editor), Matsuo Miyodarou, Hajime Harada (military advisors) and Seitarou Honda (woodwork) were hired to take charge of editing and translation. Miwa Hirose (type casting) and Sanada Kenzou (print typesetting) were invited as printing technicians to publish newspapers.

At that time, it was hard to find anybody who was well-versed in newspapers in the Joseon Dynasty except for some intellectuals, so it was necessary to get help from the Japanese. Originally, the newspapers were supposed to be published in Korean and Chinese, but only the Korean newspapers were issued in the wake of opposition from the extreme conservatives. Young-mok Min, the central figure of the conservatives, became a publisher. At that time, intellectuals who had not been experienced in conducting exchanges with foreign countries in terms of institutions and goods were tainted with Sinocentrism, and they firmly believed that the world revolved around China. However, radical articles dealing with theories of the earth were published, and they had a great impact on the intellectuals of the Joseon Dynasty.

2.2, Role and Activities

2.2.1, The Chinese Character Newspaper “Han-Seong-Sun-Bo”

Bakmunguk published Korean newspapers for the first time by using modern lead type and letterpress

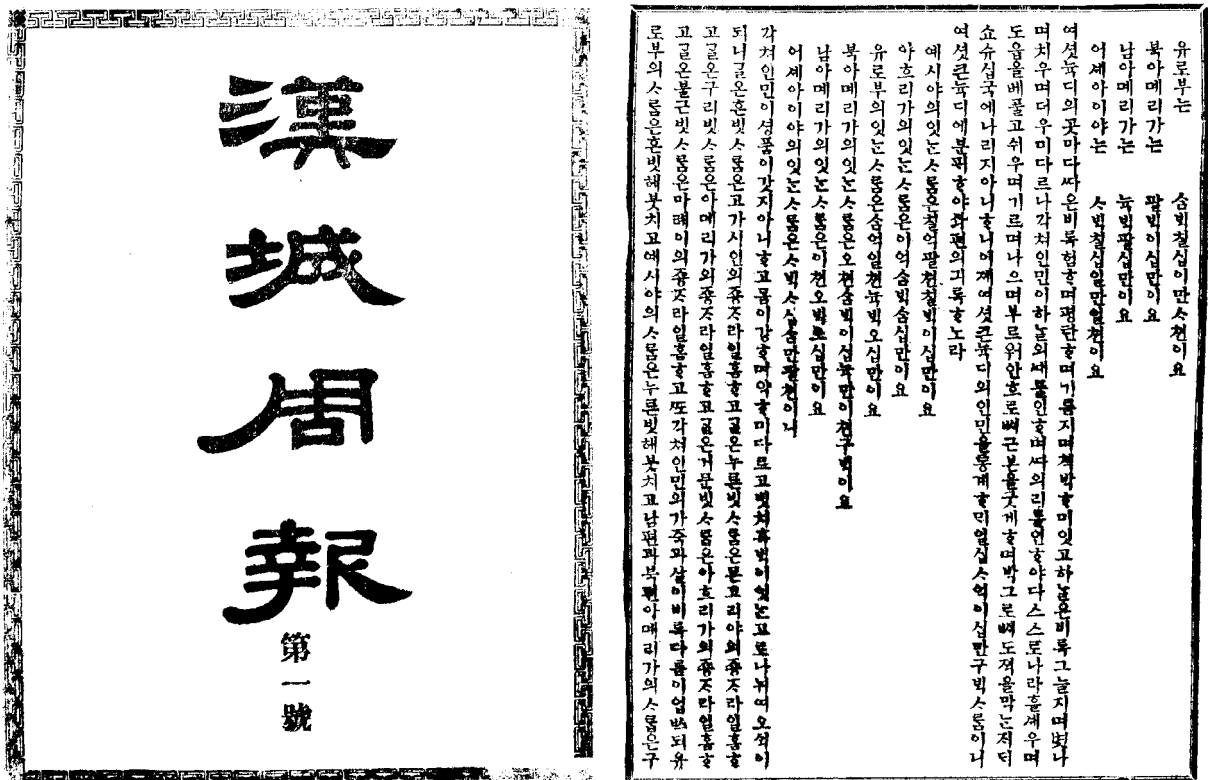

Fig. 5: Korean, Chinese Character Mixed Text Newspaper “Han-Seong-Ju-Bo”(1886)

plate printing machinery imported from Japan in 1883. From early 1884, Korean technicians began to take over the entire typesetting and printing process. The newspapers covered current events centering around official bulletins, foreign news, information on governmental agencies, and prices on the market.

Only the Chinese character type (Ming-style font) made by ‘Factory Letterpress Tsukiji, Tokyo’ was used in newspaper typesetting. The plate type was 188 × 257mm in size, and it adopted a western magazine style. One page consisted of 23 47-Chinese character lines. Each issue was composed of about 16 pages and it was released three times every 10 days. A compact manual cylinder press was used in printing. Expecting support from Japan, reformists staged a coup d'état in 1884, but it ended in a failure without help from Japan. At that time, the conservatives attacked Bakmunguk, a stronghold of reformists, to burn down all types and printing facilities. This was due to the fact that Bakmunguk took the opposite stance against the conservatives and the Ching dynasty being used as a launchpad for the Japanese. For this reason, Hanseongsunbo was published only 41 times, including the first issue, before disappearing without fulfilling its reformist mission

2.2.2, Korean, Chinese Character Mixed Text Newspaper “Han-Seong-Ju-Bo”

Even the conservatives, who took advantage of reformists as an instrument of political propaganda, recognized the necessity of Korean newspapers for the purpose of facilitating the development of the nation and fulfilling its intended goals. At this juncture, Yun-sik Kim with the Department of Overseas Trade purchased types and printing machinery from Japan, books required to publish newspapers from Germany and sample papers from China in March 1884. Bakmunguk resumed its operation in October 1885.

In January 1886, it was edited as Hanseongjubo, and 16-page newspapers that combined an official gazette with an enlightenment paper were published every week. The Korean type used in this paper was made by Su-jeong Lee, a Korean language teacher with Tokyo University of Foreign Studies, in 1882, and a new typeface based on Korean type No. 4 and Chinese character type made by Takeuji Koudrou, a sculptor with ‘Factory Letterpress Tsukiji, Tokyo’, was adopted. Bak Jang took charge of

editing and Young-han Kim and Taek-hwan Oh served as printing technicians. They were all Koreans, and this is a new historical discovery.

It carries significance in that, for the first time, newspapers began to be published by Koreans through the use of Korean types. It also reflects the fact that social needs were rapidly increasing amid change of the times. In the meantime, as Korean type was adopted along with Chinese character type, newspaper readers expanded to include ordinary people (commoners) as well as intellectuals (aristocrats). However, Hanseongjubo suffered managerial difficulties before being closed down in July 1888, and 'Bakmunguk' was completely abolished as well.

3. Nong-Sang-Gong-Bu

3.1, Background of Establishment

When government offices were reorganized during the 'Eulmi Reform' in 1895, the Camphor Unit was combined with the Engineering Unit and went through a series of changes in operation and personnel until 1910. In the same year, the Agriculture, Commerce and Industry Department began making preparations to install a Printing Office. First of all, a plan was made to educate technicians with regard to the installation of the Printing Office. The government was requested to fund the purchase of printing machinery and dispatch five Korean paper and printing technicians, Jeong-ryong Ha, Gyu-weon So, Yeon-gu Kim, Gyeong-ju Lee and Hi-jin Weon, to Japan; but the request was not accepted. In the meantime, the Agriculture, Commerce and Industry Department acquired the 18 original plates of the "Moon- Wi Stamp" (1884) that were kept in Japan. The printing house installed by the Agriculture, Commerce and Industry Department in 1896 was renamed as 'The Agriculture, Commerce and Industry Department Regulations Subcommittee' before being officially inaugurated as the 'Central Office' with the name of 'Printing Office.'

3.2, Role and Activities

The state of the printing of Korean stamps prior to 1910 has been sorted through by year based on analysis on research data. As for the order of printing of stamps from 1884 to 1903, the Moon-wi Stamp was printed in 1884, and it was followed by the Taegeuk Ordinary Stamp (1885), the "Daehan Gashae Ordinary Stamp" (1897), the "Ordinary Stamp" (1900), the "E-Haw Ordinary Stamp" (1900), the "Iljacheomshae Jeonwicheomshae Ordinary Stamp" (1901), "Emperor Gojong's 40th Anniversary Stamp" (1902) and "Eagles Typical Stamps" (1903). A total of 9 kinds of stamps were published by year.

3.2.1, Moon- Wi Stamp (1884)

The Moon-Wi Stamp, the first stamp, was not distributed as the postal system introduced as a modern institution was abolished in the wake of a coup known as Gapsinjeongbyeon. The stamp was named "Moon-Wi" because the then currency was the 'Moon.' The Japanese Printing Office was commissioned to print them, and Saito Tomozou took charge of the original drawing while Edoardo Chiossoned, an Italian, was responsible for carving the original plates.

3.2.2, E-Haw Stamp(1891)

The "E-Haw Stamp" was made in 1891. A trial stamp was made by a Korean technician, but it was referred to a Japanese technician due to a lack of technology on the part of Korea. However, Chang-han Ji (1851-1921), who stood out among painters at that time, took charge of the original drawing. Like a trial coin manufactured in December 1884, it was characterized by a pattern of Taegeuk that symbolizes the nation abroad.

3.2.3, Eagles Typical Stamps (1900)

This was designed by V.E. Clemencet and printed in Paris, France. The name Coree is the French version of the English Korea and could be used to mislead people not aware of the difference between English and French. It was the last of the Korean stamps to be issued by the Imperial Korean

Fig. 6: Moon- Wi Stamp (1884)

Fig. 7: E-Haw Stamp (1891)

Fig. 8: Eagles Typical Stamps (1900)

Government. From 1905, Japanese stamps were used to represent Korea on the international stage. In the French colonial period, postage stamps were mostly large in size. In 1900, stamps were accepted with the domestic pattern of design with an eagle symbol of the Roman Caesar., His subsequent pattern was typical of European countries.

3.3, Features of Typography

In 1884, Haeseo-style was applied to Korean and Chinese characters, and Sans Serif Style was applied to English and Arabic numerals. In 1890, designs made with only the Ming-style Chinese characters and a modern style appeared. In 1895, Haeseo-style was replaced with Gothic style in Korean, and it seemed intended to strike a balance with the Sans Serif Style in English.

Fig. 9: Inchoen Jeon-Hwan-Guk

Fig. 10: Japanese settlement in Yongsan, Seoul.

4. Tak-Ji-Bu "Jeon-Hwan-Guk"

4.1, Background of Establishment

The Mint Authority was established in a Japanese settlement in Yongsan, Seoul. As the number of Japanese residents increased, it became necessary to come up with a new monetary system in order to correct the negative effects of the existing mint system and expand governmental finance. The construction of the Mint Authority, a large-scale mint house, was initiated on land owned by the

Japanese Government-General of Korea, and it was completed in January 1885. Various machines were imported from Germany, and F. Kraus, a technical advisor, C. Riedt, a printing technician and C. Diedrich, a machinery expert, were invited to initiate its operation from December 1887.

4.2, Roles and Activities

Trends of activities conducted by the Mint Authority prior to the Japanese annexation of Korea were analyzed. The results can be classified as follows. They are divided into a total of five stages which are the Gyeongseong Mint Authority Period (1885~1888), the Incheon Mint Authority Period (1892~1900), the Yongsan Mint Authority Period (1901~1902) and the Osaka Mint Authority Period (1905~1909).

The Seoul Mint Authority imported mint machinery from Germany in 1883, and the Ganghwa Mint Authority mass-produced quality coins to be supplied to the trade market in Incheon. The name of the country and the year of issuance (1885) were indicated, and the currency unit was marked in Korean and English. Gold-gilted coins and silver coins with different values were issued in 1886. From 1888, the year of issuance was indicated to commemorate the foundation of the nation, and silver coins and copper coins began to be used. With the introduction of the New Monetary Ordinance in 1891, coins were finally issued in earnest. In 1901, a Printing Department was installed at the Yongsan Mint Authority, a regular mint house, in addition to the existing Mint Department. One month later, the Printing Bureau of the Agriculture, Commerce and Industry Department was abolished to relocate the entire carving and printing facilities, and all Japanese technicians were transferred.

As a result of a survey on figures who requested technicians at the Osaka Mint Office to provide advice and transfer technology, it has been found that Gyeong-su Ahn (an envoy of Emperor Gojong), Hayasi Yujo, Omiwa Chobe (currency expert), Endo (Director of Osaka Mint Office), Hasegawa Tameharu (Deputy Director of Osaka Mint Office) and Masda Nobuyuki (President of Osaka Steel Company) provided funds and carving technology. Masda strongly recommended the western monetary system inducing adoption of a similar system to the Japanese monetary system. In addition, such Korean technicians with Incheon Mint Authority as Hyeong-sun Lee and Seong-geun Ha were dispatched for 9 months to the Osaka Mint Office in 1891 to acquire mint technology. As there was a discussion about expanding the Incheon Mint Authority in 1892, Director Yong-ik Lee dispatched Wook Han and Sang-jun Seo, printing technicians, to Osaka. However, facilities in the Incheon Mint Authority were relocated to Seoul at Emperor Gojong's command so that they could be controlled by the Yongsan Mint Authority.

4.3, Yongsan Jeon-Hwan-Guk

All new printing facilities in the Mint Authority were introduced from Germany, and each and every department was led by Japanese supervisors. The Mint Authority printed sample notes by using hanji, traditional Korean paper, manufactured in Korea in November, and letters and figures were exquisitely indicated on an unspecified part of the notes. This was applied even to hidden documents and could compare favorably with foreign notes. However, they were not put to practical use, and the Mint Authority was closed down in 1904. After that, notes of the Joseon Dynasty were issued by the Osaka Mint Office (1905-1909), and they were generally circulated as Japanese currency.

5. Tak-Ji-Bu Yongsan Printing Office

Japan won the Russo-Japanese War in 1904, taking over the reins of the Joseon Dynasty, and Mekata was appointed as a financial advisor in accordance with the First Japanese-Korean Agreement. He shut down the Mint Authority except for the Printing Department and Paper Plant, and the Branch Printing Office took charge of printing and paper operations. As a large number of Koreans were involved in printing and paper operations, Young-han Kim (1857~1927), who accumulated an abundance of

Fig. 11: Yongsan station

Fig. 12: Tak-Ji-Bu Yongsan Printing Office

Fig. 13: First Paper Factory

Fig. 14: Japanese Government General of Korea

experiences in the printing and paper sectors while serving as an administrator of the Branch Printing Office, was sent to Japan in 1904 so that he could make an inspection. It was required to produce the various printed materials needed to prepare for a planned colonization. Young-han Kim was promoted to Printing Director of the Branch Printing Office in 1905, and he revisited Japan next year in order to purchase printing machinery. As the printing operation was highly valued, a large-scale facility expansion was implemented, and the police were dispatched to guard the Yongsan Printing Facilities of the Branch Printing Office. It has been found that Jin-ho Yu (1861~?), Sang-cheol Lee (1859~?) and Tae-hwan Oh (1873~?) worked as printing technicians with the Branch Printing Office.

5.1, First Paper Factory

5.1.1, Paper Manufacturing Plant

While inspecting the Ohkura Shou Paper Processing Office of the Printing Bureau of Japan in April 1881, Sinsayuramdan which consisted of 62 Koreans was introduced to facilities imported from an Austrian paper company and "Simili Japanese vellum" developed by Japan, and a contract was made to purchase machinery. However, the introduction of paper-making facilities was temporarily suspended in the wake of a failed coup staged by reformists. As the Japanese government urged the Korean government to pay a penalty for breach of contract, the Korean government was forced to officially establish a contract to purchase machinery in 1888.

Two ring net expression paper machines were installed at a paper manufacturing plant of the Mint Authority to produce note paper from 1902. Various printing facilities in the paper manufacturing plant of the Branch Printing Office were burned down in a fire that broke out in 1906. However, they were expanded in restoration work in 1907, and it led to a paper manufacturing plant that could produce about 800,000 sheets of paper a day by 1909. It was shut down in 1911 to be converted into the Central Experimental Station of the Japanese Government General of Korea. After that, it was operated by Fuji Paper Manufacturing Company in Japan with approval from the Japanese Government General of Korea in 1917.

5.2, Tak-Ji-Bu Architectural Office

5.2.1, Background of Establishment

With the installation of the Statistics Monitoring Office in 1906, a large number of Japanese officials were appointed, and many official residences were built for them starting with the establishment of the Branch Printing Office (Tak-ji-bu Architectural Office). As to the number of construction projects conducted up to 1910, after the establishment of the Branch Printing Office, the ratio of official residences and lodgings was as high as 83%. As the Japanese governmental organizations were reshuffled after 1910, construction of official residences was conducted at a rapid speed. At that time, Seoul suffered a serious lack of houses in the wake of a sharp increase in population, and massive distribution of official residences contributed to stabilizing housing distribution.

5.2.2, Design Features

Official residences of the Japanese Government General of Korea (Korean Colonial Government) shared common characteristics despite differences in sizes and types according to the ranks and civil service grades of residents. A case in point was spatial configuration based on a compromised formula between westernized Japan and Korea. All characteristics of Japanese traditional housing (general living space), western spaces introduced from the west in the modern era (common spaces such as a living room, a kitchen and a study) and Korean traditional space (called Ondol) for adaptation to the Korean climate were found in one house. Ondol was installed only in some rooms according to a Japanese-style ground plan so that they could be used as living spaces during the winter time. It was also possible to figure out how Korean-style Ondol was applied to a Japanese-style house.

5.2.3, Activities of Architects

The Japanese Government General of Korea was a government office installed to govern the Joseon Dynasty that belonged to the Empire of Japan according to the Japanese annexation of Korea in 1910. The government office building was established within the Gyeongbok Palace in the present Seoul. George De Lalande (1872~1914), a German architect, took charge of a basic plan, and it was taken over by such Japanese architects as Nomura Ichiro and (1872~1914) and Kunieta Hiroshi (1879~1943) after De Lalande died. The construction project was completed in 1926. After the Korean War, it was used as a government office building and as the National Museum of Korea. The building was demolished in 1995.

6. Conclusion

This study has focused on clarifying the historical development of the Korean Government Printing Office from 1883 to 1910.

(1) The historical development of the Korean Government Printing Office was divided into four periodic stages which were the introduction of new printing technology (Bakmunguk, 1883~1888), a base of establishment of new printing technology (Agriculture, Commerce, Industry Department, 1895~1910), the establishment of new printing technology (Mint Authority of Branch Printing Office, 1885~1902) and deployment of new printing technology (Yongsan Printing House of Branch Printing Office, 1902~1910). It also examined the roles and activities of the Korean Government Printing Office.

(2) Regarding the publication ssuance of “Han-seong-sun-bo” (1883), the first newspaper written in Chinese characters alone, Inoue (editing and translation), Miwa Hiroshie, a printing technician (type casting), and Sanada Genjou (typesetting) were involved. As to the publication of “Hanseongjubo” (1886), the first newspaper written in both Korean and Chinese characters, in three years, ten Korean technicians including Bak Jang (edition), Tae-hwan Oh, a printing technician (type casting), and Young-hwan Kim (typesetting) participated in its publication.

(3) New types were manufactured by the ‘Factory Letterpress Tsukiji, Tokyo’. In particular, Korean type No. 4, types that had been made to publish the Meiji Chinese Dictionary (1882) were imported, and it

was based on an original drawing by Su-jeong Lee, a Korean language teacher with Tokyo University of Foreign Studies, and carved by Takauchi Koutarou. The type was Haeseochae (text style) that was highly recognized for being elegant and sophisticated. It was introduced to the Joseon Dynasty and used for as long as 70 years.

(4) The Japanese Printing Office was commissioned to print the first “Moon- Wi Stamp,” and Saito Tomokazu took charge of designing the original drawing, and Edoardo Chiossoned, an Italian, took responsibility for carving the original plate. After that, Chang-hwan Ji, who was Korean, served as an original drawing artist.

(5) F. Kraus, a technical advisor, C. Riedt, a printing technician, and C. Diedricht, a machinery technician, were invited from Germany so that technology could be transferred from them.

(6) George De Lalande (1872~1914), a German architect, took charge of a basic plan of for the building of the Japanese Government General of Korea (1910) by adopting an art nouveau style, and the construction project was taken over by Nomura Ichiro (1872~1914) and Kunieta Hiroshi (1879~1943), Japanese architects, after De Lalande’s death. The project was completed in 1926.

The findings of this study are indispensable to education about Korean type printing and design history. Korean typographic design was endeavoring to find a way to make a fresh start based on design theories from Europe and Japan. The roles and activities of the Korean Government Printing Office defined in the study were important matters with regard to the establishment of quality typography in the future.

There were new discoveries in the history of Korean printing type.

An Equilibrium Towards 'LESS-MORE' Problems ?

The Innovative Preservation of the Modern and Contemporary Cultural Heritage in Architectural Space

Iwona SZMELTER

Faculty of Conservation, Academy of Fine Arts

Postgraduate Museums Studies, University of Warsaw, Poland

iwona.szmelter@gmail.com

Abstract

This paper presents the equilibrium of 'LESS-MORE' problems of scientific contributions aiming at restoring, collecting and spreading out the best practices of care of the latest cultural heritage. It means the implementation of knowledge and complex issues involved in care of atypical modern and contemporary art, especially murals in architectural space, both tangible (material) and intangible (idea).

In XXI century there has been an increasing focus of new ideas in all areas of care of cultural heritage, including conservation and its multi-disciplinary approach. This has been very important for the relation between architecture and different types of wall paintings, murals and atypical installations. Many factors make it essential: artwork aesthetic unity with the architecture, legal aspects, the interface between the legacy of art and the environment, paradigmatic sustainable projects and last but not least – the question: who should finance it? The idea of getting so-called "paintings installations into the space" is presented.

It addresses the case studies of famous artworks of Leon Tarasewicz and Miroslaw Balka which are narrowed to an individual macro-scale of 'LESS-MORE' an equilibrium, as a part of International Network for Conservation of Contemporary Art-Central-Eastern Europe activities (INCCA-CEE) coordinated by the author. [1]

Keywords: Conservation, Restoration, Preservation, Modern and Contemporary Art Heritage Management, Social Sustainability

1. Preface

We have observed specific aspects of 'less-more' individual contributions focused on artworks in architecture and public art, plus broad issues related to the low priority of modern and contemporary legacy and consequent they are attributed to lack of funding it is given. There is a problem of the absence of adequate models, parameters and guidelines for care of contemporary legacy in difficult economic situation.

Some of the most influential artists of the twentieth century, including Leon Tarasewicz, Alina Szapocznikow, Alexander Calder, Nikki de Saint Phalle and others - produced wall paintings, murals, painted sculpture and other forms of public art intended for installation in architecture or outdoor settings. Moreover many contemporary muralists are spontaneous and unknown. The problem of the care of latest legacy seems to be very universal and focused on the structure of administration and funding of conservation in the whole world. Some consideration are presented below heads towards the holistic care for current cultural heritage.

2. The Concept of the Complex Care of Modern and Contemporary Art in Architectural Space

The model for care of the modern and contemporary art in architectural space is very complex. The target group are: architects, curators and conservators, museums staff etc., where the conservation needs of complex installations have often been disregarded. The models have an open character, based on the needs of the individual artwork.[2] The key drivers for the care of cultural heritage are:

2.1. Concepts of Conservation - address how to preserve and restore the original expression and emanation of the idea embodied in the object, including the permissibility of the replacement of elements. The concepts also address full spectrum of project – passive care, preventive conservation/ or active conservation/restoration/ or reconstruction.

2.2. Legal issues: The legal aspect of artist's guidelines concern the principles and methods of re-installation of the object, or conservation by documentation and digital registration of ephemeral elements. The role of exhibition design is an element in preserving the integrity of the work - the important role of the space itself. Very crucial is the need for an authorization of new form of restoration, so-called emulation, neo-creation, etc.

2.3. Archives; different type of documentation containing information about artwork, the social and historical context of it , including the space and the idea it embodies on the basis of data and the historical context, interviews with the artist, press reviews, television reports, films, and contemporary documents.

2.4. Artist Participation; interviews with Artists and Various Advice Regarding the Lifespan of their Artwork

Contemporary artists have to be partners in conservation projects, starting from pre-acquisition and registration of artwork, agreement for interventions, indications etc. – all based on interviews with them. On the other hand

the users want to ask artists for 'care'. Below I quoted very practical guidelines for author's:

"Take pictures to document your work as you go along.

A "time-frame" series of images will be very useful to you in the future.

Shoot photos from the same spot, although there can be several places from which photos are taken.

Keep track of the materials you use and how you use them. Protect your work against vandalism.

Think about applying an anti-graffiti coating or using security lighting" [3]

3. Case studies - Leon Tarasewicz and Miroslaw Balka Legacy

Let me quote the legacy of artists – Leon Tarasewicz and Miroslaw Balka as problematic examples of the sorts of things we are talking about here.

3.1. Leon Tarasewicz – as an Author of Atypical Paintings and Public Art

Leon Tarasewicz is a well-known Polish-Belorussian avant-garde painter and installation artist and an academic teacher. He was born in 1957 in the Bialystok region. Last 30 years he has been actively working in Poland and abroad. He cooperates on a regular basis with the Foksal Gallery in Warsaw, the White Gallery in Lublin, the many Galleries in Berlin, many institution in Italy. He represented the Polish art at the 49th International Biennale in Venice in 2001. On the other hand he painted a monumental wall painting on open space for long-time exposition (2008, Milano) with his special care for the quality of industrial paints and environment. Tarasewicz created many painted installations in public space; he covered the painted areas of a square on the open air (Barcelona, 2002) after the temporary exhibition on the square was cleaned.

Fig. 1 Leon Tarasewicz, Paintings action on the square. Plaza Real, Barcelona, 2002

Leon Tarasewicz painted artworks in interiors on self-designed surfaces, based on classical paintings materials and technology as well as industrial paints and elements of the architectural constructions. The great part of the legacy of Tarasewicz disappeared. For example when he painted on walls and pillars (1997 CSW Warsaw), - after one year the composition were removed from the surface. When his paintings “flow down” to the gallery floor (1999, 49th International Biennale in Venice) they were removed after exhibition.

Fig. 2. Leon Tarasewicz, *Labyrinth*, .Kielce, Poland, 2011

In 2005 the artist started experimenting in public space and he was combining his large size painting on symbolic corridors with mirrors, created illusory experiences which broaden the area of expression of his monumental artwork in many galleries [3]. The painted installation were very popular in open air too. The appreciation of a great numbers of viewer's made Tarasewicz's art legendary (2011, Square of Poets, Kielce).]We have an archives devoted his artworks but most of them were ephemeral because the absence of proper care and economical reason.

3.2. Miroslaw Balka - Considering Memory and the Care of Ephemeral Art Legacy

Miroslaw Balka born in 1958 in Otwock, international avant-garde artist, last year was invited to present his work in the Turbine Hall, the main exhibition room of London's Tate Gallery, as the 10th Unilever Commission. The artist created the project called „*How It Is*”, the title is a reference to the work of Samuel Beckett. The work

which was exhibited for a few months (from 13.10.2009 to 5.04.2010) was a huge metal container 13m high and 10m wide, the interior of which is completely dark and in addition covered with flock paint, a material which absorbs light. The only light source which reaches the visitors inside is from the rectangular entrance opening to which a ramp leads. After entry, the viewer is enveloped by a dark tunnel. The work is composed of the basic elements of art, such as darkness, space, silence, meditation. It comprises an intuitive experience of reality by the viewer. The work of Balka is interpreted as a reference to the events of the twentieth century and more modern history of Poland, the Holocaust, social changes and the uncertainties that accompany them, the emigration and displacements of populations.

Balka leaves his viewers freedom of interpretation and talks of the construction of his giant work as well as his co-operation with the Tate Modern in London, and remarks on the efficiency and benefits for the artist of its system of acquisition. In effective manner the artist communicates information on the role of individual materials, and on the idea and message of the artworks. [5] After exhibition in Tate "How It Is" was demolished, but as it has been well documented, it is possible to reconstruct this project, given that a proper agreement would be obtained with Tate.

We know a precedence with reconstruction such great installation, for example Olafur Eliasson artwork called 'Your Black Horizon' exhibited a haunting light piece at the 2005 Venice Biennale in a pavilion designed by David Adjaye. The exhibition "was part of the Thyssen-Bornemisza Limited Edition Art Pavilions, which host unique specially commissioned sight-specific art projects on a rotating basis. In 2007 the Pavilion was moved from San Lazzaro Island in Venice to Lopud Island, Croatia. David Adjaye designed the Pavilion to be a flexible and easily adaptable structure with multi-purpose capabilities and over 400 square meters exhibition space" [6]. In a new context of landscape the exhibition is type of neo-creation of an artwork accordingly to new understanding of cultural heritage (as nature and 'man made').

Miroslav Balka, "1120 x 875 x 2" the exhibition at the National Gallery Zacheta in Warsaw. Currently the work is available exclusively as a project documentation (conservation via documentation) – the installation was a floor (the title of the work is "Size") covered with a trick layer of laundry soap with the specific, sharp smell stimulating our sense of smell and producing associations with the period when his type was used in the East European countries under the economical Soviet domination. The smell - soap' Balka's installation was made from Czech soap; is in the archive for emulation of smell in the case of re-installation. Re-installation is possible only with the consent and cooperation with the author.

For Balka "Contemporary time does not exist, we cannot capture what is continuous. As we move ever into the

future we are always based in the past. This is the state of my sculpture, there is heat from this pillow, and it's impossible to catch, this continuous flow. As soon as you touch it it's colder than it was at its source. Everything we touch is coming from the past, it's our access to death. For me the important thing in my art is to try to catch that consciousness of life" [7]. This allows the raising of his own personal existence and also the heritage of the most recent and dramatic history of Poland to the rank of a universal artistic message.

4. Consideration in 'Less-More' Spirit of Responsibility of an Artworks

Each of the above Tarasewicz artworks casus deserves more careful examination in the work toward the ultimate goal of developing a positive relationship between those who produce murals and those who wish to preserve them.

We will use the basic knowledge to understand the interaction between wall paintings, atypical decorations, public art and context of the aim of conservation of cultural heritage. We consider both; the idea and the matter in a model for complex preservation-conservation project. In the results of the debate about the legacy of Leon Tarasewicz I have to notice that there are a big thing more than the materials and techniques investigations, there is a need for the concept of co-operation with artists towards the registration of his intents, ideas. This is a big problem if you change the real concept of the artistic creation because legal consequences, the lack of the integrity of artwork in architectural space. Towards respecting the potential deterioration we noticed that the moisture problems should be identified and repaired before conservation. Excessive moisture can damage the paint bond, penetration, moisture saturation, and causing areas of paint; blistering, cracking, flaking, and peeling. In restoration the same type of paint should be used for all new layers of paint.

The legacy of Miroslaw Balka from my point of view as a curator- conservator; in every case of re-installation of artwork yields and requires complex information about material structure of artworks, their image and ideas. The perceptual context of changeable artwork depends on the environment in which it is presented, hanging or standing, with the quality of size and space within its philosophy *gestalt* as an object. It brings this cycle closer to open-installations. The author's radical adaptations include his guidelines for curators and conservators.

5. Public Art and Social Sustainability

The problems of the lifespan of modern and contemporary art and care of current cultural heritage in architecture and public space is well known.

The most characteristic attitude for the artists themselves is self-identification. The concepts of the artists have become part of social history and are an important context of their works. The issue of identity in culture is a

topic of interest in several scientific disciplines. As a consequence, several investigative methods are used to investigate it. from sociologic, historic, legal, ethnologic and from cultural studies.

Concepts characteristic of different disciplines are used in the interpretation of the results. Some investigators equate identity and awareness. These concepts are used to define the state of both individuals as well as groups. Public art is a critical component of the built environment and adds much to the city's quality of life. The Short North has a growing national reputation as a leader in promoting public and private art. It's status as an arts district has played a key role in its revitalization and will continue to influence development in the corridor. These guidelines seek to address the placement of public art and other related considerations, but not the content of such art [see 3]:

Example of `Regulations - Chapter 3115 of the Columbus City Code addresses the creation and responsibilities of the Columbus Art Commission. Art is defined by words :

“all forms of art, regardless of its permanence, created in any medium, material or combination thereof. Art may take the form of individual works or site- specific installations integrated into the design and physical development of the capital improvement for which the art is created [3].

(...) “Public art is required to gain approval by and meet the evaluation criteria of the Columbus Art Commission, as provided in city code. These criteria address the following topics: artistic quality/excellence, appropriateness to the site, originality, permanence, safety, feasibility, maintenance and donor requirements.

- Public art may possess functional as well as aesthetic qualities; it may be integrated into the site or a discrete work.
- Larger new development projects should include works of public art into the design of the project.
- Art should be incorporated into new public spaces and visible elements of significant infrastructure improvements.
- Placement of public art in public spaces, such as parkland, plazas and Public art should create interest and invite people to interact with the piece. sidewalk cafes is encouraged.
- The design of public art is influenced by the area's physical context in

terms of composition, scale, mass, and materials.

- Public art is designed and installed to not damage or visually obscure contributing buildings or building elements” [3]

Quoted above guidelines are pioneer’s. Despite of the very important role of public art we still have no solution for the administration system, conservation funding and social sustainability.

Another point of view was presented during symposium "Mural Painting and Conservation in the Americas" in Los Angeles, California, on May 16-17, 2003, which was held in recognition of the significance of 20th century mural art - Timothy W. Drescher wrote in his essay:

„There are community-based organizations that can carry out the conservation—the key being the group that organized the project, not just the one that paid for it. Successful restorations along these lines have been carried out in Chicago, San Francisco, San Diego, and other cities. One quails at the involvement of civic or government institutions, precisely because they do not, and probably cannot, adequately understand these works. There are exceptions, of course, but government priorities are most likely different from those of communities.

Government’s role is to provide money, advice, and equipment/material support, but not to make the decisions beyond that”. [8]

The practical question ‘who should/can pay for it’ in many cases seems be without a solution.

6.Conclusion

Concluding – the controversial issues of ‘less-more’ conservation, restoration, neo-creation of works of art in architectural space turn around the issues modern and contemporary cultural heritage. In conserving and displaying a work of modern and contemporary art in architectural spaces we need guidelines that address the artist’s intent, the materials, and the integrity of the artwork – and even the possibility of re-installation, emulation, neo-creation. The needs of paradigm of classical theory of conservation is arising and sets out a cutting edge solution for the transformations experienced by the academic model of conservation knowledge in Poland within the trans-disciplinary science and humanities. The equilibrium of the innovative conservation and care for the visual artworks of modern and contemporary cultural heritage in architectural space is possible only when it is based on complex administration system, and care of cultural heritage; between architects, conservators, curators, artists. Based upon an innovative training model and collaborative effort between academic and cultural institutions, conservator of modern art has to act as advocates and often play the role of

the orchestrators of different activities. Conservator and architect in new strategy can provide answers to crucial questions to the lifespan of the artworks and care of heritage regarding artistic identity, intent and ideas, authenticity, conservation, reproducibility and their social role.

The cities and the drawings. Street art projects as shared practices for the revitalization of urban areas

Giovanni Caffio

Dipartimento ARCH, Facoltà di Architettura, Università "G. d'Annunzio", Pescara, Italy
me@gioannicaffio.com

Abstract

In recent years we have been witnessing a reversal regarding the phenomenon of urban graffiti: from vandalism and naive expression of youth problems it has gradually acquired the status of art. The attention of the world has officially declared this grassroots form of language as an artistic expression finally worthy of appearing in exhibitions and museums. Artists, previously accustomed to work clandestinely in the streets, have seen their work exposed in art galleries.

What interests us in this essay is to emphasize the important social role played by the most advanced forms of street art as a catalyst of collective attention towards the public space revitalization. Murals allow citizens to become active part of a community; they can trigger processes of revitalization in neighbourhoods, towns and whole cities; they work to strengthen the identity of a social context; intensify existing ties, create new economic dynamics, in a joint project involving citizens belonging to all ages. The examples, of which the essay offers a study of the most significant, are numerous and growing, a sign of a growing interest in grassroots artistic movements that can change the face and the perspective to improve degraded urban areas through the conscious, and often provocative, use of drawing.

Keywords: street-art, drawing, city, renewal.

1. The street art phenomenon

"Street art" or "urban art" is the name given by mass media to the colorful and varied artistic number of experiences and experiments that have as their place of creation and manifestation throughout public areas, in particular contemporary city. Often made illegally, but also through projects shared and participated with the local community, they adopt different techniques that demonstrate all the flexibility and creativity of artists: spray, stickers, stencils [1], video projections, sculptures, installations, performances and guerrilla art actions. Contemporary street art has been developing within the more complex and articulated phenomenon of urban graffiti. The differences between these two areas are faded and difficult to detect because they share the same spaces (the street and the more degraded areas of the city), techniques (spray paint, stencils, markers, to which in street art is added a most frequently use of paint brush or roller) and the same implementation procedures based on flick and fast gestures. The element that separates the two areas of expression, however, is that in case of street art content is often provocative and politically and socially oriented, they turn to the general audience of citizens and have the deliberate aim of improving a degraded urban environment, in case of urban graffiti or writing, however, the message is fundamentally self-referential and closed within a style code for followers, it has a strong expressive value of social unease that seeks affirmation and visibility mainly within confined enclaves of the territory and, often, is accused to result in pure vandalism.

Writing is recognized as an artistic expression of New York ghettos subculture since the '70s and soon exceeded its original geographical and cultural boundaries to spread quickly to the rest of America and Europe. Although its origins are traced to the habit of American allied soldiers during the forties to draw the famous Kilroy scribble, graffiti was born on trains in Philadelphia in the late sixties and developed later in New York in the seventies up to achieve a basic stylistic maturity in the mid-eighties. First tags (*nom de guerre*) have been beginning to appear since 1972 and over time they transformed becoming larger and larger, more complex and complicated. Among the first active writers we remember names like TAKI 183, Rammellsee and Samo, signature behind which lurks the famous artist Jean-Michel Basquiat. Fundamental for the worldwide diffusion were the documentary *Style Wars* (T. Silver, 1983) and the film *Wild Style* (C. Ahearn, 1983) and the first collections of photographs and reportages as *Subway Art* by Martha Cooper and Henry Chalfant [3] and *The Faith of Graffiti* by Norman Mailer [4]. It was thanks to the work of these passionate photographers and filmmakers that we were able to document and enhance these important works with such ephemeral character. Over time, the writers more interested in developing their own artistic research began to work in dedicated urban areas such as "hall of fame", a space made available for them in which they can paint legally. These are places made available by municipalities with the aim to contain and control the phenomenon of writing, away from city centers and residential areas of value, or freely chosen by the artists in remote and deprived areas where the works of the "spray-can art" or "aerosol art", are tacitly accepted by supervisory authorities. Many contemporary artists, while retaining their roots in writing [5], have expanded their range from walls to typography, design and clothing, thus making the graffiti aesthetics a recognized and disseminated style. To mark the evolution of the phenomenon often critics speak of *Post-graffiti* to indicate the experiences that, starting from urban graffiti, are directed towards larger and more established art fields, and *Graffiti Design* for influences within fashion and graphics.

Far from being merely become a cultural phenomenon and a contemporary style, street art in hits heart responds to multiple impulses: it is an expression of subversion and anarchist critique to the private property, a reclamation of public spaces and social practices such as those produced by the mercantile intrusive advertising, a desire to introduce personal works to an audience wide and not tied to the restricted realm of galleries and art institutions. The provocative and rebellious value of street art was the main theme of the exhibition *Viva la Revolución* [6], organized by the San Diego Museum of Contemporary Art in 2011 and curated by Pedro Alonzo. The exhibition offered the opportunity to question the fundamental theme of the relationship between "illegal" art, the space at disposal (the city) and the material that sustains it (the walls). The exhibition highlights how the current phenomenon is indebted to many art expressions born in the late seventies and early eighties in which urban space, and the different cultures associated with it – from writing to advertising – was been acquiring bigger and bigger importance. The artists involved in these early experiences, from Keith Haring, Barbara Kruger and Jenny Holzer to collectives like Gran Fury and Guerrilla Girls engaged in political campaigns, deliberately worked on images and media belonging to the mainstream culture, with the aim of reaching as many as possible observer citizens. Furthermore, these artistic experiences faced with curiosity the relationships that develop between art works and urban environment in ways that certainly suffer influences from Pop Art and especially from the situationist movement and performance art, with their new forms of involvement of spectators and the practice of *détournement*. An interesting aspect that arises from this experience that took place inside a museum institution such as the Museum of Contemporary Art of San Diego is the apparent paradox that comes from wanting to expose or produce art that, by definition of the same curators, is "unauthorized and illegal" [7].

Since the '90s, a real cohesive and nomadic art movement began to spread its works on the streets of New York, Los Angeles, San Francisco, Paris and London thanks to a global urban network widespread through websites, publications and collective projects. Virtually, every major city in the world, and even some smaller ones, house forms of urban art or graffiti, but there are few places that gained more importance for having given rise to particular forms of avant-garde in both aesthetic and technical level as well as being the cradle of the first important work of street artists. For example, Paris still has a very lively art scene with artists such as Space Invader, ZEVS, Mosko et Associés, Jerome Mesnager and Zoo Project. Interestingly, these artists put themselves in continuation with previous art makers such as Jacques Villeglé, Yves Klein, Arman and Christo and Jeanne-Claude, whose *Rideau de Fer* in 1962 is one of the first illegal art work. Other precursors can be considered Gérard Zlotykamien and his work with spray paint, Daniel Buren and his interventions in the Paris metro, and, reaching the '80s, with Blek le Rat and the Figuration Libre movement.

In England the most important exponent is definitely Banksy whose provocative actions appeared first in the early '90s and continued up to his exhibition titled *The Cans Festival* (London 2008) and the great success of the show held in 2009 at the Bristol City Museum and Art Gallery. Banksy is the artist who is perhaps better than others succeeded to make public and diffuse the idea of street art as a vehicle for economic and social criticism. His works, made with the rapid stencil technique, tackle with corrosive irony social issues such as freedom of expression, the brutality of the police repression, the intrusiveness of control, bourgeois morality and prohibitionism. The American scene, after the crisis of the writing phenomenon happened after the massive effort of city governments to address vandalism through arrest and heavy penalties, see alongside established artists as Kenny Scharf, Ron English, Shepard Fairey and Robbie Conal, younger ones as Gaia, Swoon, Mark Jenkins, the duo Faile. Particularly important are some projects of urban renewal interventions through street art in numerous American cities: the project Living Walls with works in Atlanta and Albany (NY), the Miami Wynwood Walls, the important Philadelphia Mural Arts Program born in 1984 and other initiatives present for years in Pittsburgh and San Francisco's Mission District.

2. The Italian artistic scene

The theme of the paintings included in the urban context is again at the center of attention in Italy in the early '80s, in synchronism with the affirmation of graffiti also in the Italian cities and with the contribution of early researches on the subject (in this sense fundamental is the exhibition *Italian wave* curated by Francesca Alinovi). These early experiences are anticipated by those produced in the climate of the twentieth century by Sironi, Campigli and Funi, major attempts to explain, even in theory, the pictorial expression in relation to spaces alternative to the usual circuit of galleries and art venues. Emerged clearly the need to strengthen, if

Fig. 9: Microbo e Bo130, Milan. Fig. 10: Cristian Sonda, Rho, 2010. Fig. 11: 108, Bassano del Grappa, 2010. Fig. 12: Blu and Ericailcane, Bologna, 2010. Fig. 13: Ozmo, Foligno 2010. Fig. 14: Stan & Lex, Roma 2010.

not to create, a relationship between daily life and work of art painted in continuation of that trend to merge art and life that belongs to all the '900, from avant-garde movements to this days. In the apparent gap that separates research from the second half of 1900 until the '80s we can remember many examples of this art approach to urban space. There is the painted towns tradition, beginning with the earliest experiences of Arcumeggia (VA) and San Sperate (NU) to Dozza (BO), Casoli D'Atri (TE) and Maglione (TO). Smaller towns and villages, as in big American cities where immigrant communities (Latinos and African Americans) use to mark their precise identity through signs traced on the walls, adopt these forms of expression as means to declare the continuity of a collective "genius loci".

This impulse is shared by the younger writers who strongly affirm their own identity within an alienating and alienated urban setting. It is important to remember the echo on the national art scene, of the exhibition in Florence by David Alfaro Siqueiros in 1976 who exposed a great overview of the Mexican artist, a great experimenter of formal solutions and technical choices in which industrial colors and the use of the compressor combine with traditional pictorial practices. To the figure of Siqueiros we can also associate the social and political activities of artists like Aurelio C. in the Centro d'arte Pubblica e Popolare in Fiano Romano, and the Chilean artist refugees in Italy after the military coup of 1973 and in particular the Brigata Pablo Neruda. To close this short series of anticipatory activities of the street art we remember that, between the '70s and '80s, many artists often performed together in public areas such as the collective Autonomo degli artisti del Ticinese, promoted by Giovanni Rubino, the Fabbrica di Comunicazione in Milan and the Collettivo Artistico del Movimento Studentesco, which, with different attitudes and practices, experiment the relationship between work experience and urban space.

Arriving to more recent years, we can consider pioneers Pea Brain (Monica Cuoghi teaming with Claudio Corsello) and 108, while from the early years of this decade primarily three schools emerged in Milan, Bologna and Rome [9]. Among the major names involved we can mention Stan Lex, active since 2001 and

Fig. 15: Murales by Os Gemeos, Nunca and the Italian Blu realized for the exhibition *Street Art*, Tate Modern, London, May-August 2008.

considered among the pioneers of "Stencil Graffiti", Bros and street poet Ivan Tresoldi, Abominevole and Ozmo, who offer early intervention at a national level in 1999, TvBoy, now active in Barcelona, Microbo and Bo130, the illustrator Cristian Sonda, Nais and Orticalnoodles. Initially active in Bologna, but now working all over the world, are Blu, street artist and video maker worldwide famous after his participation in the exhibition of 2008 at the Tate in London, Ericailcane and, finally, Dado and Stefy. In late 2000, the movement took different courses and is now in part institutionalized through collaboration with city administrations as well as with the world of museums and galleries.

3. Street art as a new urban value catalyst

In Italy there are many policies of institutionalization and emergence of graffiti-writing conducted by several Italian councils and by private actors in recent years. Let's consider, as examples, the initiatives carried out in Turin with the project Picturin, the development project for young energies sponsored by the Italian Ministry of Youth actives in ten cities including Civitavecchia, Foggia, Campobasso and Teramo, a series of festivals run by private organizations such as the Pop Up Festival in Ancona and the Fame Festival in Grottaglie (Taranto). Through these examples the phenomenon of writing can be analyzed as a form of citizen participation oriented towards art practice marked by the urgency to assert personal existence and voice. These acts are always directed towards the general interest and are committed by individuals who, through the practices of the tags, bombing or graffiti art, trying to rewrite urban space. This is an appropriation and aesthetic redevelopment of urban space, especially peripheral metropolitan areas. Many local governments have accepted the civic potential of these practices, developed and flourished illegally, so that they can emerge, often making them institutional and, therefore, legitimate to the eyes of a, often contrary, public opinion. A punitive approach different from that one led by many Italian mayors in recent years. As we have shown above, graffiti art has a history and artistic importance now widely established, in which many writers have become established artists, able to pass from the walls of the city to those in museums. The multiplicity of the phenomenon, however, is not consumed in its artistic value but embodies ideas and needs from the world of political communication, the urban redevelopment and practices of active participation in the transformation of public space. The realized projects were able to give value to this variety of stimuli, considering the graffiti practice as juvenile forms of civic action, initially secondary and then becoming more integrated in public art forms. These actions are aimed at creating a collective voice and

Fig. 17: ROA, *Draw the Line Festival*, Campobasso, september 2011.

identity that leads to the recovery of urban space and taking possession of the aesthetic and cognitive space of an urban environment, felt first as hostile and homologising and then re-written in collaboration with institutions. The city is a system that continually produces signs and meanings, a discursive space that projects onto itself a heterogeneous text, in which frictions, human practices, social values, cultural and political issues (institutional or underground) attribute to space meanings to be deciphered and composed. In the city we have not only graffiti but a chaotic whole, from the cognitive and aesthetic standpoint, made up of street names, billboards, ephemeral architecture, street signs, voices more or less conflicting. These projects were able to trigger a common table in which testing collaboratively one of these forms of writing in the city and record the shift from simply writing on the walls to street art.

The phenomenon of graffiti/writing has long been interpreted as a self-referential practice (tag, lettering, bombing...) with which ghettoized citizens are free to speech declaring their presence in contrast to the alienation and anonymity of the suburbs produced by the industrialized society. According to this view, the art legacy of these writing actions is closely linked to the political and existential need, first individual and then collective. Let's think about the transformation undergone by graffiti in critics and in the general opinion which evolved from uncontrolled and spontaneous act to street art with explicit political values as testified by those mural produced by antagonist groups active, since the early nineties, in many European capitals and in Italy, in Milan, with the Leoncavallo and, in Bologna, with the famous XM24 where took their first steps artists such as Blue and Ericailcane.

Interestingly, from the aesthetic point of view, the shift from writing to the street art coincides with the one from forms of self-referential writing, abstract, preferring the work on the "letter" and the tag, to figurative practices, which, on the contrary, tend to experiment with representation and act as a return to more traditional techniques of painting as seen in the works of Belgian Roa or Spanish Arys. It would seem that the work of institutions and of a part of the art system, together with the development of a different views inside the new urban planning, made possible to enhance the artistic section of this form of active citizenship, reducing (or hiding) the motivations of social and aesthetic alienation that brought the first writers to compulsively prove their presence with the tags, often banal expressions of vandalism directed to occupy an amorphous urban fabric. This does not eliminate the compulsion to assert themselves through graffiti (although the phenomenon, compared to the '80-90 is much reduced if not disappeared, as happened in New York City), especially when it is the effect of a state of malaise and social marginality, but it is indicative that when the city, and its many players, seek to share the creation of forms of writing and re-write the city, the result will lead to greater social cohesion, a strengthening of local and historical identities, and the enhancement of urban space with its multiple meanings.

Fig. 18: Fame Festival, Grottaglie (Ta). Organized annually by Studio Cromie (Angelo Milano), the festival brings together artists from across the world to spend one to four weeks in the city during the spring and summer, creating installations, murals, screenprints, and ceramics in advance of a group show usually held in september. The event is away from any political interference and public funding and each year is accompanied by a vein controversy. Some of the first works, specially the ones made by Blu and Ericailcane, met a strong local opposition that caused the removal of the paintings from the walls. During these years people now seem to appreciate more and more the art touches that are coloring their city. The interventions are set non only in peripheral areas, where trivial rise condominiums in areas desolate and almost deserted, but also inside the old town, an area important for the city as the seat of the ancient quarter of ceramics. Thanks to new works of street art, the small town has gained international reputation attracting tourists interested in seeing the works of some of the biggest names on the world stage. The Festival, now arrived at the fourth edition, among the others, shows works by (from top to bottom): Sam3 (Spain), Aryz (Spain), Ericailcane (Italy), Vhils (Portugal), 108 (Italy), Nunca (Brazil), Os Gemeos (Brazil), Dolk (Poland), Momo (USA), Blu (Italy), Bastardilla (Colombia), Lucy Mclauchlan (Great Britain). Abstract

Urban diagnosis

The starting point was the development of strategies, understood as a program that is developed to achieve goals. The adjustment to those strategies have enabled the contemplation of tactical processes, discovering how to do it, 'thinking about what one does.' Selective analysis revealed invisible structures of our society.

Projects development

Converting into diagrams | The proposed concepts became diagrams. Program analysis, simplification and exaggeration of the initial situation were brought to a outlining point where one originally only knew scattered relationships: those could now be freely discussed in terms of relations of common interest.

The concept | The recovery of disused buildings has been imagined as permeable, allowing high-level relations with surrounding flows. In this way, the building would work to coexist with its troubled situation and not attempt to order it, but to allow 'stuff' to happen there.

The actions | Actions have been understood as a "bottom-up process" or renewal from below, less institutionalised, possibly more real and allowing to "think about what one does." The initiatives have led to participation, social outreach and community work.

Economic efficiency and patrimonial revitalisation | The reuse of disused buildings has pursued expanded goals, namely: functional sustainability related to interlocked programme solutions but with the possibility of independent or simultaneous activation, the forecast of future maintenance costs and, in particular, the social returns and/or cultural relationship with the financial resources invested.

Keywords: Low-cost design, Design for all, Sustainable development, Social sustainability, Economic sustainability

1. Development

Starting from April 2011, a working group participated by the University of Zaragoza and the University of San Jorge in Zaragoza, was established in order to develop the projects proposed by the Candidature for European Capital of Culture Zaragoza 2016.

The consequence... set up a workshop which we called "Urban Prospection Workshop." ⁽¹⁾ The goal was the development of projects of the Candidature, through the recovery of unused spaces for cultural purposes, to complement the existing and in the process cultural facilities.

It is relevant the role of the university: "public and the University of Zaragoza provides centrality both in terms of audiences and as generator of public spaces, in the specific process within the Spanish context". This is the new academic power into connection required with political, creative and business power to exercise positive influence in our social sphere.

The workshop was divided into two working groups headed by the rapporteur who endorses this document:

- The Scientific Committee composed of experts in urban planning and urban sociology. This is the urban diagnosis: strategy and public space.
- The Projects Development Team, formed by young architects, professors at the School of Engineering and Architecture at the University of Zaragoza and the School of Architecture at the University of San Jorge in Zaragoza, and architects from the University of Oporto, Portugal and CEU University in Madrid, Spain.

The work resulted in maps of data and link of the city, which served for reflection for further development of projects; these were published in sheets that display diagrams, concepts and images of the imagined, based on the catalogue of tools proposed by the workshop.

1.1 Urban Diagnosis: strategy and public space

It was decided to adapt the workshop to the existing urban strategy by recognizing connections and linkages between the proposals developed and between them and the equipment in service.

The starting point was the strategy, understood as a program or project that is developed to achieve objectives and that, therefore, tells us what to do, but the adaptation to a strategy allows the contemplation of tactical processes, whose show how to do it, "thinking about what we do."

It was possible to think about the concentrated and dense city. Speaking of density does not mean that there are many people per hectare or square meters built, but the city, even a park, it is interpreted as any city, as an urban artefact rather than as a residual fact. It was verified that the continuity of public space allows you to find without looking, through the necessary wealth of chance and unplanned encounters the city should offer. . We needed, therefore, open and flexible urban space that would support the passing of time and the incorporation of new elements generated by the proposed uses.

It has been revealed the recovery role of centrality of the university as a generator of public spaces, particular process within the Spanish context. Consequently, the strengthening of university spaces connected with the "cultural containers" can and should generate economies being able to conclude that culture and university are the twin engine of the city.

1.2 Maps of data and liaison

"To think Zaragoza" and adapt the existing urban strategy needed the selective analysis through diagrams development. At the beginning of the workshop were inventoried aspects related to density, type, location, etc. Through the graphical representation, abstract data were interpreted in order to describe the general structural features. Although it may seem an administrative matter, the creative moment occurred when we ask ourselves what should be registered and how. These analytical explorations have revealed invisible structures of our society that are reflected in the maps of data and liaison.

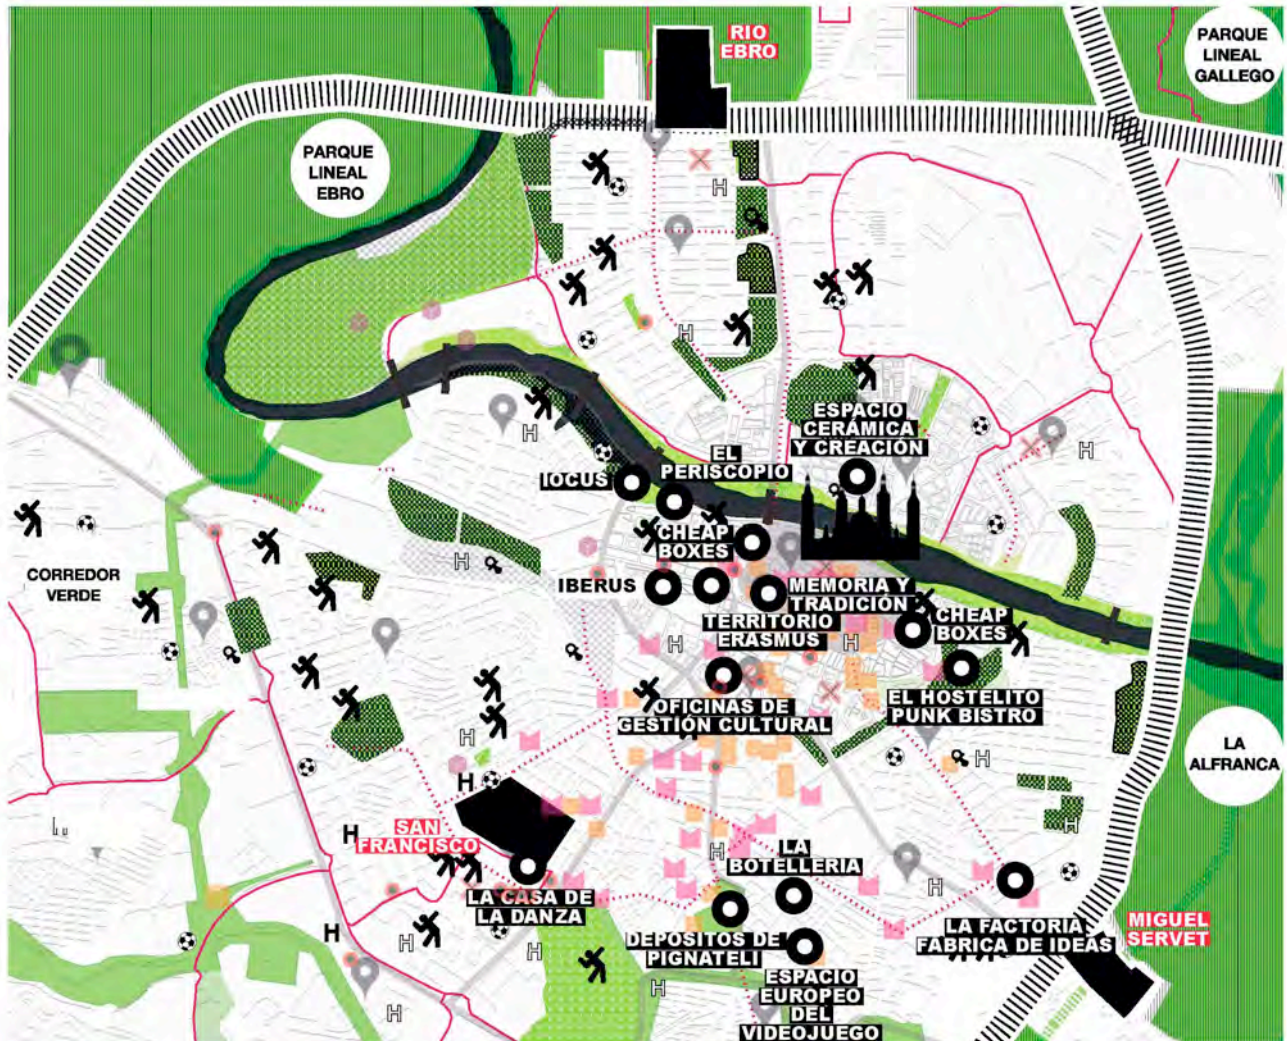

Fig. 1: Zaragoza 2016: under construction. ⁽²⁾

1.3 Projects development

The diagrams development | It was among the means used to visualize the data, and thus make them to be handled and to design. The proposed concepts became diagrams for the project development. Program analysis, reduction and simplification, exaggeration of the initial situation was brought to a point of outlining where originally we knew only scattered relationships and separated components (data, phenomena, ideas and forms) that could be freely discussed in terms of the relations of common interest.

The concept | Disused buildings, recovered, have been imagined permeable, allowing circulations highly related to environment. In this way, the building will work coexisting with its troubled situation and not attempt to order it, it only will allow 'things' to happen. It will not completely impose certain conditions, making it a flexible container stripped of coded language in forms and materials.

The actions | Those have been understood as a "bottom-up process" or renewal from below, less institutionalized, possibly more real and allowing "to think about what we do." The initiatives proposed by the workshop have involved participation, social approach and work with the community, fostering dialogue between those who do and those who use with the active participation of creators and artists. We intended an appropriate balance between the necessary actions: the institutional or "those who do," the renewals from below or "those who think" and the academic power, "one who can lead influences" in our social sphere.

Economic efficiency and heritage revitalization | It is implicit in the reuse with minimal resources, of disused buildings, recovered for culture. However, in many cases, these circumstances do not prevent high costs in relative terms, for this reason, the prospecting workshop has pursued expanded objectives in relation to this matter, namely: functional sustainability related to interlocking program solutions but with the possibility of independent or simultaneous activation; control of construction resources; the forecast of future maintenance costs; and, especially, the social and / or cultural profit in relation to financial resources invested, in colloquial terms, quality/price ratio. Moreover, economic efficiency can be also related to the actions, which seek to change the static conception of culture and art associated with their display and consumption, by other dynamics, linked to the process and production.

Fig. 2: Positioning and working tools for projects development at the 'Urban Prospection Workshop'. (2)

1.4 Positioning and working tools

It is important to position the architectural strategy that we want to outline for the Candidacy of Zaragoza 2016. A strategy able to draw up a plural outlook developed through a continuous and collective workshop that has served to analyse, diagnose and propose. That allows architecture to talk about topics of interest for the citizens, which will enjoy Zaragoza as cultural capital. Therefore, we are proposing a catalogue of architectural tools to join all the proposals. A context of common strategies allowing us to describe with the same codes the different ideas that we propose. These tools target at different fields of interest. From the most tectonic and constructive parts – to classify the kind of spatial action proposed to be developed- to those more related to urban planning that will allow us to take out the programs to the public areas of the city.

Our interests were intensified in three important points.

The first will be an acute accompaniment of the participation process of the candidacy. Different strategies will be taken on by the architectural project that will make possible design teams to be built with multiple profiles: reflecting on how citizens can have an active role on decision taking on these projects.

The second point presents the implementation of the development plan for the candidacy by means of the restoration of underused buildings. Therefore, those constructions will be recovered for the city, a latent infrastructure able to optimise the resources and considering architecture from a much more contemporary point of view.

The last point will focus on how to understand the architectural elements as progressive objects with an evaluative development. They will grow and decrease in accordance with the needs of the citizens for any program at any given moment, before, during and after Zaragoza 2016.

1.5 Actions or transforming effects at Zaragoza's city

A series of actions have been proposed for the regeneration of the neighbourhood of St. Paul in the Old Quarter of Zaragoza. The aim is its transformation into workspace, relational, and residential services for people such as college students, among others. It is in motion the creation of the 'Flower and Culture Market' in the spring of 2012, first initiative to recover unused buildings (Old Pumping Station of the city) that will serve to create public space and the social dynamics, generating independent activities and others related to the presence on site of the Seven Arts.

These are actions under way or planned in other sectors of the Old Quarter: rehabilitation of buildings; the small-scale urban developments to facilitate the movement of citizens; Recovery as public spaces of urban voids; new uses for obsolete infrastructure (designed for administrative, social or cultural purposes); the encouragement of models of public-private participation (private management of infrastructures or public services; incentives to attract the private sector; and the promotion of International Excellence Campus Iberus/Erasmus district.

The first initiative comes with the transformation of the Convent of the Order of Minims of Victory; initially designed as Museum of Fire and Fire fighters, is now a relational space for Erasmus students with study rooms and classrooms for teaching Spanish to foreigners. These actions are integrated within the Downtown Revitalization Plan "The Culture Transforms the Centre" which is expected to generate a feedback effect in the medium term, result of an integrated and continuous action.

Fig. 3: 'Flower and culture market' at Zaragoza ⁽³⁾

2. Urban.prospection.network

The opportunity to develop the Urban Prospection Workshop resulted in the creation of the urban.prospection.network, cultural and private institution, non-profit and with national and international public projection, founded in 2011 by the undersigned of this presentation.

The urban.prospection.network aims to encourage and promote sustainable development of communities through the creativity of young professionals. Aimed at cultural management, employment for young graduates and impulse of social participation, urban.prospection.network directs their field of study and action on sustainable processes of recovery and recycling of content and concepts, taking on the conceptual basis the reoccupation of abandoned urban structures and its connection with the public space and

landscape, in relation to the creative possibilities motivated by the contemporary situation. It is an urban laboratory network where professionals from multiple technical, artistic and scientific practices offer expertise in creative urban intervention, in order to cooperate in the development of urban and rural areas through multidisciplinary projects at various scales: forms of action beyond the established and generating intensive processes of creation and collective participation associated with the impulse of the sustainable city.

The pilot program is taking place at Calatayud, through the creation of the creative.factory.1|calatayud. This situation is made possible by the signature of a collaboration agreement between the urban.prospection.network, the City of Calatayud and the University of Zaragoza.

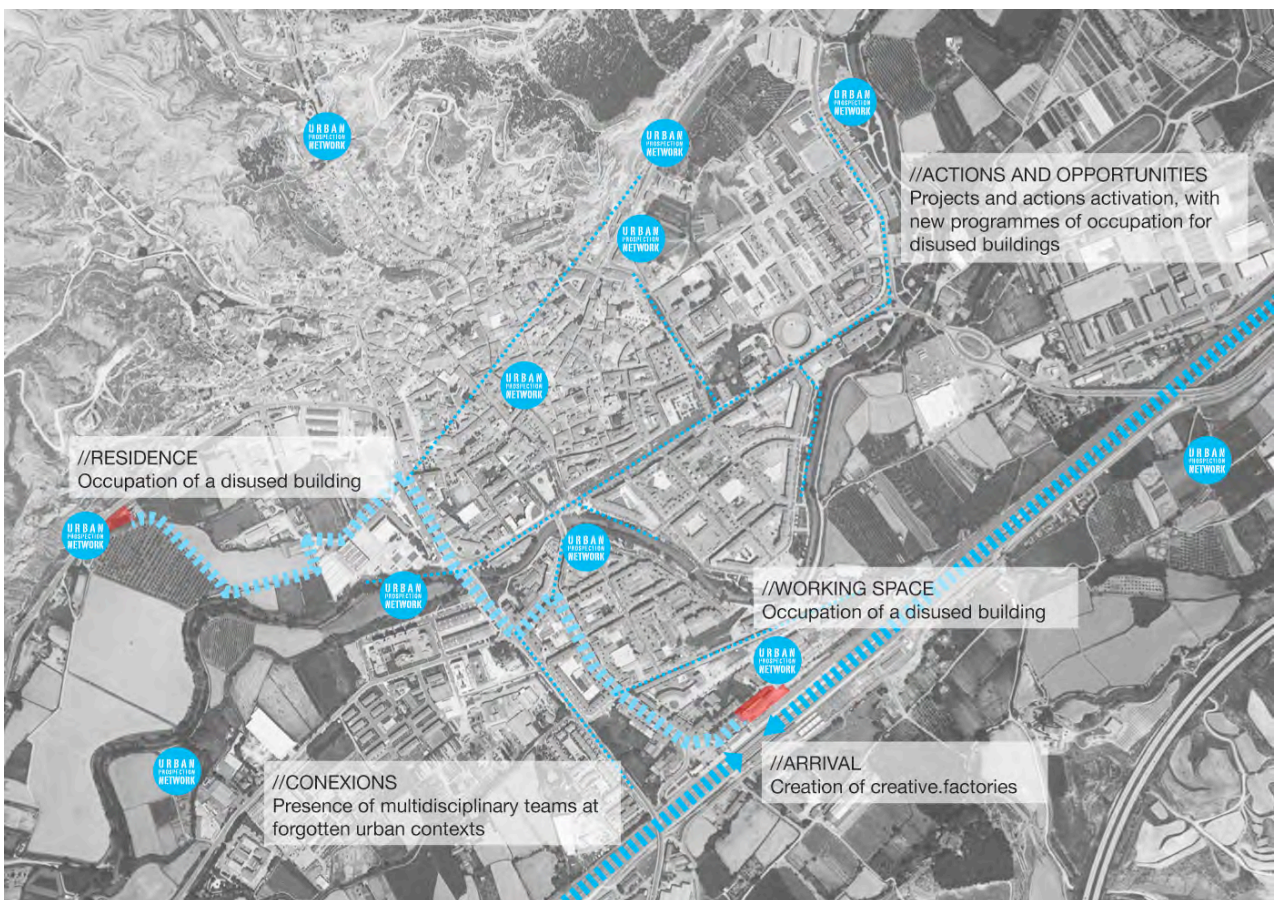

Fig. 4. Action plan at the city of Calatayud ⁽³⁾

2.1 Actions or transformer effects at Calatayud's city

Projects and management actions are being developed in order to allow the reuse of the former Water House the residence of the urban.prospection.network team from the spring of 2012. At the same time are being recovered two wagons of the train model TER 597 located in the "Railway Station Park" for use as a workplace and representing the urban.prospection.network.

To reach, To occupy (disused wagons to work) and To reside (recovery of the former Water House) is the method of implementation of the urban.prospection.network in order to identify opportunities for management and urban planning. The first opportunity for development is the creation of the Skate park at the Park of Margarita, with the aim of promoting the green axis of the channel.

Fig. 5: Rehabilitation of the 1965 disused wagons as working space of the urban.prospection.network at Calatayud ⁽³⁾

2.2 Generic goals of the urban.prospection.network

/ Urban Prospection through the promotion and defence of the concept of functional sustainability of the cities, promoting actions for rehabilitation/reuse of disused buildings and structures and the creation of public space.

/ Save from the progressive forgetting the kind of 'unused buildings' understood as 'present built heritage'. For a building to be rated 'disused' is necessary that the population and the entities assume it as such and therefore should never be forgotten.

/ To promote research that may arise, from the conceptual project, the recovery of all the in disuse built environment and its protection against aggressive real estate.

/ Establishment of processes of response to the lack of infrastructure in different settings, completing and diversifying (in audiences, functions and location in the city) the social, cultural, sports and academic facilities.

/ Development of minimal impact projects that aim functional profitability and allow the use of the buildings by completing all the space, with reduced maintenance costs.

/ To submit proposals of management and occupation that allow to identify a list of unused buildings.

/ Interventions in urban voids, regenerating degraded environments in historic centres, looking for social participation and work with the community.

/ Interventions in the gaps of the new urban spaces that arise in the periphery of cities. The occupation of spaces on the ground floors of apartment blocks, to locate basic needs of facilities (libraries, neighbourhood associations, senior citizens, school children, etc.) will create relationship and connection to public space (the house does not end at home, communicating housing and urban context) and will be complemented with the occupation of public parcels/private lots with no activity, by using recycled materials and low-cost executions, managed to create a relational urban model through the location of landmarks, axes, networks and systems.

/ Prospection of the edified and its relations with the landscape, on an urban and/or territorial scale.

/ To propose new concepts of occupation, through adaptive hybrid programs of uses.

/ Strengthening of the connections between political, creative, academic and business forces.

/ Social participation, promoting the relationship between those who do and those who use them.

/ Dissemination of national and/or international projects which transmit innovation, creativity and knowledge with the aim of promoting sustainable development and functioning of cities.

/ Strengthen global discourses that generate brand awareness and that allow the communication of the projects.

- / Encourage the growth of cultural industries, promoting active participation of citizens and creators and encouraging networking.
- / Activation of citizens potential which, by the experiences of the past, does not depend exclusively on the creation of 'cultural containers'.
- / To use relevant artists and cultural producers communities as triggers, through the display of his creative process and its interaction with other agents.
- / Organization of spaces on two levels: local communities as a tool for social innovation and 'creative economy', meaning any social intervention as a hub for creating and producing technical, scientific and cultural support for the national and international consumption.
- / Generate new economies to ensure their sustainability.
- / Connection of the social infrastructure projects and cultural strengthening at the university spaces, when available at the site of intervention.
- / Academic power must be understood as an economies generator (as well as audiences and public spaces).
- / Incorporate into the strategic vision the management details of areas and projects, to ensure that aligns with the stated objectives.
- / To work and strengthen creative and innovative community networks that use network infrastructures such as resources and organizational platform.
- / Citizen networks will generate social innovation for sustainable development, inclusive and creative; cultural, scientific, creative and technical productions as a generator of new economies through cultural entrepreneurship.
- / To create international hubs of cultural, technical and scientific economics, as talent importers and exporters of cultural production, working based on small entrepreneurship initiatives to provide them with scale through its organization in networks of all kinds.
- / Culture and university can be a twin engine of the city: culture as a tool to promote pro-active and innovative citizenship and as an economic engine. The university as a generator of public space, knowledge and innovation.
- / To create urban laboratories in order to increase the capacity for social innovation and pro-active citizen participation as well as improving the linkage of some of the potential drivers of innovation (such as universities) with the real economy and society.
- / The local 'amateurs' citizens' network who actively participate in production projects for intervention at the local level shall be learning, civic debate and collective construction communities of the city from 'bottom up'.
- / The networks of 'professional' creators oriented to the arts and culture production will have a global horizon and a potential generator effect of local economies and at larger scale.
- / Local creative professionals and local networks shall share resources and work collaboratively to develop interdisciplinary projects.
- / Creation of a platform for dynamics of citizen networks to identify, build and strengthen networks of all kinds through a combination of facilitation, resources (spatial, of knowledge and of technologies) and visibility through the actions: Mapping of existing initiatives and creators ; Visibility of creative processes (culture and technology linked to the process, to labour assets and to production); Transfer of project documentation to digital spaces; Network of managers, mediators and communicators.

/ To promote actions for local networks of 'amateur' citizens, creating an ecosystem of citizen laboratories oriented to the social innovation and based on the transmission of disciplines, the collaboration between professionals and local 'amateurs', on 'learning by doing' through the development of collaborative projects and inserted into the culture of prototyping. Living-labs, medialabs and self-managed social centres shall be taken as reference, through processes of negotiation and collective agreements between citizens and public institutions.

/ If appropriate, encourage actions to turn the university into a platform for the creation of new economies and their integration into civic innovation processes.

/ To conceive the 'university projects and containers' integrated with the proposed strategies for citizen networks to design actions that lead citizenship to the university spaces and secondly, and more importantly, lead 'the academics' to the cultural, technology, science and innovation spaces.

/ To promote the reflection and the discussion related to any area of knowledge, broadening the participation of audiences increasingly diverse and heterogeneous.

/ To promote young creative professionals in the contemporary artists scene.

/ To support the professionalization and internationalization of young artists.

/ To promote and encourage the creation of technical and scientific knowledge in technical and creative areas.

/ Encourage the exchange of ideas, promoting cooperation projects.

/ To promote personal and professional assessment through training initiatives.

/ Community awareness for creative production of young professionals, raising them to social change agents.

/ Creation of public employment, with the objectives: training of university students without professional experience, communication of a social message through creative production, and work with the community, creating social proposals through acts of prospection and response.

“LESS IS MORE”. Eternal truth, eternal good and eternal beautiful

Maria Grazia CIANCI

Department of Architectural Planning and Studies - DIPSA
Faculty of Architecture, University of Studies of Rome Three, Rome, Italy
cianci@uniroma3.it

“Less is more”

Design has undergone substantial changes over the last few years, the new technologies, the new ways of making architecture have distanced the thought of designing from its graphic representation: thought and image have not always coincided. Design's role, its sense has lost credibility, it has been emptied of meaning, it is no longer representative of itself; the relationship which once existed between idea and knowledge has altered its connotation: the idea is no longer the mind's design but the design of avant-garde technology, of the exploration of the virtual.

As Platone posited, ideas are the cause which allows the world to be thought of, they therefore form the premise of knowledge. The Idea, which is more properly translatable with «shape», is subsequently the real object of the knowledge: but it is not only the epistemology of reality, i.e. the cause which allows us to *contemplate* the world, the cities, but rather it constitutes the ontological foundation as well, being the reason that causes the world *to be*, that makes cities exist.

Ideas represent the *eternal Truth, the eternal Good, the eternal Beauty*, to which the vain and transitory dimension of sensory phenomena, of transformations of reality are juxtaposed.

Today's cities are mirrors of contemporaneity, it is as a matter of fact that the sensory phenomena which trigger the becoming of the images, homologated cities, virtual cities, mutating cities become blurred: it is no longer possible to distinguish reality from imagination. The images and their becoming overlap making “Reality” increasingly more unfathomable and there is no instrument that can export the concreteness of such transformations into time.

Keywords: Totality, knowledge, contemporaneity, homologated cities, creation.

Fig. 1: Giacomo Costa: “Fusion n.3” - A world suspended between creation and destruction.

1. A world suspended between creation and destruction

The "city", where men and his creations are compared, exchanged and connected, is and will always be a place of reflection and experimentation for architects. Simultaneously, it must become a place of protected memories. Architecture generates architecture. Conceptual thinking generates images. Images generate design. Designs generate memory.

"Today's city is a scattered reality that is no longer supported by a sovereign firmness, but rather by a shining opulence"[1]. "A world suspended between creation and destruction" is the title of one of the latest essays written by the French philosopher, J.L. Nancy; who covers aspects that are connected to the world's creativity and expressive multiplicity by addressing philosophical themes from an anthropogenic viewpoint to a figurative one.

This assertion generates different interpretations; from the most obvious ones to the more complex ones under a single interpretative matrix: the *"globalized"* world that coincides with itself. There are no figurative and conceptual elements that can represent the world from the outside.

However, the "globalized" world seems to have only acquired the ability to multiply itself - according to Nancy by all means available. This is repelling: *"it's as if the world were now a journey shaken by an impulse of death that will soon have nothing left to destroy other than the world itself "[2].*

Is it fair to maintain openness towards unpublished materials, surprise, generosity, creativity and expressive opulence?

It is certainly better to question ourselves as to the expressive complexity of architecture by simultaneously trying to find satisfying answers that can avoid any doubt.

The contemporary man is the "creator" of the contemporary world. He is also the author and interpreter of his own creation and, as such, he should assume his responsibilities: understand the events and social transformations to critically interfere in the concrete expression of such reality.

Understanding reality can no longer be achieved by exploring the virtual world. Today, more than ever, the word "exploring" no longer represents a fear towards innovation, but rather the desire to discover the unknown. However, all of this complexity and all of this expressive and architectural opulence make it impossible to read that which can be "read". By eliminating the superfluity and purification, as according to Mies van der Rohe's words "less is more"[3], we want to generate a process of exclusion: to cut, eliminate, exclude, re-dimension, subtract, simplify, lighten and reduce the architectural reality. The beauty of architecture can therefore be seen again and so can its best expression, which will also turn it into a contemporary element.

Fig. 2: Giacomo Costa: "Act no.8" – The great monsters.

Fig. 3: Giacomo Costa: "The imaginary cities no. 4" - The virtual process and the metaphorical statement of reality.

1.1 Complex Grammar

Contemporary architecture uses a complex language full of metaphors and impalpable conceptual stratifications, but it also furiously invades and penetrates the urban space. It fills itself with sensational images that touch the most intimate senses of human beings, therefore inciting uncontrollable reactions: passion, hate, interest, waiting... but never indifference. These complex linguistic stratifications belong to a subjective code; a code composed of a complex grammar that is often difficult to decipher. This enigmatic code is well represented by the horizontal architectural achievements of Giacomo Costa, a Florentine artist. These epics, personal and attractive visions of the contemporary elaborate the theme of unrealistic cities. A science fiction-like, surreal and virtual panorama, or a reflection of our contemporaneity, which assumes an entirely symbolic value to witness the colonization of humans within the natural environment [4].

The impression one gets when looking at his accomplishments is that of a lack of reality.

Urban visions suspended between tradition and modernity, between reality and dreams; complex visions that float through our minds like small "perceptive inputs" ready to stimulate our creative memory.

Fig. 4: Giacomo Costa: "The imaginary cities no. 6" - Reality and imagination.

These overlapping "visions" and these contemporary - or not - architectures contrastingly cross each other's path, therefore generating emotional outbursts. Just like the many architectural achievements of contemporary masters.

Reality is no longer static. It is in continuous evolution and the images, designs and models are able to express such changes: a back and forth rhythmic and sometimes uncontrollable yet impulsive evolution. Our perception is focused on an incomprehensible path. The trajectory is not satisfied with reality so it unveils through a space full of illusions.

Complexity and opulence often generate "monstrosity", an architectural metaphor that navigates through architectural space trying to find its definitive and final position.

This form of navigating through unknown "seas" is often turbulent. It entails great mastery and control over the "available instruments" and one can easily get lost. Not being able to control such instruments is what made the contemporary architectures deviate; far from the "still lands", without points of reference and through a very difficult journey. This tendency to exasperate in terms of shapes and ideas must necessarily end once the extremely complex and abstract point has been reached.

Finding an objective reference within this simplicity is essential: making the real world coincide with the virtual one and vice-versa, but also the complex one with the simple one, internationalization with nationalization and black with white. For this reason, one must become self-conscious and find a solution.

Maybe, the solution is simpler than one may think. We can find it in what we do naturally:

- 1) *We stumble upon a problem;*
- 2) *We try to resolve it by - for example - proposing a new theory;*
- 3) *We learn from our mistakes, especially from the ones we encountered during the critical discussion of our attempts to resolve the situation;*
- 4) and finally, we backtrack and accept our responsibilities [5].

And this is a "life lesson" we should never forget.

We must have the courage to face reality, no matter how complex or difficult it may be, and we must address it decisively and firmly.

If we direct our efforts towards a common objective, towards simplicity, then we can open a gate through the fatally contemporary trend to end the process of "exaggeration".

We could therefore go back to the "eternally true, eternally good and eternally beautiful" elements by neglecting the "*special beauties in order to reach the single vision of eternal beauty: Goodness*".[6]

2. New horizons: changes and standstills

The future things to come, the ones that degenerate or change, are *“the fruits of perfect things in a certain way”*. This is why it's good to try and find the origin of such ideas.

We need to get rid of the superfluity in order to find the real essence of things; pure beauty, absolute goodness. We need to get rid of some of the superstructures and of expressive complexity. We need to abandon excess and to find that rigor that makes architectural thinking eternal.

Mies van der Rohe's *“Less is more”* is a motto, but also a way to understand the founding reasons of architecture in order to *“fully understand the word itself and without associating it to the other meanings it entails”* (Franco Purini 2007).

We must acquire awareness on the frenetic and complex appearance of contemporaneity. Such complexity can only be grasped from a dynamic perspective. Highlighting the evolution of characters rather than their state of permanence is not sufficient.

“I think that practice is not sufficient for the arts that are not purely applied. Learning how to think is extremely crucial. An artist must be able to justify what he does.

In order to achieve this, he needs principles to determine his judgments and to justify his decisions so that he cannot instinctively say what is good or bad. Principles that will help him express his human judgment; the judgment of a man who knows how to attain Beauty and to justify himself” (Marc Antoine Laugier, 1775).

Continuous changes, temporary interruptions, other infinite variations, standstills and back and forth movements generate ideological, expressive and - especially - visual confusion.

This is a type of behavior that tries to find the new instruments of this digital revolution to compare itself to a reality that is undergoing continuous transformations: even at the cost of getting lost in the blobs or in complex geometries that can only be achieved with the help of a computer.

Thanks to all of this, the appearance of metropolis Europe has strongly changed over the last ten years.

The atopy, hybrids, out of scale figures and the new monumentality now prevail: all disarming figures!

There are no more hierarchies or measures of reference; everything is expandable.

Fig. 7: Zaha Hadid; Kartal Pendik, Masterplan Istanbul.

Fig. 8: Atelier Olschinsky; Legendary Cities. Urban complexity and stratification.

2.1 Thinking through images

The city and its architectures have become illegible and metaphorical. For this reason, we need a new code of interpretation that can allow us to translate and codify them. The ancient myth of Babel, a place of dispersion and disorder, was chosen as an example in one of Rosario Pavia's essays.

It was used as a symbolic reference to explore the shapes and identities of the third millennium's cities. It resulted in "*an overproduction of images*" that appear to be indecipherable, like a "*messy magma deprived of spaces, objects and relations*" [7].

The city is more and more becoming the fruit of an overproduction of images. Their dominance erases the scales and their disarticulation imposes new methods of orientation. The vision is swiftly centered on immediacy; the gazes are directed towards the surface.

The image of the contemporary city must not only be that of Babel and its limits, negativities and contradictions. It can and must also be part of a project, challenge and involvement; which can only be achieved by deciphering and by making the world less opaque.

By simplifying its representation, or by canceling and subtracting communication data, signs and images, we can attain a principle of continuity, narration and interrelation for the different scales.

This new urban condition allows few alternatives.

Calvin had grasped them lucidly "*...there are two ways to make sure we will not suffer from it: one is to accept this hell by becoming part of it until it can no longer be seen. The other is risky and it requires continuous learning: trying to figure out who or what is behind this hell to get out of this hell, making it last over time and by giving it space*" [8].

This simplification and critical analysis process can lead us to rediscover the primary values of architecture; therefore redirecting the attention towards the generating principles of anything.

Towards the ἀρχή.

"Thus, the ἀρχή do not only represent the similarities we see in different things, nor the dimension from which they come and go. They are the strengths that will determine the future [changes] of the world, or the 'principles' that will produce them and return them to what they were through their governance." [9].

Moving forward with one clear thought in mind from the start: discovering to improve, evolving to grow, experimenting to create and leaving to return.

The things - of the world at least - are part of Everything and they do not sit there motionless and unchanged. They move, vary, come to life and die. They are generated and corrupted, they come and go.

Richness is found within the essence of things: "*less is more*"!

"A greater part of those who first philosophized on the idea that the only principles of all things were of materialistic nature, thought that was how all things came to life or originated only to go back; while keeping their substance and changing their qualities.

They say this is the element, the principle (ἀρχή) of things and this is why I believe that nothing is produced or destroyed since the remaining substance is always preserved". (Aristotle, "Metaphysics", I, 3, 983b)

P.h.d. candidate , Faculty of Fine Arts, School of Visual and Applied Arts, Aristotle University of Thessaloniki, Greece

elinapavlea@googlemail.com

Abstract

Contemporary design thinking is gradually shifted from a physics based view of the world, to a biological one. Namely, a shift away from typological thinking to population thinking; therefore, to an architecture of performance. Contrary to typological thinking, population thinking identifies the notion of multiplicity as an organizational principle that defines a many and incites architectural variation. Thus, the architectural object would be understood by means of its morphogenetic process and defined as a multiplicity rather than a type. Artistic and scientific agendas, address a design repertoire that emphasize on process paradigms abstracted from the developmental logics of the architectures of biological systems.

The current paper will address a theoretical framework for new pathways, linking algorithmically folding procedures and bio-computational theories, with the embodied act of making & the role of the handcrafted. It will draw an argument about intelligence, performance and beauty, assessing case specific criteria to folded art-e-crafts by means of geometric behaviour, material characteristics, manufacturing constraints and assembly logics.

The paper makes a statement for the process of folding by thinking in terms of the many and applying variation as a system of thought. It relates process and form with pattern and behaviour; and designates a design apparatus driven by choreographies of inter-relationships and interdependencies as in natural formation patterns.

Keywords: morphogenesis, variation, performance, multiplicity, natural patterns

1. A ‘Many’ as a system of thought

1.1. The Natural Paradigm

Ernst Mayr states that, ‘For the typologist, the type (eidos) is real and the variation an illusion, while for the populationist the type (average) is an abstraction and only the variation is real’.

Modern typological thinking employs the idea of type to standardise norms, functions and manufacturing techniques. This manifestation does not account for the parameter of time; therefore any architecture of performance.

Peter Trummer incites a transition from type – based thinking to a population – based approach and defines the Deleuzian notion of multiplicity. A concept related to the processes that drive the appearance of the variety of forms within our world. Multiplicities are related to process paradigms; delineated as interrelated functions of form, structure and material behaviour.

The developmental logics of natural systems suggest a paradigm which focalize on the process of formation instead of a set form. Their architecture is perceived as a system comprised of and working with a series of interrelated systems. It is considered successful in the sense that it uses the minimum amount of material to make their structure and because it is optimized to influence their local environment.

Behaviour rather than form constitutes the generative pattern under investigation. Behaviour is non linear and context specific.

The physical process that underlies the development of living forms is called morphogenesis and emphasizes on the forces that generate them. Within architecture, when morphogenesis is employed as a generative design tool, it facilitates the development of component-based, polymorphic systems.

Morphogenesis comes into view by two processes: differentiation and integration. Differentiation within a system manifests itself as an increase of differences. Integration accounts for an increase in number or strength of system's connections.

A design paradigm following principles abstracted from the natural world exhibits emergent properties. It also evolves and maintains its entity under the process of self – organization. Variable materiality, assembly strategies and iterative geometry operations account for the display of emergent and self – organization phenomena. As Michael Weinstock states, an emergent whole form can be a component of a system emerging at a higher level – and what is 'system' for one process can be 'environment' for another.

1.2. Folding as a Morphogenetic Technique

The current paper will propose a methodology for assembling differentiated surface elements by addressing ordered sequences across the process of paper folding. Multiple rotations manifest the generative principle.

It suggests a morphogenetic process that demonstrates the architectural object as a physical - analogue system capable of generating surface elements, out of the inherent properties of paper folding. This involves an investigation around the definition of folding both in geometrical and material environments. It engages the resultant flat and folded outputs, geometric analysis of experiments' outputs and their implementation into an assembly synthesis.

The methodology, instead of defining a specific typology for a surface element, describes surfaces as a multiplicity and it focuses on the variation of objects and their assemblage.

Additional to form generation, the primary objectives are driven by understanding the origin; flat state and the processes that guide the evolution of the artefact. Emphasis is placed on the chains of operations that are executed and on the formation pattern of the three dimensional; folded object.

Speculations upon regularities and symmetries both in flat and folded state along with repetitive patterns, inform the morphogenetic strategy of the assembly synthesis. Analysis based on a real scale material combines geometric outputs with a structural system's logic and identifies the assemblies' performative capacities at a local, regional and global scale.

A flow chart that processes all the data into an integrated schema is illustrated as an epilogue for the specific research; providing a prologue for potential analysis methods and corresponding applications.

Design experiments, physical or digital, take place through an envelope of possible formations and produce multiple variations of form, inseparable from their structure and material. Processes where form, structure and material act synergetically so that their interactive output cannot be deduced to a single object.

Self - organization principles are expressed by means of geometry. An increase in the order of system's behaviour is generated through geometrical iterations. Material inputs and assembly strategies create differentiated behavioural patterns; while local units have a dynamic relationship to each other and to an informing global geometry.

What emerges is the necessity for redefining local and assembly inputs across the design process. Emergence is produced out of geometry and material performance, when it comes to the point where the initial inputs to the system are not identified in the repetition pattern. Then, the system needs to redefine the initial input with regards to geometry, scale and materiality. Keeping constant the geometric form, differential material inputs result in differentiated performative patterns (Figure 1).

2. Research Analogies

2.1. Pattern in Nature

In natural morphogenesis formation and materialisation processes are inherently and inseparably related. Therefore, to understand the process of folding as a morphogenetic one, it is necessary to define a fold both within a geometric and material environment.

Natural material systems involve movement to achieve adaptation and responsiveness. In plants, the mechanism is differential pressure in an asymmetrical arrangement of cells.

The behavioural principles stemming from the reaction of the sensitive plant, *Mimosa Pudica*, when it is irritated, incites a morphogenetic folding scheme associated with hierarchy interdependencies.

The plant, when stimulated, folds its leaflets around an axis by rotating and bending them downwards. Specialized organs that constitute strategic nodes within plant's topographies serve as flexible joints that control the movement sequentially. Stimulus repetition enhances the overall performance and the polymorphic output.

The movement is reversible and operates as a defensive mechanism.

Hierarchies within hierarchies are established under local interactions, expressed through sequential folding by rotations around variant angles and axes that take place across plant's topographies.

Natural systems' folding function in order to facilitate deployment, refers to a total of angles around a node more than 360° .

Deployment in nature is by definition a criterion for survival. Growth itself refers to the deployment of a single cell. Effectiveness of deployment constitutes a parameter of success for all living organisms.

Folding in plant systems is actuated by changes in shape, as aforementioned in the sensitive plant, or changes in stiffness by controlling fibre orientation.

Leaf unfolding is actuated by a single fold. It is an irreversible process that indicates growth.

The leaves of most plants while folded inside the bud, unfold to generate a surface. Symmetry with regards to axes is crucial for system's stiffness while unfolding. Namely, leaves unfold in two ways: by a primary axis that elongates simultaneously while the surface unfolds in a biaxial or in a radial manner.

The surface between axes expands simultaneously with them. The controlling factor is fibre orientation in the walls of cells of the upper and lower surfaces of the leaf. Expansion finishes when the fibres have rotated 90° , where the process ends and the surface is stiffened in the expansion direction. The process is environmentally oriented. In this case geometry is integrated into a mechanical function. The axes (veins) transport water and assimilation products within the leaf and provide mechanical support. In parallel, they enable a leaf to decrease drag in the wind and subsequent mechanical damage and sustain their own weight and other small loads (Figure 2).

2.2. Integrating Geometry and Materiality.

In stark contrast to natural deployment and within an abstract mathematic environment folding process constitutes a system of parametric equations. Folds' topology is related to rotational functions which coordinates points on a circular circumference by means of a constant radius.

Folding is accelerated [180° , -180°] or decelerated within a range of 360° . Restrictions are related to the sequenced folding actions that take place, due to the fact that each fold added, varies the relational parameters of the folding equation.

A material adds certain constraints to the rotational function that characterizes the mathematical immaterial process of folding. These constraints regard fold direction and fold angle range. Taking the logics of a very simple material system interrelated with the folding process such as paper, certain constraints and limits of making through the self-forming tendencies of the material affect the folding function.

The process that facilitates paper folding is scoring. Paper folding and scoring are mostly a matter of understanding the properties of paper fibers. While folding, it stands crucial to consider paper scoring parameters such as grain direction - the direction in which the fibers align on a specific sheet of paper, fold sequence and paper thickness. Therefore, the most efficient way to fold and score paper is positioning grain direction parallel to the folds and score.

In an attempt to scale up the process, additional constraints should be added to the folding function. Some of these constraints are related to factors such as material thickness, joint connection ensuring surface continuity and strain energy stored in each fold.

Folding as a process has the characteristic that no stretching occurs along the surface that is being folded as long as the surface thickness is relatively small.

Scale constraints of the flat pattern are imposed by sheet folding and cutting technology.

For example, a folded component is generated after a 3-fold rotation. Radius variations of the circle in which the component is inscribed is defined within a range of [75cm, 150cm] specified by flat sheet dimensions.

Static structural analysis will define the material thickness. Scale applied, is equivalent to the smallest radius $r = 75\text{cm}$ given by the aforementioned constraints at flat state. The material is structural steel analyzed under gravity loads. It designates a construction material that cannot stretch and has tensile yield strength of 250 MPa which shows significant resistance to plastic deformation. Analysis commenced shows that 1mm thickness component is the most appropriate to proceed because it demonstrates rather low stresses (the tensile yield stress of steel is at 250 MPa), while mostly deformed areas are the wide ones and the ones that are folded at a small angle.

2.3. From Mathematical Analysis to mathematical synthesis. Generating the Symmetry Operations.

Folding as a process itself constitutes a symmetry operation, since it preserves all lengths and angles occurring in an object.

A regular plane is defined as the one that is extended without boundaries in all directions and can be filled or divided into infinity, according to a limited number of symmetry operations, with similar geometric figures without leaving empty spaces. M.C Escher's regular tiling demonstrates a paradigm according to which symmetry operations are fed upon themselves to produce repetitive patterns.

Taking advantage of these dynamical relations of rotations and reflections applied sequentially, we generate a flat pattern. The component employed to proliferate the pattern is defined by a three-fold rotation of a unit of 120° . Folded assemblies are generated by the symmetry operations of rotation and reflection applied to the component iteratively, both at a flat and folded state.

The assemblies perform an incremental loop of rotations and reflections till certain conditions are met. The flat pattern, being self-generated, has the potential to be repeated and generated endlessly. A domain is defined that affects assemblies' periodicity. Having applied a specific number of rotations and reflections, the initial component needs to be redefined in terms of scale, material and geometry so as to preserve its significance within assemblies' growth, under symmetry operations.

3. Assembling 'Multiplicities'.

A recurrent assembly methodology, generates folded variations, corresponding to three dimensional artefacts and two dimensional surface elements. The proliferation environment is defined by an algorithm that drives components' distribution. The algorithm is generated by a sequence of symmetry operations – rotation and reflection. Its successive states are traced by means of 'rotation centres', a multiplicative construct that drives the transformation process into 'population' outputs. Population outputs increase in number till material and therefore assembly constraints are reached; and the algorithm recurs.

3.1. Synthesis. A lattice, a primitive cell and fold definition.

Two grids are constructed out of fold intersection. A rectangular grid resulting from evenly spaced horizontal and vertical fold lines; and a square grid from diagonal fold lines. Fold intersection, generates nodes that define a lattice as a repeating arrangement of points spaced regularly. Any point can shift onto another by using symmetry operations.

A local geometric formation within a lattice establishes a primitive cell. The primitive cell is defined as the minimum topological area corresponding to a single lattice point demonstrating translational symmetry in two dimensions.

Node connection of the two grid systems sets up a regular pattern attributed to triangulation techniques. Therefore, pattern hierarchies are invariant of node displacement.

What vary are the generative symmetry operations. Node displacement limits translational symmetry to the horizontal direction.

A fold is defined by a line. Any fold line subdivides a pattern in two regions. Any additional fold is integrated in this division. Node alignment corresponds to fold lines. Node interdependencies within this local domain generate a fold pattern. Triangle arrangements within this domain define fold sequences. Physical experimentation on paper folding detects that an angle of 120° degree appears to be the most efficient.

Folding is a sequence dependent process. Folds interact with existing folds, when a fold line is added to the pattern in an interdependent manner. Sequence and direction of folds added redefine the folded formal output.

Folding assigns rotational functions. Fold interaction synthesizes a synergetic system of successive rotational functions that exhibits self-organizing behaviours.

A fold addition adds a rotation mechanism, interrupting the relaxed folded state. A new function is defined that incorporates geometric information with regards to the points added by the fold line. Surface subdivision constitutes the corresponding output. A fold angle system is a dynamic system of sequential rotations, related to a specific fold angle.

Aggregate rotations generate assemblies' formal output both in flat and folded state. Material parameters integrated geometrically, add information to the rotational function.

A 'fold layer' strategy regulates the sequence of folds applied to the component. Folding progression characterizes component's transformation from a flat to a folded state. It constitutes of two hierarchy levels. The first one corresponds to the successive application of folds till the radial symmetry displayed in the flat

pattern is exhausted and respond as fold sequence. The second one refers to layers of folds build upon fold sequences.

Fold interaction assess differentiated symmetry patterns across the folded surface (Figure 3).

A sequential fold aggregation characterizes the final folded configuration. Assembly layer refers to a fold addition process; so as to facilitate edge connections between components while assembling.

Any interference at flat state is reflected to the folded one and vice versa. The aim of the assembly process is to identify up to what extend repetition, is identified at a folded state. Therefore, rotation and reflection hierarchies constitute the operation toolset to generate assemblies in both states.

Assembly connections refer to component possible connections. Assembly process necessitates additional folds to prevent paper from bending.

A notation strategy is used following the sequence of operations applied. Differentiation manifests itself, on account of rotation centres; a multiplicative construct that recognizes the assembly logic. A threefold assembly represents a rotation centre. Assemblies' generation establishes hierarchies within rotation centres.

4. Assembly Strategies.

Two assembly strategies direct component proliferation within system's growth process. The first one, A_1 , successively manifests itself into a three dimensional object. The second one, A_2 manifests itself towards a surface element.

Assembly A_1 exhausts its potential connections after being executed a finite number of times; by creating a loop within the global assembly system. A hierarchical arrangement demonstrates the geometric proliferation environment according to which the assemblies are self-generated under symmetry transformations (rotation – reflection). Each assembly within its hierarchy displays a geometric uniqueness.

Although the design process terminates to a surface element, the system provides variations of potential outputs. The notion of component is expanded, opening the possibility of building up a larger system. Material aspects are incorporated into assembly logics.

The component needs to be redefined to reduce and maintain the complexity of the surface element. This is achieved by any successive sub-assembly system provided that displays similar rotational symmetry to the initial component. The process is repeated iteratively in a fractal-like manner till certain constraints are met. The algorithm will eventually terminate reaching an end – state, provided by boundaries established through material and manufacturing constraints. (Figure 4).

4.1. Rotations centers and Irregularities.

Rotation centres provide the focal areas to follow the traces of the geometric progression while the assemblies' growth process. Rotation centres' hierarchies provided by the sequence of rotations applied, assign local, regional and global topographies across the formal output; which constitutes a surface element. Geometry hierarchies correspond to differentiation hierarchies induced from material constraints. Differentiation is introduced from local scale by interrupting the mathematically defined folded symmetry of the component. (Figure 5).

4.2. Symmetry and Structural Behaviour.

The symmetries of a structure often reveal secrets about how an object behaves.

Analysis is conducted by imposing acceleration loads under standard earth gravity to the component and specified assemblies. The selected material for analysis is structural steel.

A recurrent analysis commences upon component's structural behaviour. It also attempts to identify relations between deformation gradients and symmetrical features. Interdependencies between fold hierarchies and parametric analogies between material thicknesses and orientated structural performance under rotations are detected. A diagram indicates interrelations among differentiated structural behaviours at a local and regional scale.

The structure's deflection recognizes repetitive deformation patterns. Fold addition is a method to reduce deformation provided that it is coherent to the structure's symmetry.

Symmetry preserving phenomena are detected between local and global topographies. (Figure 6).

Deformation patterns display radial symmetry. A regional arrangement displays differentiated symmetrical deformation patterns. Scaling up, radial symmetry is shifted into reflection symmetry where deformation patterns are symmetrical along one axis. Rotation centres display the minimum deformation results. They function as structural symmetry regulators in a larger scale. Fold addition is a method for reducing deformation. The analysis indicates that when a fold is added the deformation is reduced by half. Deformation patterns display radial symmetry for all components regardless of fold hierarchies.

4.3. A Process Driven Diagram.

This research proposes a methodology for variable patterns and processes at a flat and a folded state, that synthesize architectures of multiplicity.

Multiplicities, in the course of the research manifest themselves as interrelated functions of form, structure and material behaviour; constrained by manufacturing and assembly logics.

Variations are the output of recurrent geometric processes. Material constraints direct the number of iterations and therefore, population's output.

Assembly organizational principles incite architectural variations, additionally.

The first assembly strategy results in populations of three dimensional artefacts. It exhibits periodic behaviour on the course of the process recurring simultaneously with open – component redefinition. It terminates when its edge connections are exhausted.

The second assembly strategy describes two dimensional populations and terminates when material properties do not allow for further geometric proliferation and necessitate either component redefinition or material substitution..

Criteria for addressing an application would include a context specific analysis conducted to an individual artefact. The contextual environment would dictate the formal output.

Further research would regard a parametric construct of all the aforementioned variables which integrates manufacturing constraints, assembly logics, material characteristics and scalability into a digital model and captures system's self-organizational properties to generate a repetition pattern. (Figure 7).

5. Epilogue.

The research paper demonstrates variable folded assemblies emerging from geometric variations under radial symmetry by addressing formal and material multiplicities.

It attempts to question the inherent nature of an s art·e·craft, following the theoretical framework and the tools and techniques available provided by nature's process paradigm. Emphasis is placed on the primary objectives and the processes that define its substance.

The effort of the synthetic process is transferred from the formal properties to determining essential criteria and establishing the interdependencies and hierarchies between them. The question raised regards the essential nature of the art·e·craft, questioning its boundaries regardless its surrounding context and getting feedback from the process that generates itself.

What is an art·e·craft ?, a process paradigm, a methodological toolset, diagramming techniques, formal variable outputs or the argument itself ?

Providing that even the most abstract formulation of thought has a material dimension.

FOUND OBJECTS AND AWARENESS IN INTERIOR SPACES

Mergül SARAF

Department of Interior Architecture, Faculty of Fine Arts, Okan University, İstanbul, Turkey

mergulsaraf@gmail.com, mergul.saraf@okan.edu.tr

Abstract

Creating a new function for an existing building directs the designer to accept some pre-made elements or arrange these elements. This arrangement, which is a radical and arguable spatial discipline, interprets rules, sometimes obeys or else disobeys them. Found object can be an example to this type of attitude. Marcel Duchamp, who created original art objects by using ready-mades like a urinal or a shelf with full bottles, is the first person who came up with this idea. A found object can add an identity to the space, create an atmosphere, correlate with the past and create a dynamic association between today and the past. In this study, the notion of the found object and sensibility in interior spaces is examined along with the relation between these concepts through several examples. The character of interior space, relationship between interior space and user, connection between interior design and art is mentioned as well.

Keywords: Found Object, Ready-made, Awareness, Responsive Interior, Autonomous Interior

1. Introduction

It is expected that a design should have been original, innovative and aesthetic, which comes up as a result of design action that is a challenging process. The aim of the designer is being unusual, functional, aesthetic, economic and permanent when creates a new space. According to this understanding, many design methods came up, for example conceptual design, sustainable design, etc. Working with found object came forward with this idea. Designer would prefer to use the history of building, structure of building, the relation between the building and local people, the building itself or an object which is completely foreign to space. At this point the designer is related with some notion and sense of art (anlamadım). Found objects are related with readymade objects which is also a sense of art, but has different features. These different features are important factors which lead designer to create original and aesthetic spaces. The notion of found object is related with Surrealism and readymade object is related with Dadaism, however both of them are basically related with Avangardism.

2. Found Object and Ready-made

The avant-garde artists take the painting out of the canvas and open their doors to all kinds of material, thus prepared the ground to bring out new possibilities in art. The tendency of putting the industrial (fabrication) products in the center of artistic creation was a common creation strategy during the Postmodern art movements. Using ready-made objects in art, was one of the basic attitude of avangardist artistic movement, mainly in Dadaism which occurred in Switzerland in 1916, Surrealism (1924 – Manifeste du Surrealisme) and Pop Art (in 1950's in USA and UK). Many other avangardist movements as Performences, Arte Povera, Conceptual Art, Fluxus, Happenings and Process Art were impressed by the movement of using ready-made in art [1].

Dadaism is a sense of art which is against the art movement of the period, based values of society and destruction of World War I. Dadaists were expressed that they refused the tradition and teased and humiliated a corrupt society. However, by art works which came up with ready-made materials, they enriched the art and had been a pioneer in many subsequent art movement [2]. The movement of using ready-mades, is a sense of art which came out with Dadaism, was a pioneer movement and had a contrary nature on the period which it came out. Marcel Duchamp, who put forward the idea of ready-mades, is one of the most important agents of the Dada movement. Duchamp turned various objects into art objects which have no values in daily life. "Bicycle Wheel (1913)", "Bottle Dryer (1914)", "Fountain (1917)" and "L.H.O.O.Q (1919)" are the most important ready-mades of Marcel Duchamp's.

"The 1936 Surrealist Exhibition of Objects brought together a bewildering range of items including natural objects, interpreted natural objects, incorporated natural objects, found objects, perturbed objects, readymade objects, American objects, Oceanic objects, mathematical objects, and Surrealist objects. Only the readymade and the found object still retain any currency. Marcel Duchamp's readymade and Andre Breton's found object have such different legacies that they now arguably constitute a categorical distinction. This was not so clear in the mid-1930s when Breton could define ready-mades as "manufactured objects raised to the dignity of works of art through the choice of the artist." [3]" Another definition for ready-made is stated in Andre Breton and Paul Eluard's Dictionnaire Abrégé du Surréalisme in 1938 published under the name of Marcel Duchamp ("MD" to be precise): "an ordinary object elevated to the dignity of a work of art by the mere choice of an artist" [4].

Breton described the found object (trouvaille or objet trouvé) as a solution found not by logical means, and one that differs completely from what is anticipated. The object found as if by chance is situated at the point of connection between external nature, perception, and the unconscious, and thus has a peculiar, elusive relation to vision. The found object is encountered and the effect is traumatic. The contrast between the Duchampian rendezvous and the Bretonian encounter should now be clear. While the readymade is essentially indifferent, multiple, and mass-produced, the found object is essentially singular or irreplaceable, and both lost and found [5]. Ready-mades are ordinary, non-featured mass products. On the other hand found objects have features like "beauty" and "unicum." When a ready-made is isolated from its nature, it gets a new identity and also a ready-made has no aesthetic feature. With these features ready-made is a different notion from found object which is a notion of Surrealism.

Fig. 1,2,3: Bicycle Wheel (1913) (on the left) [6], Bottle Dryer (1914) (in the middle) [7], Fountain (1917) (on the right) [8] by Marcel Duchamp. Undoubtedly, Fountain is the most provocative and famous ready-made of Marcel Duchamp. Fountain is the sculpture which belongs to a plumbing firm and signed by Duchamp with the name of R.Mutt. He joined to the first *Salon des Indépendants* exhibition in New York in 1917. Duchamp was one of the juryman of the exhibition [9].

3. Awareness In Interior Spaces

The training and education of an interior designer is based around the understanding and usage of the restrictions and possibilities of working with an existing building. This situation requires the designer to have a kind of awareness. In other words that is an acceptance of what is already on-site and willingness to emphasize those found qualities. An existing building offers many clues about the way in which it can be adapted. These clues include several restrictions, possibilities and qualities. The designer can prefer to accept the restrictions and use these possibilities or put forward these qualities to show awareness. The designer can use the history of the existing building or prefer to emphasize the specific qualities of that space. This may be as simple as to accept the space's structure using significant structural elements as doors, Windows, atriums or even maybe as complicated as to reveal the surfaces which correlate with the history of the existing building. Creating a new function for an existing building directs the designer to accept some pre-made elements or make some arrangements on these elements. These arrangements, which are radical and arguable spatial disciplines, interprets rules, sometimes obeys or else disobeys them.

When awareness in interior spaces and working with found objects get together, two new notions come up; "*Responsive Interiors*" and "*Autonomous Interiors*". The structural elements of an existing building can be a kind of a guide for the designer during the remodelling of an existing building. The structure of an existing building can constitute an inspiration point for the new design concept. The position of structural elements as windows may offer many clues such as how to get daylight into the space. The designer can use the history of the building or the cultural relation between the building and the local people. Briefly, the designer prefers to use the restrictions and possibilities of an existing building in responsive interiors. In autonomous interiors, the designer creates the new interior design concept without a relation with the character and the structure of the existing building. The new interior places inserted into the existing building but the effects of the existing building is limited on the new interior. However, the new interior has a significant and characteristic identity. Briefly the designer prefers to deny to use the features and the structure of the existing building.

Fig. 4,5: The Loftcube by Wegner Aisslinger [10]. Loftcube is an autonomous space that can positioned on the roof of an existing building or in a forest or even in an existing building. Loftcube is an autonomous space on urban scale.

Fig. 6,7: Vakko Wedding Nişantaşı/Istanbul/Turkey (2006, on left) [11] and Vakko Wedding Suadiye/Istanbul/Turkey (2011, on right) [12] by Seyhan Özdemir and Sefer Çağlar / AUTOBAN. Store design is another typical sample for autonomous spaces. Designer creates a brand image, based on this existing elements which can have ability to use in different spaces. Store spaces are generally temporary and are designed to live until they are out of fashion.

Fig. 8,9: Sakıp Sabancı Mardin City Museum, Mardin/Turkey [13]. This museum is a sample for responsive interiors. In the beginning this building was used as the Cavalry Barracks, then as the Tax Office Building, was restored by the Sabancı Foundation and refunctioned as a city museum and an art gallery. The narrow and long structure of the building is arranged as exhibition halls based on this structure. The main principle of the design is to create an exhibition hall that can perceive the spatial integrity which is covered with a cross vault. The existing alcoves are used as exhibition units.

Fig. 10,11: Istanbul Archeological Museum, Istanbul/Turkey [14]. This is also a sample for responsive interiors. This structure could have been a contemporary art museum as Reina Sofia Museum in Madrid, instead it is arranged as an archeological museum. The historical artifacts that inside in the museum and the structure of the building emphasize the value and historical backgrounds of each other. They also correlate with the past.

4. Usage of Found Objects in Interior Spaces

Adaptation or remodelling is a process of completely altering a building, on which the most obvious change is usually the original use or function. In this process, new spaces are designed in an existing building, new circulation areas are created and new arrangements are made on relation between spaces. This process is also named as “adaptive reuse” or “refunctioning”. The designer must have the ability to make decisions about which parts of an existing building will be protected or which parts will be removed, how to address the meaning and the value of the existing built fabric, during the process of a remodelling or an adaptation. The designer who behaves consciously, must understand and read the cultural value of an existing building and the relation between the building and the local people. Because an existing building is an important element which correlates with the past. As an architect and an academic, Jorge Silvetti explains this in his essay titled *“Interactive Realms”*: *“At the risk of sounding too partisan and biased, I would say that even in historic times documents were not always available, and buildings (monuments, vernacular constructions and public works) are themselves important texts, often providing the first and most lasting impression of a culture.”* [15].

There are different features of each architectural building and interior space. The designer can encounter with many different features of an existing building which can be reused during a remodelling or an adaptation. Using these different features can enable the designer to create unique architectural buildings and interior spaces. An unusual and extraordinary object or surface can reuse which find during a remodelling or an adaptation in its natural space, can reuse. This technique, which is using this kind of special elements that belong to the space, is called as *“working with found objects”*. An object or a surface can be found object basically. Working with found objects in space can be done basically in two ways. Found object or surface, in its natural space can be incorporated into that space. Found object, which exhibits or evokes the history of that space, can add value and character to that space, can correlate with past or with the new function of that space or can create a different atmosphere or mood in that space. On the other hand a found object or surface, completely foreign to the space, can be incorporated into that space. This found object can belong to a different age or culture; although it can have a character diametrically opposed to the new function of space. This found object which is completely foreign to space, can create an impressive expression, can emphasize the function of the space or can enable the people in that space to get into different moods.

Fig. 12,13: An interior space from the Reichstag, Berlin /Germany [16, 17]. The Reichstag Building, constructed in 1884-1894 by the Architect Paul Wallott and renovated by Norman Foster in 1994-1999. The Soviet soldiers left graffiti on the interior walls of the Reichstag during the World War II. Most of the statements expressed the relief of surviving the war, and a desire to return home. In addition to the writings, bullet holes can also be seen along walls. It was decided to leave the graffiti and bullet holes on view, as a sign of transparency and a chilling reminder of the history of Reichstag during the renovation in the 1994-1999. This is a sample for using a detail or a surface as a found object.

Fig. 14: The Reina Sofia Museum, Madrid/Spain [18]. While the Museo Nacional Centro de Arte Reina Sofia officially opened its doors in 1990, the building has been remodelled by so many architects over the years. Originally founded as a hospital by King Carlos III in the 16th century, the structure was redesigned by Architect Fernando Sabatini in the 18th century. The southwest side of the Sabatini building is the side which

the Reina Sofia reveals its uniquely modern identity, thanks to the French architect Jean Nouvel. In 1999, Nouvel designed an addition in an attempt to open more space for the museum's permanent collection, that is housing the museum's library, restaurant, and bookshop. The blazing red lacquered triangle canopy is a found object which completely foreign to Sabatini's Building. On the other hand this modern found object connects the Sabatini's Building – the old one – and Nouvel's additions – the new one. In other words we can say that the canopy – the modern found object – correlate with the past and the present.

Fig. 15,16: The Esma Sultan Waterside Residence, Ortaköy/Istanbul/Turkey [19, 20]. On the left an interior view and on the right an exterior view of the residence can be seen. The residence was constructed by Architect Sarkis Balyan, who was one of the most important architects of the period of Ottoman Empire, by the desire of Sultan Abdülaziz for his daughter Esmâ. The structure has been burnt by a fire that broke out in 1975. The front side is remaining today, after the fire, and it has been renovated in 1990. In addition, a steel and a glass construction have been created into the original external brick walls. The structure has been providing service since 2001 in welcoming (invitation and organization) sector. In addition it also hosts the International Istanbul Jazz and International Istanbul Music Festivals. This is a sample for using a historical existing building's itself as a found object. This usage is also gets in touch with the notion of sustainability.

5. Conclusion

Reuses of found objects show a kind of awareness that related with space. Found objects are an expression of respect to the space that correlate with the history of space. This situation can direct the designer to make a claim the history of space. Also the users of space can correlate with the space and its history through found objects. These personal relations can provide us to be aware of the world and interior spaces which we live in.

Found object is basically a notion of art which can incorporate sensibility of art to the space. We can feel, see and make sense of spaces in which we live and also we can correlate with the space and our own personal history through this awareness. So, people can notice that not only the users of the space are living, but also the space is a living organism.

A found object located in its natural space, gets in touch with the notion of sustainability and thus creates another expression of that respect. Reuse of an existing building is a basic act of sustainability. The existing building is already located on urban scale and waiting to be reused, just as there is a found object located on space. Reuse of existing things, revaluing and rehabilitating can be a summary of this expression which is related to showing respect.

A found object which has a historical value, refers to the history of the space, while reminding the notion of time, past and cultural value to the people who use that space. This reminding can direct us to take a lesson from the past events, also remind us the people who lost their lives in an event like a war which had happened.

A CREATIVE LAB OF DESIGN FOR OUTSIDERS

Marco BORRELLI,¹

Facoltà di Architettura, Seconda Università di Napoli, Italia
E-mail: marco.borrelli@unina2.it,

Abstract

The scientific contribution of the interior design and technological research is inspired by the social value expressed in the project "**Feli-city**", whose main object is the creation of temporary spaces or "**creative laboratory**" focused on the rehabilitation of people who are socially and psychologically marginalized such as "**hope-less**". The outsiders are generated by the advanced society giving privileges to "exclusive profit" logics rather than civil and ethical values. Hopeless is a subject with psychological hardship produced by the flexible capitalism in its recession, where the "**less**" of the project "**Feli-city**" represents "less waste of human creative asset, evaluation of unexpressed potentials as a consequence of the experiences gained". The main content of the creative lab is represented by the right dimension of an institutional contest able to interact with current psychological disease through design training.

More subsumes the less as dedicated personal services, and better prospects of listening, it means to project in the current scenario of the knowledge factory, new forms of integration through a shared system of spontaneous human relationships in places appropriately tailored to promote a "**personal outing**" in close collaboration with young designers able to manage the creative process, useful and necessary for **social rehabilitation**.

Key-words: Social Rehabilitation, Creative Laboratory, Hope-Less, More-Service, Feli-City

"One has to allow the possibility that there cannot be a complete destruction of a human individual's capacity for creative living and that, even in the most extreme case of compliance and the establishment of a false personality, hidden away somewhere there exists a secret life that is satisfactory because of its being creative and original to that human being." (D.W. Winnicott, 1896-1971)

1. Assunti, obiettivi e scenario di riferimento

The occasion of the project: The scientific contribution is inspired by the social value expressed in the project "**Feli-city**", presented in collaboration with the Designer Edgar Uggiano and with the Association for Social Promotion "Pietre Vive alla salute" for the contest organized by the Community of the Old Town Centre of Naples and "Il Mattino".

The interdisciplinare character of the actors: Such planning experimentation developed in the range of research on design and interior architecture in college of architecture's laurea degree course of industrial design of the Second University of Naples is based on new considerations and methodologies which promote innovation according to the model of the sociological-economical development gathered by the

metaphor of the *Triple Helix*¹ in which the base of success is given by the convergence of three fields actually considered distant and untied:

a) University b) Enterprise c) Politics institution.

The creation of the social value originates from action and correct synergic organization of the three factors of which we highlight the specific features:

a) University through the open source is set up in a new model of *Hybrid University*² for its main role of research and development linked with the actions of social policy, **b) the Economic System of Social Enterprise** expressed by the third sector aimed at the social progress through ecological innovation and by the Community of the Old Town Centre of Naples which finds social innovation and development of new ethic values able to promote personal and social growth of local community, and the role of the **c) Politics** expressed by the municipal corporation which represents the governance and the referential system aimed to guarantee the right balance of relationship between local entrepreneurship and research.

The mission: The construction and emplacement, where necessary, of new structures in the service of the citizen, able to intercept the social and psychic discomfort of a new category of outsiders, the "hopeless", to guarantee an earlier form of psychological outing aimed at the constitution of new **Workshops or Creative Labs**. The instrument of innovation is assigned at the definition and construction of a creative unit where two moments of doing together are activated: the bank of time and the bank of ideas owned by the creative community. The instrument of originality is assigned at the figure of design for health in social range which re-sets up consolidating the already well known declinations of user-centred design, co-design, design for all, design for interaction to offer itself as a first level structure for psychological support aimed at the redemption and recovering of discomfort and environmental context of reference.

1.1 The analytical-descriptive phase of less' dimension

The modern industrialized and globalized society engenders different forms of exclusion, discomfort and outcasting since it doesn't give the right support to all the persons, often labeled as different, who can't integrate themselves completely in the social context in which they live. Therefore these new figures need an early form of redemption through a psychological and creative outing to express their personal experiences by a system of intersubjective relations and recreational activities. Such condition of the individual results nowadays the fruit of a discomfort ripen and imposed by an economic system which advantages profit logics rather than civil ethical values and sustainability to such a point to originate, in the scientific research of interior design field too, analytical reflections on the *Third Sector*³. Toward the state the third millennium's society has noticed a detachment of the old models of welfare state since the factors dependent on labour market's crisis, weakening of the familiar fabric and loss of references into civil society have enlarged the gap between the traditional catalogue of safeguarded risks and the new set of necessities and social questions, producing a new "*Risk Society*⁴". The psychic and social discomfort condition, associated mainly with the condition of poverty has taken several connotation becoming part of a bigger phenomenon which aggregates different forms and typologies of marginalization such as social exclusion, vulnerability and lack of self confidence. Such new figures of outsiders, defined in our article as hopeless, represent new forms of psychic discomfort and isolation, fruits of "*Flexible Capitalism*⁵" in its recessive phase, where the "less" of hopeless can represent generically scarcity and instability, but also lack of references and loneliness of the isolated individual; therefore, the term "less" must be read as a quality as expression, from the individual, of internal pain and deep sensitivity as well as experiences, knowledge and trans-territorial visions. Nowadays, as the hopeless, also the jobless and the youthless are individuals who in their field meet difficulties of various nature, and so the society must trigger protective actions and safeguard about the condition of their minimum requirements of psychophysical health aimed at the social recovery and working reintegration in their autonomous creative and productive dimensions. The research is inclined to offer metaplanning inspiration's occasion on interior design and design of services' field aimed at the developing of transitory spaces or labs "of doing", simply defined "creative labs" spontaneously builded and dedicated at the social and psychological recovering of such outcasts. The **Creative Lab** represents the right dimension of a new institutional context with an outpatiently nature which acts on the current dimensions of the psychic discomfort of those who lose their job in advanced age too or for those who can't find it, and at the same time can't recuperate the right spirit of interior revenge meant as recovering of a spiritual dimension of active participation. The key character of such new experimentation starts from the assumption that nowadays exist different typologies of creative spaces or workshop labs aimed at the sharing of a "common feeling" related with the diffusion of social values such as creative handicraft, reutilization and recycle, civil and social rights of the individual, creative enterprise through small incubators of social enterprise and even the makers or "garage inventors" who are revolutioning the industry by using the internet and the open source.

Fig. 1: Outsiders trying to meet in the modern dispersive city

Here are some of the examples to be considered as “emblematics” since they represent the basics in the research of some study cases (case history) taken as sample to set up the proposed model of **Creative Lab** of the project “*Feli-city*” as pilot project:

- 1) Promotion of handicraft lab that draws on do-it-yourself’s culture (creative handicraft lab cfr. www.lamentecomune.it)
- 2) Promotion lab for reutilization and recycle as environmental sustainability with pedagogical aims (creative recycle for children lab cfr. “Le mani creano... Piccoli oggetti d’arte” www.riciclareconarte.it)
- 3) Promotion lab for social and civil rights of people wardship and their generation (cfr. Social Design Agency Lab www.thinkpublic.com)
- 4) Promotion lab for individual growth and development for assertion and promotion of interpersonal relations (cfr. www.relazioniin armonia.it)
- 5) Enterprise incubators promotion labs (cfr. www.officineformative.it)
- 6) FabLab promotion labs “Social workshop for digital manufacturing and hand-crafted prototyping” (cfr. Enterprise incubator www.fablabitalia.it and/or www.fablabtorino.org/)

The limit of such cooperative experiences starts from the presupposition that the participate contribution in which sociologists, psychologists and welfare workers, collaborates, with their institutional qualifications of subjects aimed at the formation and evaluation of discomfort, lacks the comprehension of the aesthetic-creative dimension latent in the hopeless and that cannot emerge but by the intersubjective contribution and the presence of the **designer**. The competences specifically bonded to the designers’creative actions would help in the medical history phase and in the assistance for all the actor subjects (outsiders) that after the outing must restart their own projectual dimension through the rediscovery of the “insight” (creative intuition).

1.2 The operative phase of the exercise through the "more"

The location for the set up of the creative lab’s concept would be detected in some small spaces in the hands of the current local structures(for example the municipal corporation’s headquarter or the local sanitary companies)to guarantee experimentations in favour of social assistance and rehabilitative cure addressed to such figures to favor psycho-social integration.The **innovative character** of shared participation between protagonist **actors** of the counseling intervention among which leads the designers,the psychologists and the sociologists deputied at the reception phase and at the structuring of the path into the creative work too,consists of time (bank of time) and ideas management(creative community) aimed at the recovering of a

productive and recreative cooperating dimension in terms of environmental sustainability too. Then the designer in the following phase after the medical history, by the recovering of more operativity, builds the right environmental and communicative conditions to start a process of **Creative Rehab** of the capacities and of the emotional and cognitive resources of the individual, producing immediately a sensation of independence, autonomy, serenity and self-esteem. The building of homely, stimulating and original shaped and coloured spaces and contexts, originated from shared process of auto-reproduction typical of do-it-yourself way, through the guide and control of the designer guarantees a general improvement of the perceptive condition of the individual toward the space as well as the relationship of independence between man and environment. The creative lab represents **more services to the people** prefiguring the reception space as field for planning understood as a "school" of politeness, humanity and for talents' personalization since it allows the outsiders to perceive themselves as active subjects, in reference with tools and with the utilization interactive's and attitudinal link's methodologies to build an integration. **More interactive areas** where the immaterial represents the new frontier of **creator's** dimension, more **edutainment** (education and entertainment) through events and analysis of the relationship between cause-and-effect of the outsiders operating concretely emulating models and evaluating the result.

Here are some examples of **interaction between subjects, areas and objects**:

- 1) Real and/or virtual noticeboard (database and bank of time) where the registration of the capacity and availability of the actors and creators with the counselor designer is possible in chronological order through a relationship of empathy in which emotional interrelation exchange is fundamental – **interaction between subjects,**
- 2) Utilization of tablets (materials workbenches on stalls or immaterial ⁶) useful for the sharing of a planning concept to bring in phase of progress of defined project and performable in a prototype form too (3D printers or rapid prototyping machines) through this relationship the designer is able to build new sceneries – **interaction between subjects and areas,**
- 3) Definition and realization of particular work-areas manual and technological-experimental able to explore the properties and the potential of **natural materials** for example recovery of ground scruff of mussels' and nuts' shells in order to melt it with natural glue such as resins, rabbit glue, various clay in order to obtain new self-carrying conglomerates, or and **artificial materials** of disused artefacts obtained by a first phase of comparative selection such as plastic recover which represents the artificial basic material with the worst environmental impact for its disposal (PE-polyethylene, PP-polypropylene, PS-polystyrene, PVC-polyvinylchloride, PET-polyethylene terephthalate) – **interaction between subjects and objects.**

2. Interdisciplinary work mediated by the action of the designer for health

The **originality character** of such Creative Labs consists in the identification of a new actor figure of the productive and creative management process as the **designer** who, contextually with the operation of hopeless' psychic rehab explain the topic of the **more** expressing himself as a mediator of holistic knowledge of the system produced addressing the creation's target of quality through management capacity of different experts. Such universe of objects thought and produced in a team under the control of the health's designer are thought and realized for the user considered no longer as a diseased but as a subject with specific necessities addressed at the reappropriation of its collocation.

A **supply chain of knowledge** ⁷ governed by the designer able to mediate the connection between designer counselor and actors-creators as well as processes and materials in the third sector in which the presence of the state is still late in putting in effect of social governance politics.

Such new idea of design is far from the common definitions of "user-centred design", "co-design", "design for all", "design for interaction" which considered the product-design as a tool aimed at users who started from standard situations to define objects and products of extended use, to arrive to a most inclusive form to realize a dimension of **Design for health** ⁸ mainly focused on behavioural diseases of the individual in a psychological and social context. In detail appeals on actions of control and management of designer's activities to generate a process of improvement achievable through emotional and artistic-creative solicitations, to build a form of rehab and reintegration of the individual with his provenance context. The designer as **Personal Creativity Trainer** ⁹ busy in the improvement of the active role's value of each subject creating the conditions for the change inside and outside of himself through technical and methodological processes developed as integration of psychotherapeutic protocols aimed at the improvement of self-esteem and creative talent.

The expressed value through the reappropriation of denied rights (the job) constitutes a valid mission of innovation expressed as references with triple helix development model in so far as the convergence of the three institutions offers a big projectual input of civilization aimed at the comprehension of the emerging categories until now suffused by the economic system of negative growth.

Paraphrasing **Serge Latouche's** ¹⁰ treatise on the dicotomy between **serene decrease** inasmuch as advantageous tendence to things'natural dimension, against **negative growth** as source of unequal and not in agree with the available natural resources' consumption, means in the scientific contribution of the project Feli-city to introduce a new form of related dualism **less /more**, which transposed in social context means to appreciate in the **less** creative and aesthetic dimension of the inadequacy sense generated by the consumerist society, expecially in those who lose their job against the **more** unscrupulous use of technologies in which the designer only represents the saving answer to the belonging relationships'control system to the present scenario of human existence.

Less subsumes the More as more dedicated personal services, and better prospects of listening, it means to project in the current scenario of the knowledge factory, new forms of integration through a shared system of spontaneous human relationships in places appropriately tailored to promote a "personal outing" in close collaboration with young designers able to manage the creative process, useful and necessary for social rehabilitation.

Abstract

The on-going political and economic crisis has been affecting the integrity of many countries, in a way that their expression related to design and art reflects a strong will to pursue the preservation of their identity. The academic debates indicate now solutions for how to overcome this problem in the fashion industry, leveling the interests of countries and corporations.

We analyze what Portugal, after the international financial rescue of April 2011, and Egypt, in the current period of the post-revolution of January 25th 2011, share now. While analyzing the impact of the national cultural patrimony references in the preservation of countries' integrities, we evaluate to what extent its input can develop fashion industry. When cultural richness and historical identity are connected to fashion design and textile research and development, conditions are found, especially before both traditional and technical textiles.

Sustainability of processes becomes an essential mill of the management of political and trade union strategies. Creative strategy of fashion designers is vital in the collaboration between institutions and universities, so needed for an effective solution implementation.

Keywords: Fashion Designers; Contemporary Crisis; Know-How; Culture; Economy.

1. Questions of investigation, objectives and methodology

_ How can research and development strategies, carried out by universities, companies and designers, boost the creative economy?

_ How does the contribution of the patrimony legacy in iconic textiles and cultural material and immaterial references influence design practices and textile research today?

_ Have the fashion designers been showing recently a concern in preserving their countries' cultural integrity through their designs?

_ How can the fashion designers' insight contribute to the new management strategies?

Objectives:

The research aims to highlight the importance of reviving the creative economy, by activating the role of fashion designers in the contemporary Portuguese and Egyptian fashion industry – especially after the financial rescue of April 2011 and the revolution of January 25th 2011, respectively.

Methodology:

The research follows an analytical descriptive method concerning the economic situation of the countries under study and also of the condition of their textile and clothing industry.

1.1 Socio-economic framework

Within the first weeks of 2011, the Egyptian people achieved a fundamental change in the government and leadership in its own country. This historical event, which any political analyst could foresee, has not come to an end yet [2]. Since the revolution in January 2011, Egypt economic performance has weakened, having the Growth National Product (GNP) decreased in about 4% and the industrial sector income in 12%. The tourism revenue breakdown unsettled the balance of payments, which in turn influenced the decrease in the foreign reserves. This represented a fall of 9 billion dollars during the first half of 2011, and of 11 billion, between the second half of 2011 and the first half of 2012 [11]. Estimations indicate that this may lead to a gap in the outside funding, raising a number of questions about the role of the EU in the future of Egypt, and its abilities as one of the external actors, along with many Western and Arabic countries that promised to support Egypt overcome the negative economic effects as a consequence of the revolution. Nevertheless, this support hasn't been efficiently or strategically applied. The Egyptian government tried to keep the financial balance through external borrowing, which compromised the independence of the state and its identity, under the popular rejection to that kind of borrowing. The government was forced to turn to its own resources, especially the ones that were not used or seemed to be obsolete, so as to push forward the economic cycle.

The textile industry is one of the valuable resources, since it has always played a central role in the Egyptian economy. As being the second largest sector after the agrarian industrial sector, it meant 30% of the local employment rate in 2008. It produced 3% of the GNP, representing 27% of the industrial one. 14% of the non-oil exports in 2009 were due to the textile industry contribution. According to the statistics of Central Bank of Egypt, there are more than 6000 companies related to the sector, registered at the General Authority for Industrial Development, 75% of which are garment manufacturers. They produced more than 313 million pieces for international brands such as Marks & Spencer, GAP, Wal-Mart, Levi Strauss, Target, and Calvin Klein, in the year 2009. Even so, the decline affected this industry, forcing the government to change its policy. The measures consisted in implementing a creative economic strategy to develop design procedures for the achievement of a privileged position of Egypt in the industry market – decreasing the dependence on the design prepared by the importer [18].

Like in Egypt, the Portuguese industry has always been highly focused on the manufacturing of textile and fashion goods. In 1985, Portugal joined The European Economic Community and got cash flow from European programmes to develop the country and its industry, with the expectation of becoming competitive in the emerging world market. Nonetheless, a change of paradigm was necessary [7], so that a country based on non-design production could improve design skills in order to diminish its dependency on manufacturing for others. As design was not regarded as a priority, the investment was directed to the usual manufacturing market, and so it has been, although with exceptions, until now. With the globalization phenomena and the admission of China in the World Trade Organization in 2001, Portugal had to face worldwide competition for the first time in history, as far as the textile industry was concerned. Following China, also India, Brazil and Russia started to have the means to become competitive themselves [1]. When the international economic effects led by the American subprime crisis in 2008 were taken as ended, new difficulties came up. The recent European crisis based on the countries' loan bonds, in which Portugal is included, has forced the nation to ask for the International Monetary Fund intervention for financial rescue, in 2011, with a subsequent political and governmental change.

Portugal is facing its highest rate of unemployment, estimated by 14.8% in February 2012, affecting mostly young adults below 25 years old (35%), paradoxically the most qualified generation so far in the country. The data from 2011 revealed that 150.000 workers emigrated, and the majority of them with high education. When Portugal is one of the countries in the world with the greatest percentage of senior people and the lowest birth rate, we question its development in the near future. Nowadays, the country faces an economic recession, which can get to a negative growth of 5% in 2012, according to the Bank of Portugal. Regarding the textile and garment sector, there are thousands of factories which have been closing down due to their dependence on international brands [1]. Nonetheless, the Portuguese exportations still represent 6.5% of the GNP, according to data from December 2011 – and when design starts being included, we forecast a growth in this matter, as the shoe sector has showed us.

1.2 Creative economy and culture based innovation

Before such situations, designers see necessities merging with opportunities, as the needs for economic growth merge with the requirements for the evolution of this industry sector. Lately, the focus on the development of creative economy places design as the windmill of new strategies, as said before and as

Borja de Mozotta also shows by saying that *“design activity becomes an agent of change for prototyping the new socio-technical system (...), as well as for helping companies manage the transition between the old and the emerging socio-technical systems.”* [3]. Based on these matters, some guidelines can be traced for the textile and garment industry sector. We focus on the present context of vanguard, in which the fashion system accepts various kinds of design approaches, and in which the *“specificity of creative economy, with its own wide-ranging logic (...), forces a new development approach and experiments’ exchange amongst various sectors”* [5]. From those strictly connected to the fashion trends and market researches, to others linked to conceptual design and even art, all of them can accompany peoples’ needs and feed the economic system. We can also establish a linkage to the core of creative economy, with its creative industries acting in a crossroads platform for all of the arts, business, culture and technology - enhancing the flexibility and openness to the new, and the ability to adapt. They comprise the cycle of creation, production and distribution of goods and services that use intellectual capital as their primary input [14].

Fashion design as creative industry can be empowered by the linkage to other creative and cultural industries, as well as by e-commerce, so as to find appropriate ways of stating certain designs as being Portuguese or Egyptian. For example, the idea of a «Portugal» brand is being discussed since 2005, and now is regarded as an imperative will to create a national identity in fashion design [10]. Actually, in a country where the fashion and textile sectors have a strong economic influence, we reflect on the ability to sustain it as a whole, before various qualified professionals that are able to apply design management strategies – as the survival of companies is no longer possible in an individual working logic in this climate of economic crisis [16]. Hence, we can consider that if fashion design finds a fertile cross-contamination with many fields, either Portuguese or Egyptian fashion design need to be developed in an environment of cooperativeness, in order to become competitive in the global market: combining designers, entities, companies, museums and universities. Paiva notes that the universities need a *“routine of cross-connexion of actors with ideas, being aware that the dissemination of concepts is empowered by a network of collaborative labour, which strongly depends on the capacity of convergence and meeting of investigators”* [10].

There is no doubt that a culture based innovation, founded on the existence of a motive is essential for making design competitive. The international conferences demonstrate the necessity of merging design and culture for new approaches for companies, with a focus on identity; for example, in 2012, we have the “Identity, Culture & Communication” international conference at the Saint Louis University (Madrid, Spain), the “Identity” international symposium at the Dar Al-Hekma College (Jeddah, Saudi Arabia) or the 1st International Congress on Fashion and Design, CIMODE (Guimarães, Portugal), where the “fashion, identities and cultures” theme will be discussed. Plus, the creative industries today contain the interaction between heritage and technology, and Europe has a huge stock of culture and creativity, that could be considered. Nevertheless, we identify a considerable lack of education in creativity in our society, mainly in Portugal, that would be necessary to generate a political will to allow designers to have an active role in the development process. Despite this, even the Portuguese Government recognizes that the heritage of a country isn’t *“worn out in its own contemplation and fruition”* and that it can produce culture, generate employment and improve life quality [4]. What we see is that as long as an effective implementation of new designs based on heritage isn’t actually consummated, it will only be experimental and we wonder until when. Perhaps an insight into the profits of the creative services could speed up the change.

The creative services have had a fast rate of growth in exports, with an annual rate of 8.8% between 1996 and 2005. During the period between 2000 and 2005, the trade in creative goods and services increased at an annual average of an unprecedented 8.7%. The value of world exports of creative products in 2005 increased by 424.4 billion dollars compared to the 227.5 billion dollars in 1996, according to preliminary figures of UNCTAD. This positive trend has happened in most European countries, and it is expected to continue in this decade, assuming that the global demand for innovative goods and services continues to rise. Besides that, the European brands are amongst the best in technology, luxury goods, tourism, media publishing, television, music, computer animation, videogames, design and architecture. European creators and artists in architecture, design, fashion, cinema, music, and modern art have worldwide influence [9]. It is clear that developed countries still dominate the global market for creative products. Nonetheless, many products from developing countries are already benefiting from the creative industry boom, particularly in Asia. Unfortunately, the large majority of developing countries are not yet able to harness their creative capacities for development [12]. In Africa, for instance, despite the abundance of creative talents, the creative potential remains highly unused. The continent’s share in global trade of creative products remains marginal at less than 1% of world exports, despite sharp increases. As it is the case for other developing regions, this is a reflection of both domestic policy weaknesses and global systemic biases [8].

1.3 Egyptian and Portuguese legacy: influencing design approaches

We find that the previous Egyptian governments did not provide the creative climate, neither did they support the creative economy nor the creative people, despite the presence of human wealth (artists and designers), as happened in Portugal. We can see a vast stock of ideas that can contribute to the dramatic boom of the Egyptian and Portuguese economies. Let's focus on the Egyptian case, with its clothing and textile industry, one of the most significant creative industries in Egypt. Its competitive advantages, such as availability of raw materials and human resources, meet a long history and tradition that began in the time of the ancient Egyptians. In this context, we find important to mention the Cairo Fashion Week, one of the Egyptian creative industries that combines culture and economy in a media event (Fig.1), or even Amina K's contemporary designs with traditional influences (Fig.2). As throughout history, the textile industry is closely linked to other art forms; so the history of textiles parallels the history of artefacts, to demonstrate changing materials and techniques, patterns of agriculture and trade, and distinctive social structures, such as rituals, identity, and everyday life [17].

One of the most important historical textiles, which have been recognized in a large variety of ways till today, is the one of Coptic textiles. With appealing aesthetics, the woven images they exhibit serve as reminders of the ancient interest in textiles, by holding a cultural expression related to that artistic mode. Coptic textiles derived from the Arabic word "Qibt" for Egyptian, the name Copt referred to native Egyptians as opposed to Greek or Arab. Coptic textiles have survived in such quantity and good condition because they were found in dry desert tombs in Egypt. Commonly these textiles, usually made of wool and sometimes of linen, are remnants of clothing, with which the dead were buried, in the period after the practice of mummification had ceased. Coptic textiles frequently display Christian imagery, as the birds were representative of the Holy Ghost, Christ, and so forth (Fig.3). Other themes were related to late Antique motifs, images of fortune and renewal or figures from mythology such as Aphrodite and the Tritons. As an example, we have the Orbiculus of a Warrior on Horseback (Egypt, 7th century), a tapestry weave made of wool and linen. Round shaped and likely from a tunic, it represents a mounted rider with a dog at the horse's feet, over a red background framed with colored dots suggesting the natural ground (Fig.4). The theme of horsemen, frequently found in Coptic iconography, is inherited from hunting scenes (mosaics, sarcophagi, etc.) of the Roman period. Such animated depictions, frequently narratives, woven on red grounds date late in the Christian era, usually from the 7th century. The motifs can also be purely decorative, such as the vertical row of donkeys – perhaps from a child's tunic (Fig.5) –, or naturalistic (the image of the hare), maybe recalling the Egyptian hieroglyph meaning «to endure». Many of these same images occur on Antioch floor mosaics, in Alexandrian art, and in eastern Mediterranean manuscript illustration, such as canon tables. The designs were restricted to the ornamental areas of the clothing, which were often in wool, because wool held the dyes better than linen. Curiously, different colours were used for different meanings: woad and indigo for sadness, red for anger, purple for selfishness [6]. Regarding these textiles with historical and cultural significance, we can establish a bond between Arabic and Christian civilizations, by mentioning the project of the tapestry office in Mértola (Portugal), consisting of wool textiles with Arabic influences from the 8th to the 13th centuries' occupation (Fig.6).

What we see nowadays is that valuable heritage of this kind is possible to be re-designed, having in mind new technologies that either can improve the ancient or replace them in particular pertinent cases. For example, the Portuguese case shows that different aspects of patrimony can lead to cluster design conceptions, so as to increase the range of products and investments when an economic increase is needed. Consequently, this allows companies and investigation centres from different fields to follow certain directions in which they are specialized. That certainty became clear in the Designa Conference in 2011, organized by the University of Beira Interior (UBI), in which different lines of investigation were revealed, from hi-tech to eco-design and re-design. We shall mention two of them. Gianni Montagna, Helder Carvalho and Cristina Carvalho (University of Minho – UM – and the Technical University of Lisbon) showed their analysis result about the needs of the Portuguese market regarding technological and intelligent apparel, and found important clues for product development targeted to young university students, by questioning 600 of them. Marta Ferraz (UBI) presented her investigation on *Tailoring a Future in which Clothes grow from Bacteria*, showing environment friendly designs made from bacterial cellulose (attained from *Acetobacter Xylinum*), capable of being freely moulded as a paste, when placed on top of any shape. Likewise, at the Design Principles and Practices Conference 2012, held at the University of California, Isabel Cabral, PhD student of UM, presented *Thermochromic Filters Effect on Static Light*. She showed how temperature can change the molecular structure of the thermochromic dye in its optical properties, used alone or combined with ordinary dyes on different textile surfaces (Fig.7). She got not only fabrics that were colour changeable,

but also got relevant conclusions regarding their light filter performance, under or above their temperature variation level [15].

1.4 The preservation of the collective memory: an identity in design

The preservation of our collective memory is urgent in the context of globalization, but we see little investments being made regarding the safeguarding even of our existing material patrimony. The main square in Lisbon (Praça do Comércio), iconography of the Portuguese diaspora itself, has recently been deprived of its Portuguese Pavement. We understand the alleged economic and practical maintenance reasons, but that is not coherent with the prior investment being made in Portuguese Pavement for the World Expo in 1998. Portuguese designers try then to find solutions to preserve iconic legacy, having in mind that it can be the inspiration and foundation of a sustainable design methodology. For example, fashion designer Luís Buchinho has recently presented a collection inspired in the Portuguese Pavement at the Portugal Fashion event of March 2012 (Fig.8), and the fashion designer Alexandra Cabral has created a wearable sculpture with the same inspiration, for the I Triennial of Textile Art contest, promoted by Guimarães European Culture Capital 2012 (Fig.9). But we then question ourselves about the characterization criterion of valuable resources and methodologies of implementation in creative distinctive design, in the long run.

When we analyze independent Portuguese fashion designers and Portuguese fashion labels, we can also identify a rising trend to keep faithful to certain traditional technologies and materials, combining craftsmanship with contemporary designs. As examples, we can mention the designs of Sara Lamúrias (fig.10) for Burel (a brand that works with a traditional wool fabric with the same name, in collaboration with renowned young equipment and fashion designers), and White Tent's cutting edge design, by Pedro Noronha and Evgenia Tabakova, made of one of the most representative national materials: cork (Fig.11). Nevertheless, we can see that specific valuable materials and techniques can be reproduced by other countries, so how can we meet sustainable processes with sustainable design innovation, so as to keep our design identity untouchable and always recognizable?

We consider that the solution lies in combining traditional/hi-tech technologies either with the cultural immaterial legacy, or with conceptual approaches based on a collective imaginary related to the material legacy. The University of Beira Interior develops investigation in hi-tech fashion fabrics and bags in the same region as the Burel brand; so what is in store? The global market is crowded with «just fashion», but there is plenty of space for avant-garde fashion design, mainly when information spreads instantly around the world making a brand visible, and when a nation needs to take measures urgently. Experimenta Design, the international bi-annual Portuguese event dedicated to design is *“highly committed to the construction of [that] material and immaterial legacy”* and hopes *“that [it] can be an asset to individuals and institutions (...) for the contemporary transforming intervention and mediation.”* [5].

1.5 Results and recommendations: designers role in the textile and garment sector renewal

Both Portuguese and Egyptian designers should analyse the reasons for the success of their countries' particular cases with positive impact on exportation; see why their investment in the linkage to cultural legacy (material and immaterial) in design practices turned to be fruitful, and with which design methodologies that was obtained. Besides this, there are always processes and resources that can be shared among companies, such as external distribution networks or suppliers, which they could have into consideration. Thinking globally, designers from different fields could also join efforts to provide the development of wider ranges of products based on the same materials and techniques. When fashion finds linkages with different fields of contemporary art, why shouldn't it cross-contaminate equipment design too, as the Burel brand indicates? Why shouldn't fashion also meet art in technical textiles' research and development, for the countries' promotion?

Guta Moura Guedes, director of Experimenta Design says that *“designers work with culture and with local and global values (...) thinking in a global context (...) to produce something new. Designers are probably the best decoders to do that. Because they are (...) trained in all aspects.”* [13]. More, Borja de Mozotta stresses that *“designers' skills for our present world include risk taking, experimentation, teamwork ability, narrative building, holistic thinking, and open-mindedness to transcend the existing barriers of industrial «silos»”* [3]. Thus, it seems clear that solution implementations for the Egyptian and Portuguese case might involve huge efforts, but they are possible to be achieved having in mind the latent potential of the fashion industrial and creative sectors and their cultural richness.

Portugal once was the first country to start globalization through maritime exploration during the 15th and 16th centuries, building an empire that no longer exists, but that spread culture around the world. Lately it has

held events such as Lisbon European Culture Capital 1994, World Expo Lisbon 1998, Oporto European Culture Capital 2001, and finally Guimarães European Culture Capital 2012.

When we think of Egypt, we think of the golden period of the Egyptian empire, related to the Pharaohs and their great pyramids. Much of that material patrimony has been rediscovered by the British and German expeditions of the 19th century. The knowledge thus obtained from there made us value the Egyptian cultures, as we still do nowadays. The contemporary version of the Alexandria's Library (a reference library in the ancient world), built in 2002 and funded by UNESCO and the Egyptian government, shows a statement of Egypt as a cultural reference in the international scenario.

If Portuguese and Egyptian cultures are still alive and capable of generating economy in many other fields, now cultural richness must be targeted to design investment, in order to achieve sustainable progress, and most important, help them preserve their integrities as nations.

FACTORS OF INDUSTRIAL DESIGN THROUGH INNOVATION

Abstract

There is now a saturation of consumer products, for any type of product there is a vast number of different items made by an equally vast number of manufacturers; this fact is due to the maturity of markets and the globalization of supply. It has become far harder to come up with a unique selling point, perhaps most importantly, cost competitiveness is a lost cause in Europe; production costs are not competitive with emerging countries. However, there is a field where competitive differentiation can still be achieved that can lead to market success, and this field is innovation.

Innovation can be of different types. This paper will focus on innovation that stems from industrial design; in particular, 5 design factors will be analyzed: formal factors, functional factors, use factors, economic factors and factors associated with product value, in order to determine which of these factors are most vital and what action should be taken in respect of each in order to design an innovative product.

A framework is proposed which can be used to replicate analyses that can enable us to set up a system of continuous innovation, thereby making it possible to bring innovation to bear on the product rapidly in such a way that pirated copies cannot be made through reverse engineering.

Keywords: Innovation, Industrial design, Formal factors, Functional factors, Use factors, Product value

1. Introduction

In the current global economic context, the manufacture of consumer products is widespread in many countries; thanks to the new technologies of communications, sale transactions are virtually instantaneous from any location on the planet to the consumer's home. Means of transport are so efficient that, in a short time and at a reasonable cost, a consignment of products can be moved from any continent to any other. Methods of payment are fast and secure, guaranteeing practically all transactions between individuals and producers. This is globalization, which can in time undoubtedly lead to a level playing field of opportunities among citizens of different countries, but the risk that currently we face is the specialization of some countries in manufacturing, whose only contribution is cheap labor, in tandem with other countries that consume goods at low prices, thereby destroying their traditional industrial base and generating scant profits for the manufacturing countries.

This leads to the paradox that the products made in the manufacturing countries cannot be consumed in those countries and in the long term in the countries which do consume them, the level of consumption is unsustainable because their local industries cannot compete with the exporters and this causes unemployment and loss of purchasing power among the citizens of those countries that are regarded as 'consumers'. To prevent this self-destruction of the manufacturing base, the consuming countries must make a shift in their corporate strategy as far as consumer products are concerned, in order to preserve their productive capacity and social cohesion.

In order to preserve the industrial fabric engaged in the manufacture of consumer products, which in general are low-tech items employing techniques whose patents have expired or have been structurally assimilated, in sectors such as white goods, furniture, accessories, textiles, utensils, sports equipment etc., it is imperative to produce innovative products; the key is INNOVATION.

2. Innovation.

Everett M. Rogers defines innovation as: "An idea, practice, or object that is perceived as new by an individual or other unit of adoption." In contrast, Michael A. West defines it as: "the sequence of activities whereby a new element is introduced into a social unit, with the intention of benefiting the unit, a part thereof or society as a whole. The element need not be entirely new or unfamiliar to the members of the unit, but it must involve a noticeable change or challenge to the status quo." Regis Cabral says: "Innovation for a specific network is a new element introduced into the network which changes albeit only momentarily the cost of transactions between at least two actors, elements or nodes in the network." Frascati's manual (OCDE, 1992) indicates that: "innovation is the transformation of an idea into a saleable, new or improved product, or into an operative process, within industry and within commerce or into a new method of social service". The definition given by Morcillo is: "seeing everything that the world sees, Reading all that the world reads, hearing all that the world hears, to innovate is to make real what nobody has imagined, as yet. For B. Muñoz Seca and J. Riverola (1997): innovation is doing or making things, new or old, in new ways. For the Mondragón Cooperative Corporation, innovation is the successful exploitation of new ideas. Three aspects are considered to be fundamental:

- a) The term 'exploitation' implies the notion of an end-client for the innovation.
- b) 'Successful innovation' alludes to the outcome of the innovation.
- c) By linking the success achieved with the source, this definition incorporates the dimension of the process that is needed to convert good ideas into products aimed at clients.

From the ground we have covered so far it can be seen that the key factors that define innovation are:

- 1.- Introduction of the product, process or service to the market.
- 2.- The differentiating feature that these products have.
- 3.- That this factor leads to market success, because without it there can be no innovation.

To sum up, if we analyze these various axioms we can safely state that every innovation entails at least a modification in the current situation, the way things are done within a given organisation, a re-think that results in a reevaluation of products, processes or services.

So, the meaning of the word 'innovation' varies depending on the sphere in which it is used and the period of time in which it emerges. However, it can be deduced from all of these definitions that there is a series of qualities that are inherent in the term 'innovation', among which are: creativity, change, novelty and salability, to which we might add that innovation generates intellectual property.

2.1 Types of innovation

Innovation is a whole that affects the system of production, it is an attitude that is implemented in the firm in its know-how (savoir faire, management of intellectual property and how things get done), but to apply it to each of the productive stages, it is necessary to analyze how and on which parts of the system it must act, and to this end innovative action has been segmented with respect to each sphere, giving us the following types of innovation:

- Innovation in organizational systems.
- Innovation in the productive process.
- Innovation in technology.
- Innovation in the product.
 - Innovation in organizational systems.

In this case, the change occurs at the management and organizational level, below which the production and sales efforts are developed. This is a type of innovation which, among other things, makes possible greater access to knowledge and an enhanced use of material, human and financial resources.

- Innovation in the productive process.

The fundamental aim of the enterprise is to generate profits, this can be achieved by increasing sales, strengthening its presence in markets or developing new products; the company's aim of making or increasing profits can be pursued by focusing on two factors:

- Improving the staff's performance, thereby making production more competitive and increasing output.
- Reducing the manufacturing cost of the products.

Thus, what we are looking at is a system of cost reduction by means of innovation. Innovation of this kind consists in the introduction of new methods of production or the modification of existing methods through the

application of new technologies. Innovation here can also take as its starting point doing things in a different way, in terms of the company's processes. Redefining production processes can contribute to enhancing the added value of the end product, so the first step is to define the production processes that affect the product. This progressive redefinition of the manufacturing processes begins in the design phase, in which the materials and components must be chosen correctly, moving on to the entire manufacturing process all the way up to the packaging stage.

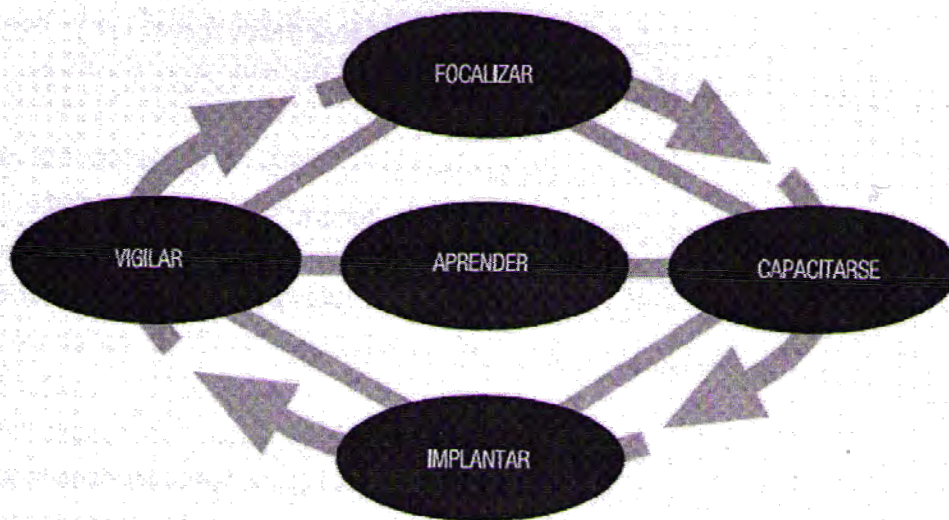

- Technological innovation.

According to the Cotec Foundation for Technological Innovation, this consists in "the utilization of technology as a means to introduce a change in the enterprise. This type of innovation has traditionally been associated with changes in the aspects most directly associated with the means of production. Technology may be created by the enterprise itself or acquired from a supplier, who may be public or private, domestic or foreign".

Two processes are involved in technological innovation, though these are not necessarily consecutive:

- 1.- Generating knowledge.
- 2.- Transforming this knowledge into a productive process, a product or a service.

The first point is indispensable, without scientific advancement there cannot be technological advancement, it is great and costly endeavor, in general carried on outside the firm, but of paramount importance for the firm. The second step must necessarily take place within the firm, but this requires an intermediary step that is of great importance for the generation of know-how, and that is the acquisition of this applied scientific knowledge. For this the firm must have a team that conducts research into emerging knowledge in the sciences and its possible application to the products that the firm produces. This team or system for the acquisition of exploitable new knowledge may be called a 'technology monitoring team'.

- Product innovation.

To be able to ascertain how product innovation happens and what are its key features, it is useful first of all to define what a product is; P. Kotler takes the view that “a product is anything that can be offered to the attention of the market for purchase, use and consumption, that can satisfy a desire or need, including physical objects, persons, organizations and ideas”. Meanwhile, P. Bonta and M. Farber define it as: “a product is a combination of attributes that the consumer believes a particular good possesses to satisfy his needs or desires”. Likewise, W. Stanton, M. Etzel and B. Walter define a product as “a combination of tangible and intangible attributes that include packaging, color, price, quality and brand, plus the services and reputation of the vendor; the product may be a good, a service, a place, a person or an idea”.

To sum up, the concept of a product is the result of a creative effort that has certain tangible features (container, color, price, size, texture, ergonomics, usability, design) and intangibles (quality, brand image, services and vendor image, distinction), which are perceived by its purchasers as capable of satisfying their needs or desires. Therefore, the fundamental objective for innovation in terms of the product must be the willingness to create added value in the product; this added value will make it competitive within its segment of rival products.

In order to innovate in terms of the product, it will be necessary to know which factors characterize products and, once that is known, industrial design can be used to work on it to produce more innovative products.

3. Specific factors that define products.

According to David Bramston’s definition in his manual “BASES OF PRODUCT DESIGN – FROM THE IDEA TO THE PRODUCT” : “The appearance of a product and its way of conveying a visual message is comparable to the way in which a person presents himself before others to transmit a message”. David Bramston attributes quasi-human qualities to products and suggests that there exist certain factors that go to make up a product that define its essential nature, factors such as personality or appearance, which also reflect on products.

In this chapter, we synthesize and isolate the various intrinsic factors that constitute the essence of the product; many authors have written about this synthesis, dealing in depth with each of the constituent factors, but none have thus far identified the inter-relationships between them such that they can be recognized and worked with in a holistic and inter-related manner. There are however many studies that deal with each factor individually or in small combinations, and we will be referring to them from time to time throughout this paper.

As a result of our research and having analyzed an exhaustive bibliography on the intrinsic factors of products, we have identified five classes of factor:

- Formal factors.
- Functional factors.
- Use factors.
- Economic factors.
- Factors associated with the value of the product.

Each class comprises a number of factors that have been classified in this way because they themselves are inter-related and because the techniques and tools that can make them more innovative are inter-related.

3.1 Formal factors.

The form of a product is the language that its design uses to reveal its essence. The form of the product is the symbol through which the product presents itself. Form brings together two basic concepts:

- 1.- Form as an element of sensorial contact (Shape, Material, Texture, Color).
- 2.- Form as a sign in semiotic terms (Perception of form, Aesthetic Perception, Aesthetics).

1.- Form as an element of sensorial contact is part of the physical dimension, the material world, what we perceive as the objective form of the product. Its factors are:

- Shape, contours, size, volumetry, relationship with space, form deriving from function.
- Material. As suggested by Bernd Löbach, the appearance of an industrially produced product is influenced not only by the designer’s aesthetic purpose viz-a-viz its possible end-users but also to a large extent by the materials and the manufacturing processes used.

When deciding what material or combination of materials and what manufacturing process to use for a given product, there are three main alternatives, as suggested by David Bramston in ‘Bases of Materials Product Design’, namely:

- Classic, traditional materials.
- New materials, generally high-tech.
- Classic materials employed or deployed in new ways.
- Texture. Wucius Wong defines it thus: "Texture refers to the surface characteristics of a shape. This may be plain or decorated, smooth or rough, and may appeal to the sense of touch as much as to sight". While materials may transmit intrinsic qualities, these may be heightened or subdued by means of surface treatments; characteristics such as glossy, matt, polished or rough modify the product; polished and shiny objects such as the chassis of an automobile lead one to attempt to maintain that appearance by washing and waxing more often than would otherwise be considered necessary, and constitute an example of how texture can influence human behavior.
- Color. William Lidwell, Kritina Holden and Jill Butlerin in 'Universal principals of design', define the influence of color on the product as: "Color is employed in design to attract attention, to group elements together, to indicate meanings and to heighten the aesthetic". From this we may deduce that color is a determining factor in the form of the design, and also a tool for the development of the product.
-
- 2.- Form as an element of communication transmission. These factors belong to the realm of the intangible, of the metaphysical, to the study of the subjective perception of products; they relate in particular to questions such as culture, education, social status etc.
- - Perception of form. The principles of perception date back to Aristotle, who identified the five senses (sight, hearing, smell, taste, and touch) as the basis of perception. Christian von Ehrenfels, considered the founder of Gestalt psychology, published an article entitled 'On Formal Qualities', in which he claimed that perception is distinct from sensations. He also proposed the axiom 'The whole is greater than the sum of the parts. Ehrenfels published an article which was enormously significant for how industrial design is conceived: 'The level and the purity of form', in which he described how in each moment of a process of realization, every form is characterized by a certain level of creation. He defined the existence of higher forms in which there is greater unity and diversity (purity of form and level of the work), unity can be described as order and diversity as complexity. This led him to claim that the level of perception of form is a relation between order and complexity. Thus geometric shapes would be considered pure forms.

In the same way, in the 1960s, Max Bense developed a concept which he called 'exact aesthetics' which had as its motto "formal creation is the production of order". Undoubtedly the capacity of selection is one of the primary features of perception; it is the choice between what appears positive, negative or neutral. To conclude, we may state that in our perception of the object there is a search for balance, under the influence of previous experience, information, education and memory, elements which tend to condition our perception of objects.

- Aesthetic perception. This is an aesthetic that is conditioned by situations and users, it helps us to understand that perception is directed by the distinct personal interests of each user and their surroundings; therefore, it cannot be merely a process of perception of the projected image, but rather it is transformed by the influence of the contents of one's memory and one's interests, as expressed by the phrase "the user and his circumstances".

- Aesthetics. There are three aspects of special importance in the aesthetic relationship value – industrial design:

Aesthetic values. Aesthetic value is a measure of the aesthetic interest in the visual appearance of an industrial product by the user and is dependent on the circle within which he satisfies his aesthetic needs.

Constitution of aesthetic values as aesthetic norms. Aesthetic norms are aesthetic values recognized by a part of society.

Aesthetic rating by persons or groups within a socio-economic framework. A designer needs to know the aesthetic valuation, or rating, that users make of products or groups of products, for this market studies are required that can collect data on the aesthetic ratings of users.

3.2 Functional Factors.

Every product is designed to be used, to fulfill the function for which it was created, to live up to the expectations that have been defined and are required of it. Each product realizes its functions as it is used or utilized. Products are conceived to satisfy a main function, this function is the expectation that the user has invested in the product; if it does not meet it then the product 'does not work'. This main function may be single or multiple, in which case they are termed 'sub-functions'. The function always has as its end a benefit of some kind for the user.

There are also secondary functions, which are those that, while not the main function or a part thereof, are related to the main function and help to complete its use.

Functional factors may be classified as follows:

- Factors related to efficacy. Efficacy is the capacity of a product to perform the main function, regardless of how this is achieved, what counts is the final result, with not the slightest room for doubt as to its reliability.

- Factors related to efficiency. Efficiency is the capacity of a product to perform the main function, using the minimum of resources necessary or the most rational use of the means available to achieve that end. The resources may be materials, energy or time.

- Factors related to quality. Quality is a factor that is perceived, care must be taken to ensure that the product transmits this value as directly as possible. Quality levels may be set for the product the level of quality of the product may be assessed; there are techniques for comparing the quality of a product to a benchmark.

The level of quality of a product can be measured in terms of its reliability. Reliability here is understood to be the ability of a device to perform its function for a given period of time. The reliability of a product tells us how long the product will function properly.

- Factors related to safety. Safety must be guaranteed for all the various uses of a product. Risks for the user must be reduced as much as possible, including the risks for the product itself. Lack of safety in a product entails responsibilities, liabilities and financial losses in the short and medium term. Safety can be operationalized as minimizing risks. To guarantee that products are safe to certain extent there are rules and regulations which compel the manufacturer to comply with specific parameters in order to ensure that products are safe. The factors of the product that impact on safety can be grouped as follows:

Safety for the intended use and foreseeable misuses.

Finishes and sell-by dates

Materials, warranties.

Instructions for use.

Warnings as to risks or hazards.

Color codings.

Protective containers, wrappers etc.

Control devices.

- Factors related to stability. A product must transmit safety, trustworthiness, durability or efficiency, but probably stability is the most indispensable value of all. All of the other values we just enumerated can be achieved with a robust design, and this transmits stability or 'ruggedness'. While stability can be basically mechanical, it also includes the ability to withstand impacts, to keep its shape while undergoing changes in temperature or humidity, to remain stable if exposed to electrical currents and to shockproof if dropped. All of these are factors which affect stability.

3.3 Use factors.

Products are intended to fulfill a function, and to realize that function they must be used. When a product is used, an interaction is established between the user and the product, in which an information exchange takes place. We may assess the ease of use of the product by looking at the extent to which this exchange is fluid, rapid and clear.

To determine the features of a product in terms of its ease of use and identify the factors that comprise them, what is known as a use analysis is conducted. To analyze the use of a product we must first of all contextualize the setting or environment in which it is to be used.

Stages in conducting a use analysis:

- 1.- Exhaustive inventory of the factors that stem from a diversity of situations of use. The sequence of use is defined.

- 2.- Additional information. All available information must be included: leaflets, catalogues, instructions etc.

- 3.-Conclusions. Defining one or several sequences of use. Profile and qualities of the product under scrutiny identifying strong and weak points. Comparative analysis of different models studied.

- 4.- Image and concept formed by users of the product on having used it.

In addition to the use analysis, it is advisable to identify the users and to create a profile of the typical user, in order to pinpoint the analysis and also to identify the various participants in the use, who are, briefly, the Designer/Value conveyor or salesperson / Purchaser / User / Beneficiary.

Some of the factors related to use are determined by what we know about the users; this detailed knowledge is the field of Ergonomics. Ergonomics is a science which brings together a set of scientific fields that are concerned with human beings and are necessary for the conception of tools, machines and devices that may be used with the maximum possible ease, safety and effectiveness. Together with ergonomics we will look

also at anthropometrics, which is the discipline that deals with the precise measurement of the various anatomical dimensions, the study of individual variation and its evolution over time.

3.4 Economic Factors.

Factors derived from economic criteria are probably those which most affect a company and consequently its product development; economic success is the result of success in the marketplace, and so if we can identify the economic factors which affect the product, we will know which factors affect the market.

Knowing the market means knowing the players as well as our own product. They are:

The consumer / purchaser.

The environment.

The competition.

We consider a consumer to be any person who is going to interact with the product and therefore this will include users, purchasers, beneficiaries, vendors, and maintenance or repair personnel. The intervention of these players can provide an enhanced brand image, an increase in sales and better positioning in markets. The mechanism used to obtain information about consumers is marketing, and within marketing we will conduct market surveys with users that will enable us to discover their expectations, their perception of our product and their degree of satisfaction with our existing products.

Knowledge of the environment can provide us with information about present and future needs of the market, the exploration of future markets and future configurations of the market. Knowledge of the environment must contribute to the achievement of objectives such as growth, profitability and stability. The environment must provide us with knowledge of four basic factors that stem from the market, namely: market volatility, technological development, degree of uncertainty in the market and growth of markets.

Competition is probably the most energizing action of markets and it is the one which involves the greatest investment in material and human resources, in order to position a product in the market. The analysis of the competition is founded on the logical basis that, in order to meet the needs of users by giving them greater satisfaction or value, one needs to have access as a frame of reference to the actions and selling points of one's competitors, since purchasers evaluate products in relative terms, comparing one with another before making their selection.

The mechanisms used to investigate the competition and their products are market surveys, re-engineering and benchmarking.

Together with these tools for the identification of factors derived from economic and market aspects we need to apply what M. Porter in the 1980s called the five competitive forces that configure the competitive environment of enterprises:

The rivalry of current competitors / the threat of new or potential competitors / the threat of products that could take the place of existing ones / the bargaining power of suppliers / the bargaining power of purchasers.

The key factors for products' success are:

The degree of superiority of products, their capacity to take a leading position.

Mastery of the principles of marketing.

Product design.

Market niches.

Branding.

3.5 Factors associated with the value of the product.

The factors associated with the value of the product are those factors linked with imponderables which are therefore unpredictable and tend to be associated with culture, education or the preconceptions of each user. These factors will be the most difficult to quantify and will be considered in a generic manner.

To investigate the decisions taken with regard to these imponderables, we will need to know how the human brain works and how it arrives at decisions. The brain has three distinct levels:

The visceral level, a layer composed of automatic systems of dispositions that are genetically determined.

The behavioral level, the part of the brain in which the processes that control our everyday behavior are carried out.

The reflexive level, where our contemplative processes are located.

It is practically impossible to design objects that are capable of satisfying all three of a user's levels and more difficult still to do so for large demographics. Nevertheless, we can establish an inter-relationship between these spheres and the qualities of the product:

Visceral Design > Appearance.

Behavioral Design > Pleasure and effectiveness of use.

Reflective Design > Self-image, personal satisfaction or memories. .

This inter-relationship generates factors such as satisfaction, status, identity, fashion – attractive objects perform better.

4. Conclusions.

The values presented in this paper are the basis for a line of inquiry which the authors are pursuing which will produce a survey that, applying these factors, will enable us to assess the level of innovation of specific products and develop a strategy to enhance their positioning.

Abstract

With the construction, in Pompeii, of the temporary museum of enterprises and activation of Officiamuseum (the Regional Museum System Design and Applied Arts), which is the driving force, it is necessary to extend the "system" in a geographically and culturally more extensive. To really make this action strategy for the revival of craft and design - not making constant reference to the European market, especially in these years - you have to devise a The Mediterranean Museum System of Design and Applied Arts. Pompeii, once an important trading center in the Mediterranean, could become one of the centers of this system with the city of some countries such as Morocco, Libya, Egypt, Turkey, etcetera. This project is currently supported by Okan University, Istanbul. Professor Ayşe Özbil about it has made a study on craft turkish. Although there was a crisis with globalization, will be enhanced by our project. Furthermore, this work is also supported by a German university, the Cologne University of Applied Sciences. The prof. Jochen Siegemund stepped in with its expertise in the field of Corporate Architecture. The "System" - a sort of international company museums - will represent perhaps a great opportunity for development in the Euro-Mediterranean design.

System – Mediterranean – Company Museums – Corporate Architecture – Artidesign

Introduction (Claudio GAMBARDELLA)

The opening in the near future of the Temporary Business Museum in Pompeii, centre of the project “Regional Museum System of Design and Applied Arts – Officiamuseumed”, marks a historic step for future development opportunities for those companies operating in the production of excellence in Campania. It is also the start of a decisive phase in the construction of design that is closely linked with local crafts – Filippo Alison and Renato De Fusco in the 1990s called it *artidesign* – with it being closer to the radical transformations, and not just economic, of our time. It is this very aspect that extends the geographic and cultural boundaries of the “System”, proposing the hypothesis of a Mediterranean Museum System of Design and Applied Arts - Officiamuseumed, with it being an extension of the system developed for the Campania region, which might be of interest to other Mediterranean countries. The following contributions will highlight the two conceptual theories of the “System”. Ayşe Özbil illustrates the contribution that can come from Turkey, a pillar of the design culture of the Mediterranean, in the interaction between museums and local crafts. While, Jochen Siegemund, through his work at the University of Cologne in the discipline of Corporate Architecture, defines the system as a modern business strategy tool.

It is not just a strategic project, but also a deeper restructuring of Design, collecting examples that come from a wide scientific subject area, geography and education. A design that is more suited to this current period of crisis, with it being able to restore the dialogue with the past as well as express a new idea of modernity that no longer based on the certainty of its Growth. A design that knows how to contrast the arrogance of globalization at home, opening up to new productive landscapes, peripheral rather than those of traditional industrial design.

1. Officiamuseum. Synthesis of the research

The idea of creating a *Regional Museum System of Design and Applied Arts* follows a decade that has been crucial for design in Campania (1990/2002). It is marked by a series of experimental collaborations between fifty-three designers and thirty-one local companies producing local handicraft goods (Claudio Gambardella had curated a lot of exhibitions on souvenirs like "Napoli souvenir d'autore", in 1990, or "I love Pompeii" in 2002), showing that it is possible to do design in a territory that lacks industries but is rich in local craftsmen. The study has been prepared gradually, through the understanding and elaboration of the enormous potential of the local handicrafts of Campania, carried out in Naples, in the 1970s and 80s, by designers and academics, with it also relating to a cultural environment that has a long history. «When in 1734, Charles of Bourbon re-nominated Naples as the capital of an independent kingdom, the city was already densely populated, with a population of slightly less in number only to London and Paris. However, it was not only due to its demographic size that Naples had a leading role in eighteenth century European society. The two centuries of Spanish rule, along with the brief Austrian viceroyalty period, [...] had left, from the perspective of cultural heritage, a fertile artistic, literary and philosophical ferment. [...] In addition to giving impetus to the realisation of the masterpieces by Luigi Vanvitelli, Ferdinando Fuga and Mario Gioffredo as well as other great architects of the time, Charles of Bourbon launched an enlightened approach to promoting the artistic, from porcelain workshops of Capodimonte to the hard stone carvings of San Carlo alle Mortelle. [...] The production of works of art became the laboratory of choice for the testing of new aesthetics. The excavations at Herculaneum and Pompeii fuelled the *imagery* of the search for ideas. The discovery of objects that animated life in the past – from pots to chairs to wall paintings – opened up new neoclassical horizons in anticipation of a phenomenon that would result in the British pottery of Josiah Wedgwood» [1] The idea of "System" comes from highlighting the presence of specialised museums in places where handicraft goods of Campanian excellence are produced as well as trying to bring the worlds of business and culture closer, a driver for development in the South. It also tries to involve small business owners, in a strategic project focused on design, that has a wider scope and is more long-term. Local development therefore depends on the museums. In 2002, the Second University of Naples, appointed by the Campania Region, drew up the preliminary project of a "regional museum system of design and applied arts", with it being conceived as a virtual regional network of twenty-one specialised museums, public and private, of applied art and crafts as well as temporary museum of Campanian business in Pompeii, located along a strategic tourist route in the region that connects Naples with the most important centres of products of excellence in the region (See: *The Regional Museum System of Design and Applied Arts*, book edit by Claudio Gambardella [2]).

2. The company museums

In the Centre-North of Italy many corporate museums have been opened over the last two decades, according to the postmodern idea of memory that favours the consecration of the product as unique and isolated from the productive life. Their low appeal, with relatively few visitors, when compared to those of other Italian museums (See: *Dossier Musei 2007* edited by Centro Studi TCI) [3], comes from the lack of clarity when defining the purposes and functions of company museums. They have become the "best living-rooms" of the companies where the family trophies are kept because their reference model is the museum *per se*, i.e., «[...] a permanent, non-profit, serving society and its development [that] carries out research relating to the tangible and intangible evidence of people and their environment; acquiring, conserving, communicating and, above all, displaying it for study, education and pleasure» (International Council of Museums - ICOM).

Is it right to conserve and communicate the tangible and intangible assets of a company and expose them for study? How can the needs of a company to promote itself be ignored and why not through its museum?

This open question, thanks to the project *Officiamuseum*, has led to corporate museums being considered as an area of scientific interest – usually not explored in academia – and recently introduced as an *ad-hoc* course (**Company Museums**) at the Faculty of Architecture of the Seconda Università degli Studi di Napoli, the first in Italian academia. Through the research and course (with a large number of dissertations), it has been understood that there is a need to give life to a new type of free architectural principles of traditional

museum design, that are more appropriate to the profound changes of the economy and markets. The company museum is, in fact, a “museum of time”, reflecting the history of the company, but at the same time registering the brand of which it is the expansion, promoting its image through a flexible design, interpreting the processes, errors, and attempts that the finished product has within its “body” covering up the invisible “fingerprints” of those invisible involved in its creation (the designer, entrepreneur, marketing expert, the advertiser, the workforce). A museum that does not display products, but illustrates the processes according to the principles of a specific “museography of business”. It may even anticipate the actions of the company becoming a place of experimentation in which to develop and submit new proposals and “expose” not so much what already exists, but what is yet to be produced. In this sense, the museum becomes the “thinking head” of the company, the driver of its strategies and place of “training” of the consumer: a consumer responsible for businesses built on quality. Finally, the company museum can become a “circular museum” that takes into account the experience from the final recipient, not just guinea pigs in the hands of marketing, but the thinking and creative subjects. The temporary business museum in Pompeii wants to express such ideas through its confrontation with the historical museums of Officiamuseumed.

3. From the Regional Museum System to the Mediterranean Museum System of Design and Applied Arts

The studies carried out in the twentieth century since Fernand Braudel highlight how in the Mediterranean, in its confrontation with the political economy of contemporary events, is a highly complex area. It may be considered not only as a given history and geography, but as the «[...] reconstruction of an open area for exchange where Mediterraneans can meet their neighbours» [4], says Mohammed Bennis, professor at the University Mohammed V – Agdal, Rabat. Subsequently, in the same wonderful post-face, quite rightly he states that «[...] the culture that was the basis of the past in the Mediterranean is the only one that can guide us in reconstructing the Mediterranean meant as an idea. The Mediterranean culture was the embodiment of tolerance, dialogue and openness. [...] It united what economics and politics managed to separate [...] If we consider culture as a founder, the reconstruction of the Mediterranean basin will become a new humanism, through which we deserve both the past and the future [...]»[5]. At the same time, he warns that this Mediterranean is part of a larger reality and that in reality the northern part of the Mediterranean is Europe. In 1995, the Barcelona Declaration (adopted at the Euro-Mediterranean Conference – 27-28/11/1995) [6] provides an inseparable interrelationship between the Mediterranean and Europe, because «[...] it [Europe] must regain its Mediterranean dimension, that is, its roots, that since ancient times have allowed it to undertake a beneficial exchange of political, cultural and religious experiences. This re-appropriation is, at the same time, a challenge for the future of the “european model”»[7]. The Mediterranean as well as Europe are concepts that require continuous remodelling and can be part of one big project that we can all help to build. A cultural project. An economic project. A peace project.

The “Mediterranean Museum System of Design and Applied Arts” is entirely in keeping with these broad themes and collective ambitions. In 2005, the project was drawn up and organized in a detailed proposal for EU funding with several Mediterranean partners (project presented on 29 JULY 2005 to the Regione Campania within Programme INTERREG III B – ARCHIMED). However, the administration of the Campania Region granted funding to other proposals. It was preferred to have meetings with individuals in order to transform the project idea into something consistent and definitive. International agreements, which form the basis of a modern university, promote the creation of these Euro-Mediterranean relationships. In particular, the “bridge” created with Turkey as well as Germany is thanks to bilateral Erasmus agreements drawn up with the University of Cologne in 2007 and Okan University, Istanbul in 2010.

What does the System propose to do? Specifically, it wants to contribute to a wide area of the Mediterranean (Euro-Mediterranean) in the construction of an alternative design that, despite the crisis, is multiplied with objects, furniture, things/goods that are not created for a particular world.

The alternative, therefore, in the hoped-for post-growth society which fully expresses the new values that are have been emerging for some time – such as the selective recovery of the past, authenticity, local traditions as well as cultural heritage (*See: La società della post-crescita*, a book of Giampaolo Fabris[8]) - renewing the relationship between design and craft (that was never completely severed in Italy). It is worth considering of the “third type”, which was defined by Alison and De Fusco in 1991, that is placed between the crafts (even more influential and vital in the Mediterranean countries) and industrial design; *artidesign* [9], i.e., not as a southern Italy phenomenon but in a broader sense, “Mediterranean artidesign”, or rather Euro-Mediterranean.

This objective will have a positive response in the knowledge of a widespread context of micro-entrepreneurial artisans and manufacturers-holders of ancient manual wisdom. With these subjects, it will be

possible to experience new dynamics (as in Campania and other parts of Italy) when introducing into the “design” moment of the craftsman a professional figure that is alien, the designer, thus interrupting the *modus fabricandi* closed between design, manufacture and sale. The Design Culture could also introduce promotion which is usually absent in handicraft production as well as modernize product distribution. The Officiamuseumed project can save crafts from isolation by introducing them into a broader economic and productive context; promoting the transformation of small artisans into businesses, always small, but implemented by the Design; aggregating them through the existing museums of applied arts and crafts. Officiamuseumed can be divided into a series of local “subsystems” in different regions of the Mediterranean and become, with their respective central organisations – the new design museums – a “Mediterranean Museum Company” with the task of promoting the development of these new companies with excellent products of a territory so vast through the careful direction of universities, chambers of commerce and trade associations.

6. Ciad / cologne institut for architectural design corporate architecture (Jochen SIEGEMUND)

Under the direction of Prof. Jochen Siegemund (architect and urban planner) in collaboration with Professors Oliver Fritz, Dr. Michel Muller, Amandus Sattler and other experts and scientists leading the Cologne Institute for Architectural Design / CIAD the Master of Arts master's degree in architecture / corporate architecture through. On this topic is in the same research focus, the Institute has its headquarters, research across faculties and disciplines. The strong labor market based profiling, as well as synergies in teaching and research, design and practice lead to the unique feature in this field of work (Corporate Architecture).

Identity through architecture

Corporate Architecture is constructed identity. The exhibitions, biennials and publications on the current architecture are influenced by projects such as Prada Stores, Niketown, the Mercedes-Benz Museum or the Allianz Arena: They are examples of an architecture that creates a certain attitude to life and creates a brand image. Architecture is playing a communicative role, since it carries the values and self-understanding of a company both internally and externally. The term corporate architecture was coined in the '90s, is now generally established imprinted on numerous projects and the design and conceptual design of architectural firms. The issue of corporate architecture covers not only the scenographic designed spaces and architectures as they are known in exhibitions, trade shows, showrooms, museums and theme parks industry. It is an expanded role at the interface of the disciplines of visual communication, marketing, design, IT, sociology and urban and regional development. Ever since the success of the Guggenheim Museum by Frank Gehry in Bilbao, we know that architecture can perform as a pulse motor and the development of a whole region.

Branding Architecture (form follows content)

Corporate architecture is a special opportunity for a new generation of young architects. This opportunity is the great attention paid to brands is receiving today. As brands and thus their architecture a global impact on our behavior and our society needs to make a corporate architecture that power advantage and responsibly deal with it. Through a holistic and integrative approaches, we can help architects design our future and part of the solution of global, ecological, economic, social and political challenges. With the help of corporate architecture to sustainable and meaningful projects for global development be designed and established.

More information can be found on our blog <http://c-i-a-d.org/>.

7. Turkish handicrafts: integrating museuming, marketing and production (Ayşe ÖZBİL)

Handicrafts reflect the characteristics of cultural identity. Unfortunately handicrafts activity and the number of craftsmen in Turkey have waned throughout time owing to multiple factors, most significantly to globalization. The world has shifted towards a single-model production as a result of globalization, which actually makes local values so important that their protection is crucial not only for the original area of production but for the entire world (Kongar 2000). This article presents an overview of Turkish handicrafts (classification and history), discusses their present day state and problems, and concludes with recommendations for their promotion and preservation.

7.1. Historical Background on the Regression of Turkish Handicrafts

Technological advancements and cultural and social transformations during the first years of Turkish Republic (1920s and 30s) had a significant impact on demographics and production activities. Starting from the 50s decline in rural population has caused rapid urbanization, with ateliers transforming into factories. Due to fast-changing social, economic and political developments encountered in the nineteenth and twentieth centuries, the terminology used in handicraft activity has been altered. Turkish culture's materialistic products named as "handicraft" during the first years of Turkish Republic. After the 30s the term "handicraft" started qualifying a larger area and was turned into "traditional handicrafts". In the 60s the concept of "handicraft" have transformed into "small industrial products". With the importance attributed to tourism during the 70s, new terms such as "touristic souvenirs/handicrafts" entered the lexicon. As such, while the materialistic products of the Turkish culture still attain their cultural and historical significance at the present day, there seems to be an increased confusion surrounding the terminology used to describe these hand made products.

7.2. Classification of Turkish Handicrafts

Anatolia, occupied by many cultures throughout the history, has been the centre of various handicrafts developed for the purposes of transportation and accommodation. Eşberk (1939) and Arlı (1990) classify the Turkish handicrafts according to the raw materials used as follows:

- Fibers as raw materials (embroidery & weaving):
Carpets, *kilims*, socks, pullovers, curtains, headscarves, any type of covering cloths, etc. Weaving materials in traditional Turkish handicrafts consist of wool, mohair, cotton, bristles and silk.
- Trees as raw materials:
Hand stamping presses, thread spinning tools, oxcarts, kitchen utensils, accessories for daily usage such as cigarette holders, walking sticks/canes, prayer beads, architectural elements such as doors, windows, locks, musical instruments such as shepherd's pipes and drums.
- Stone as raw materials:
Architectural elements such as gravestones, fountains, mosque niches, mosque doors, etc., accessories for daily usage such as necklaces, bracelets, rings, chests, etc.
- Earth as raw materials:
Vases, bowls, pottery products, ceramics, glazed earthenware tiles.
- Metal as raw materials:
Architectural elements such as door knobs, locks, kitchen utensils such as knives, wall plates, heating instruments such as stoves, agricultural tools such as shovels, jewelry.
- Glass as raw materials:
Various types of blue beads (to ward of the evil eye), *çeşm-i bülbüls*, stained glass, jewelry and accessories.
- Leather and animal waste as raw materials:
Dressing elements such as hats, boots, belts, daily belongings such as cases, cigarette holders.
- Thin branches, stalks and tree stripes as raw materials:
Basket weaving, furniture making, bags, straw mats, etc.

In addition one more category can be added to the above classifications:

- Paper and dye as raw materials:
Calligraphy which is the art of fine handwriting with aesthetic principles, and *Ebru*.

Figure 7 maps different types of Turkish handicrafts based on the location of their productions. Figure 8 shows some examples of Turkish handicrafts and their production processes.

7.3. Present State and Problems of Turkish Handicrafts

In the 21st century challenges facing Turkish handicraft production are multi-faceted. Migration from the villages to cities, increase in the machine production in accordance with the technological advancements, changes in cultural and social trends and habits, decrease in the amount and standards of raw materials, as well as the invasion of the market by the products of Asian and Far Eastern countries are some of the factors that have been influential in the regression of handicrafts (Arlı 2006). In addition, globalization affects cultural

materialistic production negatively by shifting the production to parts of the world where manpower is relatively cheaper and ample. While handicrafts used to be perceived worldwide as the materialistic dimension of the national culture and seen as part of the public economics previously, today they are evaluated as the visual products of national heritage that can be most easily globalized (Oğuz 2002). Furthermore, the absence of an integrated state policy on handicrafts results in complications in their production, marketing, collection and exhibition (Teği and Erdoğan 2008). These factors altogether have led to the diminishing of the artisans' knowledge to future generations, and thus the disappearance of handicrafts in Turkey.

In this paper the underlying problems of handicrafts in Turkey will be discussed in three headings:

Museuming (collecting and exhibiting)

In Turkey the formal institutions in charge of exhibiting handicrafts are Ethnography Museums. Table 1 presents an overview of current handicraft museums in Turkey. Museums and cultural heritage protection agencies in Turkey lack the appropriate status in which they need to be recognized as social bodies (transferring the past of the society) with political agendas (rendering conscious the society about its social and cultural structure) (Keleş 2003). The inadequate resources of museums and museuming works, lack of knowledge regarding museology, insufficient state subsidy all contribute to the deterioration and disappearance of the ethnographic materials from their environments.

| Name | Nominal | Initiated | Type of exhibitions | Location |
|--|----------------|------------------|--|-----------------|
| Turkish and Islamic Arts Museum | state | 1913 | calligraphy, tiles, stone and wooden works, and rugs as well as ethnographic displays | İstanbul |
| Sadberk Hanım Museum | private | 1980 | Ottoman and Byzantine jewelry, tiles, ceramics, sculptures and steles, glass objects, beads, coins, and coppers | İstanbul |
| Sakıp Sabancı Museum | private | 2002 | Ottoman calligraphic art and calligraphic tools | İstanbul |
| Yapı Kredi Vedat Nedim Tör Museum | private | 1992 | collections of antique coins, medallions, embroideries, cloths, worry beads, and <i>tombaks</i> | İstanbul |
| Pera Museum | private | 2005 | Kütahya tiles and ceramics (private collection) | İstanbul |
| The Great Palace Mosaic Museum | state | 1938 | mosaics from the Byzantine period | İstanbul |
| Topkapı Palace Museum | state | 1924 | examples of Ottoman architecture, miniatures, treasures and jewelry, collections of porcelain, Islamic calligraphic murals and manuscripts | İstanbul |
| The Museum of Turkish Calligraphic Art | state | 1984 | handwritten manuscripts, sheets, sultans' signatures, and miniatures | İstanbul |
| Tiled Kiosk Museum | state | 1953 | tiles-, and ceramic works | İstanbul |
| Kastamonu Handcrafts Museum | state | | handicrafts of Kastamonu region | Kastamonu |
| Kastamonu Ethnography Museum | state | 1997 | handicrafts of daily use, ethnographic works, copper kitchenware, weaving works and traditional clothing | Kastamonu |
| Adana Ethnography Museum | state | 1924 | ethnographical works, weaving, and stone works | Adana |
| Ankara Ethnographic Museum | state | 1928 | wood-, glass-, and tile-works, calligraphy, carpets, embroidery, Anatolian jewelry | Ankara |
| State Museum of Painting and Sculpture | state | 1930 | exhibitions of painting, sculpture, ceramic, printing arts and photography | Ankara |

Fig. 6: List of major handicrafts museums in Turkey.

Marketing (initiating and promoting)

Marketing is considered as one of the major underlying challenges of handicrafts. Factors such as decrease in high quality raw materials, decline in the traditional standards of production as well as lack of the production of new designs which may create new marketing opportunities both at domestic and international scales lead to difficulties in marketing. In Turkey the marketing of handicrafts is mainly carried out by the private sector. For example, the craft of woven textile in Kastamonu, a national prominent *kilim* production

province, was doomed to be perished when a collaborative initiative was established in 1995 between the local producers and a large store with the efforts of the local government (Teği and Erdoğan 2008). Recently official institutions have also begun marketing handicrafts in Turkey. DÖSİM [10] (Operational Management of Traditional Handicrafts and Stores, was initiated as a subsidiary of the Ministry of Culture and Tourism in 1979 to provide financial support for protecting and improving the cultural entities, and to raise funds for promotion activities. Most recently, GES [11] (Traditional Hand Crafts Stores Directorate) was established in 2005 within the organization of Ministry of Culture and Tourism to support the production, promotion and marketing of Turkish traditional handicrafts. In short, if handicraft activity is to proceed serving as a source of economic income, artisans need to have access to markets, and they need to be able to compete, either in price or in quality. It is possible that an improvement in infrastructure, both physical and political, as well as increased education in the field of handicrafts could impact the handicraft industry positively, but the sustainability of handicrafts production most likely requires more and better-coordinated support than is now available for creating new marketing opportunities for these local products.

Production (crafting)

The production of handicrafts in Turkey is organized by cooperatives, local governments, and mostly small and large-scale companies. In recent years many products produced in countries where cheap-labor is ample has entered the market and harmed Turkish handicrafts and craftsmen by creating an unfair product-market competition. In order to ensure the sustainability of handicrafts and promote its market value, large workshops and cooperatives that would support high-quality production are required.

7.4. The Link between Museuming, Marketing and Production

Recent debates and studies have made it clear that even in the most highly industrialized countries handicrafts continue to exist simultaneously with industrialization, and that the progress of the latter does not necessarily suppress handicraft production. In order to promote the development of handicrafts in new forms, it is essential that different parties who deal with handicrafts should work in coordination. In Turkey some initial steps are already taken towards creating links between the market (local businesses-firms) and production (designer-craftsman). A number of well-established enterprises support the production of modernized traditional handcrafted small objects designed by known designers appreciating the know-how and qualities inherited and cultivated within tradition. These firms include, but are not limited to, the following:

- *Koleksiyon* [12] (A large store that produces and markets glass-ware accessories, and carpets/rugs using traditional handicrafts but re-interpreting them.)
- *Paşabahçe* [13] (Hand-blown glass works are designed by national and international architects and industrial designers in the firm's workshops in Denizli.)
- *Eczacıbaşı Vitra* [14] (A ceramic factory which takes its cue from the millenia-old Anatolian tradition of ceramic art, reinterpreting the the handcrafted originals and adapting them to the contemporary bathroom. It also embodies a Ceramic Art Studio that aims to encourage ceramic artists and public appreciation of this medium.)
- *Vakko* [15] (A large-scale firm that produces scarves and fabrics inspired by traditional Turkish Arts and created by the ateliers of renown artisans.)

These enterprises and many more are aimed towards bringing together arts, crafts and design, demonstrating that they have invested in design throughout, from the planning stage to distribution. In recent years another type of initiation, museum-firm pair, has emerged in different parts of the world. The goal of the museum-firm pair is to link various local product institutes, small- and medium-scale firms, and museums of applied arts. In Turkey Eczacıbaşı Virtual Museum [16] is one such initiation, which brings together multiple collections and exhibitions of traditional handicrafts (i.e. ceramics), paintings, and photography by linking various Turkish museums online.

7.5. Conclusion

To assure the maintenance and prevent the devaluation of handicrafts it is a must that different disciplines should work jointly through an integrated system. This type of a framework calls for tight links between museuming, marketing, and production of handicrafts. The cooperative venture between local firms, public/private institutions and designers/craftsmen need to be extended to include the museuming of these products as well to support the expansion of a design-culture. As the above listed firm-designer/craftsman pairs indicate this interaction between culture and business seems feasible and profitable. Hence, the idea of *Officiamuseum* –the regional museum system of design and applied arts, an 'action' aimed at forming tight links between the various local realities, interacting with similar institutions, including the future museum of

design, would provide a unique opportunity to integrate museums of applied arts and handicrafts and artisan firms (Gambardella, 2005). This kind of an integrated museum system linking firms and museums tradition of arts and crafts spread over different regions both in Turkey and in other regions such as Italy and Morocco is of the greatest cultural (design-culture) and economic (marketability) importance.

Imagination applied to European norms in “humanized” hospitals. More research, less cost.

Anna MAROTTA¹

⁽¹⁾ Department of Architecture and Design, Faculty of Architecture, Polytechnic of Turin, Turin, Italy
E-mail anna.marotta@polito.it

Abstract

The architect M. Tedeschi worked to an update project for the Department of Medical Oncology at the San Carlo Hospital in Milan (1994). It was part of a larger Humanization Project for that hospital. He compared the concept of humanization to that of *Heimlichkeit*, that means the comfort feeling, quiet, peace sensations and home warmth that everyone yearns for.

In 2001, U. Veronesi - with R. Piano - presented a preliminary *Preparatory Metaproject for guidelines definition in hospitals design* in the Italian Regions, in which patients and their needs play a major role in the humanization project. This is a theme of topical interests, characterized by a lot of researches and applications.

This paper aims to verify the colour role in the hospitals humanization process and will show, with general scientific criteria, an interesting colour restyling experiment conducted (as voluntary work) by the author for the San Lazzaro Hospital in Turin, in collaboration with ANDOS, Sikkens and Politecnico of Turin.

Thus, by combining hospital voluntary work, technical and scientific research (public and private) and creativity, an important objective for the care and comfort of patients and hospital has been achieved. It has been conducted a “pilot project”, with procedures based on norms, (without costs for the public institution) replicable in other similar situations.

Keywords: humanization, comfort, design, colour, research

1. Introduction

The architect M. Tedeschi worked to an update project for the Department of Medical Oncology at the San Carlo Hospital in Milan (1994). It was part of a larger Humanization Project for that hospital. He compared the concept of humanization to that of *Heimlichkeit*, that means the comfort feeling, quiet, peace sensations and home warmth that everyone yearns for.

Unfortunately, often the formal language - and not only - of hospital architecture, informs residents, workers and visitors who stay in the hospital does not mean “dwell in the hospital,” but live in another world: clean rooms, neutral colours, cold materials, furnishings anonymous, shared bathrooms and sometimes without a mirror, impersonal and depressive waiting [2].

The problems of the disease seems to add the “punishment” of a harsh environment, if not hostile, in any case not communicative and non-interactive.

In 2001, U. Veronesi - with R. Piano - presented a preliminary *Preparatory Metaproject for guidelines definition in hospitals design* in the Italian Regions, in which patients and their needs play a major role in the humanization project. This is a theme of topical interests, characterized by a lot of researches and applications.

This paper aims to verify the colour role in the hospitals humanization process and will show, with general scientific criteria, an interesting colour restyling experiment conducted (as voluntary work) by the author for the San Lazzaro Hospital in Turin, in collaboration with A.N.D.O.S. (Turin), Sikkens (who donated paints and materials produced in observance to the European norms) and Politecnico of Turin (who has granted his patronage).

Fig. 1: Visual examples: environmental comfort can determine the quality of life in place of care, influencing the therapeutic response.

An important goal for the comfort and the cure of the patients and the hospital workers has been reached through volunteer, scientific-technological researches (public and private) and creativity: a “pilot project”, with no costs for the public institutions, started with the possibility to reapply it in similar contexts. The results of such experiments are being analyzed through psychological tests by the Clinic of Psychology and Oncology of the University of Turin.

The term “humanization”, in its broad meaning, implies, in the design and managing of the sanitary structures, the need to use other than functional criteria, also integrative approaches sensible to the psychology and the relationship system of the patient, to avoid maladjustment and improve the recovery. Particular attentions have to go on the hospital operators, doctors and paramedics, since the conditions of their job has a double outcome: on them, as workers, and on the users.

Social-cultural changes, like for example migration flows, have to be taken into account for the design part to adapt to the continuously changing reality, in order to have hospitals adjusting to the patients and not vice versa.

Many recent studies on environmental psychology show that the environment can strongly influence the behaviours and relationships of people, being fundamental for the quality of the structures. Colours and visual components can be taken as examples for what concerns the creativity.

S. Marsicano [3] highlights that in the Anglo-Saxon clinical language exist two different ways to call a treatment. Cure, more technical and used for a clinical-scientific therapy, and care, more global, which takes into account all the patient’s needs and requests. In the Italian sanitary structures the cure is usually excellent, but part of the effort is vanished because of the lack of care.

F. Spinelli, E. Bellini, P. Bocci and R. Fossati [4] are the authors of “Lo Spazio Terapeutico”. They show how “in the public construction industry the spaces, mostly the interior parts, are considered apart from the people and the activities than later will take place in them. This general project approach generated “stranger” spaces, hard to live and costly to maintain, causing environmental discomfort, lack of participation in the activities and dissatisfaction in the public services, identified in the environment itself”.

1.1 The characters

Many are the characters involved in this ambitious project: A.N.D.O.S. Onlus Foundation in Turin (President Dott. F. Pedani), the research team Policroma from the Polytechnic of Turin (Scientific coordinator Prof. A. Marotta), Hospital University San Giovanni Battista in Turin (pursuer Dott. E. Iodice), the Oncology Department of Medicine 2 San Lazzaro Hospital (Head Physician Dott. M. Airoidi and Day Hospital coordinator Dott. F. Pedani), the Director of the Psychological Oncology Clinic from the University of Turin (Prof. R. Torta and Dott. A. Varetto), the Technical Office from the Hospital S. Giovanni Battista in Turin (Geom. M. Regis), AKZONOBEL through the Sikkens sign (A. Fagotto - national coordinator for commission relationships with his team PSC arch. F. Pezzo and eng. B. Moretti).

The research team Policroma, coordinated by myself, gathers many architects – professors, researchers and

professionals - all involved in different activities, as publications and thesis, which produces a solid background to face the considered problematic. Some of them are: Serena Abello, Chiara Cannavicci, Marta Balzarro, Gaetano De Simone, Ilaria Matta, Raffaella Ricchi e Eliana Milani.

2. Chromatic restyling project

The collaboration between the research team Policroma, coordinated by myself with the Politecnico di Torino, the Fondazione A.N.D.O.S. Onlus in Turin and Sikkens, starts from the need to modify the perception of the common areas in the Oncology department of the San Lazzaro Hospital in Turin.

In the intervention of humanization the picking of the colour is never neutral and cannot be linked at automatism: it has to be ruled by scientific-disciplinary methods.

The project is born from disciplinary and specific experiences and knowledge grew in several years. Many publications and specific studies on the colour in architecture have been made, the results of those are systematically shown in the publication from the title *Policroma. Dalle teorie comparate al progetto del colore* [5].

The original approach of the comparative theories of colour for the analysis and design are confirmed : too many times authors and general public mention a general colour theory without anchoring it to the respective cultural matrices and to identifying parameters.

The research is inserted in a wider field of humanization of the public spaces, through interventions able to find or recover the “humanity” of places. The main goal of the group “Policroma” is to study the effects that the interior and exterior environment creates on the human perception. One of the key role of the study is the colour since it is one of the important factor which characterize the spaces. Policroma aims to find a guide line to humanize the public spaces throughout the analysis and application in the Turin area. The effort of the group, that concretely operates decorating through volunteering, add affective quality to the meaning of the project and the message to the patients.

For a complete explanation of the project see the attached report made by S. Abello, C. Cannavicci, M. Balzarro.

3. Themes and goals of the project

The project took inspiration from the metaphor of Ettore Sottsass (how to forget the rhetoric triad of the flores, lumina, colores) for which the architectonic language should be used in the research of an authentic relation between life and architecture. This in order to create spaces like metaphors and not only “buildings” to watch and coldly live. The project links the general meaning of the metaphor to the specific one of the floral metaphor. The thought is instead related to the garden therapy, which got many results either in the prevention and the therapy.

This is the main theme of the restyling project since the beginning, called “Rifiorisce la Vita!”. The idea shaped around the awareness that nature helps and improve the recovery but cannot substitute the conventional cures; in this way gardening helps the dejected patients to smile again and the anxious ones to dissolve the urgency to do things. From this way it is possible to face the recovery constructively and to improve it.

Fig. 2: Policroma: the icon of a historical-critical method. Systematic overview of the theories compared with the respective models. In: MAROTTA, Anna. *Policroma. Dalle teorie comparate al progetto del colore*, Torino: Celid, 1999, p. 54. Only a disciplinary warning and critical approach can lead to analysis and conscious design. Unfortunately there is often a "project of colour" without the necessary process of knowledge, capable of embodying the choices to the most suitable matrices cultural, and theoretical aspects associated with its authors.

Fig. 3: The corridor of the department of Medical Oncology 2 San Lazzaro University Hospital San Giovanni Battista in Turin before the restyling of colour.

4. A sustainable Design

A big ally that the restyling project have found is the Sikkens company [6] – world polishes producer and seller, which always pay attention and respect the environment and the people. The company's policy immediately merged very good with the project. Sikkens vision contemplate the sustainable develop and trade social liability. One of the best answer for the today market since all the products are passion made to guarantee high quality results and low impact on the environment.

This contribution has been of great importance, underlining how in a multidisciplinary project is fundamental to calculate working methods "safe" for all the practitioners. Methods close to the design demands of an hygienically controlled place, which also have to be easy to clean, with low environmental impact and enjoyable. Sikkens introduced a new product specific for the medical-sanitary market following the latest European norms. The range of produces is based on the everyday needs and problems of the related sector. Specifically for the Oncology department of the San Lazzaro Hospital in Turin these following products have been adopted:

- *Alpha Sanoprotex*, water painting useful to inhibit the proliferation of bacteria(*Staphylococcus Aureus* *Meticillino-Resistente* – MRSA, *Escherichia Coli*, *Pseudomonas Aeruginosa*, *Acinetobacter Baumannii*, *Enterococcus Hirae* e *Streptococcus pneumonia*). The secret is in the silver ions acting on the bacteria with the addition of a particular washable and resistant film. (Classe 1 EN 13300). The efficacy increases when washed and rub, it isolates the Isobetadine and other sanitizers;
- *Wapex 660*: water epoxy product bi-composed for floors and walls. Covering suggested for locales in where the use of solvent products is not permitted. Low odour and low COV content(less than 15g/l), it has been approved by the norm ISO 8690, also applicable in locales with the presence of food (UNI 11021).

Fig. 4: 2012, Anna Marotta with Policroma group. Each function is characterized by a flower and its colour. Flowers and colours become the elements that help the Hospital users not to experience feelings of alienation from space and places of care. In this picture, the hallway of the Department of Medical Oncology 2 San Lazzaro, University Hospital San Giovanni Battista in Turin after the restyling project.

CAMPANULA

Fig. 5: 2012, Anna Marotta with Policroma group. Illustrative examples of abstraction that led to the creation of the stencil.

5. Colour and emotional comfort

The multidisciplinary of the project also enclose a phase of analysis and check. It is scientifically tested by psychologists from the S. C. D. U. Department directed by the professor R. Torta and from the A. O. U. Team from the S. Giovanni Battista Hospital in Turin.

The assumption is, as said, the existence of hidden messages contained in the environment that the workers and patients can interpret in different ways, consequently this can influence the final result of the cures. So, the goal is to plot the colour perception in sanitary locales related to the psychophysics wellbeing of people. The challenge is to unify the objective measurements of the emotional changes related to personal perception and codification of colour and visual field in general. The tools used are psychological tests composed by a semi-structured interview on contexts/colour. All the results are going to be statistically organized.

Rowlands, in 2008, referring to this subject wrote about three important topics: the direct view on nature and its colours can mend the stress and reduce the pain: improve the locales allocated to social purposes accommodates the psycho and physical recovery; finally sticking to the cures reduces anxiety in the patient and in the patient's family.

The research's expectations can be summarized in: a reduction in the anxiety symptoms, a correlated reduction linked to the picking of colours, an improvement in satisfaction for the cures received. The goal the will be anyway achieved is a higher attention to the humanization of the medical field and more colour in the everyday work in the hospitals.

6. Conclusions

Architects and builders cannot of course “donate” therapy, but they can for sure give quality to the hospitals: this is what our project is about.

Considering the preset goals the following are the one achieved: a concrete example to show and use for future applications, derived from a accurate research on the lowering of prices and a careful picking of chromatic aspects. This to avoid the wasting of money, mostly public, on dispersive actions not profitable for the patients, visitors and medical operators.

At San Lazzaro Hospital in Turin “Rifiorisce la Vita”

The life flowers in the sanitary system, in the prevention, in the efficiency of the therapy, in the effort, competence and passion of doctors and their helpers. In the fight of the single patient and its family and friends. In volunteering, in generosity of private companies, in everywhere, but especially in the hospital!

Abstract

In the context of initiatives, studies and investigations for the hospital humanization in Turin, the research group "Policroma", coordinated by A. Marotta (Polytechnic of Turin) has gained a large and specific set of experiences. Architect, Ph.D., Full Professor of Drawing, Marotta - author of specialized studies and publications (concerning the colour in architecture, city and landscape field) exposed in a systematic way in his publication called *Policroma* (1999) - has established a Colour Laboratory that conducts and coordinates. The research group is composed by many architects - teachers, researchers, students and professionals - engaged in various types of related publications, theses and dissertations.

The paper illustrates the latest activities involving the non-profit organization ANDOS Foundation, the Polytechnic of Turin, Sikkens company and the Molinette Hospital Direction, which began last summer with the transfer of the Medical Oncology Department of San Lazzaro Hospital in Turin. On this circumstance the promoters wanted to develop a restyling project, characterized by a high cultural level (which also included the colour), with minimal financial investment. The final goal is to create, through a carefully thought project and the application of specialist and critically selected colour criteria, comfortable environment, thus contributing not only to the psychological well-being, but also to a better therapeutic response.

Keywords: humanization, comfort, design, colour, research

1. Introduction

In the context of initiatives, studies and investigations for the hospital humanization in Turin, the research group "Policroma", coordinated by A. Marotta (Polytechnic of Turin) has gained a large and specific set of experiences. Architect, Ph.D., Full Professor of Drawing, Marotta - author of specialized studies and publications (concerning the colour in architecture, city and landscape field) exposed in a systematic way in his publication called *Policroma. Dalle teorie comparate al progetto del colore* [3]. She has established at DINSE, actual DAD department, a Colour Laboratory that conducts and coordinates.

The research group "Policroma" represents the outcome of long and extensive research in the field of color and visual perception, in this case aimed at improving the quality of life and the humanization of public and private places through projects that can found - or rediscover - "humanity" of places.

The chromatic element plays a key role in this study because it is one of the most important factors that characterize the space. In this sense, through the analysis of case studies and practical applications in the Turin area, the group "Policroma" aims to study the influence that the environment - external or internal, with its characteristics - has on the human perception, seeking to identify the guidelines for a possible and desirable humanization of public and private places, with particular interest directed to care spaces.

The research team, coordinated by the scientific knowledge of A. Marotta, gathers many architects - professors, researchers and professionals- all involved in different activities, as publications and thesis, which produces a solid background to face the considered problematic. The group is helped by a company which has a long history of chromatic renovation; R. Ricchi and E. Milani (experts in frescos renovation in epoch building) are the precious link between theory and practice, very helpful in applications and projects like the one that it is going to be introduce.

S. Abello and C. Cannavici, graduating in Cultural Heritage at the Polytechnic of Turin, have been working with the professor Marotta for many years developing studies and theories on the scientific field of the visual perception. Experimenting through various applications, the possibility of rehabilitation of the spaces using consciously the color. In particular Chiara Cannavici is developing a research about the use of color and comfort in the medical buildings. This will be useful in her thesis in which she addresses the problem that the color does not have enough importance especially in fields like architectural heritage and sanitary buildings. Another important contribution is given by I. Matta, architect that from 2006 cooperates with the Regional Agency for Sanitary Services (A. R. e S.S.) in Piedmont. She is involved in projects that concern the analysis of the medical regional estate and the developing of methodologies, criteria and parameters for the evaluation, the design and management of hospitals. Additionally M. Balzarro, neo architect that evolved a thesis titled "L'ospedale a colori a misura di bambino" (relator: A. Marotta) and G. De Simone, architect, technician graduated from the Polytechnic of Turin which collaborates in didactic activities in the methodological analysis of architecture as a complex computerized procedure.

2. From theory to experimentation: the collaboration with A. N. D. O. S.

Many recent studies show how each color has its own characteristic, which stimulate an emotion influencing not only the human psyche, but also the way to it operates in locales where the color has been carefully chosen.

Too many times the Italian sanitary structures are impersonal and monochromatic locales, and added to the long time waiting, generates real discomfort like anxiety, impatience and bore.

For the OMS (World Health Organization) the environment is defined as an integrated system of anthropologic and physical factors which influence the health of the community. These factors are fundamental for the health of people in its broad meaning, not only the absence of sickness but also considering the complete physical, psychological and social wellbeing of people.

The collaboration between the research team "Policroma" coordinated by Anna Marotta and the A. N. D. O. S. Onlus Foundation in Turin begins from the need to modify and improve the just said aspects, in particular the common area of the oncology department of the San Lazzaro Hospital in Turin. The goal was to create comfortable spaces using light colors, soft shapes to avoid stress contributing to the wellbeing of the patients and the workers.

The studies and the researches made by Policroma found a wide possibility to experiment new solutions that before were just used for single projects: the collaboration with A. N. D. O. S. permitted the experimentation of the acquired knowledge and the assumed solutions. The collaboration has as main goal the modification of the visual perception of the common areas of the San Lazzaro Hospital, starting from the concept that the picking of the color cannot be linked to automatisms or be neutral: the picking of the color have to be moved by scientific and methodological approaches.

The will to deepen this theme starts from the specific and disciplinary experiences grew inside the group coordinated by the professor Marotta (*Dalle teorie comparate al progetto del colore* [3]).

The research is inserted in a wider field of humanization of the public spaces, through interventions able to find or recover the "humanity" of places. The main goal of the group "Policroma" is to study the effects that the interior and exterior environment creates on the human perception. One of the key role of the study is the colour since it is one of the important factor which characterize the spaces. Policroma aims to find a guide line to humanize the public spaces throughout the analysis and application in the Turin area. The effort of the group, that concretely operates decorating through volunteering, add affective quality to the meaning of the project and the message to the patients. For a complete explanation of scientific and disciplinary approaches of the research group see the attached report made by Anna Marotta.

3. Project description and realization phases, expected outcomes.

In the summer 2011 it was decided to transfer the Department of Medical Oncology 2 of the San Lazzaro of Turin from the second to third floor. On this occasion the A.N.D.O.S. wanted to implement an important chromatic restyling project and for this purpose has partnered with Anna Marotta, known as a leader in the field of color studies. The project has been characterized, since the earliest stage, by a great cultural depth; it could have required a significant economic investment, but the project was all volunteer, involving A.N.D.O.S., Politecnico of Turin, Sikkens and Molinette Hospital management. An initial analysis has focused on the study of functions and their distribution in the available space of the department.

Fig. 1: The corridor of the department of Medical Oncology 2 San Lazzaro University Hospital San Giovanni Battista in Turin before the restyling of color.

As usual, the theory have to meet, clash and then adapt to the bureaucracy and practice. For this reason the project had to be adapted to the reality of a department that has not stopped his activities during the realization phase and that it have organized and reorganized itself several times in the available space. The distribution of functions was determined according to the doctors, nurses and patients needs.

The design project made by the research group "Policroma", coordinated by Anna Marotta, has affected the Department in its overall image - at least in the corridor - and involved the restyling of some rooms and clinics.

Anna Marotta was activated immediately to implement the project and, involving Sikkens firm [9], has found the donation of the necessary colors. Of course they are not generic color but products suitable for the sanitation of the hospital environment. Sikkens [9] paint manufacturer is the company that is committed to providing all the necessary material allowing "healthy" ways of working for all professionals and the environment.

The project was carried out with absolute emotional transportation and ethical commitment of all who have given their contribution; the only common goal is improving the lives of hospital patients and those living in the medical department even if only for activities of Day Hospital. The project is called from the beginning "life flourishes" in honor of all who fight their disease every day and challenge the fate to live better and with more energy. The awareness that nature helps healing but that is not a substitute for conventional care becomes a necessary condition for understanding how people with depression may find the serenity while controlling anxiety. In this context, the environmental comfort (visual and multisensory) determines the quality of life in care spaces, influencing also the therapeutic response.

Fig. 2: 2012, Anna Marotta with Policroma group. Early drawings for the project definition. On the top: the plan of the entire department and the overall design of the corridor. You can see the overturning of the two main elevations where predisposing the first attempts of communication functions. On the bottom, enlarged, a zoom from one of the walls with the first proposals for stencil: shapes, colors and communication.

Fig. 3: 2012, Anna Marotta with Policroma group. Early drawings for the project definition. Each function is defined from a flower that characterizes, from the corridor wall portion which correspond to that particular activity.

Fig. 4: 2012, Anna Marotta with Policroma group. Each function is characterized by a flower and its color. Flowers and colors become the elements that help the Hospital users not to experience feelings of alienation from space and places of care. Figure 5: The hallway of the Department of Medical Oncology 2 San Lazzaro, University Hospital San Giovanni Battista in Turin after the restyling project.

The fulcrum around which the project develops is the corridor - a place full of activities and flows (routes) - which expresses the whole philosophy behind the intervention. They were chosen colors that bring back to nature and the warmth that every person, especially if weak, want to have around him. The choice of colors and shapes is related to the natural environment and experiences of living common to most individuals, the wall decoration is characterized by a basement of lively green color (the reference to the nature, structures that give rise to flowers) reaching an average height of 120 centimeters - which includes the handrail - complemented by a sunny yellow strip that takes the form of a wave. This is meant to bring to mind the cyclical life path characterized with soft variations (as not often happens in real life). The wall is painted to the ceiling with a lighter tone of yellow (the sunlight). This coloring is the basis for proceeding with the project: the realization of the stencils as a real way finding project, allowing the identification the different department functions. A flower is assigned to each function and each flower will characterize the portion of the corridor where the function takes place. The chromatic restyling project blends and integrates with the patient way finding project within the hospital space.

IBISCUS

CAMPANULA

Fig. 5: 2012, Anna Marotta with Policroma group. Illustrative examples of abstraction that led to the creation of the stencil.

Fig. 6: 2012, Anna Marotta with Policroma group. Project for one of the lounges, photomontage to illustrate the feasibility of decoration and for determining the correct colors according to the same functions.

Fig. 7: 2012, Anna Marotta with Policroma group. Project of decoration of the chemotherapy room. Some poppies placed between chemo's armchairs recalls the flowers painted on the walls of corridor. The poppy is stylized and simplified.

The colors choice that characterizes the flowers of the stencil has been undertaken with the aim of stimulating the viewer in the searching for "fun" of his target, dampening the tone austere of the traditional hospital. They are colors that through different types of contrast brighten the atmosphere. All the senses come into the play: I see the flowers and I feel safe because they help me to orient myself in the space and through them I can also touch the flowers in the space for the therapy. Precisely this is considered the last step to close and complete the whole project multisectoral and multidisciplinary. The idea of involving patients, especially in summer, to take care of certain plants placed in two small terraces of the department comes from the general view of Anna Marotta, who has pledged to seek a donation for A.N.D.O.S. some pots, soil and plants.

The technical department of the Hospital has provided the general plan of the department that has been verified on the spot for the environments included in the project. For bureaucratic reasons we proceeded to

the realization of the corridor in two phases involving the decoration of seven rooms that looked out on it. It was during the realization of the first part of the project, thanks to its first positive results reported by patients, it was decided to proceed with the deployment of the remaining portion affecting even places like the dining chairs for the chemo therapy and the rooms intended for the short stay in hospital. The greatest emotional effect on patients occurred precisely in this phase, at the point at which the old and new - before and after - ward were immediately comparable.

One of the core values of this experience is the scientific field in which it originated, of course it is important to remember that knowledge is never neutral - especially never indifferent - and the results achieved are the result of long studies and analyzes conducted by Anna Marotta during her professional and academic life. The multidisciplinary aspect of the project includes the implementation under appropriate supervision as well as a phase of analysis and verification. The realization will be scientifically tested by psychologists from the same hospital. It is in progress an implementing phase of study on the perception of the intervention carried out through a large number of patients, first users of this new space.

4. Probable development

Sikkens [9] has introduced a range of products specifically for the demands of the healthcare market. In particular for this project they have donated products designed for the sanitation needs of hospitals, tested in their performance:

- *Alpha Sanoprotex*, water painting useful to inhibit the proliferation of bacteria (Classe 1 EN 13300).
- *Wapex 660*: water epoxy product bi-composed for floors and walls. Low odour and low COV content(less than 15g/l), it has been approved by the norm ISO 8690, also applicable in locales with the presence of food (UNI 11021).

These products are characterized by very short processing times that affect their application. The specialized use of these materials is then vital in influencing costs. On the other hand, the company raises the question of further research on these materials that allow the diversification of products and simplifying the process of color application .

5. Conclusions

The importance of a chromatic project can be well explained using Kandinsky's abstract: "It is clear that the harmony of the colour is based on one principle: the effective contact with the soul" (Vasilij Kandinsky, *Lo spiritual nell'arte*) [3]. The colour stimulates all our senses, starting from the eye, it brings up memories, sensations or odours linked to places, sounds, etc...

The comprehension of the perceptive phenomena in their clinical- scientific aspects is well studied by David Katz, Rudolph Arnheim, Gaetano Kanisza – different authors all from the Gestaltheorie School – and other positivists (from Roland Barther to Alexander Lurija). In the same group can be located the colour psychology studies made by Max Luscher [3]. The IACC (International Association of Colour Consultants/Designers) bear the argument that the "colour consultant" is a real job.

It has been shown that the environment in its whole vehicles important messages which can be interpreted from the patients and from the workers in different ways. This can influence the results of the cures. The goal that will be achieved in any case will be the improvement of quality in the hospital life through a focusing on aspects of humanization, like giving more colour to the everyday work.

To end a quotation from Paul Cezanne cited in the book *Policroma* (Celid, 1999) by A. Marotta[3]: if "it exists a coloured logic", then can also exists an ideal, cosmic and vital "polychrome energy" generative of a will of knowledge and comparison, desire to feel and express, curiosity to experiment and create through the colour.

Abstract:

The identity reflects the actual substantial features of anything that distinguishes it from others. The cultural Identity of any nation consists of the most essential, stable, and common features and general subjects that distinguish its civilization from others.

So, the identity is one of the most important elements of a successful design, which gives it uniqueness and originality. It doesn't mean that the identity should inspire a complete design, but the intent is the availability of the spirit of identity in the design. There is no doubt that the Arabic identity has been involved in the system of Global Cultural Production and that various Arabic/Islamic arts remained as one of the most essential components of the Arabs' identity.

For that reason, researchers chose to use the identity as one of the elements of uniqueness and originality in design to develop the creativity of the Fashion Design students through the development of innovative designs inspired by the Saudi identity that could contribute to the apparel industry in the Kingdom of Saudi Arabia.

Keywords: Saudi national identity; Originality and Creativity; Fashion Design; Garment Industry

Introduction:

Privacy civilization of any nation is based on several axes of the most important cultural heritage that preserves national identity of the nation and distinguishes it from others, which maintain the identity and heritage in the light of rampant globalization, a force which dominated largely, as a pretext of urbanization, and thus melt the nations and the civilizations, that has to preserve the cultural heritage and provide for its civilization, Because the fate of modernity is to return to the heritage .

So here is the question: Why study heritage, if our goal is to design the future? One answer can be found in philosopher George Santayana's famous proclamation, "Those who cannot remember the past are condemned to repeat it". This quotation is widely used to argue that exploring the past helps us to understand who we are today and where we are going. For ubiquitous computing, historical awareness can deepen designers' understanding of the context they are designing for. [8]

Identity as a concept has social and physical connotations. It constitutes a collection of cues recognized by a group of people at a specific time and place. People and places, however, are exposed to change over time. In that sense, identity may change and people may resist this change because they want to feel that they maintain a certain level of continuity. However, continuity of identity is a very debatable concept. Every society faces a real challenge to maintain its identity for any length of time, especially under conditions of rapid economic and technological change. It is important to understand how the concept of identity is perceived by people and designers.

This raises the following questions:

- *What do we mean by identity?*
- *How do people express their personal and social identities?*
- *Is there any action we need to take to maintain individual and social identity? [7],*

So the identity Reflect the fact of the absolute thing which is containing substantial features that distinguish it from others ,and it is one of the elements of successful design, which gives him uniqueness and originality, doesn't mean that one is dying a complete design identity, but its intent is the availability of the spirit of identity in the design.

One of identity's kinds is The cultural identity which is one of the main elements of the national identity of Nations and one of the most important aspects that distinguishes a nation from another, because the dominant culture in a society is just an extension of the legacy of civilization and cultural heritage of the nation handed down from grandparents to their children to mix their experiences, and then they develop it according to the data of their time being. [4]

Another think that cultural Identity of any people is the stable, hard, essential common features, and general subjects that distinguish its civilization from others, it is worth mentioning that the concept of "contemporary does not mean subordination and the commitment of the other"; it means to contribute in the arena of contemporary thought to provide original and not copied. It remains the intention, to increase the stock of creative and not repeated world. While heritage is stock of philanthropy, it is not determined in time that has elapsed, but in time continuous, one to the other .

Throughout the lifetime of an individual, culture surrounds and shapes the individual in ways that are barely recognizable to him. What people know and think are the mentor acts of a culture, which includes ideas, ideals, values, knowledge, and ways of knowing and part of it would "know how to dress".

Dress includes more than clothing, it includes a wide array of other supplements and attachments to the body, such as makeup, masks, shoes, headdresses, wigs, accessories, and hair plugs. Appearance and dress often provide the most immediate and apparent visual cues about age, gender, ethnicity, social status, and social roles. Dress is more than objects and materials people put on their bodies. Dress can be a sign or symbol that refers to and stands for meanings. It expresses personal values and values of the society in which and individual lives. The physical body when dressed reflects the "social body" or surrounding societal system,so, we express much through dress, including our personal identities. A phenomenal amount of information is transmitted in one appearance. [5]

Dress is one of several modes of nonverbal communication, which means that it does not involve verbal expression through speaking or writing and it is often tends to be stable or unchanging for many hours of the day so, a wearer puts clothing, hairdo, accessories, and grooming together to produce an appearance and may assign meanings to that assembled appearance. Each observer of the appearance may agree or disagree with it. Disagreement does not mean that communication stops or fails.

Throughout much of the world during the late 20th century, dress meanings tend to be vague and hard to verbalize. A certain appearance may tell thousand words, and those thousand words are hard to pin down. In addition, changing fashion trends continually modify meanings of dress, adding further lack of clarity of meanings,in contrast to the modern attire worn throughout the world today, dress in traditional cultures tends to change slowly over time and may incorporate long-used symbols that are attached with meanings.

The idea that appearance styles or looks are negotiated as people influence each other on what to wear and how to wear it is fundamental in understanding social processes of fashion. Places and communities have identities, which is no longer restricted to geographical location. It is possible to be influenced not only by immediate, local, cultures, also by globally circulating images and commodities.

Constructing and reconstructing appearance and, in part, identity, becomes a process of figuring out how we fit in and depart from a vast array of possible looks. To some extent we want to express our inclination and ability to belong to certain groups and communities. Yet somehow we balance this desire with assertion of individual uniqueness. Identity politics are involved in process of imitation and differentiation. Issues of gender, race and ethnicity, sexuality, nationality, social class, age, and leisure time preferences all enter into the creation of the group in which we see or do not see ourselves. On a cultural level, we seem to be collectively working through ideas about what appearances say about individual, community, national, and global identities. [3]

There is no doubt that the Arab identity has been involved in the system of global cultural production and the various Arab arts remained an essential component of the identity of the Arab.

Saudi Arabia has seen a great development in various fields of life, which led to the extinction of many of the customs and traditions, especially in the clothing, which leads to the disappearance of a large part of the heritage of Saudi Arabia and there is no doubt that the art of fashion design influenced greatly, when the design style used in the Kingdom of Saudi Arabia, does not find an answer to this question of the absence of method, after what he characterized this art in the past in a unique style and privacy of an absolute.

In addition to that the Kingdom of Saudi Arabia seeking a comprehensive development in all fields, especially in the garment industry in order to raise the level of the economies of the country's sound and scientific means and methods. They gave garment industry some importance, because it is one of the necessary industries, and to keep pace with global developments, especially in design, supporting those involved in the incumbent garment industry in the Kingdom and developing the process of delivering a product with originality and uniqueness in the same line with trends in international fashion, prompting the researchers to use the identity as one of the elements of uniqueness and originality in design, supporting the development of creativity and innovation of students of the Fashion Design department - Dar Al Hekma College in Jeddah, Saudi Arabia, and through the preparation of innovative identity designs, which can contribute to the garment industry in the Kingdom of Saudi Arabia.

Hence, the research problem, which unfolds in the following questions:

1. What is the fashion link provided in the Saudi Arabia national identity?
2. What are the scientific steps to achieve Saudi national identity with development of originality and creativity among students of Fashion Design Department, Faculty of Dar Al-Hekma?
3. What's the importance of the student's designs for the customers and the garment industry in K.S.A?
4. What is the role of educational institutions to support the garment industry in K.S.A?

Research objectives:

1. The use of identity as one of the elements of uniqueness and originality in design to the development of creativity and innovation for the Fashion Design students - Dar Al-Hekma College
2. The preparation of innovative designs with Saudi identity, which can contribute to support the garment industry in the Kingdom of Saudi Arabia.

The importance of Search:

1. Find help in providing fashion with Saudi identity and fit at the same time with the international fashion trends.
2. Supporting of the policy of Fashion Design Department, Faculty of Dar Al-Hekma in support of the garment industry in the Kingdom of Saudi Arabia.
3. Recognize positivity of Dar Al-Hekma College and its understanding of the role placed upon it and its mission in the overall development in K.S.A.

Search terms:**Saudi national identity:**

National identity is not formed in a vacuum, but is a composite of individual people. [6]

Originality:

1. The quality or state of being original.
2. Ability to think or express oneself in an independent and individual manner; creative ability.
3. Freshness or novelty, as an idea, method, or performance. [9]

Innovation:

1. The act of introducing something new.
2. Something newly introduced. [10]
The researchers believe that creativity is the invention or designing something new unlike the tradition that goes behind the creative, the creator creates the design or production of something then go to be innovated in another area.

The garment industry:

Makers and sellers of fashionable clothing. [10]

Research procedures:**Research Methodology:**

Research follows both the analytical and descriptive approach quasi-experimental approach so as to achieve objectives suitability of the research and check the homework.

The research sample and limit:

The research has been applied on 13 female students from the Department of Fashion Design - Dar Al-Hekma College - Jeddah - Saudi Arabia - for the academic year 2012 spring semester.

Research tools:

1. Questionnaire is used to survey the opinions of the producers the student's designs.
2. Questionnaire to survey the opinions of consumers in the student's designs .

Steps of the research:

The researchers took a number of actions to reach the objectives of the research, and answer the questions of this research problem.

Procedures are summarized in the following:

1. The researchers gave a lecture to the students to define the research goals and its importance.
2. The students made brainstorming on the subject of Saudi identity without interference or influence from the researchers.
3. Each student identifies a number of words that inspire the identity related to Saudi Arabia. The researchers discuss the motives of the students in the choice of words and extent of their relationship to Saudi identity.
4. The students collect images that are directly related to the words chosen by each student to be a preference to the photos by themselves.

5. Students are identifying the appropriate images that have details which can inspire them.
6. The students prepare Mood Board to help the students to highlight the a general idea
7. The students do the observational drawing for what they see in the images as to inspire them, coloring the drawing, using different mediums.
8. Observational drawing is displayed to the researchers, brainstorming them to explore how to be inspired by.
9. The students make a customer report and choose the target market through a number of interviews with numbers of customers
10. Researchers start a discussion with the students and review the target market and clients compatibility with the product to be designed
11. Students express the target market and the client by preparing customer board
12. Students prepare fabrics designs which are inspired by the observational drawing.
13. Researchers discuss with the students the proposed designs of fabrics, and method of preparation to reach the appropriate quality.
14. Students do the real fabrics according to the preset design using different methods of fabrics preparation and decoration (such as printing - dyeing - Embroidery - beading - patch work - raw materials), and the innovations of all styles of students.
15. The students design and prepare for the fabric board.
16. The students start in the preparation of designs inspired by the observational drawing.
17. The researchers discuss with each student the sketches prepared by and how it fits the source of inspiration and their compatibility as a design with each other, and give advice and guidance if the students need that.
18. The students choose the final collection of designs and draw it neatly.
19. The students choose the color combination for their collections by selecting colors from one of the images that were collected prior and inspired by the Saudi identity.
20. The students color the designs and then select the appropriate accessories for it.
21. The students prepare the collection board and submit them for display.
22. Each student required to present 4 boards as following:
Mood Board,customer board,fabric Board,Collection Board

The research results:

After the students did the boards,The researches are displayed the Designs for a sample of consumers which is consist(30), and sample of producers which is consist (7) of producers and fashion houses in the Kingdom of Saudi Arabia, Jeddah ,and the following table will show the iterations of arbitrators (**consumers-producers**) answers and the percentage of agreement for the arbitrators (**consumers-producers**) for the students designs .

Fig. 6: shows Table for the occurrences of the arbitrators answers (customers).

The above table shows that:

Collection (1), ranging from (70% : 93.3%) and all counting rates are high
 Collection (2), ranging from (76.7% : 100%) and all counting rates are high
 Collection (3), ranging from (73.3% : 100%) and all counting rates are high
 Collection (4), ranging from (70% : 100%) and all counting rates are high
 Collection (5), ranging from (86.6% : 96.7%) and all counting rates are high
 Collection (6), ranging from (70% : 86.6%) and all counting rates are high
 Collection (7), ranging from (76.7% : 93.3%) and all counting rates are high
 Collection (8), ranging from (86.6% : 100%) and all counting rates are high
 Collection (9), ranging from (76.7% : 100%) and all counting rates are high
 Collection (10), ranging from (80% : 93.3%) and all counting rates are high

Collection (11), ranging from (76.7% : 93.3%) and all counting rates are high
 Collection (12), ranging from (80% : 100%) and all counting rates are high
 Collection (13), ranging from (73.3% : 96.7%) and all counting rates are high.
 So the previous results indicate high acceptance of designs by the consumer which is answer the research questions.

Fig. 7: shows Table for the occurrences of the arbitrators answers (producers).

The above table shows that all the Collections ranging from (71.4% : 100%) and all counting rates are high.

From the previous results , we find that the almost of student's designs have the Saudi identity and in the same time match with the international trends and it suit for the Saudi women and can find a good market here, which will support the garment industry by offering new trends in the fashion market and by that we can consider that the students achieved the creativity in their designs because they could offer original and new designs in the Saudi market which is accepted and by that the researches answers the problems questions .

Prototype design. Recycling, eco-compatibility and de-contextualization

Antonino CALDERONE,¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Aversa, Italia
antonino.calderone@libero.it

Abstract

Every prototype is the result of a series of actions aimed at transferring in the final output that little extra something which meets and satisfies all customers' demands. Of course, for these reasons the definitive object prototype has to be just alike the output, be it a tapping screw or a medical prosthesis, or a part of machine, or a component of engine, or a design product. As we know, the processes of original design are prototyping, testing and making. As I have tried to explain in this last seven years to my Industrial Design and Fashion Design Courses students, the product meant to the industrial fabrication, less or more automated, is the result of a series of considerations of complex nature (material and immaterial) and comparisons with contemporary homologous production, that take place during the different phases from the concept to the fabrication up to the retailing. Sometimes it's necessary to rectify technical adjustments and improve possible innovative organizational and management processes. There will be feedback relating to project reviews, method of manufacture, shape modeling, materials, practicality, manufacturing costs analysis, logistics respects, packaging, storage, quality control, up to just in time fabrication. But this is unsatisfactory: one has to bear in mind eco compatibility instances, e.g. recycling programs, issues relative to LCD (Life Cycle Design) product and sometimes those ones concerning ethical, educational and cultural plus value too. Independently of possibility to the use of fabrication machines, we have worked towards examination and cognizance of the shape and function of the prototype, the base of any additive or subtractive method of fabrication, it be handmade or automated, preferably testing recycling methodologies, or de-contextualizing materials such kevlar and carbon fiber. At the first step, the pencil sketches and, if possible, the handmade fabrication are still the best ways to realize an intrinsic contact with the embryonic concept and its initial developments. Otherwise I have remarked that even in the drawing step some students prefer the immediate use of CAD; I have to confess that sometimes the results are even appreciable. It's a new kind of sensitivity, often more standardized, but in any case able to find a synthetic fusion between formal and technological layouts. On the other hand, this is similar to what has happened in writing since the introduction of Microsoft Word, that has surely influenced it displacing creativity from the pen world to the pc keyboards one.

Key words: eco design, multi functionality decontextualization, tradition-innovation, landscape.

1. Prototyping between research and teaching

In the homework and exam work, we have tried to establish, as a starting point, the search for the optimal intersection point between shape and function, so as to ensure a good symbiosis between technological and practical aspects on the one side, aesthetic and formal qualities on the other side. For this reason, we have made it clear that those industrial aspects whose project is characterized only by a study of components and of functional and technical aspects (e.g. components of an engine, circuits of engines, pieces of machineries) does not belong at all to the field of design, in much the same way as we cannot regard as parts of design those products deriving uniquely from a search of volume or shape. In the prototype shown in Figure 1 we have experimented the manufacturing-by-subtraction procedure by removing wood shavings through a table milling machine monitored numerically and a finish with the help of a device of length/thickness 10mm. The opportunity of using a true milling machine that makes it possible to employ a subtraction process has made it appear as less relevant the problem of having to choose a material different from the one originally conceived for the bottle: glass or pet. As can be seen, it is a simple object in charge of containing drinkable

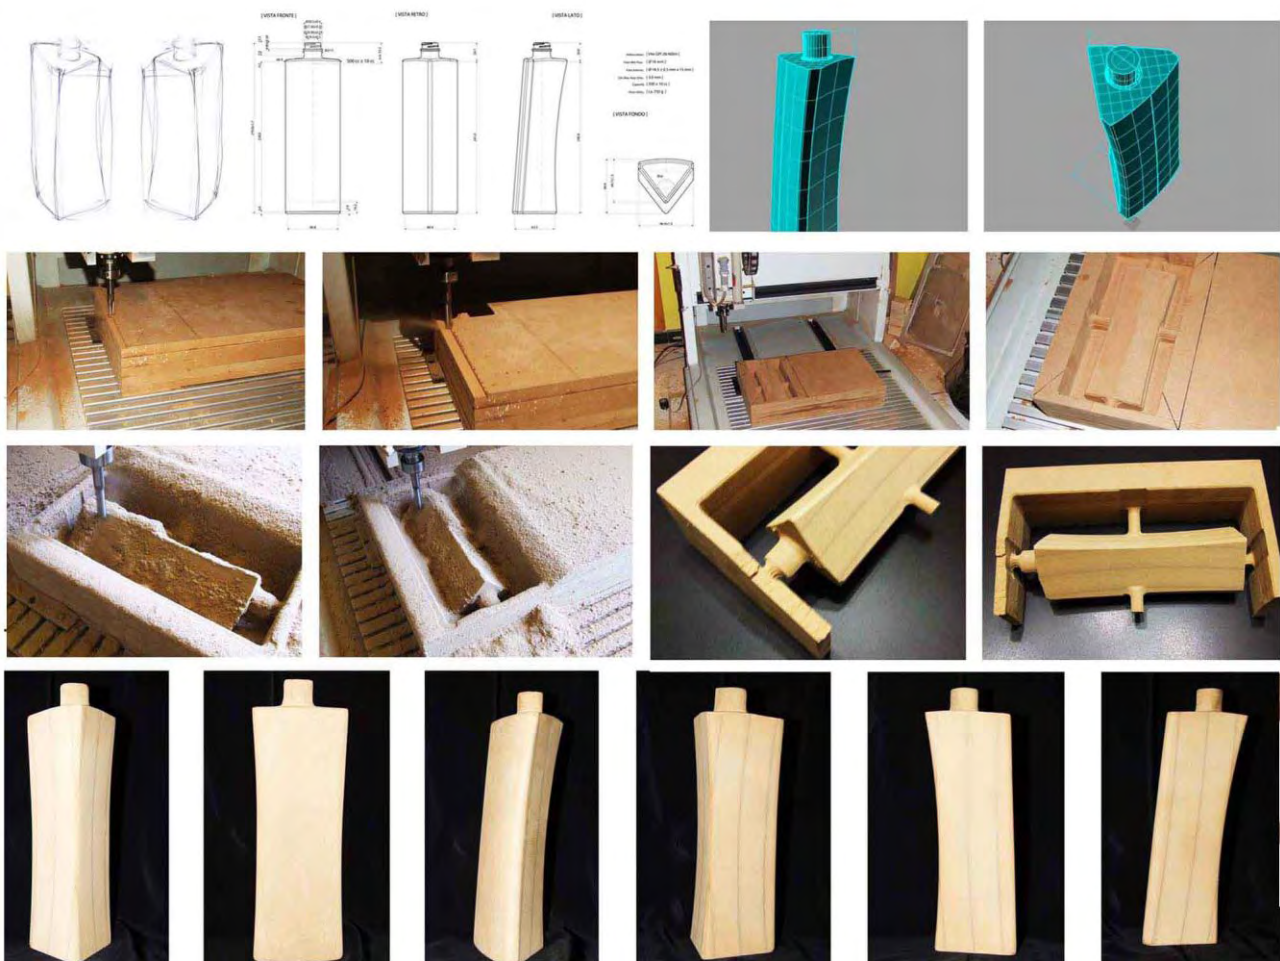

Fig. 1: Design and prototyping of a wood bottle by subtractive fabrication process. Computer numeric control (CNC) milling by removal of chip and CNC finish by 10 mm utensil. (Student R .F. Nicolò)

liquids (water or fruit juice). Anyway, we have performed all actions that characterize the various phases of a correct project; we have elaborated a series of drawings to search for the best shape, so as to find the correct winding procedure for the bottle top, trying to obtain the appropriate correspondence between formal identity and affordance, while paying much attention to the size of the object. In this example we have not passed through an actual ergonomic study for the handhold, even though we have taken into account shape and size so as to obtain a bottle that can be easily handled, despite it is here clear that we are eager to achieve an essential style with a definite shape. In the subsequent stage we have replaced the preliminary drawings with technical drawings with the help of the CAD software. Last, as far as the building up of the object is concerned, i.e. its prototype implementation, before passing to the final experimentation with the help of wood, models with plasticine and clay have been built, and during such intermediate stages it has proved useful to improve the acquaintance with techniques for such materials, in particular the techniques dealing with dried clay and with dung inserted into printouts created ad hoc and later cooked at 130 Celsius temperature. It is worth pointing out that, according to different choice of material, not only is the primary role of the object completely changed, in disagreement with its nature, but also its symbolic role and its message to the exterior world get spoiled. Also in other homework, for strictly pragmatic reasons, in light of the modest tools at our disposal, in the majority of circumstances we had to perform a sort of translation in the choice of materials, distinguishing between those which are peculiar of the project and those which merely help in the effort of experimenting the manufacturing procedure, which should indeed remain the final goal of a course in Prototype Implementation Laboratory. In some cases we have paid less attention to the degree of originality of the concept, choosing to pass directly to the implementation phase of objects actually existing

on the market, or inspired by the production of great leaders (Maestri) of historical design, which is still available on the Market thanks to the proposals of Industrial Companies which, in light of the great demand of the market, have reproduced their principal models; sometimes there has been instead a true assessment of the main aesthetic components of the existing product, so as to vary or widen out its role, or to create the formal excuse for a wider operation, knowledge- and form-oriented, related to the themes under investigation. We have therefore gone ahead by following the redesign or restyling criteria, according to Dorfles, criteria followed, as is well known, by several design industries dealing with house interiors, in their effort of proposing again some cult objects first created by some great architects and designers of the past. On the other hand, in several industrial processes, for example those of car industries, the restyling has been chosen ever since so as to keep on the market, thanks to slight changes of aesthetic, functional and optional nature, the production of some models of cars, while waiting for new models that take over. Of course, such choices rely upon a series of involved strategies related to problems of economical and productive nature that should be described in a separate context.

2. Targets and aims

As far as targets and aims of the course are concerned, in all cases, in order to help developing a critical attitude on the side of the students, we have always tried to encourage them in such a way that, even just through the mere experimentation of redesign and prototype implementation, they can manage to find a good excuse for starting a sort of regeneration or semiologic renewal of the product. In some cases, the revision procedures have been able to change completely even the meaning and the peculiar properties of the product in light of new ideas and of the most recent advances in knowledge. The capability of creating so as to enhance a social and environmental action, is nowadays, even more than in the past, a distinguishing feature of the designer. Precisely for this reason it is ethically correct, on the side of the designer, to make the best possible use of his role, being aware that he can give rise in due course, with the help of industries, to an authentic sustainable reeducation of the individuals' conscience through an evolution of taste, and making sure that the renewed needs of the consumer and hence of the market become compelling needs. In the homework, the difference between project making and experimental implementation of the prototype has been more visible in the case of objects viewed with an eye to technologies and materials of last generation such as composite materials. This has nevertheless made it possible to give rise, with greater consciousness, to deeper searches and different deductions that stand on their own, linked on the one hand to the peculiarity of the original project, and relative on the other hand to the prototype to be realized in order to pass the exam. Anyway, the investigations on problems relative to the capability of inserting or not in a production framework the object designed have not been lacking, based on consideration of its peculiar properties, nature of material, methodological and operational tools. We have delved into the various issues related to prototype implementation and industrial reproduction; with the help of ministages, and simulation of industrial scenarios it has been possible to approach cases where checks, revisions and feedback have been performed on the concept and project for a better insertion of the product in the market strategies, until its completion was achieved just in time. At the level of classroom laboratory, we have gradually added the investigations on the optimization of manufacturing techniques and on materials used to achieve prototype implementation. Having established this as a firm point, besides the material eventually used to realize the prototype, which in some cases was the result of further deepening, every project has been always and invariably inserted within a production framework and supplemented by a market analysis, devoted to costs, incomes, possible production risks, sustainable quality and environmental compatibility, emphasizing in some circumstances the deepenings concerned with higher or lower level of adherence to ethical questions.

3. Handmade prototypes and fabrication technologies

As far as totally handmade prototypes are concerned, it has been clearly deduced that, for some of them, the foundations were lacking for being able to talk about industrial production. On the other hand, it is precisely in these cases that, in the experimentations, we have preferred to give priority to manual control of form, so as to make sure that the object works properly and that the aesthetical outcome is the best possible. Several prototypes have been conceived so as to witness a symbolic cultural value, resulting from the evolution of lifestyle. Thus, their commonly accepted meaning has been replaced by a local cultural value, in the name of the southern nature and of the recovery of local traditions, while bearing in mind the renewed needs for recycling and intelligent reapplication. By the way, some class work has provided the excuse for investigating traditions of Campania region and southern Italy, our productive handmade and industrial activities, and we have tried to unify tradition and innovation, taking inspiration from working techniques of the past and adopting materials that are typical of our environmental and productive landscape. In general, for the

prototypes we have studied also packaging systems and ad hoc logos, including graphics, that might have been able to express the underlying themes of the product, its target, and could have made it easier to display its peculiar properties in case it is put on the market. Among fabrication processes and materials more frequently used during prototype classrooms one should mention laser and covered-lamp stereolithography, turning, milling, the straining of silicon rubbers in ad hoc silicon moulds, wax and plasticine, balsa wood, polystyrene, dried clay, clay, dung, honeycomb cardboard, corkboard, wood, ecoskin (law UNI 11427/2011). Recycled materials have been used such as tins, light bulbs, glass and pet bottles, bottle tops, clippings of cloths, wires of intimate clothes, broken vinyl pieces and greatly many other.

4. New materials and new key points. The carbon fibre from airplanes to furnishing

The advanced design has always played the role of general program of vanguards. The chair is one of the most fascinating and beloved objects from designers. On it, all most important actions in the life of human beings take place, from eating to signing contracts, as Rossella Colombari, gallerist and great supporter of the work of the architect Carlo Mollino, would put it (she has recently given a plenary speech at a Conference in our Faculty). The chair has inspired experimentations also during our courses. At the end of the fifties, with the advent of the Panton Chair (1959-1960), a revisitation is made of the Zig-Zag chair introduced by Rietveld almost thirty years earlier, in 1934. The Rietveld chair was representing a sort of monument of the neoplastic design, with its roots in the van Doesburg geometries, and it is still a sort of "manifesto" of the new ideas put forward by that group of artists, architects and sculptors who stayed together at Leiden in the name of the "de Stijl". The spatial and winding coherence of the Panton Chair, named after the Danish architect who signed it, initially produced in plywood and reproduced, in the nineties, in painted glass fibre (Hermann Miller – Vitra), pushes to the extreme consequence the concept of spatial suspension of the sitting act, and softens the rigidity described by the Rietveld lines, which was realized, in addition, in a traditional material, i.e. cherry. Moreover, it moves the emphasis of the project on the side of the ergonomic study, that was instead nearly absent on the chair of the Dutch architect, who was attracted by the geometric three-dimensional misalignment of the planes, and wanted to recover in sculptural shape, through the wood, the particular decomposition that his fellow Dutch, Piet Mondrian, elaborates in painting. At the end of the seventies the reproduction of the Zig - Zag chair, revisited by Mendini himself (1978), despite being much closer to the ancestor chair as far as material and shapes are concerned, becomes the excuse for an irreverent religious theme, given by the cross-shaped back, a way to state that rules and tradition should be carefully studied and well understood before being turned upside-down without worries. Other redesign examples that come to my mind are the contemporary Pick Chair of the Dutch Dror Bensherit (produced by BBB Emmebonacina): it also reminds clearly of Rietveld, but becomes mainly the excuse for developing the multifunctionality to which it tends more than ever in an epoch during which the internal space becomes always a precious thing: it gets turned into table, cube and even panel, according to the various needs. Relying upon such examples, during classrooms, we have developed prototypes which, on the one side, were including the peculiar features of Zig-Zag and Panton chair, and on the other side were becoming the excuse for deepening the structural aspect of the carbon fibre, mainly used to strengthen composite materials, in particular plastic polymers. The various categories of carbon fibres have different elasticity parameters, mechanical resistance and density. On the chemical point of view, the technological procedures linked to carbon make it possible to drive the molecular chains along the direction of the fibre, and to create tissues (even mixed up with glass fibre, kevlar and so on) of different substance and orientation, depending on the rigidity features and pressures that the object should be able to sustain. As was learned during the various visits, with students, of excellent industries in Campania such as A-technology s.p.a., and thanks to supplementary teaching activity of one of their leaders, the engineer Angela Pozzi, expert in composite materials, invited for this purpose by the undersigned, we have at our disposal composite materials strengthened with continuous or discontinuous fibres, and they can be of oriented, random or hybrid type. The carbon is well known to be a material of great potentiality and lightness; it may display very high rigidity and resistance when subject to traction or torsion or compression. Its use is, after all, still partial within the framework of design, being still confined to industrial production in the areas of aerospace engineering and car racing. In this respect, since the year 2009, the production of airplanes for civil airlines which use largely the carbon fibres has been initiated; for example, the 787 Boeing consists, for more than 50 per cent, of carbon fibres.

5. Evolution of the shape

Despite all this, assuming as a prerequisite that the designer should know how to affect the market and

Fig. 2: The *Tape Chair 2010 Design* is conceived in carbon fibre, along the lines of the *Zig - Zag* revisitatio to which it adds the *Panton Chair* shapeliness, but the prototype, in reduced scale, has been realized in copper foil.

reduce costs and prices of a product as its demand grows, it is worth pointing out that the use of the carbon fibre or yet other materials of the last generation within the framework of domestic design and furnishing is really revolutionizing the taste of consumers. Logically, it is a closed loop: the new forms of design evolve on the basis of experimentations; in due course they turn into true dictat the needs and renewed desires of an increasingly large portion of consumers, which in turn enhances the demand. The surface table with ultrathin carbon fibre, created by the designer Terence Woodgate and the Formula 1 engineer John Barnard for the English industry Established & Sons, exposed at the Casa Ferrari museum as a true masterpiece, is long 6 metres and exploits the intrinsic rigidity of stratified carbon fibres. It represents an example of how far can one go in terms of technical renewal, and hence in terms of change of aesthetic taste. Even in the field of musical instruments, already at the end of the eighties, also in Italy, many viola, violin and violoncello players were using arcs in carbon fibre, regarded at that time a great innovation for their lightness and their quick response when the string is hit by the arc. I, myself, being a violinist before being an architect, I have often used carbon arcs and I have noted an elasticity that, in some sense, was making life look easier during some passages of undisputable difficulty for the arc. Reverting now to the production of industrial design, let us recall, among the many, carbon resin examples such as *Hot Rider* of Jordi Mila` or *Din Don* of Romolo Stanco, of thickness 15mm, or the *Oscar Bon* chair of Philip Stark (Driad); yet again, the *Tite lamp*, winner of the prize *Compasso d'oro 2001*, by Marc Sadler (produced by Foscarini), made in Kevlar, a synthetic fibre 5 times more resistant than iron or glass fibre. The *Tape Chair 2010 Design* (Figure 2), prepared during the 2009-2010 course in prototype implementation, is conceived in carbon fibre, along the lines of the *Zig-Zag* revisitatio to which it adds the *Panton Chair* shapeliness. The further reduction of thicknesses, gives to the object a greater lightness with respect to the *Panton* model. The structural texture of carbon fibre becomes at the same time an element of pleasant and elegant visual impact, and is a single thing with the surface of the chair, and is not a mere decorative element. The prototype realized in reduced scale has not been realized in carbon fibre but in copper foils, with the help of a handmade procedure. The wood mould and countermould have been built in reduced scale and modelled with a blade machinery (subtraction principle), after this some copper layers have been inserted (until the desired thickness was reached), pressed in between mould and countermould in such a way that they take the desired double-curve shape. Last, the sheets modelled in this way have been glued together (hybrid procedure: addition and conformation methods). As always, intermediate and final checks have been made, reflecting therefore on the shortcomings of procedure, materials and devices, in this case rather inadequate, in particular for the purpose of managing profile curves.

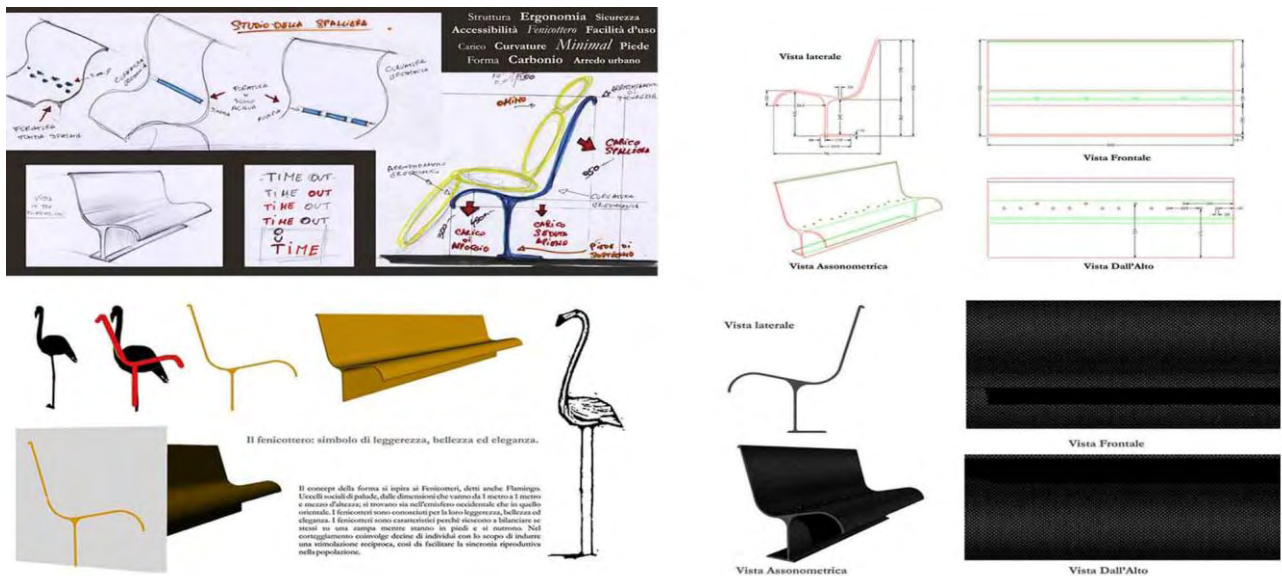

Fig. 3: *Time out*. Design of a bench conceived in carbon fibre and realized in copper foils (Student: M. Policano)

6. Polymeric resin prototypes and composite ones

In other cases it has been possible to become familiar with stereolithography processes, albeit sometimes with reduced scale prototypes. The “24 hours suitcase” (Fig. 5) has been only an excuse for testing the use of the CAM (Computer Aided Manufacturing) software, i.e. an additive production machine that makes it possible to build an object in its various parts through the stratification of resin materials sensible to light and empty bath processes, i.e. according through the so-called selective light-induced hardening procedure. In such a case, the project elaborated with a CAD software, Rhinoceros, has been directly red and printed in three-dimensional way from the machine according to the fast prototype implementation criteria (RP rapid prototyping), and hence one finds evidence of full correspondence between “render” and prototype. This is the clearest case where the project phase has played a secondary role with respect to production: we have a project with no innovation potential, which does not add anything to function and shape, without mentioning the lack of symbolic value that an object in the framework of design should have. Yet, it was worth pursuing it. We have also built objects for a real personal use such as the Kitesurfing table, a sport that is becoming increasingly popular among youngsters, which is played, exploiting wind speeds in between 12 and 24 Kts, thanks to an appropriate table and a kite manoeuvred through a bar linked to it by cables of dyneema, a synthetic fibre appropriate for the production of traction cables. The elaboration and research work, culminated in project making and production, consisted in four main phases, all suitably described by means of images of the various steps: analysis of what exists and informative contributions to the concept; profile of a model existing on the market (state of the art) as a reference for dimension and composition; project with development of the three-dimensional mathematical model; prototype implementation. In light of a series of considerations of technical and structural character, we have tried to pursue a thinner table with respect to the tables available on the market, mainly formed by thin layers of wood covered by resin. We have focused on the best possible properties that the product should have, giving priority to a greater lightness, mechanical resistance and flexibility. For the purpose of further and intermediate dimensional verification, we went on to realize a vinyl model. Last, after further deepening on the features, we have built the final version of the model. The material used for the Dibond prototype, i.e. a panel consisting of two Aluminum layers of thickness 0.3 mm with a polyethylene nucleus. The Dibond is used also for the furnishing, for covering walls and columns and in all other solutions that require a material with extremely planar surface. It can have a variety of sorts of finish. For the double curvature of layers we have realized an iron template, evaluating the desired deformations. After gluing the layers, we have implemented their lateral lock and their lock with the template. To obtain a permanent deformation, the prototype has been pressed for nearly four days in the template.

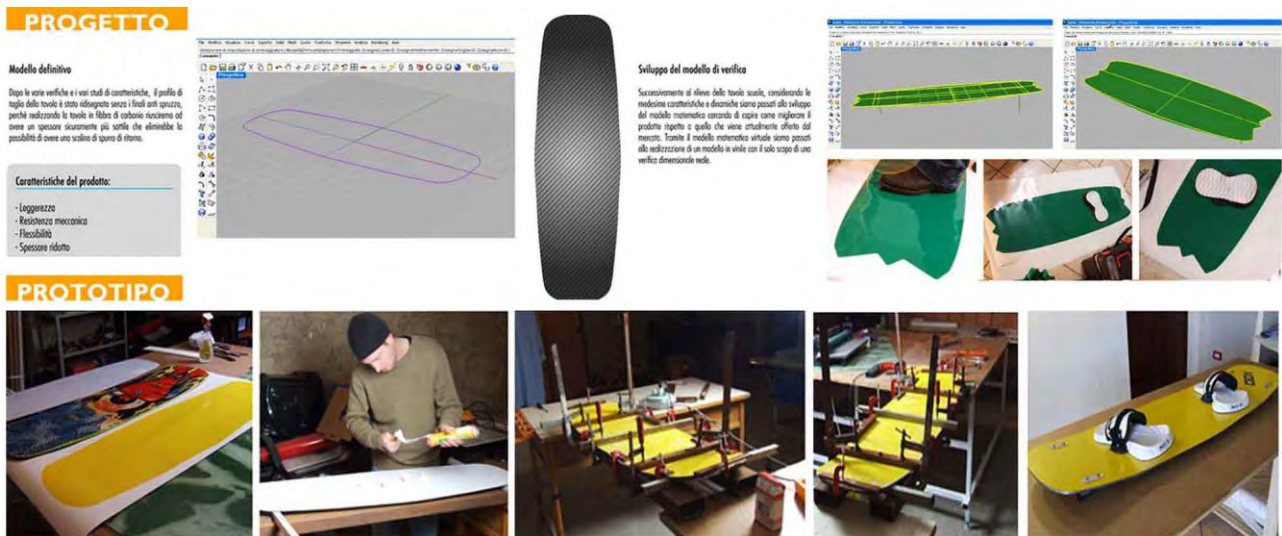

Fig. 4: Design and pictures showing work in progress and final prototype of a kitesurf board realized in Dibond (Students: R. Noccolò, A. Prigiobbo).

After such a phase, we have performed drilling and assembly of pinnules, pad and handles. To sum up, it has been a job that has forced interested students to a truly full immersion in the problems resulting from the attempt of building a Kitesurfing table, and in light of the good results obtained one can say that the aim of the classroom has been completely fulfilled.

7. Production and Eco Design. The competitiveness on the basis of sustainability

Undoubtedly, on the side of experimental manufacturing, in some home works we have taken second place the application and the problems relating to recycling matters, as LCA (Life Cycle Assessment) and its derivations, i.e. Eco Design and Environmental Design, that define the guide lines of the System – Output Design. Anyway, several works in which we have decided to apply the principles relative to eco sustainable design, low impact technologies and environmental friendly output - prototypes have not been lacking. On the other hand, on recent investigations it is possible to deduce that the increasing sensibility to themes related to degradation of environment and the raise in demand relative to goods and services in accordance with specific criterions of certified quality on the basis of international standards and laws have gradually diverted market towards natural outputs. For example a part of market has been turning round wood ones, certainly because of their beauty, but also because of their lower ambient impact. Perhaps in this context it wouldn't be necessary to underline it, but I should like to take this opportunity to remember that their real ambient sustainability is the consequence of a concrete sustainable forest management, i.e. of the balance between the quantity of cut trees' wood and the quantity of trees that are growing in the forests, balance that it's possible to reach only if new plants are really replaced in the place of cut trees. But it's not enough! To start a virtuous circle it's necessary to safeguard habitat even through the respect of the wellbeing of workers, forests' owners, local people and promoting the local progress, being aware that these are indispensable behaviours from which the health and the survival of the same forests depends. This could be and should be guaranteed by mechanisms and external certificates related to the conformity of the management and clear rules which could be complied with, to facilitate the commerce and the increase of the output profitability. Thus the rational use of resources must necessarily become a competitiveness factor for the companies on the international market just like other factors, i.e. price, quality, design. On this front Italy is still very backlog, but the virtuous examples have not been lacking, e.g. the Swedish and Canadian ones; differently, what is missing in our country is a serious programme of reforestation and, in some areas, a real education, as well as an efficient awareness campaign about these problems and measures. Having said this, besides the close examinations about "technological" materials, that often haven't a low impact on the environment, I have tried to sensitize students' awareness about the use of natural materials, not of animal origin, such as, precisely, wood and cork boards that not only spontaneously regenerates and is a long standing material, but is not toxic, transpiring and non-flammable too.

Fig. 5: Renders and prototyping of a 24 hours suitcase in reduced scale (Stereolithography) (Student: G. D'Amico)

8. Cardboard prototypes

I have also illustrated to my students the innovative and intelligent use of cardboard, that is fully ecological, being recycled and recyclable. It combines weightlessness with resistance and it's cheap too because the final output costs less than other ones realized by different materials. Furthermore, the whole process of mounting and fitting, even during the marketing campaigns, turns out to be economical because of the pliability of this material, starting from the easy and fast assembling/ transport/ disassembly – even for not experts – to the waste disposal. Versatility, easiness of movements, strong communicative value and, at the least, but not the last, undoubted aesthetical quality, are some of the features of the cardboard. It's no accident if all that has excited the fantasy of many famous and minor designers that have fully tested the features of the cardboard, creating variously shaped objects, previously unthinkable. Among others we remember F. O. Gehry that in 1972 created the wavy cardboard Wiggle Chair, produced by Vitra. Even the students of the course in Prototype Implementation Laboratory have fervently applied themselves into the making of cardboard prototypes, often directly recycled by themselves. Following famous models or on the basis of new projects, from time to time, they have converted it into bookcases, seats, chairs, shelves, toys, jewels, gadgets; all these objects had the common denominator of showing cardboard terseness, enhancing, never disguising, its natural peculiarities. In principle and for these reasons we have been excluding non closely functional elements, or foreign to the nature of the cardboard, avoiding screws and metal junctures. In general, we have applied the criterion of the use of a single material (the only cardboard); sometimes it has been combined with another material, in concordance or dissonance, as metal, plexiglass, wood, straw. If on the one hand the use of wavy cardboard seems simple and within range of everybody, on the other hand it can offer itself to original cues for unthinkable creations, only if we deepen its mechanical characteristics based on the different kinds of “papers” that compose it, that is to say the “covers” (“chamois”, “test”, “liner”, “kraft”), the “stretched papers”, the “waves”. These different layers are held out by glues deriving essentially from mize starch. It is not that in this context we would teach a lesson about cardboard, but it is interesting to underline how many focused uses can develop on the basis of considerations relative to papers' substance, to the thickness, to the number of the waves (1 wavy cardboard: E/microwave, B/low wave, C/high w.; 2 wavy cardboard: EE/bimicro, EB/microtriple, BC/triple, CC and CK/ 2 high w.; 3 wavy cardboard: BCK /triple w.). The Comfortable Chair, (Fig. 6) and the honeycomb cardboard bookcase (Fig. 7), made during the course in Prototype Implementation Laboratory, are two examples of prototypes inspired to existing products put onto the market by designers specialized in the use of cardboard.

Fig. 6: Cardboard *Comfortable Armchair* Design. Specifications and prototype. On the right, details showing work in progress (Students: L. Palumbo, R. Chiarolanza).

Fig. 7: Honeycomb cardboard bookcase prototype. Details of work in progress (Students: S. Esposito, F. Sorbino).

Fig. 8: Corkboard prototypes (Student: C. Lucamante).

9. Recycling and decontextualization. Looking at the landscape

As we hinted before, In many other cases we have been working on the principle of decontextualization related to the recycling process, through experimentations that have given rise to a huge variety of projects and prototypes, often able to play many roles, ranging from “ecological” cigarette lighters to beach bags which can be turned into picnic cloths, from lamps made with canisters of chickpeas and peeled tomatoes to those created with cassettes which are no longer usable, the last traces of a technology which has become superseded only recently. In this framework the manufacturing techniques have been almost always characterized by chance, i.e. the mere experimental attempt verified and double-checked step by step. As we have mentioned in section 3, in several cases we have chosen to associate the creativity suggested by the process of recycling the Neapolitan culture, so as to transmit the importance of recovering our roots not only in terms of consciousness of belonging and additional value, but as regeneration and resource in a wider and more complete meaning. I have in mind a magazine stand built with pieces of vinyl obtained from broken records coming from the most ancient recording studio in Europe, the Neapolitan Phonotype (1903) which contains a piece of history of music through records of Caruso, and of many other more or less known artists. In particular, with the students of the degree course in Fashion Design we have assessed, as landscapes viewed as possible sources of inspiration, the old Neapolitan dressmaking and we have performed experiments on the process of recycling in another context its devices including metres, reel and buttons; or we have looked at warping and silk drawings of S. Leucio of the age of Ferdinand IV; or to the geometries of Vietri ceramics. We have taken our inspiration from colours of the landscape, ancient architecture, mosaics and marquetrys of the churches of Amalfi’s Duomo, friezes and columns of Pompei’s Scavi, Etruria’s fragments, so as to create objects, jewels, sandals and bags, revisited and conceived according to modern taste, and sometimes through matching with materials completely extraneous if not in disagreement with the sources of inspiration. What comes to my mind are all collier inspired by laces of Neapolitan pillow, made of silicon, i.e. through the straining of silicon rubber in empty moulds created “ad hoc” on the original drawing. Nothing borns out of nothing, and the tradition is almost always a primary source of innovation. We, ourselves, are the outcome of what we were in the past, and the prerequisite of what we are going to become.

Fig. 9, 10: On the left, a collier realized by the straining of silicon rubbers in ad hoc made mould (Student: B. Frettoloso). On the right, renders and wax models of rings inspired to campanian etrusian archeology, realized by the laser stereolithography (Student: L. Gambero).

Less versus More; Pondering Architecture and its Embodiment of Crisis.

Gerhard BRUYNS,¹

⁽¹⁾ Delft School of Design [DSD], Faculty of Architecture
Delft University of Technology,
Delft, The Netherlands
E-mail g.j.b.bruyns@tudelft.nl

Abstract

Questions of uncertainty [related to the issue of 'less'] loom larger within the global climate. Uncertainty regarding the futures of political domains, economic viability, social and human sustainability, not to mention the uncertainty related to the influence that architecture, as praxis and critical discourse, may exert as stabilizing moments within territories, environments and more importantly, humans and social sustainability.

The focus of this paper will be on the aspects of 'more', as its attempts to render visible the relations between [a] the operational logics within *competing rationalities* [modernism vs. specific] as basis for a critical approach and [b] to address by way of example the specific approaches for territorial governance and social sustainability through a highly and rather specific take on architecture and urbanism. The explorations made will reflect on the problems encountered within a post graduate [architecturally focused] education program, the aspects of environmental management and the obstacles encountered within the design work as moments of engagement within a larger landscape strategy. Examples will show the points of departure, the moments of critical inflection, and larger landscape strategy as means to produce a fully integrated urban model entirely focused on a communities assets, skills and labour qualities and housing stocks.

Keywords: Crisis, Co-production, Radical Urban Strategies.

Background

The International Herald Tribune, of the 18th March 2012, had a headline that read: "*Greece urged by European officials to do more*". Another headline stated: "*Woman bear the brunt in Austerity in Britain*", with others reading; "*Side by Side Look at Destruction and Renewal Japan*"¹.

The article on Greece quotes the director of the International Monetary Fund [IMF], Christine Lagarde, though her praised of Athens for; "[...] *its tremendous efforts to implement wide-ranging, painful measures over the past two years*". She stated that despite their efforts, Greece needs to do more. She continues by saying; "*Greece's priority is to undertake competitiveness-enhancing structural reforms*", and that, "*significant further fiscal adjustment is necessary to put debt on a sustainable downward trajectory.*"

News headlines dated the 28th March, of the very same newspaper read; "*In Paradise, but Closing In On Disaster*"². The article elaborated on life in the Maldivian archipelago, and its ever present and inevitable crisis, as the islands is being threatened by rising water levels and constant erosion. However, the most striking headline of the day remained a smaller less visible headline. It stated; "*Borderline: War over a One Horse Town*". As a small, and yet powerful headline, it reflected on a so-called 'one horse town' of *Tsorone-Zalambessa*, situated between Eritrea and Ethiopia. The dispute in question deals with the establishment of a definitive national border, between the two aforementioned countries, all questioning *Tsorone-Zalambessa's* literal position, either as part of Eritrea, or, as part of Ethiopia. Continuous disputes between Eritrea and Ethiopia, a matter of conflict with its origins in 1889, have in recent days, once more, culminated

into a critical situation with ever more uncertainty for both *Tsorone-Zalambessa's* citizens as well as for respective nations. Although less of a 'global' threat to world stability, the headline once more confirmed the legacy of how national conflicts disregard local folk or how disputes affect livelihoods.

This paper will explore how urban practices, **specifically those related to** architecture and urban design, continuously engage and address critical and uncertain spatial landscapes within the 'critical' paradigm. The issue under question is not as much a concern of how to identify 'crisis' or 'uncertainty', but to explore the role of design as; [a] a mediating material praxis and [b] an activity, which negotiates and directs a material and spatial reality as methods of improvement.

The text will first of all establish the **material realities** when questioning the paradigm of crisis. Explorations will establish the manner in which architecture and the city absorb critical moments at the levels of social, political and economy, which form part and parcel to the larger spatiality's of the geopolitical and socio-political crises.

Thereafter questions are posed to reflect on the **mental and conceptual frameworks**, which help frame specific attitudes that deal with crisis. A section called 'What others have said', looks at the local conditions of a global crisis before addressing the aspects of '*more*'. 'More', in terms of how a conceptual framework can possibly shift spatial praxis to maximize effects *and* potentialities. Here the focus will be on the clarification of what Low [2012] calls '*competing rationalities*' within operational logics. Exploration of the 'competing rationalities' concept and terminology will elaborate on old as well as new conceptual frameworks, whereby the architect will stand central within the process of being a 'conductor' or 'director' of urban and spatial strategies.

As a third and last step, the paper will reflect on how the concept of '**co-production**' finds embodiment. It will show how co-production is implemented by way of radical experimentation within an academic - design - research project. Specific post-graduate projects will intentionally show the possible spring-board positions from where to approach various social and political instabilities which intentionally follows radical experimentation within the Urban Asymmetries Research Program, of the TU Delft. Specific examples will explore the points of departure, the moments of critical inflection and larger landscape strategy as a means to produce a fully integrated urban model. Results will discuss the types of urban taxonomies made as part of the strategies that absorb skills, labour, materiality and existing housing stocks. Moreover, it is hoped that a debate, aided by the work, may emerge in favour of how to design with 'less', as a specific method for territorial governance and social sustainability.

Crisis and uncertainty, a possible material reality.

Both '*Uncertainty*' and '*crisis*' have become key words for the 21st century. National and global media constantly provide live coverage of the multiple types of crises found in various parts and corners of the world. BBC World News, CNN live, El Jazeera, and France 24, as well as many other news channels, show the same images, streaming similar news 'feeds'. Live media elaborates on the conditions and causalities of crisis. Commentators discuss the influences to each crisis, highlighting a number of perspectives, fed with live and up-to-date information on the situations, as they unfold.³

Realities of the crisis can be found in various world regions. Crisis at the European scale, directly impacts the material realities of cities. Riots in Athens, sparked by the tough austerity measures, have had radical repercussions both in terms of how, on the one hand, a society in general deals with an economic meltdown and on another, and how individuals struggle to sustain daily life for its citizens. Greece has witnessed the alteration of political policies, the rise of social unrest, a revision of its tax systems, and most significantly of all, the spatial and material modification of its city. Elsewhere the consequences of uprising and war due the 'Arab Spring', and its wave of revolutionary moments have shown similar tendencies. The world has witnessed, in rather graphic details, the destabilization of political regimes in Tunisia, Algeria, Iraq, Jordan, Kuwait, Yemen, Libya and Egypt. Cities in each of the aforementioned countries have had to deal with the transformation of streets into places of crisis and resistance. However, uncertainty, crisis and the spaces they occupy, are not restricted to conditions of war or famine alone. Countries who are undergoing rapid and excessive urbanization also face a level of heightened and critical awareness as part of city life.

In summary, irrespective of being European, Asian, South American, African, or, a country part of the developed world or still in the process of advancing, the issues presently remains global. Whether it is a

crisis at the *socioeconomic* and *geopolitical* levels, crisis related to war, famine, human rights, gender or governance policies affecting local inhabitants, one thing remains certain; crisis and uncertainty have become part and parcel to a double edge sword continuously threatening nations' stability. More importantly, and of primary concern within the architectural and spatial discourses, is the consequences of the **material and spatial realities** any crisis creates.

What others have said.

The free dictionary⁴ defines the word '*uncertainly*' as:

"Not known or established; questionable: domestic changes of great if uncertain consequences, [b] Not determined; undecided: uncertain plans and [c] Not having sure knowledge".

'*Crisis*' is defined as:

"A crucial or decisive point or situation; a turning point. An unstable condition, as in political, social, or economic affairs, involving an impending abrupt or decisive change, and "A point in a story or drama when a conflict reaches its highest tension and must be resolved".

Both definitions clearly delimits the open-ended and multiplicity of the *problématiques* surrounding crisis or uncertainty.

For Manuel Castells, author of the *Rise of the Network Society*⁵ and the *Urban Question: A Marxist Approach*, the complexity-surrounding crisis is primarily structural and systemic, more than it is material. Essentially, Castells primary contribution to the question of crisis is in an approach that favours a financial and systemic position, before ever engaging with its material realities.

In a paper delivered to the *International Forum on Urbanism; the Urban Question Conference [2009]*, Castells presented a paper entitled; *Beyond the Crisis, towards a New Urban Paradigm*⁶. The paper presents a 1st world account of much required policies and strategies to address, what he terms, sustainable development in light of the 2008 world financial collapse. Design proposals used as part of his narrative was shown reflected on what one may see as mediated solutions for the 1st world. Each proposal took material shape in the juxtapositioning of newly emerged urban functions [commerce and public spaces] against already established infrastructure [roads, bridges, houses]. Very few examples provided possibilities of extreme or radical forms of intervention, or radical moments of crisis.

Castells' work in recent years has extended his position of financial instabilities, as generator for other levels of crisis. *The Aftermath project*⁷, was initiated to address what Castells refers to as the 'Carpe Diem period' within social immediacy and instabilities. Interestingly enough, Castells frames the *Aftermath project* through its development and origins, only in financial terms. The 2008 financial crisis - with its financial bubbles – is historically located before teasing out the effects at the levels of; [a] the industrial crisis, [b] crisis of employment, [c] fiscal crisis and [d] governmental and European crisis. What is shown is the critical particularities and its effects on sciences, social, political warfare, tolerance and religions. Castells further draws from a range of global experts to steer the research initiative, to ultimately rethink, address and navigate the possible outcomes and way forward in the periods of crisis.

During the 33rd Lecture on Globalization⁸, delivered on the 6th of December 2011, Castells orally produced an insightful overview on the possible outcomes and future prospects, as echoes to the 2008 financial implosion. According to him, various resistances against capitalism, by organizations such as 'Occupy Now', has made a clear and definitive statement by redefining the levels of uncertainly. He further stated that no social or cultural domain would be unaffected. Secondly, and of crucial importance, is the emphasis placed on the crisis seen as a '*Non-Global Global Crisis*'⁹ condition, that is to say, a local and spatially specific crisis at a global proportion. Interestingly enough, what Castells presents as part of the *Aftermath project*, its analysis and the possible realities of the Carpe Diem periods are radically different to those proposals made as part of his *Beyond the Crisis paper* in 2009. Projects in the *Aftermath* scheme addressed the material significance of reactions and the levels at which social groups resist uncertainly and the levels of redress in terms of daily process, housing and individual urban realities.

Still, the solutions, terminologies, and logics Castells discuss all relate to market systems and political economies. What essentially remain missing are the conditions under which the crises unfold spatially as they take shape in a material sense.

If the crisis is simultaneously 'global' and 'local', then the counter strategies would somehow also have to relate to the local spatiality's and its material forms. From an architectural perspective, how would the spatial disciplines address crisis and uncertainty? The world has witnessed the spatial specificity with which certain urban resistance is met. The various locally specific - 'occupy now' demonstrations - the initiatives taken by individuals to move beyond the financial collapse and the countless community incentives are but a few examples of resistance. We are still left with major questions related to urbanization at times of crisis. Moreover, how would architecture contribute to, or, form part of a counter strategy to help sustain human livelihoods on a daily basis? The main question therefore endures; can architecture exert or provide stabilizing moments within territories, environments and more importantly, can architecture provide stabilizing moments to facilitate human and social sustainability in times of crisis?

In a recent interview, Low and Bruyns [2012]¹⁰ questioned the role of design within the formulation of spatial urban strategies for developing countries. Pertinent questions at the time related to; [a] to the role of the architects within developmental and urban sustainability, as well as [b] the negotiability of important and peripheral issues when considering any approach as a possible routes for feasible, sustainable and spatial development.

The questions raised were not exclusive to the Southern African or Sub Saharan context. As part of this encompassing interview Low verbally elaborated on both the consequences as well as the conditions under which architects and planners engage when addressing rural and inner city slum development. For Low, the concept of *co-production* remains the key aspects when dealing with uncertainty and crisis.

Co-production is defined as a concept whereby all parties who are directly related to, or involved with, a specific problem, collectively produce or contribute to its resolution. According to Low, the operational framework of co-production implicitly establishes *horizons of connectivity*. In other words, it is through the types of relations, how the various parties collectively collaborate and draw from resources, how they facilitate, organize and implement skills in order to accomplish a task. Only through the *horizons of interconnectivity*, through the manner of negotiation and the drawing together of individuals is a sustainable solution both possible as well as viable. The architect or designer becomes, in a metaphorical sense, a 'conductor' or 'orchestrator' of many parts, sections and variables. It is within this role that the architect becomes the mediator of chaos. From Low's perspective the question posed should be those that try and establish what variables allows for things to co-exist, and not establish a position of the 'master builder' or 'master designer'. As an alternative Low postulates that design can only take on a meaningful role through the managing of relations, by way of the agency of design itself.

Furthermore, Low stressed that co-production and horizontality is implicit of a *non-hierarchical* position. That is to say co-production is in favour of an emergent and equal process, in comparison to a top down [modernist] approach. Emphasis should therefore shift from the singular to the plural, in order to incorporate social anthropology, political economy and question marginalization as part of the designer's awareness and skills.

One of the best examples Low provides is on how to read contextual dependencies in any landscape. A comparison is made to the manner in which a medical physician would read and diagnose human illness, following a very strict medical protocol. One muscle in the human body is similar to muscles found in other humans. The generic and medical protocols become instructive, in terms of examination and cures, that is to say human diagnoses and prognosis. For the architect this is rather different. Each site, each portion of the city or landscape is different and specific. Nothing is generic or neutral. It is therefore the role of the designer, to not only mediate the context, resources and use, but also to mediate the users, parties and their combined possible futures.

Other questions, such as ethics, education and valance, simultaneously step forward within the praxis co-production. Although too complex to elaborate here, the question of ethics and design implies a moral obligation within design practices. In other words, those who do the design work have to question their ethical and more values in relation to those for whom the design is meant. Similar questions are valid at the level of [design] education. What should form part of a design curriculum, especially when the merger of

socio-political, political economies and geopolitical issues are immanent and ever present, within the design discourse. How does one teach co-production as well as its awareness to mediate chaos? Finally, and in addition to the other aforementioned factors, how does one spatially engage, with a spatial problem that seeks to establish valance within its strategy, opening possibilities to engage with future financial and social possibilities. To what extent does both the architect and design have to accommodate or become flexible when thinking of future and alternative scenarios?

In summary it remains a problem of *competing rationalities*. Low refers to 'competing rationalities' in as far as two specific mind-sets, dialectically opposed to each other in terms of approach and thinking. One mind-set, which can be referred to as the modernist 'mind-set, looks and seeks out to place orders and hierarchies into the world. This is referential to the so-called top down approach. It is an outlook, which has had a tremendous historical significance, at various levels of society, politics and governance. Most colonial policies of the 18th and 19th centuries used the modern belief as a wielding instrument to govern regions, society and people. Architects are generally all too familiar with high modernism and the consequences of their architectural and spatial legacies. In contrast, the second minded is one termed as the grassroots rationality. Within its frameworks the grassroots rationality appears to be locally driven, sensitive to people, culture, program and any spatial as well as material solutions. Furthermore, it has to be mentioned that although the grassroots concept is nothing new, its power lies in the revision of its working method and how it engages with a number of grassroots level factors, making it more meaningful for zones of uncertainty or landscapes in crisis.¹¹ It is within this 'rhizomatic' web of power, once more a reminder of the horizons of interconnectivity, that lends new agency to the grassroots concept. A more familiar grassroots example could be found in the expression of African city places and its continuous reprogramming, based on the influence that mobility has on specific parcels of land. Grassroots level thinking would be able to access the process in which a number of users reprograms places in a temporal process as well to be able to read the importance of the vernacular structures, users and daily dimensions as part of a solutions which seeks to establish valance and meaning.

Low further describes grassroots levels concepts using the analogy of the kaleidoscope. Viewing of the kaleidoscope is nothing new. Movement in the kaleidoscope results in the collective displacement of the particles, causing them to shift and establish a new image. Essentially it becomes a product of how gravitational forces exert pressure on the collective body of glass that then establishes a reconfiguration in terms of form and pattern. Grassroots level rationalities therefore fall part and parcel within the co-production mind-set, which become fundamental to both, context and praxis. Although easy to grasp as concept, this adaptation as praxis will probably take years to germinate. Low is of the opinion that the grassroots idea remains a problematic concept for those who still seek to address urban spaces through a conventional 'western' design attitude. This has been evident in the manner with which many architects still cling to western operative logics as design process for critical landscapes. A number of proposal by famous architects have become immediate failures as designs fail to merge the rationality of a western mind with that of, lets say, an African or any critical landscape.

Spatial and design Co-production.

The following section focuses on the examination of specific approaches which question territorial governance and social sustainability through a highly, and rather specific, take on urbanism and the role architecture plays. The work shown explores the fundamental differences of how the grassroots rationality differs from a modernist attitude by showing how architecture becomes an instrumental device at the design level.

Two main comparisons, between a European and non-European landscapes, are meant to show how the crisis registers different applications as part of the same problem. These comparisons should be seen in light of the how spatial practices differ, and design intentions materialize, even though the problem remains of a similar nature.

As part of the *Faculty of Architecture*, the *Delft School of Design's Urban Asymmetries Research and Design* unit deals with radical experimentation to engage with urban and architectural problems, caused by Neoliberal attitudes towards development. As a program it critically questions a number of urban landscape, marginalized due to either financial policies or social unrest. At its basis, the DSD's core content focuses on urban and architectural strategies, in light of the various socioeconomic, neo-liberal and geo-political

mechanisms of specific urban territories, by exploring both consequences and design possibilities through a highly critical and theoretical reflection.

Within the Faculty of Architecture, the unit sets itself apart from other research programs, as it views architecture as a subservient mechanism, a technology so to say, meant to serve a specific context and community. Instead of seeking solutions at the pure pragmatic side or with an intention to design in order to create wealth and image, the DSD's projects mediate the various urban and architectural realities in order to produce solutions at a number of levels. These include the design of; social planning structures, financial strategies, self-driven improvement strategies, [landscape]architecture and community involvement.

What is more, as a graduate program, the DSD has been fortunate to have had the freedom to lecture and educate students at both the urban and architecture scales as part of its curriculum. The Urban Asymmetries Research Program [UA] commences from the premise that any interaction with the city, can only commence if it accepts the conditions of the city as being 'urban'. That is to say, that although the results may be architectural, the approach ground itself within all scales of the city in order to question the asymmetrical and uneven forms of development and how to form counter strategies at each scale. The definition of what is called *urban* is further extended to include an understanding of the city in terms of city processes, temporal urban dimensions, social compositions, political variables, economic strategies, social movements, material possibilities, labour types and possible spatial stratifications.

It is at this junction, at the intersection of the praxis and embodiment of both the architecture and urban disciplines that the UA studios critically examines, disfigures and deconstructed the variables involved with each urban moment, before any attempt is made to rethink any possible solutions. Feasible interventions are in most cases extend beyond the scope of architecture. To date, the UA design work has looked at architectural types which form part of; mobility's and other forms of 'infrastructure', financial counter strategies, socio-economic strategies, managerial and regulation policies for neighbourhoods.

The fusion of the architectural and urban design praxis and its intentionality to counteract neoliberal conditions, has concomitantly highlighted a number of obstacles. Inability to 'literally' draw limits around each discipline has proven to become an ever-larger grey domain. Students have faced great difficulty in making the transition between architecture and urbanism, the theoretical critiques and the specific interventions themselves. Where architecture ends and where the urban domain commences is not as clear and definitive as one would have thought. This is ascribed to the number of variables and the levels of critiques in which students become entangled. What commences as an architectural project quickly moves towards larger city strategies, continuously alternating between design scales associated with environmental project and those scales of the material reality of bricks and mortar. A second aspect, one tied to the former, is the overbearing influence of research and data. Students become entangled with the statistical side of the analytical work making the transition from analysis to a formal design labour intensive. After 6 months of research students are forced to somehow engage with the possible ways forward without compromising the thorough analysis. Certain students develop design blocks the moment before proposal of a possible solution in a material sense is due. Participants are therefore always advised to continuously move between the various design levels, city scales, and construction detailing. The formalization of a possible design strategy soon enough highlights any possible weaknesses between the overall and specific strategy, theoretical critique and its materialization. On the positive side the DSD has witnessed the radical position taken by students when questioning uneven development. In their professional capacities graduated students continue to follow a critical and explorative position either within architectural practice, NGO structures or as community volunteers.

DSD UA program has successfully completed a number of Graduation studios. Up until 2012, the DSD has completed studios on Mexico City [2008], Santiago De Chile [2008], Newark, NY [2010], London [2011] and Amsterdam [2011]. The current studio re-examines the city of Juarez [Riberas del Bravo] in Mexico, due for completion in July 2012. Each studio saw the emergence of rather diverse design strategies, exposing the possibilities of how architecture becomes operative and instrumental within the asymmetrical - and highly contested - urban condition. Although similar in approach, each studio exposed highly contextual realities. A number of projects, from the Mexico and Santiago De Chile studios, dealt with the notions of 'self-help', self-built' schemes, whereas other projects looked at the possibilities to self-help financial strategies. Some project explored the possibilities of intervening at levels of urban-agriculture as revised modes of production, landscape design, and public space definition. One specific Newark design project examined the possible

and alternative strategies available to the homeless. Something as mundane as a shopping cart took on a material transformation, addressing the issue of shelter, whilst at the same time taking on a political, financial and social material form within a capitalist driven metropolis.

Co-production at the urban scale remained a key challenge. Within the Santiago studio, 3 students elected to develop and implement a coordinated effort wherein all the architectural projects had to find 'ground'. This saw the co-operation and co-production at two levels. At first students were forced to collectively contribute to one overarching strategy, coordinating efforts and proposals for the entire region, making decision on infrastructure, housing types and areas earmarked for immediate and later development. Secondly, the urban design strategies had to act as facilitators to the smaller architectural 'pockets', forcing architectural students to deliberately negotiate as well as coordinate all architectural interventions with their urban counterparts. Without proper urban frameworks, it was found that the architectural interventions were adrift amongst a sea of endless possibilities.

As a process, it was interesting observe the intense and sometimes conflicting negotiating processes between urbanism and architecture students. Students from both tracks negotiated, whilst collaborating, initiated heated debate, based on their findings; fieldwork and in-situ community work. One particular student Shirin Jaffri,¹² consolidates all the urban and architectural strategies into a comprehensive and congruent project operating as program and project coordinator. Project details dealt with the implementation phases, financial structures and political facilitation at the governmental as well as neighbourhood level. All the architectural interventions of the studio found resonance within this particular project. Jaffri's proposal stood as the literal embodiment of what co-production meant as well as how to tie all projects into a spatial, and more importantly, financial whole.

Although to many to mention, one can reflect on a number of other architectural projects that attempted to look at the collaboration and horizons of interconnectivity within a community, at an architectural level. The project of Dirk Robers¹³ [2011], explored the possibility of collective co-operation between community members to extend existing single-family housing stock. As families grew, extended with 3 – 4 members at a time, the pressure to alleviate dilapidated residences was essential. Robers' project, entitled *Core*, drew from the availability of materials in local hardware stores, local building skills and a program to rotate building equipment to facilitate the scheme. The result was a design that commenced with the 'core' element as addition to the existing dwelling. By adding the core element, the design secured structural stability for future additions, a new wet core service to the current and intended extensions, as well as delivering a new architectural typology for a very standard and monotonous single story landscape in its allowance to extend to a double story house. The building process was executed by locals who would contribute with skills, in return for similar assistance on their own future designs and homes.

Other examples of how the architectural profession may possibly address places of conflict and uncertainty through the notion of co-production are evident in the current 2012 UA studio, with its focus on the *Ciudad Juárez, Riberas del Bravo*, Mexico. Presently, the studio has just started its second semester of the graduation track, defining the final spatial and material interventions. Located on the Mexican side of the Texas border with El Paso, the Ciudad de Juarez finds itself caught in worlds of extreme. It is a city wedged between various types of violence and conflicts, between being a border condition of developed and 3rd worlds, caught within hyper-employment and unemployment, and most crucial of all, caught between being inhabited and uninhabited. Therefore, Juarez forms a perfect study case. As an urban landscape, most of its housing stock is presently empty and abandoned, thanks to the influence of economic, social and drug cartel related forces.

The studio has directly challenged the role of the architect as mediators within an elaborate meshwork of social issues. Students soon realized that the problem they are faced with extends far beyond their architectural comfort zones. Students soon had to merge important aspects related to environmental ecologies, human ecologies, political economies and social welfare into their immediate analytical as well as design scopes. The studio has, as a result, delivered a specific urban critique, teasing out a number of issues. They include issues which relate to; the impact of global events on local developments, the historical development of border conditions and landscapes, the relations of war on economy, the roles of border societies, and finally, urbanization in terms of morphological and typological development in the city.

Combinations of the various critiques, analysis, and spatial layers have culminated in, what the studio calls, 'Urban Taxonomy'. As the accompanying image [below] shows, the taxonomy includes all details and

Furthermore, spatial discourses seem to have the upper hand above other disciplines that attempt to address similar context within similar questions. Students of sociology, economy and political sciences have difficulty in translating notions to the spatial and material domain. Here specifically, the role of the architect and urbanist is significant. Spatial students ruptures any obstacles through their spatial and contextual insights, in relations to a landscape's historical development, current social practices, economic variables, political constrains echoed within the material reality. One could say that the students' spatial background help develop a deep and fundamental insights into various types of complexities associated to each uncertain or instable urban moment.

Thus far the design proposals for Juarez covers a range of functions, programs and scales. Probably the most ambitious proposal thus far is a proposal which intents to address the treatment and management of water. As a project the proposal by *Sara Navrady*, draws into its scale the redesign and management of the water purification systems through passive technologies. It further includes a redesign of a present derelict water canal to become a community driven project as facilitator of a restructuring project for the Riberas del Bravo neighbourhood. The project is ambitions as the canal in question stretched the entire length of the site, with no less than 4 km of redevelopment. The project is meant to coordinate mobility, infrastructure, public space and production industries within its scope of work.

Another project of importance is the strategic planning of a new urban infrastructure system, which would connect resident to both the area as well as the larger city scales. *Revathi Pillai* has rethought transportation in and from the region, establishing bus, minivan and car 'transferium'. Like most project within the studio, this projects is established at the very edge of the water treatment project, harnessing the potentialities of the green and newly renovated public spaces into a coherent spatial structure.

Each project of the studio reconsiders the abandoned housing stock of Riberas del Bravo. Many students feel the need to rethink the possible modes for dwelling in light of the financial crisis, buy way of bringing together both issues of [a] the extended families and [b] the possibility of seeking alternative [home] sources for income. A range of smaller proposals is inserted to establish stable moments within the neighbourhood meshwork, in relation to the larger citywide infrastructure framework. Identifying specific sites as potential locations for home and neighbourhood clinics, urban agriculture and food production, educational facilities, colleges for the education of building skills and day care completes the overall urban strategy.

European context.

What happens to the role of the architect when resources become less, with the focus of achieving more? For most cases in Europe, it is not so much a crisis of warfare, but one of economic as well as material resistance. How does the European architect become instrumental in his approach to [co]producing, directing as it were, forms of social resistance? More importantly how does crisis register differently to the examples shown in Riberas del Bravo, and what spatial practices are understood as relevant for the wider notion of design development, with respect to both European and non European places?

One of the main aims of the Urban Asymmetries project is to allow students the possibility to engage with a variety of contextual issues. Material realities encountered in Mexico or Santiago De Chile is inapplicable to a European landscape. Each urban landscape represents and embodies different and various levels of control, policies and financial processes, which form the substructure to a number of highly specific *problématiques*.

Using this as background the question of 'less versus more' becomes paramount. The Amsterdam studio, entitled *Amsterdam 'Re_figured'*, investigated the city as part of larger and encompassing Randstad urban megalopolis. More specifically, *Amsterdam 'Re_figured'* embodied a year long strategy which attempted to access the structural layers of the both the Dutch Randstad as well as the place and context of its capital, Amsterdam, as part of the poly-nodal, con-urbanized landscape [Bruyns, 2011]. The project commenced with reading the traditional morphological elements [infrastructure, building distributions, settlement patterns, typological order] before inverting the traditional narrative to include other 'urban variables' [economy, social structure, labour forces and global markets]. A bilateral reading of the Randstad and Amsterdam, immediately revised traditional explanations on what the city is and how it is understood, in favour of a view that accepts a city within a historic and social narrative. What was shown in the formal analysis was a settlement 'in-formed' by way of various trade strategies [Dutch East India Company], labour forces [migrant labour], and production types [from the bulb producing region to a managerial service industry]. It further

looked at possible ways to clarify Amsterdam's social-political position within a highly specific web of political economies and consistent deindustrialization processes.

At its core, the Amsterdam Studio deliberately sought to produce alternative narratives of urban form, through exploration of the conditions, intricacies, levels of influence and praxis related to neoliberal development and its specific 'uneven' or 'asymmetrical' tendencies. Amsterdam's relatively new IAMSTERDAM urban image program reveals a partial side of the city without highlighting the sub-currents, which also make up for the city.¹⁴ The power of the free market system, the creation of gated communities, socially driven enclaves, the influence and power of financial and global powerhouses, the influences of a social elite and gender inequality are as a group of aspects, simultaneously compared to the material realities of how lives are lived and the creation of financial inequality. Consequences of the payoff between the aforementioned aspects directly highlight power structures in relation to the 'non-global' instabilities at the material level.

One specific post-graduation project of the Amsterdam studio directly addresses the matter of socio-economic structures as part of Amsterdam's political economies. Pinar Balat's¹⁵ project saw the resolution of the socio-economic discrepancy through a spatial approach. Essentially the project questioned the allotment of wealth within a specific social group of Amsterdam. Entitled "*Socio-Economic and Spatial Re-Organization of Albert Cuypmarkt: Integration of Low Income Groups into Wealth-Generating Urban Structures*", the project produced a highly social critique, taking into account wealth generating structures, social layering and temporal urban processes before even considering architecture as a material solution. Co-production was emphasized through the question of how low-income groups enter into wealth-generating economic structures. Attempts were further made to question the necessary steps in order to unpack socio-economic advantages in a spatial sense. The investigation was carried out through re-organization of the market at the urban scale as well as its internal architectural configuration. Questioning the cohesiveness of the market-entity simultaneously meant rethinking spatial quality, rental rates, working hours, work flexibility, building materials, construction costs, and income levels. The Albert Cuypmarkt was therefore seen as a perfect site for experimentation. As Amsterdam's biggest market, the Albert Cuypmarkt forms an important wealth-generating urban structure, which presently remains inaccessible to low-income vendors. By default the market structure favours middle to high-income groups, supported through its spatial characteristics, mechanization and economic organization.

The project engages with the problem by reframing the existing commercial unit types, in terms of rental rates, working hours and temporal flexibility as well as spatial quality. Within this literal reframing of the market, it is hoped that a differentiated economic force will emerge at various times of the day. In addition, it is expected that the differentiation of the various income groups in relation to the various stall types, will eventually open possibilities for low-income producers to step into a thriving market economy, implementing a self-help, self-driven process.

Commercial units are, in a literal sense, daily orchestrated to overlap with a spatial-socio-economic strategy. Spatial transformation of the market occurs at all hours of the day. Less expensive market stalls are available at early and late hours of each day. More expensive stalls are available at the peak periods of the market. Assembly and dismantling of the market is reserved for those who wish to pay less stall rent. Different income groups will therefore co-exist, operate and negotiate a similar spatiality generating individual wealth. Benefits at the neighbourhood level will be rechanneled to allow for much needed renovation of the existing buildings and housing stock. For the city, the improvement will be at the level of image and neighbourhood upliftment. More importantly, the spatial and materialization in such a project is just as important as the strategy itself, through its deliberate and forceful acts to immediately counter gentrification and capitalist tendencies.

Although Balat's strategy is focused on the alteration of the market at the local or neighbourhood scales, the question of the larger socioeconomic policies cannot be overlooked. The project therefore draws from the larger urban scales, to include within its perspective, the spatial distribution of income groups, housing stock and basic urban amenities, such as day care, beyond the market's zone of influence. What is more, the project further elaborates on 'workers' migrations, which may occur within Amsterdam. Routes to and from the market for both people and produce are defined and re-planned. It is therefore a strategy, which dialectically co-produces and directs, whilst negotiating the very local in relation to the very global.

Fig. 4: Albert CuypMarkt architectural embodiment. MSc Architecture Project. Pinar Balat. 2011.

Conclusion.

In conclusion, this paper examined possible strategies through which the architectural and urban negotiate critical landscapes. It was further shown how various forms and types of crisis registers different spatial and material modes within cities.

A first conclusion has to question the types and modes that establish crossovers between the architectural and urban solutions when addressing crisis. Form an architectural perspective the solution is one of a material result, found in a material-spatial reality. It is suggested that possible solutions may be found within the spatial domain alone. In other words, intervention aimed to alleviate crisis can possibly focus on spatial strategies alone without any building or construction work involved. Reconsideration needs to be given to

the spatial-material relationships, the balance so to say, of how much a pure spatial strategy versus the use of a material strategy.

The second conclusion extends the aforementioned spatial-material question through the notion of coproduction. 'Spatial practitioners' are, through the various complexities of urban landscapes, presently forced to take ownership of a vast number of additional 'contextual' variables within their design *problématique*. It is hoped that governmental agencies will take cognisance of co-production as concept. Secondly agencies need to recognise the importance of a spatial position as part of any critical landscape's developmental process, before allowing financial and the political factors to undermine the pace of urban improvement. What is more, governing bodies should be made aware that a neglect of addressing social demands could result in the public to reclaim ownership of the city's space and its future trajectory.

Thirdly, there exists an ever-present optimism amongst the citizens of critical landscapes that a mentality shift should occur, from a *contradictory* mind-set to one that is defined through its *complementary* methodology and praxis. Over and above the ethical position of the architect to co-relate, co-produce and link factors with each other, a similar position is deemed necessary by all levels of governance, policy makers, NGO' and smaller financial institutions. Co-production should be seen as the general norm and not as a concept only applicable to moments of crisis.

A fourth and final conclusion is on the matter of crisis and technology. Technology has had a tremendous impact on how crises are dealt with in terms of much needed relief and shelter. Although technology's value and contribution remains essential, its contribution measured on the sustainable scale remains to be questioned. In most cases technology provides instantaneous relief. Communities still face despair once the technology is removed or once the aid is withdrawn. Sustainable solutions are only possible once the societal, spatial, labour, skills and educational factors are fully equated within any technological strategies.

Technology, society, crisis and sustainably, should therefore be seen as the new synonyms to all to familiar 'less verus more'.

DUALISM AND SENSORY AWARENESS IN ARCHITECTURE AND DESIGN

Anna Marie FISKER, Mads Harder DANIELSEN

Faculty of Engineering and Science, University of Aalborg, Aalborg, Denmark
fisker@civil.aau.dk, mdanie08@student.aau.dk

Abstract

By using the term *less* we focus on architectural heritage; can a heritage from a modernist architect show that less does not exclude *more*?

In the search for a hierarchy of relevant sustainable investment in architecture our paper focuses on the architect Arne Jacobsen.

We focus on the dualism of privacy, the layers of intimacy and private space, and interpret the sensory awareness that is represented in Jacobsen's designs.

Into the discussion we draw Mario Praz who uses the term *Stimmung* to refer to "the sense of intimacy". We focus on the famous picture of Jacobsen's chair, *model 3107*, where the controversial English model Christine Keeler sat astride, and we analyze the photography's iconic status.

Arne Jacobsen also created *the Egg*. Is the Egg bilateral? Does the back rest create an intimate universe on the inside, and interplay with the strict geometry of the SAS hotel on the outside?

We seek the architectural works ability to communicate, seek answers to which languages are spoken – can languages reach beyond the age of the works and spread to a present value? We try to relate the languages of senses and affect to the works of Jacobsen, the sensory awareness to architectural design.

Keywords: Dualism, Sensory awareness, Sensualism, Architectural heritage.

Moment by moment, as we go through our lives, we are called to respond to changes. Even on very basic levels, we are always in a dynamic relationship with the world. Architecture is one of the strongest media through which to express this dynamic condition; the perpetually changing relationship and interplay between the traveller and the travelled. This is where we may become astonished by the grandour and captivated by the smallest detail. Architecture includes scales that not only relate to the scale of the human body, but also make the body relate to its own scale. Thus, architecture does not only serve as a framework for our bodies due to its physical manifestation; it also makes room for our self-awareness in a world dominated by floods of fleeting impressions.

Life calls for presence and willingness to change. Discord sets in when we try to resist change and hold on to what we believe to be ours. Through the lens of sensory awareness, we have, in this paper, decided to explore the way architectural design interact with life. Guests walk into the lobby of the Royal Hotel in Copenhagen, expecting very simple explorations for a one night stay, for rest, for sleep, for food and entertainment; i.e. in standing, walking, sitting, eating and lying. By heart, we know that at times we very quietly attend to the subtleties of breathing; at other times we interact with other people or objects, allowing natural responses rather than imposing our will onto the world. On a late night in spring, we are entering Arne Jacobsen's Royal Hotel. The building is a salute to the modernist ideal of the unobtrusive skeleton construction shielded by a transparent membrane [1].

Let us see if we can uncover, in this place, the dualism of architecture, examine the inherent qualities of the architecture and simultaneously bring the dualism into focus and try to relate the language of sensing and affect to the works of Jacobsen.

However, inspired by the conference theme, *Le Vie dei Mercanti*, we take the first steps into the theoretic disciplines by using the tragic comedy of Shakespeare, "*il Mercante di Venezia*" with its dramatic scenes, which, still today, are so absorbing due to their wealth of human characterization and enchanting poetry. With "*The Merchant of Venice*" as our entrance, we remember our last visit to Venice, recalling how Piazza San Marco is defined as space by the architecture surrounding it. But that day, sipping our coffee at Café Florian, we also *felt* the atmosphere of the square. Seeing how people in general were able to *recognize* the surroundings as architecture, our discussion that afternoon pointed out that it is not only architecture itself that defines the atmosphere of San Marco Square. That atmosphere is also generated by the sound of the tourists, the feeling of the paving stones, the birds, the warmth of the sun and the smell of the Laguna.

The Norwegian architect, architectural historian and theorist Christian Norberg-Schultz states that a place cannot be considered by its visual appearance alone. If we want to define the whole atmosphere of a place, we must, according to Norberg-Schultz, ask ourselves the following questions: "*How is the ground on which we walk, how is the sky above our heads, or in general: how are the boundaries which define the place.*" [2]

The surroundings of San Marco Square communicate with the body as you move through the space, as you feel the texture of the old, impressive walls with your hands, hear the footsteps echoing through the hallway, feel a cold breeze on your neck or walk towards the light.

As you experience scenery like this, sitting comfortably in a chair with elegant waiters around you dressed in white, it is not only the eye that creates the experience. It is the combination of all the senses together, which creates the *atmosphere* or the character of the space. In this square, described by the writer and literary critic Henry James as "*the drawing-room of Europe*" searching and understanding through the uncommonly erotic language Henry James dedicates to Venice: "*You desire to embrace it, to caress it, to possess it*", we start the journey towards a higher sensory awareness of perception in architecture [3].

One person who managed to create a beautiful synthesis of the strictly geometrical and the organic in architectural design was the Danish architect Arne Jacobsen. This synthesis is particularly evident in the Royal Hotel from 1958, and it is our thesis that we in this architecture can demonstrate a sensory awareness. It was built according to contemporary construction principles and has strong international references, yet also its very own, distinctive character [4].

At the time, the sharply cut outer form appeared as a gigantic, homogenous glass volume in the center of Copenhagen. The building consists of two large cubes, of which the uppermost stands on top of its similarly sized counterpart, which is laid down. It is a rare agreement between building and design. Both are characterized by the sophisticated version of modernism of which Scandinavia was an exponent.

By enriching the building with human concepts and experiences, Arne Jacobsen achieves something quite remarkable, which is expressed most clearly through the interior of the house; for behind the straight lines of the glass facade, Jacobsen unfolded all of his talents in the period's most consistent example of total design, comprising everything from furniture to textiles, cutlery and door handles [5].

Shakespeare was also working with sensory awareness when he wrote the comedy, "*The Merchant of Venice*," in 1596; here, however, it is in the form of a woman who dresses up as a male lawyer, and through the act of switching the male and the female, private space is expanded. The idea of privacy, or "private space" for men or women was relatively new in Shakespeare's time compared to analyzing the issue of privacy and private space in the architecture of Jacobsen. It is difficult to predict how we will perceive the surroundings, woman dressed as a man or not, because the experience is related to our emotions and senses. Let us therefore move closer towards the language of sensing and sensuousness in architecture, or sensory deprivation. In our search for parameters for this, we study how architecture plays with the senses. We focus on how Jacobsen worked with the dualism of privacy, the layers of intimacy and private space, and interpret the sensory awareness that is represented in his designs and architecture.

One of the goals of the odyssey we were intent on completing at this mundane hotel, the Royal Hotel in Copenhagen, was obviously to stay in room 606. On this late night, the stars, intermittently visible through the dark clouds in the windy spring sky above Copenhagen, were just right. The otherwise unwavering receptionists surrendered and granted us access to this exceptional room in Jacobsen's modernist temple; a stay that began when the hall porter in his impeccable uniform unlocked the door to room 606 and stepped aside, allowing us to reach for the door handle to open the door to this unique room.

As the chairs, the Egg and the 3107, which we will introduce in our paper, the handle is one of the highlights of the unique style that Arne Jacobsen developed during the 1950s and 1960s. With its hyper elegant curves, the door handle that Jacobsen designed for the hotel is a strong reference to the furniture's organic shapes that form a playful contrast to the building's geometric, straight lines, such as the frameless door it is set into. Where the essence of the curvy, simple forms in the sweeping lines that are experienced as the handle almost fills one's hand when gripped, in effect fill the void of the movement of the hand.

The chairs and the door handle are all works that are characterized by an exact and expertly control of the double curvatures; without compromising functionality, that is. Contrary to many designs in the organic languages of the period, the handle of the door to this room in which we have undertaken our exploration, with its representation of free curves, is the organic main feature. A main feature that, in the words of the architectural theorists Thau and Vindum, is unified through a minimization of the material, constructive rationality and the demands of industrial production [6].

It was not there, in room 606, however, that we were to discuss and work out the basic elements of our research and work with the dualistic elements of Arne Jacobsen's works. This was done at the very top, almost among the rushing clouds, with a view of Copenhagen, in room 2006 on the top floor. With a certain degree of satisfaction, we put the dramatic expedition behind us and opened a bottle of champagne, sitting exactly 14 floors above room 606, the design of which, as the only room in the hotel, had been left untouched after a renovation of the interior of the hotel in the beginning of the new millennium.

The difference from the sofa set we are seated in here is that we are now beholding the bed mercilessly directly; unlike room 606 where a curtain of lace from the ceiling to the floor divides the room into a public and a private part.

Jacobsen had a remarkable aptitude for the tactile qualities of materials and their potential, and, moreover, his ability to unify image and structure was unique, which is especially evident in his work with textiles with overt references to Japanese arts and crafts [7].

We recall how, 14 floors below us, as our gaze turned to the bed, we could barely make it out; not directly, but through the sensitive and damping veil of a textile. Thus, Jacobsen, by way of the transparent curtain, half drawn in front of the bed, creates the possibility to both hide and, simultaneously, reveal the sensual lines of the body, setting the stage for a far more sensual seduction than the interior in room 2006. In this sense, the curtain urges the fulfillment of the lovers' dream of union, of becoming one. At this point, we wish to emphasize that the characteristically Scandinavian tradition for being attentive to the character of the materials, the sense of the fabric being processed properly, so it, when exposed, conjures up this world of something magical; a dualism of sense perception that oscillates between something spiritual and something tactile. This is the role of the curtain in room 606.

With reference to Tintoretto's painting "*Paradise*" in the Ducal Palace in Venice, where we had viewed this enormous and formidable painting in which action and dynamics become one grandiose whole by virtue of the painter's ability to effectively force the light into the foreground, we are making the point here that by perceiving Jacobsen through the lens of Tintoretto, and without becoming manneristic, we are viewing the elements of an optimal, animated spatiality; a spatiality created through the use of a transparent curtain where light and shadow, the naked and the covered, engender the longing for a sensual seduction.

Let us point out that Jacobsen's vocabulary and sensibility to materials owes much to his idols, Adolf Loos and Mies van der Rohe; although they, according to Thau and Vindum, belong to the aristocratic modernists, whereas Jacobsen does not express the same constructional monumentality but rather an aestheticizing lightness, a grand finesse in the "local" structures, panels, and especially the porosity of the surfaces. The constructional lightness of the building appears as an evolutionary skeleton – optimized through years of selective use of materials and shaped in the spirit of experience until the supreme lightness has been achieved, and nothing can be removed or added. The rectangular regularity of the skeleton expresses the materiality of the steel in a clarity, which simultaneously separates man from building in a contrast-filled manner and gives the building an identity that circumvents Miesian monumentality. In this process, a lightness is born, which transcends the scale of the building and relates to the human body. The paradox of this duality is redeemed in Jacobsen's interior work, which becomes a part of a whole – as the organic flesh is attached to the skeleton in the creation of a bodily whole; a whole in which room 606 is the heart still beating vibrantly in spite of its 54 years.

As the skeleton loses its body without the flesh, and the flesh loses its structure without a skeleton, the Royal Hotel is in a constant, dualistic dialogue, and the whole of Jacobsen's design can be viewed as containing two basic, contrasting cores that, solely because of each other, become more than either one could ever be on its own. In this context, we find it relevant to bring into play the interpretation of the concept of "the objective box"; i.e. the way in which a modernistic building volume can be explained through the lines of the

façade, structural transparency in the interior sequences, and, not least, the ability to emphasize one's furniture through sculptural abstraction. Thus viewed, it is evident that Jacobsen works directly as well as indirectly. In their book, "*Jacobsen*", Thau and Vindum show how Arne Jacobsen has paid homage to his debt to Mies' conception of contemporary architecture [8].

Briefly explaining such an approach necessitates that we mention "International Style", which was the dominant paradigm of 20th century architecture, and which emerged when the architect Philip Johnson, architectural historian Henry-Russel Hitchcock, and art historian Alfred Barr organized the significant and epochal exhibition of the same name in 1932 at the Museum of Modern Art in New York. This work and mindset were also the starting point for formulating the conception of architecture, which had only arrived in Scandinavia a few years earlier. As regards Arne Jacobsen, his point of departure in this architectural conception became quite visible in his buildings and modeling in the 1950s and 1960s.

Jacobsen also became an exponent of spacing the room and its surfaces in order to achieve a balance of pure relations, often with a chromatic harmony in his use of colors. In the German periodical *Bauen+Wohnen*, Arne Jacobsen has stated that his fascination with Mies was related to his sense for the nature of materials and the reduction of *the gestalt* to bare necessities, not only, but in conjunction with a good eye for proportioning. Jacobsen also speaks of the stringent beauty he finds in Mies' works, in buildings, furniture and details [9].

Arne Jacobsen was able to see himself in the Miesian approach, which is comparable to an intensive intellectual analysis having found its way into an objective, clearly structured architecture.

In 1932, Henry-Russel Hitchcock and Philip Johnson described the new conception of architecture which insists on volume over mass; this, along with the addition of regularity over axial symmetry as an overall building principle, and, ultimately, that the bare aesthetics of production in standardized materials avoids random ornamentation and decorations [10].

Further, Alfred Barr has written of the modern architect working within this new International Style that he does not work with a structure of bricks and walls with thick columns and supporting walls placed heavily on the ground, but rather with a skeleton contained within a light shell. He, the architect, thinks volume – rooms framed by planes and surfaces – as opposed to mass and solidity.

International Style introduces a new language and the Royal Hotel is described by Thau and Vindum as the jade-toned super structure, which, in a magically floating way, exists in the fade between crystalline sharpness and floating clouds; a building, which, in a deliberate and cultivated way, is assimilated into the bleak, Scandinavian sky [11].

The solitary location of the building, towering in the Copenhagen skyline, is pronounced; this also applies to Jacobsen's incredibly carefully drawn diminutive mesh width in the curtain wall grid of the façade, which is almost floating due to its very thin profiles, where the hinged windows are quite small and thus contribute to creating this tight "net" that comprises the house of the volume. An effect that makes the building appear less colossal to the beholder, less "blocky", and which also, when viewed, makes it difficult to assess the actual dimensions of the box.

At this point, we would like to call attention to the fact that in a dualistic line of thought, the building is to be seen almost as a compass-less sphere, a condition without unambiguous direction, which makes the building seem lighter than it really is.

Like the curtain in room 606 allows the orthogonal spatialities of the hotel to provide a framework for sensuous magic, in the hotel lobby, Jacobsen also introduces an element sensually akin to the curtain and the door handle. The lobby is located on the street level but is separated from the traffic-related pace and dynamics of the street by a number of shops. These shops pose a physical barrier that allows for the existence of a universe that not only utilizes the said shops as a physical intermediate zone, but also exploits this boundary to create a filtered light and sound intake from the surrounding streets. The context is made partially accessible through the shops that simultaneously blocks and creates the connection. The lively, colorful streets of Copenhagen serve as a backdrop for the reality of the lobby; the movement and dynamics of the street are accessible as silhouettes in the world that Jacobsen brings to the fore in the lobby, a balance between private and public.

Thau and Vindum write of the original furnishing of the lobby that the entire service system that is created, this soft sound scenery, is characterized by a "*pervasive shore*" of light brought about by Jacobsen's grey-green range of colors in the lounge [12].

Jacobsen consistently balances private and public through several scales in the lobby. He designed the Egg in 1958 as a part of the interior of the Royal Hotel, and this particular armchair is a continuation of both Jacobsen's sensual mode of expression and his views on private and public.

In the lobby, the Egg was placed in groups around tables, and these groups of armchairs form a subdivision of the world of the lobby by virtue of the closed and static shape of the circle. The possibility for conversing and connecting in a hotel lobby, which, at the same time, functions as a main entrance for guests of the hotel, is established, and transit and lingering are contained in the same motion [13].

In each individual Egg, Jacobsen adjusts the relationship between private and public. The Egg provides shelter for the body – the legs can be drawn up, making the periphery of the shell all-encompassing. The breaks in the shell of the Egg are used to create ambiguous spaces. Viewed from the side, the forward inclined upper part of the shell reveals to the seated person even a fleeting glance from an onlooker. If complete privacy and shelter from the world of the lobby are required, the chair may be turned, and the surroundings are faced only by the woolen textures of the back, which, as a curtain, covers the view of the private space in the encounter between furniture and the human body.

Even though the Egg serves as an element of the unified spatiality that is the lobby, the chair takes on the properties of a private retreat. Within the encoded boundaries of the lobby, the chair thus encodes an almost post-structural language of dwelling. To encode means both to hide and not to hide. The message is hidden insofar as the eye cannot perceive the combined meaning with the significance of the details [14].

The prerequisite for being able to make this interpretation is that the form is not perceived merely as a silent, material, physical shape, but that it *communicates its own existence*, or, in other words, that it holds *meaning* to a group of receivers [15].

We have used semiotics, a discipline originating in linguistics, as a route towards this understanding. Semiotics is the science of signs and codes, and the point of departure is that any creation of meaning takes place through signs and sign systems. In this analysis of architecture as a meaningful sign, we are positing *function* as the focal point, and we refer to the French literary scientist Roland Barthes whose “*Rhetoric of the Image*” from 1964 presents examples of such semiological readings of images through the concepts of *denotation* and *connotation*. Barthes views *denotation* as the basic meaning of the sign, the literal level, or that which can be physically seen and felt. In turn, he views *connotation* as the derived meaning of the sign, its symbolic level; in other words, everything that is connected to the sign and which is not encompassed by its basic meaning, in this paper termed sensual awareness.

Thus viewed, the denoted message of the Egg is the *immediate applicability* of the chair, while the connoted message is related to a number of *symbolic meanings*, which have to do with this applicability. It is thereby the codes that determine the reading of architectural design as a characteristic form. The interpretation of a modernist building, a chair, a handle or a transparent lace depends on the code that is applied in the construction as well as the reading.

Jacobsen explored the relationship between furniture and body in the Egg’s path towards its sculptural identity. He worked with 1:1 plaster models that were added to and ground off until the unity and the right interplay with the body had been achieved. The finished sculpture was realized as a piece of furniture in steam molded polystyrene, which was developed by Henry W. Klein in the mid 1950s. Jacobsen was critical towards the compliant nature of the material as there was insufficient resistance in it to generate tension in the double curvature, but decided to explore it anyway due to its potential to exceed the structural limitations of laminated wood, which he had previously pushed to its limits in his design of the chair, the Ant. With polystyrene, Jacobsen achieved an expression in which seat, back support and armrest were combined in one shell. The unity of the Egg must be articulated by virtue of its foot being separated from the shell by introducing a connection point that enables rotation - the footstall does not move, but the shell can be turned and tipped freely in floating movements [16].

The armchair was designed specifically for the hotel lobby but was also used in the furnishing of the rooms, which, just as the lobby, reflect the stringent geometry of the exterior of the hotel.

The sculptural nature of the chair demonstrates not only the dialogical abilities of forming – between organic curves and the systematic patterns of geometry – but also Jacobsen’s sensitive accentuation of the encounter between the human body and physical objects, just like the curtain and the door handle. Jacobsen’s original intention was that the Egg should be covered solely with leather, but he ultimately opted to cover the majority of the Royal Hotel’s chairs with wool. *The pervasive shore* of light in the lobby is thereby also represented in room 606, as the blue and green pastel shades counter the warm, earthen colors of the teakwood panels. The Egg in room 606 is consequently covered with the original mint-green wool. Sitting in the chair, one can feel even the minutest roughness of the woolen texture; a sensual feeling that today, as well as in the 1960s, reveals the form to the seated body.

The Egg thereby embodies the handle’s sensual curves and the curtain’s seductive accentuation of the swaying materiality and transience in what is hidden and revealed by and behind the textural veil.

As previously mentioned, the purpose of this paper is to investigate whether it is possible to reveal an architectural dualism in the Royal Hotel through an examination of the inherent qualities of the architecture and, furthermore, try to relate the language of sensing and affect to the works of Jacobsen. We approach the Royal Hotel, first and foremost, through a semiological analysis of the work, the primary aim of which is to investigate the work on the level of *meaning*, or, one might say, its contents. It is our thesis that this analytical approach is relevant when focusing on the motif of the work, and when one wishes to investigate the implications of the motif, how *meaning* has been brought about, and to whom the work means just that. This is where the guest meets the Royal Hotel.

In such an approach, one might label the contents of a work thematic or subject-oriented, symbolically, allegorically, politically, or otherwise. Popularly, one could refer to the content as the message of the work. The content may appear highly distinct, expressing an unambiguous message, as is the case with the simple, stringent geometry of the building, or it may be of a more equivocal nature, as is the case with the organic form of the Egg. The content, however, is the narrative, which the designer, here Arne Jacobsen, expresses by way of his chosen means.

It has been interesting to examine whether the meaning of a work, here the Royal Hotel, and the architectural design that characterized Arne Jacobsen with total solutions from door handle to textile, from furniture to wall, is perceived differently by a historical and a current viewer. It has also been interesting to reflect on how meaning is actually created. Is meaning inherent in the work as a hidden core; a core that we are supposed to find? Or is meaning something that is negotiated between the work and its observer at the exact moment in which the work is experienced?

In his essay on interior decoration, Mario Praz uses the term *stimmung* to refer to “the sense of intimacy”, on which he elaborates by stating that “..for the soul, the house where it lives is nothing but an expansion of its own body.. The surroundings become a museum of the soul, an archive of its experiences”. In the above, we have focused on this kind of intimate privacy in the works of Jacobsen, but the most outstanding example is one of the most famous pictures of Jacobsen’s chair, Model 3107 from 1963, where the controversial, young English fashion model Christine Keeler sat astride the, then, future international commercial success. Mario Praz uses the term *stimmung* to denote the “sense of intimacy” created in the home. For Praz, a lack of *stimmung* is a lack of sensing; that is, sensing is a prerequisite for intimacy.

In the book “*The Truth At Last*,” Christine Keeler tells of her affair with the British War Minister, John Profumo; a relationship which would turn out to have serious consequences for the British government. Can we find evidence of the sensation of taste in this fulfillment of sensual appetites? Can a chair, the Model 3107, signal more than a seat? Can a sensual experience be related to architectural design?

In 1963, as Keeler was having her affair with Profumo, she was depicted with Jacobsen’s model 3107 by the photographer Lewis Morley. Keeler had signed a contract obliging her to pose nude in adverts. During this significant photo session, Morley used three rolls of film. The first two consist of a scantily clad Keeler sitting next to the chair. For the third one, the producers demanded that Keeler undressed completely. Keeler, however, had regretted her acceptance of this part of the contract. Morley appeased her reluctance to being exposed in full nudity by photographing her sitting naked on the chair – and having the chair cover most of her. Everybody except Keeler and Morley left the room before Morley took 12 pictures of her, of which the last photograph is the one that achieved global fame [17].

The demand for nudity and Keeler’s reluctance were an obstacle, which, as it turned out, actually paved the way for the subsequent status of the photograph. The brief, 5-minute photo session during which Keeler was undressed in addition to the contrast between nudity and cover lend the photograph a cursory balance. The erotic significance of the photograph is achieved through the awareness of the naked body, the sensuous is achieved in the contact between two elements – two archetypes: The naked womanly body against the cold back of the chair. The boundaries between the two “bodies” are erased, and from the moment the photograph was taken, sensuality became as much an inherent part of Model 3107 as of Keeler.

Some bonds are so closely tied that they are never completely broken; and while we will not put into question that Model 3107 had a relation to the human body prior to the photograph, the articulation of the photograph leaves no doubt whatsoever. The naked bodies are the core – there is nothing but the two – and for this very reason, there are no longer two bodies – there is *less*. The two are fused together; they are one. Subsequent to the photograph, the chair is *more* than before. It has *it*, the simplest, most direct and pronounced kinship between man and object.

The chair achieved iconic status for when Keeler had first sat in Model 3107, she never left. Present demands indicate that the photograph captured something that involves much more than shaping and producing a chair; also more than the story of Keeler as an extravagant personality, and the ability to depict a sensual womanly body in a photograph and, further, in a series of newspaper articles a woman’s emotional

life. The exact atmosphere that is expressed through the sensuousness in the encounter between Keeler's body and that of the 3107 is something quite unique. It is our assertion that it is the story of man and this materiality that architectural design brings about in our lives.

This kind of argumentation has been made possible with reference to the iconographic method developed by the German art historian Erwin Panofsky, which is presented in the book "*Studies in Iconology*" from 1939. Here, Panofsky promotes iconography as the science of motifs, which is primarily based on literary sources. We have been able to determine that such an analytical approach deals with iconographic motifs. Panofsky's principal idea is that the *meaning* of a work can be investigated through contemporary sources, which, as in this paper, means an investigation based on articles published in newspapers and journals in addition to photographic material. It is a method which, to the best of our belief, points to the *meaning* of the work, the 3107, being approached as a kind of hidden "core" inherent in the work. Consequently, it is our thesis that this analytical approach has enabled us to demonstrate the "hidden" meaning of the work, the sensuality between Keeler and the 3107.

In our analysis of the Egg, we have taken this approach and view one step further, and by following the pre-iconographic description that may be perceived as an immediate identification of the motif, in the sense that through such an approach we have described the work, and by way of this description identified its means, its tactile and sensual address to the human body.

Thus, we have viewed the Egg both from a visual approach and from a tactile one, in the touch of the textile; but a significant dimension is obviously also related to the title of the work, the Egg, which in itself identifies its main concept. An identification of the style of the work also belongs under the pre-iconographic description. The style is thus defined by describing the formal qualities of the work. It should be emphasized that the pre-iconographic analysis contains both an identification of what is depicted and a definition of the stylistic period of the work.

The iconographic analysis is first and foremost an analysis of the conventional meaning of the work; the Egg is a chair. The word "conventional", however, also refers to the meaning that is traditionally ascribed to the work. The iconographic analysis is therefore also a close-reading of symbols, figures, stories and also allegories; i.e. an analysis based on contemporary and/or older literary sources or other works. In conclusion, one could say that the work is placed in an architectural historical tradition.

The idea of the analysis is consequently to acquire new knowledge of how the architect may have drawn upon contemporary conventions regarding the meanings of architecture. We believe that we have gained an insight into the potential meaning behind the motif. Through his fascination with the great modernist masters, Arne Jacobsen had a powerful approach to contemporary models and manifestos, other architects' statements and image material. This is a meaning that can be ascribed to his work, the Egg.

Finally, we wish to point out that in continuation hereof, the iconographic interpretation – the so-called iconology – is also an analysis of the semiotics of the work in an architectural historical context; the way in which the 3107 and the Egg can be interpreted in the light of the fact that the historical period – International Style – had a specific world view and ideology. The analytical move we are making here is to view the work as an expression of the predominant world view of the period. The architect's intention is used to explain the particular philosophical, religious or political parameters of the period in relation to its world view.

A photograph; we have observed the woman who is seated on the chair, her nudity and the fundamental truth that the essential parts remain hidden. The contact between the two bodies, the physical design, the chair and the living body that stays hidden as we are faced with the back of the chair, hiding the woman.

What happened there? We have labeled the historical development and its constitutive events as a fulfillment of the story. The iconographic analysis has enabled us to broach Arne Jacobsen's architectural legacy. We have situated ourselves in a landscape of the psyche, which houses the past and the present, the entire world of night, dreams, hopes, memories and premonitions.

We have become conscious of the fact that the past and the future share a closer connection to each other than they do to the present. We have tried to track significant events back to their historical conditions in order to trace them to today in a search for a hierarchy of relevant sustainable investment in architecture; a reconstruction that has displayed the movement of the events from the possible to the real.

We have maintained a conception of the event in its historical fulfillment, whereby the historical time has been subordinated the movement of the possible towards the real. We have attempted to uncover the iconography of the motif; i.e. its cultural, historical and design-related meaning in the broadest sense of the word. We have tried to demonstrate some connections between a period in architectural history on the one hand, and the current representation of the 3107 and the Egg within the rational, geometric framework on

the other, and we have established a high degree of sensory awareness. There is an immediate connection between the two phenomena of architectural design and sensory awareness.

To us, the photograph represented an invitation to abandon the simple, classical point of view, which tradition almost dooms us to adopt, in favor of moving freely, at least in our imagination, around the represented object, the 3107, and further about in the building in order to meet its history, the reality behind this building drawn by Arne Jacobsen.

As is often the case with modernism, the simultaneous representation of mutual reciprocity is implicit. This image, this appreciation of two separate, yet inseparable, bodies, allows for complementary attraction, and it would be contradictory to refuse such an invitation – we were invited!

And the term *less* became by our focus on architectural heritage and through the sensual awareness *view more*.

Abstract

This article – which represents the very first step in a research process – aims to provide a general overview of the main features of the *Urban Interaction Design* project. A series of case studies will be discussed which constitute the crucial reference point for investigating the complex relationships between urban spaces and activities, generally of a spontaneous nature, undertaken by citizens. These activities are aimed at altering the physical structure and relational components of public spaces.

The research concerns the theme of *Urban Interaction Design*, an appropriate research field for defining the tools and processes of intervention. This type of design project is considered to be the result of negotiation practices and of an analysis aimed at transforming the components of the intervention sites into design proposals and decisions. These design proposals are based on the capacity to 'identify' and 'describe' the identity of urban contexts as the value that defines the places and their systems of reference. In this sense, the term *Urban Interaction Design* does not refer to the use of a specific technology, but to an approach to design which can accompany, and occasionally surpass, the actions and strategies of urban and local marketing in favour of a broader and fruitful dialogue with other disciplines. In particular, it is designed to be used in conjunction with the specific discipline of representation in order to rethink the traditional models of narrating places. Communication strategies and forms of data-gathering need to be introduced which are careful to interpret reality not as overlapping levels of information but as a collective way of thinking about living space and capable of communicating identity effectively.

The article also seeks to focus on the research of design objects, including spontaneous and/or anonymous ones, and possible ways of cataloguing them in relational terms. The article analyses the concept of a design process of urban spaces in which the communities that inhabit them and enliven them play the leading role.

The research will proceed with an application of a specific example - the urban area of *Lavinio* in Naples - which will be examined by the Research Unit (the two authors). The research objective will be to provide guidelines and suggestions about a social interaction project which is both a repeatable methodological model and, at the same time, is capable of producing artifacts and actions related specifically to *Urban Interaction Design*.

Key words: spontaneous design, fun theory, mixité, environmental interaction design, marketing places, social interaction design, urban interaction design, behavioral design,

1.0 _ The design process as device.

We are used to recognising efficiency according to parameters that involve minimal wastage and the minimum investment of resources; we can also define any object and/or action as effective if it achieves its objective; but what happens when the objective comes as a surprise? This is the case when the objective of the project does not lie in putting a product on the market, in transforming an idea/object into a saleable product, but rather in meeting requirements considered excessively private and restrictive by the majority of investors/entrepreneurs.

One possibility is to consider design as a discipline concerned with the invention of processes, as well as objects; this does not mean the design of a process or a service but rather the quality and ethics of the design, defined as social responsibility which contrasts with egotistical constructive narcissism.

In this sense, it is more topical than ever to refer to design beyond the mass produced product, searching for the less and the more by shifting the contents of the reasoning from the design of a mass-produced object to

an object that is appropriate for a community, even a very small one, and even individual one-off solutions which can be repeatable but never without adequate and careful adaptations. In short, the question refers to the possibility of searching and working on processes and objects which do not define the result from the perspective of the product and the market but which take account, first and foremost, of real needs, however exceptional they may be.

It is a sort of design of rarity, which eludes the conditions of luxury in order to prioritise all threshold situations between the public and private spheres and in order to meet minority and contextualised needs, even with regard to potential solutions. This means taking account of the importance of involving the user, the culture of specific places, the possibility of social mixing and, above all, the desire to share the advantages for wellbeing of specific solutions, both in terms of social satisfaction and the advancement of knowledge. At this point, appropriateness cannot always correspond to efficiency if account is taken of the evaluation of the resources employed with respect to market profits; however, the investment of resources and the balance of profits also refer to objectives that cannot easily be evaluated or that can be evaluated in terms of social, and therefore collective, resources. Furthermore, it is always worth remembering that knowledge is the only form of matter that, when shared, is not halved but multiplied.

Therefore, considering design and research for design as shareable material also means interpreting the store of knowledge as an inexhaustible resource. In this sense it might appear horrifying to recall that know-how does have a price in business negotiations; this is not the right context for the discussion, but the issue regards the role of the design project for social policies and especially the ethical position so that the produced goods, at least in part if not entirely, should be assessed in terms of profit and collective wellbeing. It is also necessary to reflect on the objectives of the design project and decide that there are project fields that are more interesting than others. It is therefore necessary to decide whether manufactured objects are designed to be civic devices: in other words, are they suitable devices for supporting and promoting dynamics aimed at achieving communal wellbeing, the outcome of social responsibility?

From this perspective, it is interesting to refer to the work of Joseph Alois Schumpeter (1883-1950), the advocate of an economic vision that refers to the model of creative destruction. Drawing on Schumpeter's ideas, Alberto Cottica proceeds by differentiating between accessible technologies and non-permissive technologies: «from the economic perspective, non-permissive technology has a strategic consequence; it creates barriers of artificial scarcity around the immaterial component of the price of industrial products [...]. 60 to 90% of the price of a hi-tech product consists of patents, design and marketing; in other words, in terms of bits, the hardware counts for between 15 and 30%. The bits are fixed costs and these products therefore have high margins, and the activity of producing them is profitable. At the same time, this makes it vulnerable because in principle it is possible to produce a rival product which costs much less, intervening on the cost of the bits. This requires design and engineering skills. We are used to imagining that these skills can only be found in the *Research & Development* laboratories of large companies. Nowadays, however, there is another solution: open source communities. Many individuals work together on developing a technology designed to be a shared resource [...] At the centre of these communities, there are open, enabling technologies designed to be clarifying, and therefore [...] invested by a stream of innovation» [32].

2.0 _ Urban Interaction Design _ preliminary remarks.

The premise therefore lies in considering objects and artifacts, the outcomes of the *Urban Interaction Design* project, as devices suitable for stimulating and solving actions and practices between the different players of an urban space while a transformation of this same space is proposed, together with the search and explanation of its own identity. The concept of transformation includes the well-known categories of urban upgrading and design which the urban interaction project supplements and partly overlaps with respect to the methodological approach of intervention.

From this perspective, the identity of urban spaces becomes a crucial issue, both with respect to the definition of their original context and with respect to the other parts and the whole system of reference.

There are therefore two levels of reflection and action, to which we could add a third. The first one concerns the knowledge of the urban fragment, the second regards the relationship with the system of reference while the third is related to the narration of identity to different interlocutors [06].

In this sense, the role of surveying and representing places acquires central importance in the design process. Narrating identity is the preparatory action for identifying any possible strategy and it is an action which the places of contemporary reality – which are complex places, marked much more by the fluid dimension of moving rather than the sedentary action of being – urgently require with new forms and multiple approaches. One idea that is gaining ground is to proceed with representation through a 'sensitive' survey where the emphasis is on a lateral approach to reading the landscape which presupposes a transversal analytical approach aimed at studying local areas from different viewpoints, angles and scales of interpretation and, above all, with a focus on perceptive, anthropological and sociological aspects. It is a method that derives from the well-known studies of Lynch and Cullen. However, the method now has new results in the form of dynamic maps and visual and perceptive images, in the installations of what can be referred to as the new eclectic atlases of urban spaces [23] where the physical marks of the landscape are

overlapped by the traces of flows, behaviour and lifestyles through which the processes of modification of places are made manifest. The result is a heterogeneous, representative artifact – a kind of atlas – which is created using different supports, representative strategies and different perspectives. They are provisional maps, biographies of places, ways of looking at identity and their narration in a space where the physical dimension and the dimension of mental space overlap, where the arrogance of zenithal representation leaves space for the emotional representation of places to be used as a circumstantial paradigm from which to derive hypotheses for action and shared design.

Summarised very briefly, the design process that we propose to activate is based on several of James Lerner's ideas about the selection of possible actions and the inappropriateness of acting out of necessity [08], supplemented by the role of *Interaction Design*, as defined by the *Makers' Movement* and expressed very clearly by Giorgio Olivero (a former student of Massimo Banzi at the Interaction Design Institute of Ivrea and currently co-founder of the *TODO Design Studio_Interaction and media design*, 2007, Turin): «interaction design (can be defined as) the activity of orchestrating and designing interaction between the people, spaces, things, products and services that surround us, [...]; for us, design is not a static quality, it should not be restricted to the definition – however important – of the formal quality of what needs to be designed; instead, interaction design is an activity in progress with an aim and a direction; the central part of our approach to design consists of relations and experience and behaviour» [37].

The aim is also to look at existing objects and artifacts to be produced as relational devices; in this sense, it is useful to carry out research into the definition of codes related to objects. In order to prepare the research, a useful starting point could be the exhibition *Offjects, concept and designs for a change of Century* [04], as well as the various case studies described below.

3.0 _ Case studies: brief notes.

The design project for social interaction could be oriented through the close examination of a series of case studies of various kinds. These may range from initiatives of citizen activism to the spontaneous design of objects and devices, to works of environmental interaction, or of behavioural interactive design.

A series of brief case studies are described below with the aim of highlighting - despite the fact that the various examples refer to different technologies and different cultural contexts - that the involvement of the authors and the users is the cornerstone of each project that is presented.

Each of these examples, whether material or digital objects, has the enormous power to encapsulate a story, which is a relational history rather than an industrial one. In this perspective, one possibility that is gaining ground is the idea of viewing urban design as a form of design that encourages social interaction. In this case, innovation does not lie in the application of state-of-the-art technologies but rather in a combination between vision and design actions that stem from a conscious interpretation of user-feedback, deriving from a design methodology that is sensitive to the interpretations of the user-experience of urban spaces and bottom-down transformational possibilities.

In this perspective, these case studies represent the basis for a field study aimed at implementing specific investigative techniques, linked to listening and observation, taking into account that «place-making can also be regarded as a linguistic matter. To understand what urban places are and how they work, Michel de Certeau, in *The practice of everyday life* (1990), introduces the metaphor of “textual poaching” to feature a tactic (distinguished from a formal strategy) ordinary people creatively perform to resist, counter-act and make active sense of mass consumption and domination strategies in contemporary societies. Why “textual”? Textual poaching corresponds to a practice of active reading, based on the idea that, when we read a text, we're not just passive recipients of a written message, but we actively collaborate to recast and make our own sense out of it. In this metaphorical perspective, the reader is the city dweller and the book is the urban space, made of symbols, signals, linguistic codes, to be interpreted properly and quickly, in order to cope effectively with the multiple strains and unforeseen occasions contemporary city steadily offers (Lietao, 2006). Everyday life can be depicted as a constant, creative (even subconscious) dialectics/struggle between different practices, where institutions compete to address/regulate/assimilate the *everyday man*, his preferences, behaviour, movements, life style into normative and somehow pre-fixed schemes. In de Certeau's perspective, this struggle is substantially a clash between different linguistic codes» [12].

- **Homemade:** Vladimir Archipov's book, *Homemade: Contemporary Russian Folk Artefacts*, aims to study «the self-production of everyday things [...] made in Russia»[1]; the author, who spent eleven years exploring rooms, wardrobes, storerooms and streets shows his collection, his *Folk Museum of handmade objects*, together with the accounts of these spontaneous designers. The objects are all basic in the sense that they express their own permanent nature that stems from necessity; they are more than useful, they are so indispensable that they were created as a result of the real need of the maker-user. The Archipov collection contains over thousand objects that reflect a Soviet culture borne out of necessity and the lack of consumer goods. Tools, mechanical objects, contrivances, toys, devices, means of transport, musical instruments tell the story of a country, of the collapse of the Soviet Union and the needs of its inhabitants.

Fig. 01: Television Aerial, Albert and Ivan Chmelyov, Kaluga region, 1999. «[...] We wrapped copper wire around two bicycle wheels [...]. To get good reception we planted this kind of cylinder in the ground and nailed a stick to it so that we could turn the aerial towards the point from where you could get a better signal» [01, p. 162].

Fig. 02: Queen Bee's Hive, Sergej Charitonov, Voronez, 1996. «This tiny hive is designed to protect the queen bee from attacks from other bees [...] (it is made from) one of my grandmother's curlers and a bottle cap [...] the elastic band is required to hang it within the beehive so that the bees can get access to the queen. They have to feed her [...]. Several years ago, I recall, my grandmother used to curl her hair but she doesn't do it anymore, so she was very happy to give us these curlers for this device» [01, p. 40].

Fig. 03: Television Aerial, Vasilij Archipov, Kolomma, 1993. «[...] it is well-known that resonators are fundamental: In this case we used forks to improve reception. [...] My mother used to keep the forks in a cupboard: she had bought the forks when the country was in chaos and these were the only things sold in the shops. They were not even made of high quality material but they were perfect for the aerial» [01, p.151].

Fig. 04: Doormat made from bottle caps, Aleksej Solomkin, Vladimir 1995 [01, p. 26].

Fig. 05: Dustman's shovel, Vladimir Antopiv, Moscow 1998. «[...] I was loading rubbish into the lorry when I found this street sign. I was about to throw it away, but then I realised it was really light. Ahah! I thought. This would be fantastic for shoveling snow in winter. They gave us shovels [...] that were completely useless» [01, p. 174].

- **Low cost design**: Daniele Pario Perra's book, *Low Cost Design*, is a collection of 7000 photos; it is «a search for the essence of spontaneous creativity. It is a project that stems from an extremely simple idea: we are surrounded by thousands of objects and structures that do not follow the rules of conventional design; these are not just the products of the intellect, but cultural indicators of collective design skills» [30]. «The links between people, small economies, neighbourhood relations, are characteristics that cannot be separated from the sense of a traditional community which nowadays is often being irreparably damaged by the large scale of contemporary urban planning. As an alternative [...], listening to the spontaneous examples of creativity in the local area is a fundamental aspect of sensitive design» [17, p. 26].

Figs. 06, 07, 08: «These forms of experimentation arise [...] from situations of necessity, on the margins of the most frenetic consumerism, in which the tradition of the art of know-how and sharing is handed down from generation to generation, and in which a degree of precariousness becomes a source of creativity, exploiting unusual resources and a search for opportunities. Spontaneous creativity, for want of a better term, can be studied as a social phenomenon because it is free from external conditioning. It is not generated by applications on the market or by a specific course of technical knowledge. The tangible demonstration of how these uses are generated by precise social relations is the discovery of similar objects and uses in places that are remote from each other but comparable in terms of the socio-environmental conditions, united by the same needs» [17, p. 19].

Figs. 09, 10, 11: «These gestures are full of a great visionary ability applied to practical experimentation. If we associate

these observations with the history and lives of the inhabitants of a place, we can develop an infinite number of links, from sociology to design, from art to architecture, from town planning to contemporary ethnography» [17, p. 17]. The initiatives and artifacts that concern public spaces are the result of an action that «[...] also represents a more complex dimension of appropriation and of the desire to participate in the process of using the city. Football pitches drawn on the paving of our squares and piazzas, the chairs hidden in the nooks and crannies of buildings, the self-produced street signs, the makeshift repairs to public benches and rubbish skips point to the emergence of a dynamic vision of the urban context which is constantly renegotiating its own role and the use of public spaces» [17, p. 22].

-The Fun Theory Award: The *Volkswagen* company finances a project in Sweden to encourage ethical behaviour so that it becomes fun.

Fig. 12: The Anywhere Organ: «public installations of individual pipes connected to a central air supply through a long hose, allowing anyone to play the organ anywhere» [31].

Fig. 13: Bottle Bank Arcade Machine: «Many of us return our plastic bottles and cans. Noticeably fewer recycle their glass. Maybe that's because we don't get any money in return, as we do for cans and plastic. Can we change this attitude by making recycling glass fun to do? So you are not just rewarded with a good conscience, you also get a smile» [31].

Fig. 14: The piano staircase: «take the stairs instead of the escalator or elevator and feel better is something we often hear or read in the Sunday papers. Few people actually follow that advice. Can we get more people to take the stairs over the escalator by making it fun to do?» [31].

- Critical City Upload: project by Matteo Battaglia, Matteo Uguzzoni, Augusto Pirovano, Davide Portanome, «*CriticalCity Upload* is a pervasive game which, through a web platform, encourages players to go outside and asks them to carry out "missions" in the city. The missions are actions designed to get players to interact with the urban space in a new way which is fun, at times provocative and always unexpected» [33].

Fig. 15: Critical City, trademark and logotype and different versions of the trademark.

Fig. 16: Critical City, images of "missions".

- **Domesticità _ urban actions:** *Domesticità* (Domesti-city) is an initiative promoted by the architects Valentina Costa, Laura Di Stefano and Pierluigi Ventura. «The "Domesticità" project started in Rome in 2005 at the initiative of a group of young architects based on the observation of a public space: it questions the effectiveness of the simple act of design since it proves insufficient for making these places work as catalysts for the collective activities which would be expected of them, both by definition and for historical reasons. In our opinion, it is vitally important to have a radical rethink of design tools and above all, the indicators used to evaluate the designs of public spaces. [...]» [36] .

Figs. 17, 18, 19, 20, 21, 22: The images refer to a series of initiatives and designs by the Domesticità group: *Lavagna Urbana (Urban Blackboard)*; *Message in a Bottle*; *Mail box*; *l'Orto Pubblico (Public vegetable garden)*; *la Mensola Urbana (Urban Shelf)*. «The 'urban shelf' harnesses the principle of overturning the concept of indoors/outdoors since it places the furnishings and fittings of a domestic space on the city walls. The shelf interprets the most practical aspect of virtual communication [...] acting as the physical interface for a postponed form of barter. [...] the *Urban Shelf* exploits the iconic value of the object rather than the principle of overturning the concept of indoors/outdoors. A blackboard is a portion of space devoted to writing or drawing, therefore communicating. [...] The Blackboard comes with chalks and a rubber and, in this case, the instructions that explain the possibility of using it freely are also included. [...]» [36].

- **Urban activism:** Taken from the Manifesto for urban activism in Turin, written by Alessandra Rasetti and Maurizio Zucca, January 2010: «The term 'urban activism' refers to a series of actions carried out by groups of citizens with the aim of generating a positive change in the environment of contemporary cities, in the way of inhabiting them and imagining them. These human engines for change are architects, engineers, heads of local public administrations, university professors, students, children, artists, skateboarders, cyclists, pedestrians and many other citizens. They are spontaneous actions that start from the bottom up, often imposed by necessity, where personal interests converge with the interests of society and the environment, invoking positive emotions, simplicity of action, vitality and a spirit of initiative. Nowadays, this phenomenon is gaining considerable ground in cities worldwide where the inhabitants are increasingly convinced that the traditional processes of top-down city planning are insufficient and need to be replaced by new approaches and tools which should be developed from the bottom-up» [35].

Figs. 23, 24, 25, 26: Urban Activism Actions: «The actions are intended to identify solutions for food production through urban agriculture, solutions for sustainable mobility, the creation of public spaces for strengthening social interaction, new forms of communication, ideas for sailing and swimming in urban rivers and any other ideas that may gradually emerge to improve the environment inhabited by citizens, giving them the freedom to interpret and have an impact on the space in which they live. These actions should be considered a resource since they represent an invaluable mirror of the real needs of the urban environment, besides having an important design significance: indeed, the variety of proposals and perspectives that stem from them could not emerge from the traditional top-down approach to design.[...]» [35].

- Environmental interaction design

Fig. 27: Dune, project by Studio Daan Roosegaarde: «DUNE is a public interactive landscape that interacts with human behavior. This hybrid of nature and technology is composed of large amounts of fibers that brighten according to the sounds and motion of passing visitors» [42].

Fig. 28: The Climate Wall, project by the Center for Digital Urban Living, Aarhus University: «During the climate conference Beyond Kyoto, citizens of Aarhus could engage themselves in the struggle for large-scale climate improvements by using Climate on the Wall, an interactive generator of climate statements that uses Ridehuset, a prominent building in the city centre, as a backdrop. The installation is part of the Municipality of Aarhus' campaign CO2030, dedicated to engaging citizens in the efforts to achieve carbon neutrality by the year 2030» [44].

Fig. 29: Serendipcity, project by Interaction Design Studio unit of the Design Computing Program at The University of Sydney in collaboration with the City of Sydney. Serendipcity is an urban exploration app for mobile devices that encourages serendipitous experiences.

Fig. 30: Sensitive City, project by *Studio Azzurro*, «The idea of *Sensitive City* stems from a request by the Italian Pavillion of the Universal Expo in Shanghai in 2010 and draws on the great tradition of imaginary cities, from the *Città del Sole* of Tommaso Campanella to the *Città Invisibili* of Italo Calvino, [...], a literary invention which, however, is ideal not just because it still does not exist but because it could do. Siracusa, Matera, Lucca, Chioggia, Trieste, ... are all different from each other and it is necessary to walk round every part of them repeatedly in order to be able to describe them. There is increasing interest in using the idea of the anti-utopian city as an opportunity to provide ideas, subjects for debate, in order to generate a vision of what a city in the near future might look like» [43].

- Audiovisual design

Fig. 31: Risveglio (Reawakening). Allegory of figures and music, 2011, project by *Studio Azzurro*, Videomapping on the buildings of Piazza Scala, Milan 2011 [43].

Figs. 32 and 33: Tracce e partecipazione (Traces and Participation), project by *Studio Azzurro*, Videoinstallation for historic facades, whispers, images and texts, Corso Bettini, Rovereto 2008 [43].

- Behavioral interactive design

Fig. 34: Sustainable Dance Floor, project by *Studio Daan Roosegaarde*: «is the interactive dance floor which generates electricity through the act of dancing. The first dance floor created by *Studio Daan Roosegaarde* uses mechanisms and embedded technologies to harvest energy. Via interactive technologies a sensual and interactive environment is created in which dancers are engaged with the sustainable experience» [42].

Fig. 35: Liquid Space, project by *Studio Daan Roosegaarde*: «is an interactive space that becomes physically bigger, smaller, and brighter in relation to human behavior. As an organic fusion of mechanisms, embedded electronics, sound, and LEDs, the artwork creates a playful dialogue with its visitors» [42].

Fig. 36: DWI_ Design with Intent: «a design tool for influencing user behaviour» [45].

Fig. 37: Lotus 7.0, project by *Studio Daan Roosegaarde*: «is a living wall composed of smart foils that fold open in response to human behaviour. Walking by Lotus, hundreds of aluminum foils unfold themselves in an organic way; generating transparent voids between private and public» [42].

From sustainable design to empathic design

Ornella ZERLENGA

ARV_Architecture “Luigi Vanvitelli”, Second University of Naples, Aversa, Italy
ornella.zerlenga@unina2.it

Abstract

Today the global issues of ecology and consumerism impose a call to the consciousness of design to assume its responsibility with respect to the environmental sustainability of a contemporary lifestyle.

The challenge for sustainability is to limit and manage Western consumption while raising the living standards of the developing world without increasing the use of its resources as well as its environmental impact. This must be done by adopting strategies and technology that break the bond between economic growth and environmental damage.

A major obstacle to achieving sustainability is the alleviation of poverty. It has been widely acknowledged that poverty is one of the main sources of environmental degradation: «poverty is a major cause and effect of global environmental problems. It is therefore futile to attempt to deal with environmental problems without a broader perspective that encompasses the factors underlying world poverty and international inequality» (Brundtland Commission, report *Our Common Future*).

In Italy, Riccardo Dalisi (author of the Manifesto of the Compasso di Latta) promoted the first edition of the “Premio Compasso di Latta”, aimed at carrying out new research in the field of sustainable design in the light of human support, environmental compatibility and de-growth. While, the Associazione Designer Senza Frontiere has been working on the themes of empathic and craft design as a generator of economic and social value since its founding..

Keywords: sustainability, sustainable design, empathic design, crafts and design.

1. From sustainable design to empathic design

Today the global issues of ecology and consumerism impose a call to the consciousness of design to assume its responsibility with respect to the environmental sustainability of a contemporary lifestyle.

A “sustainable” process must use natural resources at a rate so that they can be regenerated naturally. Today, humanity is living in an unsustainable manner, consuming the limited natural resources of the Earth faster than it can regenerate them. The collective social effort to adapt the human consumption of these resources within a level of sustainable development is a matter of paramount importance for both the present and future of mankind.

Since the 1980s, the term “sustainability” has been used more in the sense of human sustainability on planet Earth and this has resulted in the most widely quoted definition of “sustainability” and “sustainable development”: «sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs» (Brundtland Commission of the United Nations, March 20, 1987).

While raising the living standards of the developing world, the challenge for sustainability is to limit and manage Western consumption without increasing its use of the resources as well as its environmental impact. This must be done by using strategies and technology that break the bond between economic growth and environmental damage.

The concept of “sustainable development” is used in the context of development economics to analyze economic processes, with the concept of economic sustainability being at the core of the considerations that contemplate the future possibility of a ‘hard’ economic process over time. In this perspective, consumers are using their purchasing power for ‘ethical consumerism’ practiced through either ‘positive buying’ (the ethical products are favoured) or ‘moral boycott’.

A major hurdle to achieving sustainability is the alleviation of poverty. It has been widely acknowledged that poverty is one of the main sources of environmental degradation: «poverty is a major cause and effect of global environmental problems. It is therefore futile to attempt to deal with environmental problems without a broader perspective that encompasses the factors underlying world poverty and international inequality» (Brundtland Commission report *Our Common Future*).

In this sense, sustainable design (also called environmentally conscious design) is the «philosophy of designing physical objects, the built environment, and services to comply with the principles of social, economic and ecological sustainability».

The intention of sustainable design is to «eliminate negative environmental impact completely through skillful, sensitive design» [1]. Sustainable design does not require non-renewable resources, minimising the environmental impact and relating people with the natural environment.

Beyond the “elimination of negative environmental impact”, sustainable design must create projects that are meaningful innovations capable of shifting behaviour. A dynamic balance between economy and society, with the intent of generating long-term relationships between user and object/service as well as be respectful and aware of both the environmental and social differences.

In a memorial service held in Tucson, Arizona (on January 12, 2011), President Barack Obama called on the Americans to “sharpen our instincts for empathy” so that we can become a more civil people.

In the opinion of Jeremy Rifkin (author of *The third industrial revolution* and *The empathic civilization: the race to global consciousness in a world in crisis*), being empathic means being open to the plight of others. For Jeremy Rifkin, empathy is the emotional and cognitive means by which we express intimacy and sociability. To empathize is to experience another's condition as if it were our own. It is to recognize their vulnerabilities and struggle to flourish and be. Empathy is the real “invisible hand” of history. Today, empathy is beginning to stretch beyond national boundaries to include the whole of humanity. We are coming to see the biosphere as our indivisible community, and our fellow human beings and creatures as our extended evolutionary family [2].

In this sense, empathic design is «a user-centered design approach that pays attention to the user's feelings toward a product» [3]. The foundation of empathic design is observation, with the goal being to identify latent customer needs in order to create products that the customers do not even know they desire or, in some cases, solutions that customers have difficulty envisioning due to lack of familiarity with the possibilities offered by new technologies or because they are locked in an old mindset.

That is why the X International Forum “Le Vie dei Mercanti” *LessMore architecture design landscape* was organized. In this perspective, ‘Less’ does not mean less investments or cuts, but rather to identify a hierarchy of relevant sustainable investment funds based on the search for the know-how as well as the reduction of the waste of goods (raw materials, human resources, assets) and the use of heritage to create richness and workplaces, ‘More’.

In this sense, starting from the cultural concept of “creativity” formulated by UNESCO, three Italian experiences will be described, “Compasso di Latta”, “Designers Senza Frontiere” and “Visual Identity for the complex of late antique and early Christian basilicas in Cimitile”.

1.1 UNESCO and the network of creative cities of Design

Creativity is one of the main themes of cultural interest of UNESCO. While, on the website of the United Nations Educational, Scientific and Cultural Organization, “Building Peace in the minds of men and women”, the concept of creativity as well as the goals of the creative industries, of the relationship between Craft and Design, of creative cities network are well defined [4].

By encouraging diversity and contemporary creation, UNESCO endeavours to ensure that all cultures – with due respect for their equal dignity – benefit from the development opportunities opened up by creative industries by strengthening local markets and providing better access to international markets, particularly by means of North-South and South-South cooperation.

Creative Cities Network

Fig. 1: UNESCO and the network of creative cities of Design. Saint-Etienne innovating in the face of social change: urban transformation; exhibition *City Eco Lab*, fifty people, three ways to move (2006 Saint-Etienne International Design Biennial); Matali Crasset, *Cohabitations* (2008 Saint-Etienne International Design Biennial).

In this perspective, the Convention on the Protection and Promotion of the Diversity of Cultural Expressions was adopted in 2005, and partnerships have been established in the framework of the Global Alliance for Cultural Diversity.

UNESCO believes that the cultural industries, which include Music, Gastronomy, Media Arts, Craft and Folk Art, Literature, Cinema and Design, have a determinant role to play in the future of culture.

The world map of these industries reveals a yawning gap between North and South. This can only be counteracted by strengthening local capacities and facilitating access to global markets at national level by way of new partnerships, know-how, control of piracy and every form of increased international solidarity.

As the only international organization with a global vision of the socio-cultural and economic role played by crafts in society, UNESCO has, for many years now, endeavoured to develop well-balanced, coherent and concerted action in favour of the sector of Crafts. The programmes devoted to crafts facilitate training and promotional activities as well as stimulate the necessary cooperation between the relevant national bodies and regional, international and non-governmental organizations. The aim of the different actions undertaken by UNESCO is to prove to the concerned authorities that the artisanal sector deserves priority in national development plans.

According to the definition adopted by the UNESCO/ITC Symposium “Crafts and the international market: trade and customs codification” (Manila, 6-8 October 1997), the artisanal products are «those produced by artisans, either completely by hand, or with the help of hand tools or even mechanical means, as long as the direct manual contribution of the artisan remains the most substantial component of the finished product. These are produced without restriction in terms of quantity and using raw materials from sustainable resources. The special nature of artisanal products derives from their distinctive features, which can be utilitarian, aesthetic, artistic, creative, culturally attached, decorative, functional, traditional, religiously and socially symbolic and significant».

UNESCO has been particularly involved in both the promotion of quality handicrafts as well as the commercialization of artisanal products on the international market. In this view, a series of activities have been carried out for the training of artisans, along with the promotion of craft products outside of their place of origin.

Moreover, UNESCO encourages regional and international cooperation by supporting the organization of meetings of experts. The aim is to improve the life and working conditions of the artisan in order to protect craft creation.

In this perspective and framework of design, with the aim of stimulating and recognizing the creativity of young designers worldwide, UNESCO implements the “Design 21” program, the International Competition launched in 1995 by UNESCO and the Felissimo Corporation (Japan) with the purpose of discovering and promoting young talent from all corners of the world, while encouraging a spirit of understanding and sharing among young creators from different cultures.

On these assumptions, UNESCO created a network of creative cities to promote the cultural, social and economic development of cities. It supports the improvement of creation poles as well as the sharing of the know-how, experiences and abilities of state, regional and local authorities.

The Creative Cities Network connects cities that not only want to share ideas and experiences for cultural, social and economic development but also support other cities, particularly those in developing countries, in nurturing their own creative economy.

The concept of ‘Creative Cities’ is based on the belief that culture can play an important role in urban renewal. Nowadays, more than half of the world population lives in cities and Policy makers are increasingly taking into account the role of creativity when planning economic policies. As creative industries contribute to a city’s social fabric, cultural diversity and enhance the quality of life, it also strengthens a sense of community and helps define a shared identity.

In the network of creative cities, member cities are recognized as: “Creative hubs” that promote socio-economic and cultural development in both the developed and developing world through creative industries; “Socio-cultural clusters” connecting socio-culturally diverse communities to create a healthy urban environment.

Once a city is appointed to the network, it can share experiences and create new opportunities with other cities on a global platform, notably for activities based on the notions of creative economy and creative tourism.

 **IL COMPASSO
DI LATTA**

Fig. 2: Premio “Compasso di latta” (Tin Compasses Award): Riccardo Dalisi in his studio; tin compasses; sustainable jewelry; 2010 Triennale di Bovisa (Milan), collection and workshop.

As already mentioned, the UNESCO Creative Cities network includes creative cities for Design. In order for a city to be part of the UNESCO creative cities network of Design, it must adhere to the following criteria and specifications: established design industry; cultural landscape fuelled by design and the built environment; design schools and design research centres; practicing groups of creators and designers with a continuous activity at a local and/or national level; experience in hosting fairs, events and exhibitions dedicated to design; opportunity for local designers and urban planners to take advantage of local materials and urban/natural conditions; design-driven creative industries.

Design Cities include: Santa Fe, Nagoya, Shenzhen, Kobe, Buenos Aires, Montréal, Seoul, Saint'Étienne, Shanghai, Berlin and Graz.

1.2 "Compasso di Latta" Award

In Italy, after a long preparatory research, Riccardo Dalisi promoted the first edition of "Compasso di Latta" (Tin Compasses) in order to promote new research in the field of design in the sign of human support, environmental compatibility and de-growth.

During the International Furniture Fair (14-19 April 2010) at the Triennale di Bovisa (Milan), Riccardo Dalisi presented the Manifesto of the "Compasso di Latta", with several significant pieces.

«The idea of a "Tin Compasses award" exists over and above any reference to the famous and prestigious "Golden Compasses" and the role that this has played in the history of international design. In the current climate of recession and the consequent changes taking place in every economic, social and cultural aspect, the aim of the Tin Compasses is to emphasize the revived need for inventions, ideas, projects, procedures and techniques in the artisan sector of small productions, embryonic, organizational initiatives and micro productions with a clear social purpose, at times even alternatives to the use of mechanical procedures and in the industrial sector at long last focused on sustainability. It may even be possible to stray into the general procedures of highly and scientifically qualified productions».

«[...] It also wants to be characterized as a dialogue that is complementary to those sectors which have always represented the inventions typical of classic design. In some cases, it may even reach out to dialectic challenges, exploring new areas for reflection and experimentation which can be combined and considered as reasons for increased knowledge and creativity and new opportunities. [...] A further example of reflection, source and of stimulation has been the frequent occurrences of contamination – of bi-polar unions between different worlds, between the craftsman and industry, manual work and the machine, thought and action [5].

The "Compasso di Latta" is a symbol between the serious and fun of global ecology as well as the issues of consumerism, an experiment, a set of related disciplines by the idea that art ("Poor", says someone; "simply inventiveness", to many others) should recover its social value through the use of a more traditional method and based on the principles of sustainability and degrowth, who enliven their theoretical approach and their work.

1.3 DSF_Designers Senza Frontiere

"Designers Senza Frontiere" Association (Designers Without Borders) has worked on the themes of empathetic design and craft design as a generator of economic and social value since its founding.

In a recent interview (February 2011), Maria Pellerano, President of DSF, exposed the social-economic purposes-ethics of the Association. Pellerano has clearly expressed the objective of the mission, based on an idea of Design attentive to the micro and medium-sized businesses working in the South of the world as well as seek to achieve social and environmental economy. It is a sustainable and sensitive design attentive to these issues. The aim is to participate in a different design, that is sensitive in creating a data-base of skills to support the southern hemisphere. DSF has recently worked for a NGO (Non-Governmental Organization) with a workshop for domestically abused women, by socially relocating them. It developed and implemented a training course on the textile processing, resulting in a line of furniture for the home and Italian partners interested in selling products within a large distribution network in Italy. It is a sensitive design that deals with the issues mentioned [6].

In particular, during the interview Maria Pellerano not only mentioned the DSF projects, but also an ethical and sustainable design and architecture and conference called "Design 'other' for the southern hemisphere", in collaboration with "Bottega Solidale" and Faculty of Architecture of Genoa.

Fig. 3: "Designers Senza Frontiere" Association (Designers Without Borders): implemented development projects in Algeria, Guinea, Benin, Rwanda, Philippines.

DSF is the agreement of a group of people who have been actively engaged for years in the world of international cooperation and the field of fair trade. Over the years, DSF has matured the belief that projects in developing countries can truly generate economic and social value only when taking into account the real needs of producers under real market conditions.

The purpose of DSF is to bring together two 'worlds' that generally have difficulties in coming into contact, allowing for a sustainable and lasting progress in the development of the craft community.

Designers without borders offers the culture of design for development of the Southern world crafts. The development of technology skills passed down from generation to generation, traditional production techniques, and raw endemic is a fundamental aspect of the activity agreement of economic growth.

DSF works for poverty reduction through educational development projects [7].

DSF has proposed or implemented development projects in Algeria, Benin, Guinea, Philippines, Rwanda.

1.4 Visual Identity for the complex of late antique and early Christian basilicas in Cimitile

The project presents the results achieved by educational activities at the *Laboratory of Graphic Creations* (prof. Ornella Zerlenga in the undergraduate programmes of "Design and Communication" and "Fashion Design", a y 2010-11, Faculty of Architecture "Luigi Vanvitelli", Second University of Naples) and develops several research projects aimed at achieving identity projects which can enhance the basilica complex of Cimitile (Italy) both by identifying its distinctive features of the local culture as well as the general membership of the site to a wider geographical catchment area. It also includes tangible measures and promotion of events appropriately designed for the site which, in this perspective, is no longer interpreted as a passive 'location' but rather as a 'cultural identity' returning 'added value' to formulated projects.

During the activity of the *Laboratory of Graphic Creations*, visual communication projects, brand design, web sites, video-installations, exhibitions and events, performance art and fashion catwalks, textile and gold products for fashion have all been elaborated [8].

Color, Culture, and Communication

Laura CARLOMAGNO¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Aversa, Italia
laura.carlomagno@unina2.it

Abstract

Color is one of the most important keys to communication in the global market and it plays an instrumental role in attracting, capturing and retaining attention, shaping the perceptions, attitudes and opinions, and finally influencing the decision to buy or not our products or services.

Colour is architecture, object, painting, image, research, music, poetry, prose, city, landscape: it possesses physicalness, a body which requires to be analyzed both in its full shape as *res extensa* and in its inner being. It appears as a fundamental element in the representation of the nature and the territory, in its double immanent and becoming aspect. It is one of the main aspects to be considered in any communicative choice or in any action of analysis of a heritage to be taken in its multidimensionality, thanks to its various aspects of symbol, communicative element, graphic, anthropological and socio-cultural element.

Colour is radiation, energy acting positively or negatively on us, even if we are not aware of it, and its action has to be felt and understood not only as an optical event, but as a psychic and symbolic action as well: indeed, man perceives the colour and plans it, giving it in both activities a visible and (in)visible dimension. The limit between visible and invisible is just where the colour takes shape and what the observer perceives, with distinction, both as a recognition and as an inescapable destiny which connect him with what he observes or creates.

Even before the invention of the alphabet, primitive peoples and civilizations expressed themselves through images, signs, symbols and signals, usually with the help and support of colors, to which they attached precise meanings. So color is a means of connection between the world and its meaning, between the individual and the culture he belongs to and, according to the use made of it, transmits cultural and anthropological differences as well as codes and symbolism.

keywords: Color Culture Communication Intangible

1. Color/landscape

The landscape today, as it unfolds before our eyes, is complex and divided. It is difficult to represent and describe as it is articulated and disassembled on a complex network of semantic fields characterized by the coexistence of heterogeneous elements and overlapping signs and traces. This makes it difficult to display a synthetic image that can express its meaning in a clear and readable manner. The local networks that describe reality for us and are themselves networks of information overlap and create sometimes unexpected visual and symbolic relationships between objects directly produced by man and traces of natural processes preserved in the ground.

The secrets, signs of the passage of time and interpretive schemes that originate from fragments of history are layered and overlap, and, over time, each new element overlaps the other without completely erasing the earlier signs. This landscape, understood as a complex system of spaces, forms, signs, sounds, colors, symbols and traces, is the link through which we access the history and memory of places, environmental and cultural values and their inherent dynamism. Through a careful multidimensional analysis and interpretation of the elements discovered, understood as reflecting the material culture of the territory, the

past, present and future unfold before our eyes: in fact the traces of past and present events give us a glimpse of the possible futures of the places.

The earth reveals itself every day with an endless array of colors, signs, symbols and nuances. It entralls and catches our eye daily: and what our senses perceive is a mixture of feelings and emotions that are nothing more than the harmony and balance created between artifice and nature, both past and present. What we observe in fact is not a simple summation of natural, architectural and symbolic elements, but a comprehensive package of all the constituent units in our territory. Man and nature have contributed to the ongoing definition of reality, pursuing a delicate balance that has led to the articulation of the scenarios as we perceive them. This synergy between man and nature has often led to the definition of images and views as articulated and detached as frames of a single narrative; identifying and representing a very specific place.: The many aspects of a territory or a location that we investigate therefore define the identity of a place and at the same time jealously guard its memory.

2. Color/traces

The tools available to individuals for communicating and interacting within the tribes and primitive forms of civilization, have always been among the most important aspects of human life and the primary requirement for survival. Even before the invention of the alphabet, primitive peoples and civilizations expressed themselves through images, signs, symbols and signals, usually with the help and support of colors, to which they attached precise meanings. Color is a means of connection between the world and its meaning, between the individual and the culture he belongs to and, according to the use made of it, transmits cultural and anthropological differences as well as codes and symbolism. Man has always used color as a symbol and in ancient times, the more a society was strong and organized the more color was used and its symbolic meanings were defined.

The indelible traces of the communication links established between individuals went beyond physical locations. They spanned geographical boundaries and established spatial-temporal relationships between seemingly distant generations. All these apparently unrelated signs, shapes, colors and these graphic traces to be collected and re-established belong to the DNA of the territory [2]. They were created in a particular environment and assume a semantic value in accordance with the evolution of the place to which they belong. They are mainly the product of a sometimes contradictory usage of land by very different social groups.

Every place is in fact an expression of a particular society that is strong there and that strongly identifies with the context in which it has evolved: this context has an identity, a material and immaterial order and symbolic meanings that reflect its norms.

Measurement, therefore, is at the root of all knowledge and representation of the physical and intangible values and the recorded traces of the location and its biological evolution based on its environmental context. Measuring and capitalizing on the infinite reasons of nature, as Leonardo suggested, is to recognize the genetic heritage, the names of places, the foundation of this continuous process of restoration and regeneration as a modification against any prospect of change. To understand, therefore, the general organization of places, but especially also to prefigure their protection and regeneration, requires an innovative methodology to study the area that, starting with the identity of places, returns to them and represents them as a homogeneous set of elements in order to restore them with a meticulous representation or discretization and measurement, capable of expressing tangible and intangible values [1].

Human beings have always regarded colours as symbols, associated as they were to the natural elements lying at the heart of the primeval conception of the universe. Ever since prehistoric times, human beings have manipulated what they were given by nature every day, mixing clays, squeezing plants, grinding stones, in the attempt to leave a coloured trace testifying their presence on earth, recording moments of their lives. The remains discovered in Altamira (Spain) and Lascaux (France) together with the parietal paintings in Hierakonpolis (Egypt) prove that ancient painters were skilful and clever at finding and blending colours. At the beginning they only collected them from the places where they settled down, but afterwards they managed to achieve a wider and wider range of colours thanks to accurate researches and experiments that slowly led to a scrupulous and refined chemical composition of pigments.

From these early experiences of the individual with nature and the environment around him, the concept of color was conceived and developed in our mind and created an image of itself. Each color adheres to unconscious themes, acting on emotion with attraction and repulsion, expressing mental and emotional attitudes in preferences or in rejection, it displays intense and ambivalent language, reflecting the individual and the image of the world and becomes a place of real and unreal. And its understanding is born of conventions dictated by experience, that the color is between two poles and stems from the tension that is generated between identity and misunderstanding. Color, in fact, originates in a particular environment and

becomes a semantic value in accordance with its evolutionary process. Depending on different cultures, the symbolic meaning of color changes on the basis of different religious philosophies and on socio-cultural factors. For this reason, based on our experience and our evolutionary process, certain colors do correspond to certain names and characteristics that endow them with a precise identity and inevitably cause misunderstanding, because in another setting, in a different context, or in different time-space conditions, our assumptions may prove invalid.

3. The n dimension of the color

Going through city streets, passing by places where artificiality and nature get mixed up, we gaze upon more or less details depending on the level of our attention; in doing so, our gaze turns into an act meant to acquire some knowledge of the urban sceneries that surround us. In fact, at first we tend to notice the appearance of the things that catch our eye, the “skin” of buildings and objects, and then we further and skillfully analyze the beauties created by nature and human beings. Colours, like a thin veil that seems to hide objects and artefacts and is often ignored and underestimated by observers, actually contain a great deal of material and immaterial information. We are unconsciously used to believing that colours cover objects, thus concealing their essence, their core, and then fade away slowly beyond appearance (the word “colour” – “colore” in Italian from the Latin “colos” – has the same etymological root of the Italian verb “celare” meaning “to hide, conceal, cover”). Nonetheless, colours do not conceal, they actually unveil and reveal what is sometimes apparently invisible. In order to uncover the many facets of colours, we need to view them as complex systems to be represented in their n dimensions. Therefore, while regarding colours as complex systems, we also need to take into consideration every science in which they are involved: when dealing with physics, optics, chemistry, acoustics, anthropology, etymology, symbolism, psychology, digital, a methodological approach is necessary to fully understand such an articulated world. In fact, within each colour, many different semantic levels and languages coexist and interact, which we do not generally find in other visual variables: material/immaterial, analogical/digital, anthropological/biological, material/symbolic, physical/metaphysical. These elements seem to be in contrast with each other, but their interaction determines both the intrinsic and extrinsic qualities of the colour itself, in the infinitesimal space on the border between the physical and the psychical where sensations and perceptions merge into one another.

In order to distinguish a colour, we need to see it close to other colours and other elements within the visual field, but, above all, we need to view it on a(n) (in)visible conceptual background where all immaterial components converge. Indeed, colours only exist insofar as they are viewed and experienced by human beings. They originate from the synergy and synthesis between natural and physical components, the physical and material properties of objects, the observer's mood, the general conditions, the cultural context, the social status, the biological conditions, experiences and aspirations, which jointly affect the way you see and represent the world. As a matter of fact, all objects, even those that are apparently monochrome, never feature just one colour, but rather multiple colours, as many as viewpoints and spatio-temporal conditions .

[SMART]²: Sustainable Smart Innovation in Industrial Ceramics for Custom Multi-Product Design and Fabrication Strategies

Stefano ANDREANI

Design Robotics Group, Graduate School of Design, Harvard University, Cambridge, USA
andreani@gsd.harvard.edu

Abstract

Ceramics as building material in architecture has been widely used for centuries, yet its speculative applications in avant-garde design are limited by either current established fabrication methods or expensive and inefficient customization techniques. The presented research explores one of the most widely used industrial production processes of bricks and tiles – the extrusion – for hacking and combining it with advanced computational methods in order to propose a new way of designing and fabricating ceramic building components. In particular, by CNC controlling the cutting process of extruded clay and by slightly modifying the wire-cutting tool, it is possible to generate custom-shape components through an efficient, sustainable, and multi-production fabrication method. In fact, ruled-geometry bricks, tiles, and shading elements can be generated in the same production line by separating extruded clay bodies with a numerically informed and specifically treated wire. The envisioned industrial scenario is here emulated through the development of a systematic workflow that starts off by digital modeling custom ceramic units and ends up by fabricating a series of prototypes with the use of robotic technologies. In virtue of this sustainable serialized mass-customization process, a variety of design and market opportunities opens up, eventually producing a new language for architecture in which innovative bricks, tiles, and shading systems are logically implemented. Tradition and innovation are thus combined under the objectives of material efficiency, industrial processes optimization, new market opportunities, and novel design strategies.

Keywords: Industrial Ceramics, Robotic Fabrication, Sustainable Architecture, Mass Customization

1. Introduction

Design customization in architecture has recently become a prominent feature, in terms of both trend- and performance-driven design. In fact, variation in architecture not only allows for achieving appealing design solutions, but also increases the building's response to environmental aspects. Although computational design techniques now substantially facilitate the customization of building components in the digital domain, their material counterpart often requires expensive and articulated methods of fabrication. In fact, the production of unique, highly differentiated elements involves the use of non-standard supportive materials and special tools, such as complex moulds or special bending machines. On the contrary, industrial production processes are characterized by production lines or highly efficient methods that allow to fabricate building units in a serialized and cost-effective manner, making customization extremely complicated though.

Production lines constraints, packing principles, and transportation systems, in fact, deeply affect the possibility of customization, often preventing design speculations that involve differentiation. In this context, the role of ceramics is emblematic, being a material widely used in architecture with a high level of standardized fabrication processes and final products. Ceramic building components are indeed deeply characterized by well established production methods that leave little room for design customization. Instead,

ceramics embed certain properties that make it an ideal material for product differentiation. In particular, as this paper demonstrates, its plasticity in the pre-firing state offers enormous possibilities for the creation of complex-shape building components – opportunities enhanced by contemporary computational design and digital fabrication techniques.

2. Industrial clay extrusion

Industrial clay extrusion is a process in which ceramic components are produced in a serialized and continuous linear manner. During the process a helical extrusion mechanism forces clay through a die that imposes a continuous shape on the material. The extrusion dies represent one of the only integrated mechanisms for custom shaping in industrial ceramic production, although their cost and implementation requirements make their number of different shapes highly limited. During extrusion, components are supported by a conveyor or roller system that carries the extruded elements through several automated production cells that dimension, fire, finish, and package the ceramic parts. Dimensioning of individual linear elements is often accomplished by automated and exactly coordinated wires or blades that make cuts perpendicular to the extrusion direction. In the case of bricks' production, the process is so that the extruded clay body is cut at regular intervals separating the body itself into fixed-length units, which are then separated with successive cuts creating the single elements. This row of bricks are then piled up by a robotic arm and carried on a conveyor that take them through the drying and firing rooms. Finally, the elements are properly packed for optimizing the shipping process. Most of these phases basically characterize the production of extruded tiles too.

3. Multi-product sustainable customization

The presented research proposes to revise the industrial extrusion process, being one of the most common and established fabrication methods of clay bricks and tiles. In particular, the study investigates two aspects of the wire-cutting mechanism: the first one deals with the way in which the wire is controlled, whereas the other speculates on particularly treating the wire itself. The objective is to demonstrate that by slightly modifying only the cutting process out of the entire production line, a remarkable series of design opportunities emerge.

3.1 Ruled-geometry wire-cutting

The proposed process intervention adapts the integrated dimensioning cell to incorporate a numerically-controlled wire-cutting tool designed to enable shape customization of single elements during linear processing. In this scenario robotically-guided wires are programmed to cut each component along ruled surfaces. Part dimensioning during industrial extrusion is in fact characterized by wire-cutting that, when numerically controlled, could achieve complex ruled surfaces if the wire's extreme points move vertically. By addressing differentiation in a single production cell within the larger extrusion system, this process would thus enable the manufacturing of mass-customized ceramic elements defined by ruled geometries.

Fig. 1,2: Industrial processes of clay extrusion and cutting.

In this envisioned industrial scenario the wire-cutting process would separate the extruded clay body in two different elements. One of the main assumptions of the presented research is that these two complementary elements would not be detached, but would rather maintain this same configuration till the final packing and shipping phases. In this way, the production lines principles would remain exactly unaltered: robotic arms could pick the pieces up for ordered piling, and packing mechanisms would follow the same logics of efficiency and optimization. However, in order for this process to take place, the two separated elements need to not stick during the firing phase. Although the industrial extruded clay is usually very dry, a simple cutting metal wire might be not enough for preventing the two pieces adhering to each other. For this reason, the Design Robotics Group at Harvard GSD has been elaborating several strategies for manipulating the wire to the treat the interface in such a way that sticking would not occur. In particular, one method involves the use of a hot wire that would burn the two facing surfaces sufficiently to create very dry layers of material. Whereas the other method concerns the deposition of hydra alumina powder in the interstitial surface – a technique widely used in the world of ceramics, though never applied in the wire-cutting mechanism.

3.2 Multi-product method

For the purpose of keeping unaltered the established industrial principles of production lines, the fact of not separating the two cut, facing elements is thus essential: customization would be easily coupled with industrial fabrication resulting in economic and efficient design variations and complex-component production. In particular, this research proposes a multi-product fabrication method that involves the use of either one or two numerically-controlled wires that would cut through an extruded ceramic element, thus producing digitally-informed, all-different units. In the imagined process, a clay body would be first cut with CNC wire/s for a fixed length, then vertically separated from the rest of the extruded body, and finally cut with traditional vertical wires for creating the different, multiple ceramic units. This series of components could be labelled either at the beginning or the end of the extruded element in order to be easily recognized during the on-site assembly process. In this way, each row of components would be identified with a clear noting system that would follow the assembly logic defined by the designer. This same assembly logic could be used for defining both the packing and shipping processes: rows of elements could be piled up in relation with the assembly order, thus defining the shipping mechanisms, times, and procedures accordingly.

As further illustrated later on, with this process different types of custom elements would be produced at the same time, exploiting the existing logics, systems, and tools of the ceramics industry. In addition, this multi-product method would embed advantages related to sustainability, economy of production, and efficiency. First, the envisioned process would not waste any material, but rather the material itself is optimized to create different products out of the same extruded element. Second, this fabrication technique would be cost-effective, because only a slight variation of the wire-cutting mechanism would be changed – the entire production process being unaltered; in addition, ease of customization would be an asset for the industry, eventually gaining more profits. Third, the combination of logics of customization and industrial principles of production would result in highly efficient ways of design variations and easy assembly on-site procedures for complex projects.

Fig. 3: Envisioned industrial method of automated wire-cutting.

4. Design and fabrication robotic workflow

The envisioned industrial scenario is emulated through the development of an integrated workflow [1] that combines computational design techniques and robotic fabrication methods to foster innovative ways of conception, implementation, and production in the context of ceramics for architecture. [2] Integrating top-down and bottom-up approaches, this workflow starts off with the digital generation of the overall building system – e.g., walls, cladding solutions, shading systems. After that, a coherent logic of fabrication and assembly procedures needs already to be implemented in this design phase; in this way, consistent sequences of units can be properly organized. From the digital model, the geometric information regarding each ceramic element is then extrapolated for driving the automated wire-cutting process. In particular, for each component the developed algorithm outputs wireframe data that serves as guiding lines for the ruled-geometry wire-cutting method. The objective is to derive machine codes from the digital geometries within a *Rhinoceros™*-based digital design platform. Industrial numerically controlled wire-cutting was simulated during prototyping by a 6-axis industrial robot used to guide a custom steel cutting wire. Automation of robotic programming was facilitated by the *Hal™* plugin for *Grasshopper™* which was used to generate, simulate, and optimize each of the cutting paths. In particular, for every individual component the workflow progressed by processing the input data derived from the digital model: the wireframe geometries describing the unit's edges were used to define ruling lines and generate the wire-cutting information for the robot. Once positioned relative to the robotic work cell, these lines served in the generation of cutting paths for each element. To further verify the cutting paths, each robotic movement was simulated in proprietary ABB simulation environment *RobotStudio™*. Finally, to facilitate maximum robotic freedom, a custom steel fixture was created to support the wet clay block during cutting.

Fig. 4: Integrated robotic workflow: from design to fabrication.

5. Design strategies and market opportunities in architecture

The presented custom multi-product strategies in the world of ceramics open up a series of design and market opportunities in the realm of architecture and building solutions. The objective is to combine the tradition of ceramic materials with the potentials of technological innovations. In fact, if fostered by computational design and digital fabrication techniques, the tradition of ceramics could be remarkably enhanced acquiring new meanings and architectural languages. Looking at both design needs and industrial constraints, this research focuses on three different – though related – types of products for a variety of applications in architecture. The first line of research investigates new types of bricks for creating complex doubly-curved building walls. The second study proposes the design of kinetic shading systems made of curved louvers. Finally, the third application concerns building cladding and panelling with the use of complex tiles. These potential ceramic building systems were tested through the development of a series of prototypes fabricated with robotic technologies. Due to its inherent properties and aesthetic qualities, the material used was in particular terracotta.

Fig. 5: Research strategy: production development + design opportunities.

5.1 Smart bricks for complex walls

Although their conception and digital representation has become relatively straightforward with current computational techniques, doubly-curved building walls still present inherent difficulties related to fabrication and assembly aspects. [3] This is particularly true when dealing with standardized ceramic units, whose assembly for achieving complex wall systems require either skilful craftsmanship, intricate guiding devices, or on-site robotic techniques. The presented solution aims to combine the advantages of industrial fabrication and transportation mechanisms with traditional on-site assembly methods. The result is an innovative use of ceramics through custom – though easy-to-aggregate – units for enhancing the aesthetic qualities of differentiation in doubly-curved surfaces.

For creating these complex walls, the design process starts by modelling a custom input surface, then moving to the creation of two complementary walls the share the complex surface; the thickness of the two walls is achieved based on fabrication constraints – specifically the dimension of the extrusion die; after that, the surface is discretized in the different units, following the structurally-efficient staggering principle; at this point, fabrication and assembly optimization rules are applied by selecting proper series of elements – e.g., a row-by-row principle; from these geometries, wireframe data are extrapolated for the automated process of wire-cutting; finally, the cutting process itself is performed.

Fig. 6: Robotic fabrication of ruled-surface ceramic units for doubly-curved wall systems.

5.2 Turning louvers for kinetic facades

Shading systems play a dominant role in contemporary architecture morphologies, yet their design mostly relies on conventional horizontal louvers – made of a variety of materials. The proposed solution offers an innovative approach not only for screening building glass facades, but also for adding unique aesthetics values to the overall project. In fact, this system is composed by a steel vertical frame that supports curved ceramic louvers at their extremes – these joints having the possibilities to rotate around their horizontal axis. The developed design strategy begins by using an image as input for creating a certain pattern for the facade through the shading system. This image is then overlapped with the frame of the facade and processed for mapping the angle of rotation of each louver's joint. Once the angle range is set for a desired visual effect, the geometries of the louvers are then finalized. Due to the kinetic properties of the joints, a variety of different pattern solutions for the facade can be explored and dynamically changed over time. Concerning production procedures, each louver would be fabricated through an extrusion mechanism in which two CNC-controlled wires would be implemented. With the overall purpose of zero-waste production principles, the leftover material – the top and bottom elements – could then be used for panelling and cladding solutions, following the presented multi-product fabrication logic.

Fig. 7: Single components of unfired (green) terracotta and assembly simulation of a doubly-curved wall section.

Fig. 8: Pattern design and robotic wire-cutting of curved louvers for kinetic shading systems.

5.3 Waving tiles for cladding systems

Ceramic tiles have a long tradition as cladding material, with an almost infinite range of solutions offered by the market. However, the ubiquitous flat tile is here innovated by adding complexity in the shape of its exterior surface. By applying the same principle of wire-cutting through an extruded element, it would be in fact possible to produce tiles that, once assembled, create a continuous pattern. In this way, for example, an ordinary space could achieve unexpected spatial qualities by adding “vibrating” elements to its wall’s surfaces.

Fig. 9: Design speculations and robotic fabrication of complex terracotta tiles.

6. Conclusion

The presented research investigated one of the most widely used industrial production processes of bricks and tiles – the extrusion – for a meaningful integration with computational and numerical methods in order to devise innovative solutions for designing and fabricating ceramic building components. In particular, an automated cutting process of extruded clay implemented in the production line would generate ruled-geometry components through an efficient, sustainable, and multi-production fabrication method of mass-customization. This envisioned industrial scenario was emulated through the development of a systematic workflow that linearly linked design conception and digital fabrication, resulting in the development of a series of terracotta prototypes with the use of robotic technologies. In the logics of this sustainable serialized mass-customization process, three different lines of research have been investigated: smart bricks for complex walls, turning louvers for kinetic facades, and waving tiles for cladding systems. Pursuing design technology research in the world of ceramics in architecture, tradition and innovation are thus combined

under the objectives of material efficiency, industrial processes optimization, new market opportunities, and novel design strategies.

“PLUVIOGRAMMI” WITH HIGH TIME RESOLUTION

Giuseppe D'ANGELO,¹ Maria Cristina MIGLIONICO¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura, Seconda Università degli Studi di Napoli, Aversa, Italia

E-mail: giuseppe.dangelo@alice.it; mcristina.miglionico@unina2.it.

Abstract

The knowledge and variability of rainfall system, fundamental for the catchment management and planning, of agricultural crops, of the civil and industrial water requirements and of hydroelectric energy production, are strictly linked to the climatic variations. The climatic system, not only, is affected by environmental factors: solar radiation, volcanic ash and aerosol, but also by anthropogenic factors, as greenhouse gases emission and the improper usage of the ground with intensive farming, urbanization and waterproofing. Any change of the statistical distributions of the weather variables can have a significant impact on the nature and humanity. Between the most important weather variables for the water balance, a fundamental role is played by the space-time of the precipitations, fundamentally, in characterized areas by a complex topography such as the Italian. Among many aspects, related to the observation and modeling of the hydrological cycle phenomena, is particularly interesting the definition of the appropriate critical “pluviogrammi” for the drainage networks design. In design practice, in fact, except for the occasional cases, it is assumed a uniform spatial-time distribution of the critical precipitation and, respect to it, it is possible to do the sizing of the network hydraulic manifolds. The present work develops an experimental study of “pluviogrammi” with high time resolution, obtained by processing the observation recorded by a specific weather station, installed at Aversa (Caserta) on March 2006. This station is capable to acquire various information on various weather conditions: including, rain height, temperature, humidity, atmospheric pressure, wind direction and its speed. In this study have been analyzed, principally, data of the rain heights, acquired with a sample time of two minutes.

Key words: rain; pluviogrammi

1. Introduction

As it is well known in the literature, the term "precipitation" is indicated all liquid and solid products of the water vapor condensation that reaches the ground falling from the clouds. The precipitation, once started, is supplied by the contribution of water vapor, with an ascending movement, that rises to high altitudes and condenses in the form of small drops, reconstituting the cloud. The dynamics of rainfall is therefore linked to the movement of large air masses. The precipitations, in fact, occur when the air rises and it cools adiabatically below dew point, generating not only clouds, but, also, rain, snow and hail.

2. Measurements of the height of precipitation

The quantity of water that reaches the earth's surface can be valuating, locally, with measurers capable of detecting the height of rain or precipitation. In the time interval t can be defined as the ratio between the rain volume $H_{t,S}$ precipitate in t on a portion of the Earth's surface and the area S of the horizontal projection of this surface area:

$$h_{t,S} = \frac{H_{t,S}}{S}$$

This measure is, in practice, the height of the liquid layer that would be to deposit on the ground, where all the downfall water remain stagnant without being subject to evaporation, infiltration and outflow.

The precipitation height has dimensions of a length and is measured in mm or m. During a rainfall event the height of rain punctual varies in space and time:

$$h = h(x, y, t)$$

where x and y are spatial coordinates and t is the duration of the rain event.

The readings of the height of precipitation can be performed with the aid of two different instruments, the rain gauge and pluviograph.

The intensity of average rain is the ratio between the precipitation height h , expressed in mm/h (or m/h), and the corresponding duration t :

$$i(x, y, t) = \frac{h(x, y, t)}{t}$$

The instantaneous intensity of rain is the limit which tends to average intensity when the time t goes to zero:

$$i(x, y, t) = \lim_{t \rightarrow 0} i(x, y, t) = \frac{dh(x, y, t)}{dt}$$

For a given duration of observation the histogram that represents the height or the average intensity of precipitation in each elementary time interval Δt is said "ietogramma".

3. Elaboration methodology of rainfall observations and acquisition data

The rainfall data acquired with a weather station are used for the analysis of rainfall with small time scales, concerning the Aversa territory. The work has been developed in two following phases: the acquisition and subsequent data processing. The observation period and data acquisition is lasted about three years; the records have been made every two minutes.

Data processing has been carried out by determining, in the first phase, the number of rain events; the identification of these events has been carried out by selecting, as a criterion, to match each rainy day with a single event of rain. Within each event has been identified the different showers, which, have been characterized with appropriately chosen parameters.

In the next diagram (Figure 1) is shown the daily Aversa pluviogramma. It is important to underline that, in the period under study, have been registered 143 significant rain events. The most significant event has registered a rain height of 45 mm, occurred on 01 November 2006, followed by the event registered on 27 September 2007 with 42 mm of rain. In particular circumstances most significant rainfall has been registered, for example, from 15 September 2006 to 18 September 2006, or, from 24 January 2009 to 27 January 2009. Thereafter for each individual event will be detected showers that compose it. For every shower will be route the diagram of accumulated rain heights and to ietogramma with high temporal resolution.

Figure1. Aversa daily pluviogramma

4. Showers selection

Identified rain events, successively it has gone in search of the showers to analyze. This phase has been, preceded by a preliminary work performed on the returned data from the station. In fact, it has created a table (Table 1) where are inserted only the date column and the absolute height.

| Data | Absolute height [mm] |
|------------------|----------------------|
| 17/09/2009 14:32 | 1759 |
| 17/09/2009 14:34 | 1760 |
| 17/09/2009 14:36 | 1760 |
| 17/09/2009 14:38 | 1760 |
| 17/09/2009 14:40 | 1760 |
| 17/09/2009 14:42 | 1760 |
| 17/09/2009 14:44 | 1760 |
| 17/09/2009 14:46 | 1760 |
| 17/09/2009 14:48 | 1760 |
| 17/09/2009 14:50 | 1760 |
| 17/09/2009 14:52 | 1761 |
| 17/09/2009 14:54 | 1761 |

Table1 – Rain height data

Regarding the minimum duration of a dry interval (idm) between two consecutive showers it has been established to consider the following cases:

Case A with $idm = 15$, ie, with a dry interval of 30 minutes;

Case B with $idm = 30$, ie, with a dry interval of 60 minutes;

Case C with $idm = 90$, ie, with an interval of 180 minutes dry.

For the other thresholds, it has been decided do not vary them, in order to highlight the dependence of the minimum number of showers in a dry period.

5. Data processing

Each shower has been characterized by plotting both the height of rain h [mm], as a function of time t [min], and the rain intensity [mm/h].

To examine the diagrams above depicted, it has been calculated a number of parameters properly selected (Cernesson et al., 1995).

The calculated parameters are:

- number of peaks of each shower [peaks number];
- total height of rain - h_{tot} [mm];
- total duration of each shower - d_{tot} [min];
- average intensity - i_m [mm/h];
- maximum peak intensity - i_{max} [mm / h];
- $IMAX/i_m$ ratio;
- maximum peak duration - $d_{maxpeak}$ [min];
- ratio between the duration of the peak and total duration of each shower $d_{maxpeak}/D_{tot}$;

- the position of the peak (minutes) and the total duration ratio of each shower $-t_{\text{maxpeak}} / D_{\text{tot}}$.

In the case, where more than a shower is present on two or more successive peaks of equal intensity, has been conventionally considered the second peak. The processing was carried out for all the three identified cases.

6. Conclusions

In the first analysis have been considered rain events of the whole registration period through the tracking of a daily pluviogramma, have occurred totally 2425 mm of rain.

Identified rain events, successively has been searched the showers for the analysis. This phase has been done, with a preliminary work performed with the returned data from the station. It has been necessary to fill any periods in which data were missing with the zeros. This operation has been necessary to know, precisely, the date and time corresponding to each height value of the rain, from a predetermined starting point that, in the following case, is represented by 10:20 on 09 March 2006.

For the minimum duration of a dry interval between two consecutive bursts it has been considered three cases:

Case A with $idm = 15$, ie, with a dry interval of 30 minutes;

Case B with $idm = 30$, ie, with a dry interval of 60 minutes;

Case C with $idm = 90$, ie, with an interval of 180 minutes dry.

For the case A are present 706 showers, but from this quantity must be eliminate 443, which are preceded by showers or a hole. They do not to allow the knowledge of how the rain falls, or, the showers having duration less or equal of the data scan time acquisition that produce 1 mm of rain in two minutes: have been analyzed 263 showers.

For the case B are present 540 showers, but from this quantity must be eliminate 292, which are preceded by showers or a hole. They do not to allow the knowledge of how the rain falls, or, the showers having duration less or equal of the data scan time acquisition that produce 1 mm of rain in two minutes: have been analyzed 248 showers.

They are either the showers that are unchanged compared to the previous case, both those arising from the sum of several showers, first, separate from one another. The cause of this union is the increase the dry between consecutive showers.

For the case C are present 351 showers, but from this quantity must be eliminate 136, which are preceded by showers or a hole. They do not to allow the knowledge of how the rain falls, or, the showers having duration less or equal of the data scan time acquisition that produce 1 mm of rain in two minutes: have been analyzed 215 showers.

They are either the showers that are unchanged compared to the previous case, both those arising from the sum of several showers, first, separate from one another. The cause of this union is the increase the dry between consecutive showers.

For the case A, the values of the parameters of the 263 showers allow to make two observations:

1) from examination of the assumed values by the ratio between the intensity of the maximum peak and the average intensity of the same shower. It is possible to observe that in three circumstances (22.03.06, 19.03.07 and 03.05.07) the intensity has occurred more of 4 times of the one average. In 80% of cases, this ratio varies between 1.00 and 2.00, the examination of the assumed values by the ratio between the maximum peak duration and the total duration of the shower. The 78% of the precipitations, object of study, have of the maximum peak duration less than 20% of the total duration. In 18 cases the peak lasts for the half or more of the shower;

2) from examination of the assumed values by the last parameter taken into consideration. The ratio represents the position of the maximum peak intensity of rain respect to the total duration of each shower. It has been observed that 62% of the precipitation, object of study, had the maximum intensity at rain beginning, precisely less than or equal to 25% of the total length, while only 8% of the showers had the highest intensity at the end of rain, greater than or equal to 90% of the total duration.

For the case B, the values of the parameters of the 248 showers allow to make two observations:

1) from an examination of the assumed values by the ratio between the intensity of the maximum peak and the average intensity of the same shower. It is possible to observe that in 8 circumstances the assumed density is more than 4 times of the average intensity. In two circumstances the density is more 5 times of the average and in one case is more than 7 times (16.01.2008). In 70% of cases, this ratio varies between 1.00

and 2.00. The examination of assumed values by the ratio between the maximum peak duration and the total duration of each shower, shows that 82% of the precipitations, object of study, have a duration of the maximum peak less than 20% of the total duration. In 16 cases the peak lasts for the half or more of the shower;

2) from an examination of the assumed values by the last parameter taken into consideration. The ratio represents the position of the maximum peak intensity of rain respect to the total duration of each shower. It has been observed that 60% of the precipitation, object of study, had the maximum intensity at rain beginning, precisely less than or equal to 25% of the total length. Only 9% of the showers had the highest intensity at the end of rain, greater than or equal to 90% of the total duration.

For the case C, the values of parameters for 215 showers allow to make two fundamental observations:

1) from an examination of the assumed values by the ratio between the intensity of the maximum peak and the average intensity of the same shower can be seen that the intensity in 11 observations occurred is more than 4 times the average, in 3 circumstances more than 5 times, in 2 over 7 and 1 more than 9 times (27 January 2009). In 54% cases this ratio oscillates between 1.00 and 2.00. The examination of the assumed values by the ratio between the maximum peak duration and the total duration of each shower, shows that 85% of the precipitation, object of study, the duration of the maximum peak is less than 20% of the total duration, while in 8 cases the peak lasts for half or more of the shower;

2) from the examination of the assumed values by the last parameter taken into consideration, the ratio indicating the position of the maximum peak intensity of rain with respect to the total duration of each shower. The 56% of the precipitation, object of study, had the maximum intensity at rain beginning, namely less than or equal to 25% of the total duration. Only 15% of showers has had the highest intensity at the end of rain, specifically greater than or equal to 90% of the total duration.

Abstract

Amman's land typology is characterized by hilly slopes, and this presents challenges and opportunities for architects and designers aiming at delivering sustainable buildings. The research focuses on the importance of any site's given criteria; mainly its slope and topography on the delivery of sustainable buildings.

Amman city consists broadly of two main types of buildings; apartment buildings and villas, by studying each type of building with regard to its environmental context on a given site in the city; the research seeks to identify the sustainable variables that site topography delimit or facilitate, using a set of attributes for each building type.

The main objective of this research is to highlight the sustainable approach for building on sloped sites throughout the building project life-cycle in general, and to set a sustainability framework for designers during the initial design phase in particular. A number of case studies for both types of buildings are studied and analysed, and conclusions are given based on syntheses of available data from literature review or case analysis.

At the end, the research provides a mechanism for the development of guidelines for sustainable and passive viability on preferred buildings orientation in hilly areas with regard to local climatic data..

Keywords: Sustainable Building, Topography, Sloped Sites, Sustainable Design Guidelines.

1. Introduction

Sustainable development issues and environmental concerns continue to gain interest as demand within Jordan's residential construction industry escalates. Current construction practices adhere to traditional methods of construction, with inherent weaknesses such as high labour costs, negative environmental impact during and after construction, and minimal technological advancement.

Sustainability in buildings and urban design is a regional issue, and quite specifically site- related. In this regards, Amman is a city characterised by its hilly topography. The slopes represent challenging constraints for designers, especially when considering sustainable building measures. Therefore, to construct and maintain a sustainable building is to choose the suitable site and to allocate the building

to site correctly. Design decisions in the initial phase would affect the building layout, and eliminate negative impacts associated with negative construction practices.

This research deals with designing and building residential buildings in Amman, the capital of Jordan, with emphasis on two types of building, the apartment building and the villa. The research seeks to outline a framework designing residential buildings, especially, villas and apartment buildings, for designers in the early stage of the design process on the best layout, orientation, and functional layout on sloping sites in Amman city.

1.1 What is Sustainability

Oxford Dictionary defines sustainability as the ability “to be maintained at a certain rate or level: sustainable economic growth or conserving an ecological balance by avoiding depletion of natural resources: our fundamental commitment to sustainable development”

The most common definition comes from „Our Common Future“, also known as the Brundtland Report: „Sustainable development is development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs“ [1]. This definition contains three key ideas: development, needs, and future generations. According to Blowers (1993); development should not be confused with growth. Growth is a physical or quantitative expansion of the economic system, while development is a qualitative concept: it is concerned with cultural, social and economic progress. The term „needs“ introduces the ideas of distribution of resources: „meeting the basic needs of all and extending to all the opportunity to satisfy their aspirations for a better life“[1]. Moughtin (2005) thinks that the pursuit of a sustainable future for the human race will require the design of effective policies and programmes which directly address the related problems of unsustainable activities and environmental degradation. Any sustainable development at the building and neighbourhood level should ensure that the needs of the current users are met without compromising resources or the quality of built environment on the long term.

1.2 Sustainability in Buildings

Buildings account for 40% of global warming emissions [2]. Sustainable building management has received much attention in recent years. Many communities throughout the world are struggling to develop efficient and effective tools for assessing sustainable buildings. However, there is no universal method or tool yet. Sustainable buildings are at the core of any sustainable development, for the sustainable building, the objectives of decreasing both adverse environmental impact and cost are in conflict. In addition, even though both objectives may be satisfied, building management systems may present other problems such as convenience of occupants, flexibility of building, or technical maintenance, which are difficult to quantify as exact assessment data.

In Jordan, sustainability is a new concept still, and many of the very few aiming-to-be sustainable buildings are not quite mature yet. With the first building to gain a LEED silver certification in 2010, figure 1, Jordan is still long way away from developing a strategy for sustainable building industry.

Fig. 1: Dutch Embassy Building- First Green Building in Amman- Jordan with LEED Silver Certificate (www.archined.nl, 2012) .

1.3 How is Sustainability Measured

To some, sustainability is a matter of numbers, scores and graphs. The ESI clearly probate that we live in an era of numbers. In many realms, decision making has become increasingly data-driven. But the environmental domain has curiously lagged in this regard [3].

On the large scale, there's the ESI, see figure 2. The 2005 Environmental Sustainability Index (ESI) provides a composite profile of national environmental stewardship based on a compilation of 21 indicators that derive from 76 underlying data sets. The ESI offers a tool for shifting pollution control and natural resource management onto firmer analytic underpinnings. In this regard, the heart of the ESI is not the rankings but rather the underlying indicators and variables. By facilitating comparative analysis across national jurisdictions, these metrics provide a mechanism for making environmental management more quantitative, empirically grounded, and systematic [4].

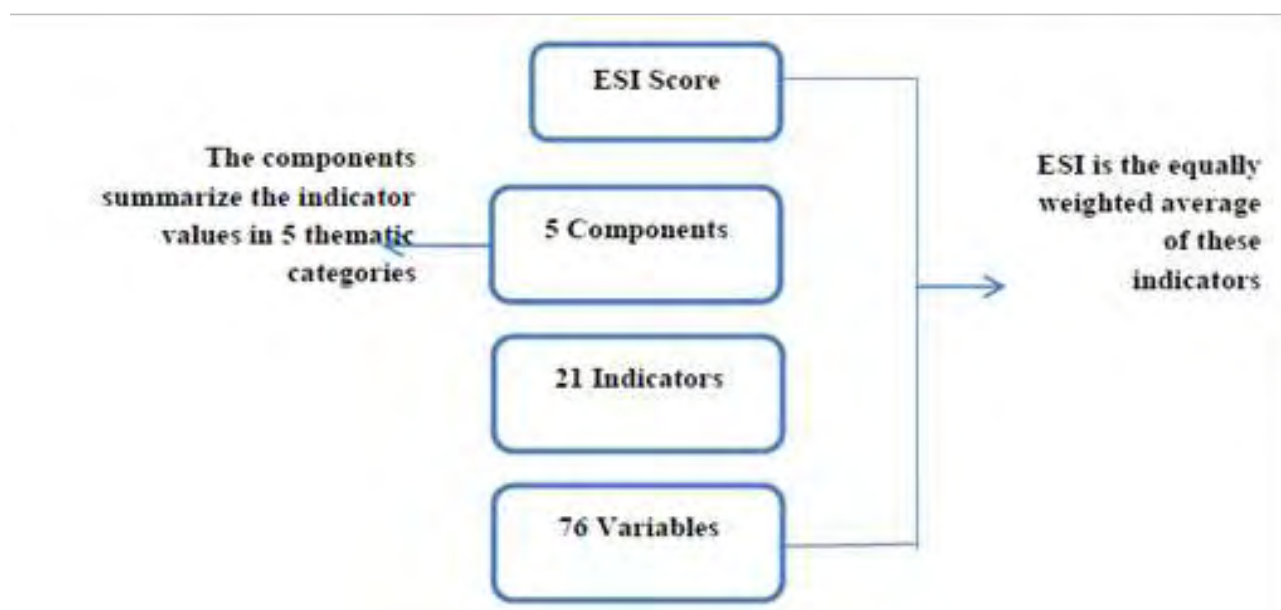

Fig. 2: Constructing the ESI Score [4].

The higher a country's ESI score, the better positioned it is to maintain favourable environmental conditions into the future. The five highest-ranking countries are Finland, Norway, Uruguay, Sweden, and Iceland – all countries that have substantial natural resource endowments and low population density.

Table 1 shows Jordan's position on the 2005 (ESI) world score. Almost two points lower than world median and behind leading countries like Finland. Jordan is a world standard performing country when it comes to energy resources and impacts on the environment. As a developing country, large part of its residential building activity contributes to the country's overall performance on the ESI scale.

| ESI Rank | Country Name | ESI Score |
|---------------------|-----------------------|--------------------|
| 1 | Finland | 75.1 |
| 45 | United States | 52.9 |
| 55 | Tunisia | 51.8 |
| 65 | United Kingdom | 50.2 |
| 75 | Indonesia | 48.8 |
| 83 | Oman | 47.9 |
| <u>84</u> | <u>Jordan</u> | <u>47.8</u> |
| 136 | Saudi Arabia | 37.8 |
| World MEDIAN | - | 49.7 |

Table 1: Jordan on the (2005) ESI World Score [5].

1.3.1 How is Sustainability Measured in Buildings

There are many tools developed in the field of the performance assessment of the buildings sustainability. Starting from the 90s, many different evaluation systems and tools of environmental performance assessment for buildings have been developed, as BREEAM in the United Kingdom, LEED in the United States (prompted by the US Green Building Council, Energy rating in Denmark, ECOPROFILE in Norway, ECOEFFECT in Sweden, ESCALE in France, TOTAL QUALITY in Austria and the DGNB procedures in Germany [6]. These tools are applied for different purposes like combining the energy problems with economic and social concerns; enhancing relationships with urban plans; applying the appraisal procedures in the different stages of the building life-cycle; including the urban context and site features in the evaluation and involving different stakeholders and shareholders (as designers, evaluators, users, investors and researchers) in the evaluation process while promoting the performance approach.

1.4 Sustainability in the Arab World

The Arab world is faced with many urban challenges; in “The Revolving Arab City”, [7] suggests that regional policies (pan-Arab unity) and social security are not a priority anymore. Rather, the private management of public property is becoming more prominent. The creation of private development companies backed by banks or hedge funds, like Al-Abdali in Amman, figure 3, Solidere in Beirut, Saphia and Bou Regreg in Rabat, Tunis” Lake are examples of the new globalised spaces that aims to provide high returns on investments for firms like Sama Dubai, Emaar, Saudi Oger and other national developers (Mawared in Jordan and Caisse de Depot et de Gestion in Morocco) [8].

Fig. 3: Al-Abdali represents a new vision of High-rise development in Amman (www.abdali.jo, 2012).

Arab cities demonstrate multiple layers of development through history. Over long periods of development, land uses have been adapted to suit inhabitants. Conventional urban configurations were based on densities, mixed uses and bottom-up urban growth, reflecting people's daily needs. Modern Arab cities demand an accelerating increase in transportation mobility pursuant to inappropriate land use distribution. These requirements do not consider the current spatial morphology of the urban fabric, nor its role as a stimulus in successful locations. The differences between traditional and modern extensions for Arab city centres on the basis of sustainable land use location

should be re-assessed to evaluate current land use distribution and forecast the success of any future intervention.

The traditional methods of sustainable buildings in traditional Arabic context were mainly focused on techniques that enhanced indoor quality in hot and arid climates. Hassan Fathy was a pioneer in incorporating traditional methods of building into rural areas of Egypt. However, these traditional methods do not solve today’s problems for buildings. Many modern day architects have used successful symbolic precedents in modern architecture by means that convey nostalgic reference rather than careful study of these symbols as effective sustainable solutions. The works of Rasem Badran and Abdelwahed Al-Wakeel bear witness to such attempts.

The Arab region geographical typology varies extensively from east to west, and so is the building technology used in every region. In Jordan a variety of geographical typology is also present, and that also adds to variety of building techniques.

1.5 Sustainability in Jordan

The scientific community expects that the world will start to face critical shortages in its supply of fossil fuel in the near future, with the expectation for most oil resources to vanish within the next 50 years [9]. During the past decade, and as a result of the significant increase in the population in Jordan, multi-apartment buildings became the most dominant building format, especially in Amman the capital. The lack of well-developed passive heating, cooling and energy saving solutions, made the reliance on central heating in winter and air conditioners in summer the prominent choice for residents [10]. Jordan is a developing non-oil producing country. Jordan imports 95% of its energy from neighbouring countries. In general, large cities in Jordan are comprised of multi apartment buildings, usually about four storeys high. Energy consumption for residential purposes accounted for 18% of the total consumed energy in 1999. By 2009, energy consumption for the residential sector jumped to 30% [11], and is projected to increase if energy saving techniques are not implemented.

1.5.1 The City of Amman

Amman, the capital of Jordan, is experiencing a significant urban and economic growth. The fast increase in population and the growing economic demand for business growth have increased the need for comprehensive planning agendas, see table 2.

| Census | 1994 | 2004 | Increasing % |
|----------------------|-----------|-----------|--------------|
| Buildings | 504,000 | 636,000 | 26.2 |
| Housing Units | 832,000 | 1204,000 | 44.7 |
| Households | 672,000 | 946,000 | 40.8 |
| Persons | 4,139,000 | 5,323,000 | 28.6 |

Table 2: Population and Housing Census in Jordan in 1994 and 2004 [5].

Amman as a city has developed 8000 years ago, due to its suitable climate and availability of water. In the year 1200 B.C it became the Ammonite’s capital, and ever since then it has been in the central attention of many civilizations, until the time it became the capital of Trans-Jordan in 1921 [12]. Amman now is a city of nearly 2 million inhabitants, see table 3 - it is becoming a mega-polis. With the city aspiring to grow and advance - in a world of many environmental concerns like climate change and sustainability – the challenges facing city planners, architects, designers and decision makers are overwhelming. Globally, urban population have increased much faster than rural populations [13]. The ecological footprint of a city can be many times larger than its physical size. Urbanised areas cover 2% of the earth’s land surface, but account for 78% of carbon emissions. Similarly 60% of water use and 76% of wood used industrial purposed occur within urban areas [14].

| Governorate | 1994 | | | | 2004 | | | |
|--------------------|------------------|----------------------|-------------------|----------------|------------------|----------------------|-------------------|----------------|
| | No. of Buildings | No. of Housing Units | No. of Households | No. of Persons | No. of Buildings | No. of Housing Units | No. of Households | No. of Persons |
| Amman | 144491 | 337071 | 271604 | 1576238 | 182961 | 498085 | 382674 | 1939405 |
| JORDAN | 503894 | 831799 | 672472 | 4139458 | 636088 | 1204398 | 945806 | 5100981 |
| Amman's Percentage | 29% | 41% | 40% | 38% | 29% | 41% | 40% | 38% |

Table 3: Population and Housing Census in the City of Amman Compared to the Total in Jordan [5].

1.5.2 Residential Buildings Types in Amman

Amman's typology is defined by hilly slopes; the topography of the city consists of a series of steep hills and deep and sometimes narrow valleys. Most of the districts of Amman take their names from the hills or jabals on which they are situated, figure 4. Whilst initial development was principally on the upper slopes and crests and the lower slopes of this hill-valley system, the upsurge in urban development over the last sixty years has involved extensive development on the frequently steeper mid-slope locations.

Fig. 4: View of the Old City – Jabal Amman Hill.

The original site of the city of Amman occupied seven hills or „jabals“ around the Wadi „Ras el Ain“ which flows north-east from the plateau towards the River Zarqa basin. The original central part of the city was at an altitude of between 725 and 800 meters, figure 5.

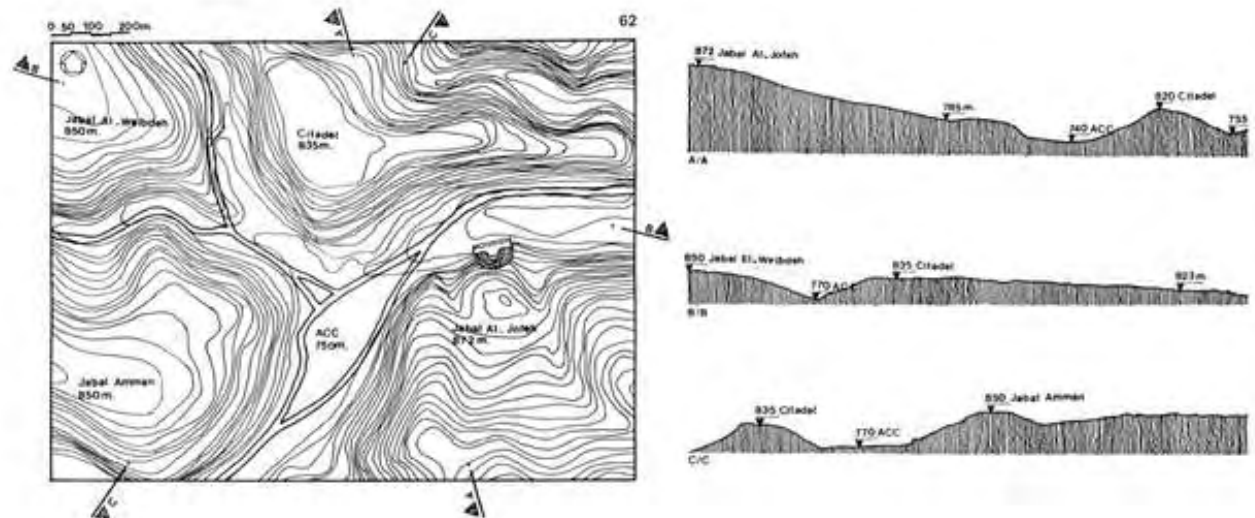

Fig. 5: Topography of Amman City Centre (ACC) and surrounding hills or Jabals [15].

Expansion of the city in the past twenty-five years has resulted in the occupation of some nineteen hills in total with an altitudinal extension to above 875 meters. Given all information about Amman typology and geography, it is inevitable that builders and designers in Amman are faced with many challenges. Sustainable building design places significance importance on site, and the relation between building and site that best serves aesthetic, climatic and economical sustainability values. In Amman, construction practices that adhere to traditional methods are obsolete when it comes to serving environmental issues. They are mainly based on wrong design choices at the beginning of the design process. They are also neglecting building orientation and functional layout that contribute to effective passive design.

1.5.2.1 Apartment Buildings

Up to the 1970s, it was very common for people in Amman to build freestanding, one-story, single-family houses. Such houses most often would later be expanded vertically to reach two or three stories. The owner of the house would build these additions for the use of his or her children (usually sons) for when they grow up and have their own families, or to rent out as a source of additional income.

During the late-1970s, the apartment building emerged as a more prominent residential building type in Amman. By the 1990s it became the predominant building type. In fact, of the 2.18 million square meters of construction permits granted in Jordan during the first four months of this year, 1.8 million square meters were for apartment buildings [16].

The impact of the spread of the apartment building has been tremendous on Amman. It definitely has raised the density of habitation in the city, figure 6.

Fig. 6: Computer Visualization of an Apartment Building in Amman.

The typical four-story apartment building, which usually includes two apartments on each floor, will have about eight families inhabiting it. Of course, there are the more luxurious apartment buildings with one apartment per floor, but there also are apartment buildings that have additional living units because of their location on a sloping site. Many apartment occupants, especially in western Amman, have cars, and the construction of each additional apartment building puts further pressure on the movement of traffic in adjacent streets and on the availability of parking spaces. Also important is that with the exception of ground floor apartments, the inhabitants of apartment buildings do not have access to gardens. At the same time, apartment buildings in Amman are too small to support communal open recreational spaces. The problem is exasperated by the fact that Amman still suffers from a shortage of public neighbourhood parks, see figure 7.

Fig. 7: Apartment Buildings Occupying a Hill in a North Ammani Neighbourhood.

1.5.2.2 Villas

Villas represent the high-end single family dwelling option for buildings in Amman, especially in its western part; they usually comprise one or two floors, figure 8.

Fig. 8: A Modern Villa in Western Amman.

1.6 Sustainable Design Criteria

Site selection and building orientation come at top priorities in any sustainability assessment tool. Therefore, the site typology - especially its slope and natural topography is of great importance to the sustainable design decision. If a site is flat, the topography may not influence the location and layout of the building, but on a sloping site, the topography is likely to be a significant design factor. The slope of a site or the slope of adjacent sites may affect access to sun and views; the need for excavation or fill – as well as increasing costs [17]. Large-scale earthworks increase the risk of erosion by altering soil stability and water run-off patterns, and significantly affect natural biodiversity by removing soils and plants.

The significance criteria lie in the fact that when designing in Amman, designers cannot overlook the typology of its most vacant sites. The hilly slopes of Amman are challenging sustainable design by delimiting passive cooling and heating for buildings if the building is not correctly placed on site [18]. Construction works that are contributing to negative environmental impact can be minimized if more site consideration was done during the initial design phase, and the building layout, orientation, etc. was based on more sustainable decisions.

Design should foresee that during construction the amount of site work and disruption is at minimum, the visual impact of the building form on the landscape is not disturbing and the orientation of the building is optimizing the passive heating and cooling of the building [19]. Non-sustainable current construction practices in Amman have visual and cost-related negative impacts on the environment, see figure 9. The excessive use of retaining walls to solve severe slope cuts is very common, see figure 10- a practice rendered sustainably nonviable, besides its failure with regards to visual and aesthetic aspects.

Fig. 9: Current Practices of Building on Slopes in a North Ammani Neighbourhood.

Fig. 10: Retaining Walls on Severely Cut Slopes.

1.7 Conclusions

The paper addressed several issues, and these issues are:

Analysed the challenges and opportunities provided by land topography in Amman and its effect on delivering sustainable buildings.

Provided recommendations about how the outcome of this research can help planners and designers in the early stages of the design process to have an insight into best strategies for passive housing layouts on sloped sites.

Provided a mechanism for the development of guidelines on preferred buildings orientation in hilly areas with regard to local climatic data.

Outlined major disparities between the two main residential building types in Amman, the Apartment Building and the Villa, and the best design guidelines for sustainable and passive viability on sloped sites.

Abstract

The paper discusses the 'top down' planning approach used nowadays on urban redevelopment projects in São Paulo versus spontaneous manifestations regarding the meanings of the space of the city, using the new Urban Operation Lapa-Bras brief document and Minhocão's demolition plan as a case study, Minhocao is an elevated express avenue that crosses the center of the city dividing districts and neighbourhoods, causing a huge impact on the landscape. However, unexpectedly, it also has a different meanings and interpretations – apart from being an equipment of road infrastructure– for the different groups that lives in its surrounding areas. For them the space is seeing as a park, an art gallery, a market and many other functions, as it is spontaneously appropriated in different ways during the moments of the day and night when it is closed for cars.

The paper debates different meanings from different stakeholders involved in the project for the area. Its shows how do the surrounding inhabitants live and relate to this specific space of the city, apart from the planners point of view, and, most important, how do they transform it, from a heavy and aggressive piece of urban infrastructure to a public space, an important social infrastructure that is part of their daily life.

Minhocao is, in one hand, from a 'top down' perspective, a terrible loss of value for the land and building owners and a damaging and replaceable urban infrastructure for the planners. Meanwhile, for others, from a 'bottom up' point of view, it can also be considered as a social infrastructure for the inhabitants of its surroundings that, due to its appropriation, claim the space as their "place".

A "non-place" (Auge, 1995) or generic space for some, a part of their "piece" (Magnani, 1996) for others. These are the multiple interpretations that Minhocao has and this paper aims to discuss.

Keywords: *Urban Development, Infrastructure, Public Space, Sao Paulo.*

1. Introduction.

During the late 60's and along the 70's, a period of important economical and geographical growth in São Paulo, a decade in which the city's number of inhabitants grew 56% , strategic planning was used for the first time in a cohesive way, to organize the city's expansion.

One of São Paulo's master plan was being discussed and a number of road interventions took place in order to control the chaotic congestions that started to appear, due to lack investments on public transport, increasing incentives for private transport – in order to promote the car industry, back then the main economic driving force of the region on the 50's, 60's and the 70's - and an uncontrolled urban sprawl, causing an expansion of the urbanized area not predicted and never foreseen.

One of these interventions is the objective of this analysis. Commonly known as Minhocão , it is an elevated express way that passes thru the center, responsible for improving the car connection between the west and east part of the city.

It was part of a series of interventions at the center that did not aim to improve its urban space, only establish connections between the city's different zones, using the central region as a crossing point, without any mechanism that could attract people or economical activities to the area. In this process, a fragmented and disjointed region was left behind, with very few private or public investments with the aim to enhance its urban environment.

Within this context, Minhocão is one of the most discussed interventions of the period. It is a 3,5 kilometres, 4 track express elevated avenue that crosses 3 central and highly 'verticalized' neighbourhoods of São Paulo. Constructed passing over existing avenues, in which high rise buildings were already placed without any retreat, it passes only 5 meters distant from some of the facades. Due to its size and profound impact on the urban landscape, it calls the attention of the public ever since its construction in 1970, during the military dictatorship.

Fig. 1,2: Minhocão views from below and above. Images from the author.

In its 40 years, several proposals were made in order to minimize its negative impact on the surrounding area, and since the 80's, after Peter Hall has chosen it as one the "positive great planning disasters" , its demolition it has been discussed.

In 2006, the municipality and its urban development agency EMURB, announced a plan to bulldozer the elevated express way. A range of discussions took place, many of the main actors involved were listened to – except the population that lives on the surrounding area – and a competition was launched by the municipality to generate design proposals, in order to envision different solutions for the area.

The designers could propose anything, as long as the structure was not thrown apart or completely disassembled, neither the use as a car connection should be disregarded. The brief of the competition was questioned by the participants, the actors and the Brazilian Architects Institute (IAB), that ceased supporting it, causing many architects to cancel their application. Nevertheless the competition continued.

The final design proposal, through an extensive analysis of the region and the daily life of the surrounding neighbourhoods, took advantage of the 'informal' uses and people's spontaneous social, economic and artistic appropriations of the site, making them the starting point of the design process.

This detailed and considerate look showed that Minhocão, apart from being a road, has another very important function. Since 1976 it is open only from Monday to Saturday, from 6h00 am to 10h00 pm, in order to minimize the noise effects on the adjacent buildings. This resolution, however, brought an unexpected use for this unpleasant urban infrastructure, that could not be disregarded. The lack of an adequate public space in these neighbourhoods triggers a surprising appropriation of its four tracks during the night and weekends. As soon as the tracks are closed for cars, they become available for the surrounding building's residents.

1.1 Minhocão's informal uses

Artistic Interventions: Both the spaces above and below the elevated are used by street artists, putting up temporary installations (as seeing in the two first images) and graffiti panels.

Fig. 3,4: Artistic Interventions on Minhocao. Images from the author.

Economical activities: Street sellers often occupy the space on the weekends, taking advantage of the floating population. Bike rent and fix "shops", foods and drinks tents, along with arts and crafts tents are the most common informal economical activities during the weekends.

Public events: A range of public events take place at the site. An open movie session, a path of a street race and a runway fashion show are some of the events that it hosted in the last few years.

Linear Park

Fig 5,6: Minhocao as a Linear Park. Images from the author.

Fig 7,8: Minhocao hosting Baixo Centro Festival. Images from the author.

Fig 9,10,11: Minhocao hosting Vodoowoop party. Images from the author.

Taking advantage of these informal uses, the proposal kept the elevated tracks and covered them. The space above was turned into a linear park open every day for the population. On the spots that Minhocão faces existing squares and open spaces, glass-made extensions were put, functioning as the entrances of the park (through lifts and stairs), as well as art galleries and popular shops for the users.
Final Design Proposal by Frentes Arquitetura - Sections:

Fig. 12: Generic Section of the project, showing the tunnel with a gallery on one side. Source: Frentes Arquitetura.

Along the 3,5km of the park the section adapts itself, according to its urban insertion, the height and occupation of the surrounding buildings.

Fig. 13: Photomontage of the project. Source: Frentes Arquitetura.

The design also won the first prize of the 7^a International Architecture Bienal of São Paulo in 2007, and was shown in the 10th Venice Biennale of 2006.

Time passed by, the municipal administration changed – from a right wing party to a centre-left party – but maintained its neoliberal orientation. Now, the master plan is being revisited and some special areas are being stimulated, in order to organize the spatial development of the city, with the aim of increase density in the sectors and districts that already have urban infrastructure, generating new dwellings and job opportunities.

Part of this process, the brief for a new plan of redevelopment was launched on May of 2010, containing an adjacent neighbourhood of the elevated highway. The plan consists on creating a new road and a linear park along the existing rail line, as a way of increase its density and stimulate real estate development of the area. This way, once the new road system is finished, there will be no need for the elevated express way as a car connection between the west and east zones. Therefore the plan suggests to destroy it, at the estimated expense of R\$80 million (approximately 35,5 million euros).

This paper intends to discuss, crossing the different interpretations of this place, if this demolition is really necessary as part of the new redevelopment plan and if all Minhocão's functions (formal and informal) are being taken under consideration.

It is, in one hand, from a 'top down' perspective, a terrible loss of value for the land and building owners and a damaging and replaceable urban infrastructure for the planners. Although, for others it has different meanings. From a 'bottom up' point of view, it can also be considered as an opportunity to some less wealthy inhabitants to live in a gifted area of the city and a social infrastructure for the inhabitants of its surroundings that, due to its appropriation, claim the space as their "place" .

A "non-place" (AUGE, 1995) or generic space for some, a part of their "piece" (MAGNANI, 1996) for others. These are the Minhocão's multiple interpretations.

2. Top down: The owners and planners point of view.

Minhocão is often seen as a negative urban externality. Considered as a necessary infrastructure to avoid urban chaos when it was conceived, it immediately caused evasion of the middle class, until then predominant, of its surrounding blocks, due to its degrading factors (noise, pollution, visual barrier, among other). The process itself induced a downfall of rent prices, which eventually caused major property devaluation. Many of the buildings remained empty for some years, until the market value was balanced, at a

point when many owners had put their properties “on sale”, allowing people from different social backgrounds to rent and buy apartments, beginning to live in the area.

Since its proximity to the center, to Paulista Avenue and to several wealthier – but saturated – neighbourhoods, the area still has the potential to become attracting again to the private investors, but Minhocão has always been ‘standing in the way’.

Now, with the real estate market acting frenetically all around the city, in some cases developing housing and office buildings in areas that are not as well provided with urban infrastructure as this, the site called again the attention of the planners.

The current master plan of the city was approved by the city council in 2002 and it specifies several areas to be improved and stimulated – redeveloped – by public and private investments, through the offer of differentiated parameters of construction.

Fig. 14, 15: Urban operations and New Urban Operation. Maps from the author. Source: EMURB.

These areas share a lot in common: they are relatively well located in within the city, are close to existent urban infrastructure and have a history of being occupied mainly by industrial facilities, an economic sector that is decreasing its importance inside the city since the 80’s, in a process similar to the European and North American experiences, but with a slower rhythm.

In a system of public auctions, an amount of extra squares meters are offered to real estate developers and land owners, in order to increase density and collect private money, applied latter in urban renewal and infrastructure enhancement and construction. It is supposed to be, according to the city planners, a virtuous cycle:

“(generates) more investments, increasing value, increased value attracts private investments, more private investments generates more resources and more public investments in that region of the city” .

Ten Urban Operations were established by the plan of 2002 and until today, only four were developed. Changes in the political administration, the lack of sufficient staff members in the urban development agency and secretary to develop new specific plans, the necessity of the approval by the city council of these specific plans and an economic crisis in 2002 – leading to a Real Estate crisis – are some of the reasons why none of the other Urban Operations got off the ground. Meanwhile, the real estate business - mainly on the housing and small offices sector – experienced an expansion cycle after 2006, due to some federal resolutions and economic policies, process that not even the 2008’s global economic crisis was able to break.

Many critics have being made to this planning system, mainly by academics – some planners, architects and urbanists - regarding its tendency of increasing social exclusion, the lack of public participation and the control of the urban redevelopment process by the private investors, along with the European-north American mainstream urban geography and sociology analyses that highlights that the renewal schemes in developing countries are, in practice, “undertaken for commercial reasons rather than for social-welfare objectives” (PACIONE, 2001. Pg.539).

In this panorama, a new area called Lapa-Brás was proposed, adding three existing Urban Operations, summing up around twelve linear kilometres. The main goals of the new operation are:

“achievement urban transformation, structural and social improvement, environmental enhancement, especially enhancing public spaces, arranging transport, deployment social housing programs and improvements in infrastructure and road system in a given area, the optimization of areas involved in urban interventions, divide and recycle areas considered underutilized, recovery and creation of environmental heritage, historical, architectural and cultural landscape, and stimulation of areas in order to generate jobs” .

Fig. 16: Perimeter of the new Urban Operation - Lapa Brás . Map from the author. Source: Google Earth.

The aims are very bold. If accepted by the city council, this will be the bigger urban intervention of the city's history, especially considering the size of the project and its strategic position. Proposed to be the unification of several interventions and plans, its brief document contains the parameters of the studies to be hired, that eventually will put the plan together in order to be approved by city council.

The necessary studies for the new plan, according to the brief document, concern urban design, mobility infrastructure capacity, economic evaluation, environment studies and communication plans.

Public participation is not intended to be part of the process. Some public meetings, as a bureaucratic requirement, are planned at the end of each study, to show the results to the population, in a scheme of informative session, not participative construction.

Two major interventions are already determined: The necessity of changing the level of the rail line, allowing the north and south parts of the neighbourhoods to be reconnected and the demolition of the elevated highway – Minhocão – to be yet confirmed by traffic and mobility simulations studies.

The first resolution can easily be connected to the major aims listed above. These areas between the rail line and the river's express way are disconnected from the urban fabric, suffering of an island effect, causing massive damages to the urban environment and landscape. The main functions existent are soft industrial uses and logistics facilities. Due to its proximity to the center and valued neighbourhoods, eliminating the border set by the rail line is an important step towards achieving a better use and occupation of the area, attracting more coherent functions as residential, commercial and service.

Aiming to become eventually, instead of an isolated “in between” zone, a sequence of the existing urban fabric. According to its main goal, it aims to:

“Overcome the barrier of the rail line and the redevelopment of its edge, presented as an important structural element to order the territory, covering improvements of mobility and accessibility, the restoration of the urban fabric, the continuity of the circulation system, the possibility of occupying empty or underutilized areas, the induction of the occupation of areas already urbanized with new standards based on the increase density of population and built areas, balancing the supply of housing and jobs, the increase of soil’s permeability, vegetation, and public spaces for socializing and leisure.

(...)

Starting from the complementary concepts of Landscape – set of natural and built elements that are seen from a certain area of the territory) and Space (the accumulated result of society’s actions – such as production, dwelling, leisure, or, summing up, the life that animates the objects that composes the landscape), the improvement of urban conditions and environmental quality may be understood as measures to diversify uses and functions, increasing built and demographical density consistently with the existent and planned infrastructure, increasing green areas and public spaces, improving drainage, adapting typologies, accessibility, mobility, properly converted in spatial terms and translated in urban form.”

Regarding Minhocão’s sector, the aims seem different from the main goals. The following sentences, withdrawn from the brief document, set the tone of what is intended by the project:

“[The removal aims] to promote the urban and landscape recovery of the areas close from the elevated avenue. (...)Recovering the urbanity of Amaral Gurgel avenue and Padre Olímpio da Silveira(...) Recovery of vast well located areas.”

“[The removal] should allow the sprawl of the Higienópolis’s qualities to this [Santa Cecília] region (...) shall provide the reinsertion of the blocks along its path. This re-qualification should be seen on Vila Buarque and Barra Funda, besides it can, potentially, bring new features to public spaces of great meaning to the city, as República Square, Arouche, Santa Cecília and Marechal Deodoro Squares.”

Apart from mobility, there is no consideration about the other functions – mainly as a social infrastructure – of the elevated high way. There is also no explanation on how to propitiate the urban “recovery”, “reinsertion” and “requalification” desired neither the project of new areas that could possibly replace its social use. The existent blocks are already connected, since the Minhocão does not interrupt mobility between its surroundings, as the rail line does.

Fig. 17: View from Rosa e Silva Street. Image from the author.

Two of the sentences listed above, however, begin to explain the intentions behind the removal. When the municipality’s plan mentions “sprawl Higienópolis qualities” and “new features to [existent] public spaces” it does not only implies its spatial characteristics, but also social and demographical. Higienópolis is one of the richest neighbourhoods in the city. Its typologies are not the same as the ones in its surrounding neighbourhoods. This innocent qualitative sprawl means, in practice, erasing and upgrading existent housing typologies, without creating conditions to keep the inhabitants in the region, a process similar to what already happened in other Urban Operation’s areas.

Different from the other underused areas that need “improvement of urban conditions and environmental quality” as the plan aims, the mentioned neighbourhoods and adjacent blocks of the elevated already presents “urbanity” enough.

What could be the problem? Which kind of “recovery”, “reinsertion” and “requalification” are really aimed?

The humanist approach on Urban Geography, according to PACIONE (2001), recognizes two different structures in which urban space occur: Physical and Cognitive. If so, the same urban space can be seen in different ways, according to its individual and personal meanings, its users life styles and different background. To be able to construct or - using the planning term - develop urban space it is necessary to recognize both realities of the city: “the city as a concrete construction (thing) and as an abstract representation (idea), and examine how each influences the form of the other”. (PACIONE, 2001. Pg. 22)

The author distinguishes the significance of “space” and “place”, emphasizing the importance of the “construction of places” while restructuring contemporary cities, differentiating top down approaches as the ones that construct “generic spaces” and bottom down approaches when the attempt is to construct, develop, keep and transform “places”.

The Structuralist approach relates the production of space to the economic relations, rooted in Marxist thought and class antagonism. According to this stream an important distinction has to be made between “representations of space” or “conceived space” made by planners and designers and “spaces of representation” or “perceived spaces”, when they become appropriated by people, similar to the Humanist notion of “space” and “place”. Therefore, part of the inability of São Paulo’s planners to acknowledge the fact that Minhocão is a “perceived space” in the city originates on the fact that it was never a “conceived” social space.

Still through this stream, the different interpretations of city space rely on the antagonism of public and private space along with “city life”. From one side one can find, on the public realm, “public culture”, a space to socialize with others and where “shared citizenship is created”, and in the other the “fear of other”. According to Pacione, some contemporary urban groups (mainly middle and upper classes) don’t usually appreciate the “encounter with difference”, replacing open public spaces by closed and “sanitized” spaces, where “out of place” individuals can be excluded (PACIONE, 2001).

Architecture and planning are, according to structuralism, a product of dominant social groups. They reveal the power of these groups influencing the urban structure. In a way, the absence of recognition of Minhocão’s area vitality comes from the fact that it’s inhabited by those considered “out of place”, a different interpretation from its users.

The post-modernist approach however differs from this perception:

“The different urban landscapes are the result of this dialectic relationship between social practices and the physical. The same urban space can therefore have a different meaning for different social groups, a situation that can lead to conflict over the appropriate use of land (...) the urban landscape is the product of both culture and economy, and a proper understanding of urban environments must be based on explicit acknowledgments of this complexity” (PACIONE, 2001. Pg.162).

A point of view similar to the social science’s regime theory:

“regime theorists represent something of a synthesis of the two outlooks (Pluralist -liberals and Marxist-structuralists), control of capital outweighs other sources of power, but development process cannot be understood simply through examining a ‘logic’ of capitalism, since that logic is itself fabricated through human activity, including the resistance by other groups to capitalist aims.” (FAINSTEIN, 1994. Pg. 264).

According to these two streams, in order to understand the urban environment in the proposed Lapa-Brás diagnosis and contradicting its traditional top down planning approach, it is necessary, as much as the economic study, a broader social study, identifying – not assuming – the region’s inhabitants needs, their “perceived spaces” and the existent urban spaces’ meanings and potentialities, in order to include them in the master plan and projects.

Not exactly an easy task for a neo-liberal oriented Urban Development Secretary. The discussion of “urbanity” – as the plan refers – or “liveability” – the equivalent urban geography term – should be employed in both objective and subjective evaluations: “the city on the ground and the city on the mind” (PACIONE, 2001. Pg 397). This accomplishment São Paulo’s city planners are apparently still far from achieve.

3. Bottom up: Urban infrastructure appropriation and the making of urban Piece and Place.

“The one actor in the urban development process not yet considered is, in some settings, the most influential” (PACIONE, 2001. Pg.161)

Elevado 3.5 is a documentary wrote and directed by the architects João Sodré and Paulo Pastorelo; and the politic scientist Maíra Bühler, first prize winner of “É tudo verdade” Film Festival of 2007.

Alternating a sequence of images and scenes of Minhocão and its surroundings; with personal testimonials of twenty characters, inhabitants of its adjacent buildings, from different ages, social and demographical backgrounds and living in different positions in relation to the elevated high way: first floor, middle floors and last floors of the buildings, but all with something in common: a window or a terrace door facing the Elevado. The delicate film reveals the complexity of the area’s figures, but also several different typologies, building densities and possible urban relations and interpretations. To each of them, the elevated high way has a different meaning, with multiple relations between their urban space and “place”. The words “pride”, “life”, “need”, “leisure”, “place”, “home”, “memory”, “happiness”, “sadness”, “dream”, among others permeate their imaginary, in contrast with the asperity of “recovery”, “reinsertion” and “requalification”, the planning terms mentioned.

When asked about what the window (or terrace door) facing the elevated high way means to them, many related the view with positive sensations. About the demolition, none of the characters that addressed the subject were in favour.

The close relation of the surrounding inhabitants with Minhocão as their “piece” and “place”, along with the appropriation of it by, not only them, but by all the surrounding neighbourhoods residents, and – through the popular events, street art manifestations and happenings – by the whole city, raises an inevitable question: demolition for whom?

4. Conclusion

“The struggle over collective urban spaces and the representation of differences in them are indispensable elements for the advancement and spatialization of democracy. They introduce new political subjects and new rules into cultural and social life, and create possibilities for widening the exercise of citizenship, from the abstract realm of nation-state to the concrete realm of urban spaces” (PALLAMINI & LIMA, 2007)

Fig. 18: Minhocao and its users. Images from the author.

The present paper, through alternating São Paulo’s current planning statements and resolutions towards urban redevelopment, with different theoretical approaches on Urban Studies (Urban Anthropology, Geography and Sociology) and a record of its inhabitants’ testimonials, discuss the “top down” character of planning policies historically applied in the city and, in spite of it, the creativity of its population concerning urban informal and unexpected appropriation.

By architects, urbanists and planners Minhocão is, by consensus, an urban aberration. Product of an authoritarian act that “privileged the circulation of cars over pedestrians, and efficiency over socialization”, its construction by no means could be considered a good solution for the area.

But the city embraces the good and the bad planning practices. It forgives drastic design proposals and overbearing approaches; it adapts, copes with it and eventually accepts it as its own piece. People transform and appropriate urban space in unexpected ways that, in urban renovation processes, cannot be disregarded.

As a final revenge, what was a negative externality for some – the formal actors, land and building owners – became a positive externality for many – accidental figures that, because of Minhocão's existence, have the meanings to live in one of the most well served areas of the city in terms of job offer, public transport, educational and health facilities, overcoming decades of territorial exclusion and "peripherization". A spontaneous demographical process caused by economic dynamics, that the new plan itself intends to induce: the increase of inhabitants in the central area.

"While many cities and citizens are linked into an electronic 'non-place urban realm', place – based relational networks that rely on propinquity and physical interaction – the key characteristics of urban places – remain central to the experience of human social, economic and cultural life" (PACIONE, 2001. Pg.24).

Drawings for Engineering

Laura INZERILLO¹

⁽¹⁾ DARCH, Facoltà di Ingegneria, Università di Palermo, Palermo, Italy
laura.inzerillo@unipa.it

Abstract

In the representation of knowledge can not miss all those geometric, static, functional, and specialized notions in infrastructures that characterize the shape of a Civil Engineer. We take this opportunity to show how complex the representation of a hydraulic overflow, how bold is the company wanting to bring the cross sections, the view from above, the longitudinal section. And, yet how essential is the knowledge of descriptive geometry to determine the intersections of complex surfaces, the application of engineering has great feedback.

An engineer must know how to read and know how to make a drawing, must learn to identify the main characteristics, must be able to focus on the goals and be able to identify the reading of the representation of another author. An engineer must be able to express in terms of own project idea without has any limits of freedom of thought. Sometimes, in fact, a drawing doesn't have the fundamental informations about the representation and that is the limit of the project.

This study intends to show some drawings of civil works project requiring the knowledge and understanding of the fundamentals of descriptive geometry, without which the expressive potential of the author would inevitably be compromised.

Keywords: Civil Engineering, drawings, homology, sections

1. Introduction

Within the Civil Engineering and Environmental and Territorial Engineering training, the area of the Representation have sometimes a sacrificed and marginal role. Only from few years, in the Civil and Environmental Engineering Degree of Palermo has led the Drawing from 3 to 9 credits giving back to the graphic area a more suitable and dignified cultural position. In the educational difficulties of approach to class of students foreign to representation techniques, results essential to place the Drawing as primary tool for the divulgation of the project idea and not, like fundamental language in the professional engineering sector, as starting base in the communication of complex realities and structural integrations.

The professional approach predisposes the learners to a more careful listening, sure of relapse in qualitative terms of their figure of Engineers in the field work. The potentialities offered by different representation techniques become, in this way, a not only divulgative tool but also cognitive, of analysis and survey which completes either the moment of the reproduction of the real either the ones of design of the virtual. Appropriate the graphic restitution methods, confers to the learner the skill to be able to express the results of a study executed with diligence and attention, and with the mastery of the graphical means is possible to transmit to who will use that heritage as knowledge, as service fruition, as community heritage.

The applicative experience of a project material enthusiasms the learner which had to find himself to must possess the representation methods to tell that project of which isn't author, but of which could potentially be.

1.1 Representation of an hydraulic overflow

It's reported below the experience of an hydraulic overflow, of which the learner had to interpret the constructive and functional values for then translate them in graphics that would consider the different intersections, the different projections of the complex surfaces that make it up.

The overflow in hydraulic engineering is a particular artwork, which is being used to move away, or otherwise to separate part of the water from a canalization to an opportunely identified direction.

In general way its operation is in relation to a threshold, above which begins the water conveying to another conduit.

Exists different types of overflows: the weir overflows, the dischargers subject to saturation (chalice, etc.), the siphon dischargers and the dischargers with floodgates.

In the case of the exercise we had available documentary for a chalice overflow.

The flood drainage should be entrusted the predominant part to the surface dischargers, which will be arranged out of the body of the barrage.

The profile of the top of the facing downstream of the overflowable dam must be chosen so that the overflowing vein clings to it, without depressions, on all the height, namely that detach oneself after the summit threshold, providing in this case, with adequate devices, the ventilation below. In any case have to do, usually with the aid of models, the protective provisions from erosions at the base of the structure.

As a rule is to exclude the overflowability. If, in special cases, it is considered of having to have recourse, shall not be allowed the free fall of water among the buttresses, to support the overflowing vein for all the height the fall and it will be followed by the energy dissipation devices, protective from erosions of the bedrock.

The maximum flow rate to unload for the heaviest flood event expected must to be evacuated only by the surface dischargers. They may be constituted by one or more free thresholds or by thresholds equipped with automatic floodgates. In this second case, considered the hypothesis of non-operation of the floodgates, the flow rate of at least half the maximum that is provided to unload for the most burdensome flood event, must be evacuable with the free thresholds, provided, however, that in this condition the sharp clearance is reduced to values less than half of those listed above, subject to minimum of one meter. Where such surface overflows is meant to take the chalice type or similar, subjected to saturation, the size of them must be such that the level of saturation was higher than the maximum flooded increased by two-thirds of the net franc. Overflows of this latter species will be subject to specific tests on model.

In any case must be equipped with large ducts for the air supply to the passage of current from the vertical or subvertical shaft to the subhorizontal gallery and to any other point of singularity of the current.

The project flood flow rate of the surface discharges and all other associated works is assumed equal to the sum of natural flow and maximum flow into the reservoir from any waterworks in its tributaries (gutters, etc.). The natural flood flow of the basin underlying the barrage is assessed by reference to a return period of not less than 100 years ($T \geq 100$) for barrages with a height up to 10 m, giving rise to total volumes of reservoir up to 100,000 m³, and with reference to a return period of not less than 500 years ($T \geq 500$) for the barrages with a height greater than 10 m (and up to 15 m) or that give rise to total volumes of reservoir above 100,000 m³ (and up to 1,000,000 m³).

The possible effect of lamination played by the reservoir should not be taken into account for the purpose of determining the said project flow rate, except for the reservoirs made specifically for the flood lamination.

The dischargers of surface must be made with fixed thresholds appropriately shaped, without moving parts of interception or regulation. The dimensioning of the overflows must be such as to permit disposal of the project flood flow rate with a maximum load (defined as difference between the height of maximum flooded and the top of the overflowing edge) with respect the prescribed clearance. For new designs are not allowed dischargers of the chalice type, autoluring siphon type or any other type however subject to saturation (operating in pressure).

The barrages in loose materials must be non-overflowable and their surface dischargers must be made of masonry construction independent from the survey; in case they are adjacent to it or interconnected, must be made with linking techniques to the survey such as to prevent the triggering of siphoning along the contact surfaces.

For the masonry barrages the surface discharge can be made on the same body of the barrage (barrage partially overflowable).

If however, applying this criterion, the length of the overflow proves more of the same length of the crowning, it may be assuming that the barrage is fully overflowable; in this case the maximum hydraulic load on the overflow must present a clearance from the intrados of any service walkways equal to half the prescribed clearance. It's still to be aware of the danger of clogging due to the floating bodies, also in relation to the particular characteristics of the vegetation existing in the basin directed upstream of the barrage.

The overflow artefact must in any case be dimensioned so as to avoid that downstream of the threshold arise current depression phenomena and/or cavitative phenomena, also for the maximum values of the flow discharged.

The restitution of the discharged flows must be studied in order to avoid underminings or however not correct dynamic behaviours of the current to the foot of the barrage body, as well as dangerous erosions of the bed or of the downstream evacuator channel.

All these considerations of specially typological nature of operating and design are of fundamental importance for the realization of a graphic paper in which doesn't appear substantial geometrical differences compliance with the rules that serve as guide.

Fig. 1: View of an overflow in full-water condition.

From the Fig. 1 one can infer the importance of this hydraulic element always placed near close to a dam. It would be more opportune to speak about fundamental element of operation of a dam in the check of the water progress for a proper water operation of the natural landscape and man-made environment.

The operating conditions must to ensure a proper effectiveness both in the summer and in the winter. The temperature change undergone by the overflow, require a careful analysis of the elasticity range of the material deformation and the effort resistance of the safety valves and linking structures more generally. In this view, results of fundamental importance an accuracy in the representation, a precision in the sizes indicated and in the sections individuated in order to make some tests of seal which ensure a proper operation of the overflow. The responsibility, therefore, of the representation rises to a primary role in which cannot separate from the scientific both analytic-mathematical and geometric-physic. The representation become communication, but at the same time surveying and intervention tool, if necessary.

In the view from above of a graphic paper is of fundamental importance the apparent contour of the artefact. In fact, thanks to the representation of its view on a horizontal reference plane, we perceive the maximum

encumbrance and, particularly, being the inlet of the overflow an horizontal circumference, the apparent contour will be given just by its representation along the radius (Fig. 2). To make graphically that it is a “clove” surface, from a well-defined section profile, would enough to subdivide the profile curvature, made by the cross section of the artefact, and projecting in first projection the references for the representation of concentric and equidistant circumferences. These, in first, would closer and closer as you approach to the vertical inlet, up to be superimposed.

The longitudinal section in Fig. 3 is made at the height in which the overflow run through the underwater layer indicating, therefore, the behaviour of the underground waterworks of discharge and charge of the waters.

Fig. 2: Surface overflow: view from above

In reading the graphic paper evinces the projection of the apparent contour of the inlet of the overflow. This view turns out to be indispensable for a proper read of the artefact to comprehend both the proper structural and water operation and to read the correspondence of representation. Just for what was said, it reads the projection of the view from the above, as projection of something that is above the plane of section.

The tunnel for inspection, along which is made a cross section, is connected to the walls of the principal collector and this determines a connection of the section lines which does not permit the presence of triple points that would denounce a lack, under the knowledge profile of the science of the representation, unacceptable though frequently found.

Often, in fact, we witness to approximates sections, in which the section line is suddenly interrupted by others section lines, in which the planes of section are inexplicably staggered over other planes, in which the passage from material to empty space is fictitious and where the mix between projection and section is state of the art!

Fig. 5: Surface overflow: cross sections

Cannot miss in a representation of an artefact the three-dimensional view that males, more than multiple orthogonal ones, to an untrained eye, the overall geometry of the element.

The orthogonal axonometric view well lend itself when one represents a graphic paper of relative size like ours, in which one doesn't want to give a visual impact established in the territory, impact that would instead require the use of the perspective.

But, as in every representation, it's important to know to do but also know to read. In Fig. 6, for example, it's clear that we put with the upper inlet on a plane parallel to xy and the upper circumference becomes, in projection, an ellipse whose major axis is parallel to the t_{xy} track, and the minor axis is affected by the shortening of the maximum inclination line of the xy plane. Read this, it's easily reconstructible the belonging homological relationship of the xy plane and, consequently, it's possible to trace the real form and size of the geometrical forms also not having them in the multiple orthogonal projection graphic papers.

Fig. 6: Surface overflow: orthogonal axonometry

Conclusions

We can conclude that the representation of an artefact is the more complex the more detailed and articulated is composed in its own externalization, the more complex is the artefact geometry, the deeper is the knowledge of the discipline. The absence of an objectification that makes it universalizable, on the contrary, the subjectivity of the choices that distinguish it, gives to the science of the representation a difficulty more and more extensive as the largest are the irresponsibilizing behaviours. Since from the choice of the representation technique rather than another, the scale rather than another, views, rather than others, the sections rather than others, makes the drawing a versatile and sometimes hostile discipline, but more than ever fascinating and of primary need, when one knows from deep, within the professions of engineers and architects.

Abstract

This paper is intended to present an environmental planning methodology for small and medium scales based on the presuppositions set forth in Federal Decree No. 4.297 of July 10, 2002, which establish criteria for the Brazilian Ecological-Economic Zoning– EEZ.

The compilation of social-economic data related to the determination of the potential and emerging environmental fragility, in addition to the legal regulations, renders possible the performance of an ecological-economic zoning considering abiotic, biotic, social and economic variables (ABC method) intended for the ordering and development of any given region.

From this interdisciplinary point of view, the environmental planning precedes and supports the Brazilian municipalities upon the performance of their Master Plans, as its more comprehensive view of the set of variables of a territory for that specific municipality corrects any distortions and promotes the compatibility between development and environmental conservation.

To exemplify the method, we will work with the South coast of state of Bahia like case study. This region is a touristic zone called Cocoa Coast, near Salvador city, the capital of Bahia. These cities are tourism hot spot in Brazil and they are target of real estate speculation. The ABC method turns possible to define areas to the touristic use as well other land uses and preservation.

Keywords: environmental planning, economical-ecological zoning, sustainable development.

1. Introduction

Territorial planning in Brazil is considered something new, and even nowadays is considered as part of a general plan. Planning, through this point of view, is also considered as one of the subjects connected to the growth of the cities, even under a strong ideological content, and it explains the revitalization of the theme. For Villaça (1999), between 1940 and 1990 - the Brazilian Urban Planning, which had the idea of a master plan, hasn't minimally achieved the proposed goals.

Essentially agricultural until the 50s, Brazil would experience large urban and industrial outbreak due to the Fordism expansion of industries all over the world. Countries like Brazil at that time had an intensive industrialization as well as a national redesigning of territory, much because of Cepal (Latin America Economical Commission) recommendation, created in 1948 by UN (United Nations), which had as its main objective the economical diagnose the causes of economical delay in Latin American countries. Industrialization had been the alternative proposed, in a unanimous decision, aiming to accelerate development.

In this context, the Federal Government was responsible for the infrastructure implementation and legislation to make industrialization possible. Under the slogan "50 years in 5" President Juscelino Kubitschek (1955-

1961) implemented the "Plan Goals for Brazil," and thus, the Brazilian process for road constructions was undertaken in the following decades as the automobile industry was implemented. It was the replacement of an agro-export model for an industrial model in association with foreign capital, which would let worldwide companies enter into the country. It was through this developmental and structuring plan of spaces that the Brazilian cities started becoming more and more urban and needing regulation and discipline for land use, housing problems solutions, clandestine subdivisions, sanitation, transportation, etc. Until the 30s, the planning of cities represented only beautification and the opening of avenues, during the 60s the urban problems would get more serious with the population growth. The Brazilian population rose rapidly from 41 million in 1940 to more than 190 million in 2010.

Considering those aspects, two questions should be clarified: the inclusion of environment as a parameter for the planning and the order of planning, gaining a connotation, from the national to the municipal vision. It's this way that after one year the Ecological-economic Zoning Decree was approved, introducing a new planning and land order concept, totally opposite to what was adopted earlier in the century, when the cities used to have their development from the city center to the outskirts, forming, pretty often, a patchwork like territory.

1.1 The Ecological- Economic Zoning as an instrument for an Environmental Planning

If Urban Planning in Brazil was just known by its ideological meaning, the Environmental Planning would only exist as a new vocabulary by the end of the XX century. This new nomination of planning was a result of the new environmental wave, which since Stockholm Conference, in 1972, started gaining a new format and media space on territorial design planning speeches. The apex of discussion would only happen when definition of sustainable development had its classical definition: "sustainable development is the one that provides the needs of the present time without impairing the possibilities of future generations to provide their own" (CNMAD, 1991). The concept introduced by Brundtland Report, in 1987, became the preparation stage for the United Nations Environment and Development Conference, known as Eco 92, which took place in Rio de Janeiro.

Eco 92 contributed for a greater diffusion of the environmental problem and introduced new planning paradigms involving the adoption of environment into the planning processes and territorial order. Through out this view, spaces would not be managed by anthropic interventions, but considering the interaction between biotic and abiotic and the human presence.

Many laws in Brazil were approved to ratify state actions with the adoption of an environmental sense and public policies. The 6938/81 Federal Law, which established the National Environmental Policy was certainly the first step in this direction (as part of the result of the Stockholm Conference, in 1972) which brings in its 9th Article the definition, that years later, would come as law regulations, establishing quality environmental standards and evaluation mechanisms of environmental impact (Conama Resolutions - which publications started in 1986) or through the creation of protected territories (National System of Conservation Units - Law 9.985/2000) or through the Ecological Economic Zoning - ZEE - promulgated by Decree 4.297/02.

ZEE brought some news in its planning conceptions and territorial ordering, starting by the obligation to be followed when implementing plans, constructions, public or private activities (2° Article). In its sole paragraph of the same Article it is stated that the ecosystem limitation and fragilities must be considered while distributing space for economical activities, which means an enormous space intervention advantage.

The contents, that contemplates the definition of each area, data for diagnosis as well as general and specific guidelines is expressed in Chapter III of the referred Decree. However, the lack of obligation in considering ZEE as a planning instrument in public, federal, district, state and municipal institutions make this powerful tool still neglected as a primary instrument for territorial zoning. This assertion finds support when consulting the Ministry of Environment electronic page it's possible to find out that the ZEE development process, in its macro or state scale, is moving ahead slowly and that there are hard difficulties to prepare the technical diagnosis, to get to general and specific guidelines and then transform the entire contents in a decree.

In short, we can ensure that understanding the environmental planning through an Ecological-Economical Zoning is extremely important so that we can get to a turning point in the Brazilian planning history; which means understanding the territory through out the interaction of its abiotic, biotic, social, economical and cultural attributes that are essential for sustainable territorial development.

2. Methodology

The area named Costa do Cacau (Cocoa Coast) lies in the south coastline of the State of Bahia, Brazil. The region concentrates the municipalities of Itacaré, Uruçuca, Ilhéus, Una and Canavieiras. It's the region that most preserved the Atlantic Forest, the most threatened tropical forest in the world due to anthropic action.

This happened, in part, because of the cocoa plantation (*Theobroma cocoa*), typical plantation of the region, that grows in the shades of big native trees. Because of natural beauty and its landscape value, the region is considered one of the Brazilian coastal tourist poles. For the preparation of the ecological-economic map of the region, the “ABC” methodology was used, considering the biotics, abiotics and socioeconomic variables, which are focused in this study.

2.1 Building the potential fragility chart – the variable A of environmental planning.

The methodology to determine the potential fragility of its natural environment and/or modified by human action was made by Ross (2001) about the morphological dynamics of its landscape, considered as eco-dynamic units, seen through the understanding of its natural dynamic between the environmental variables: climate, topography, rock formation, soil, vegetation, land use, etc.

Starting from these assumptions, building the potential environmental fragility chart on this study, we considered an overlay from the geomorphological mapping, as well as from the soil types organized by the Radam Project Brazil, in 1988, in which it was possible to identify homogeneous areas with types of topography and soil, assigning scores and weights according to the classification proposed by Ross (2001). After this mapping, we proceed to the classification of environmental units that resulted from the geographical processing of cartographic information in SIG (Geographical Information System), and the completion of the potential fragility chart, which brings, for each polygon, presents two different indexes: firstly for topographic variables and secondly for the soil variables. Through these information it's possible to value the fragility, if hard or light, of the units that make up the Cocoa Coast (figure 1).

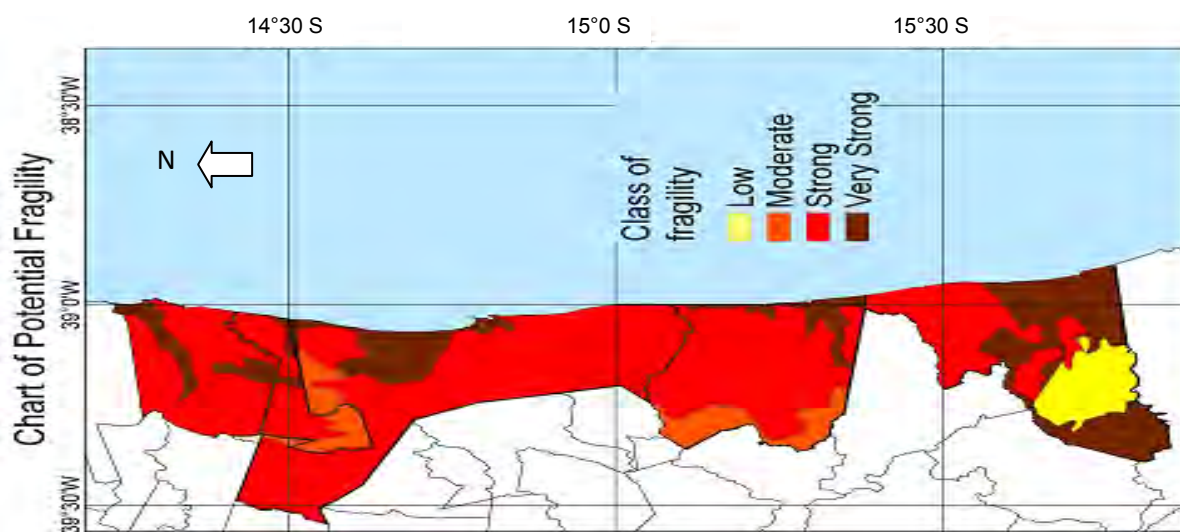

Fig. 1: Potential Environmental Fragility of the Tourist Zone of Cocoa Coast, Bahia, Brazil – produced by overlapping images of the geo-morphological and exploration of soil maps.

2.2 Understanding biotics data and legal regulations - variable B of the environmental planning

Understanding the biotic variables that involve planning and the creation of protected areas in a territory, aims biological diversity conservation and its ecological interactions, as well as the maintenance of ecosystem for ensuring human welfare and effective participation of society in the process of creating and managing these areas.

Especially in Brazil, where its possible to find various kinds of biomes and an ample diversity of fauna and flora, which characterizes the country with mega biodiversity, planning becomes fundamental for protecting its biological and ecosystem services in local and global scale. However, human activities, particularly the ones related to economical and political subjects, exert strong pressure on ecosystems, that results in environmental degradation and human welfare reduction.

The variable B of the environmental planning involved the principles of the conservation biology. The basic principles of this science are based on important theories, like island bio-geography, geometry of the landscape, population and community ecology and, particularly the landscape ecology (Forman and Gordon, 1986) which allows understanding the spatial patterns of landscape and landscape scales. This science also

considers development and spatial heterogeneity dynamics as part of the biotic and abiotic processes and the management of its spatial heterogeneity for the benefit and survival of society (Odum and Barret, 2008; Risser et al., 1984).

Using SIG tools and the official data of vegetation (and its successive levels) of the focused area, we also created a map that provides the understanding of distribution of the landscape biotic constitution. As we are able to understand the scientific guideline aspects for the protection of natural environment, particularly the Forest Code – Federal Law 4771/1965 and the The National System for Units Conservation – SNUC – Federal Law 9985/2000.

It's important to mention that it's being discussed, in the National Congress and in the Chamber of Deputies in Brasilia – Capital City – changes to be introduced to the Federal Law 4771/1965, considering the aspects brought in 1999, with participation of the National Federation of Agriculture, which proposes flexibilization of use for Permanent Preservation Areas, as well as in some percentage of the Legal Reserve. However, both the Brazilian Society for the Progress of Science and the Brazilian Academy of Science, consider the proposals “without a solid scientific basis”, as their proposal goes against planning and conservation principles, the main subject of this Case Study.

2.3 Building the socioeconomic diagnosis – variable C of the environmental planning

The historical and socioeconomic survey comes from the demographic census issued by IBGE – Brazilian Institute of Geography and Statistics. Through data compiling it was possible to get to the diagnosis of potentials and fragilities, from the socioeconomical point of view, for this group of municipalities. Here are the statistic information considered for this research. (Table 1)

| Subject | Information | Goal | Possible Actions |
|------------------------------|---|--|--|
| Synthesis of Information | Population in 2010 Territorial Area Unit | Checking the population growth Population density Urban and rural population | Public policies of population control |
| Population and Housing | Income Years at school Age group | Population percentage with a formal working contract Educational level of the population Age pyramid | Educational public policies for the generation of employment and income |
| Agricultural Census | Area destined for rural zone | Percentage of useless or degraded land at countryside | Management of land use capacity and function and environmental fragility |
| Gross National Product - GNP | GNP by sector | Municipal economy predominance (primary, secondary or tertiary) | Incentive for highlighted activities |

| | | | |
|---|------------------------------|---|---|
| Healthcare services | Beds and hospital facilities | Comparison of existing beds in hospital facilities with the number established by World Health Organization (WHO) | Investment in hospital network and health equipment |
| Education | Enrollment | Comparison of school-age population with the number of enrollments by level of education | Creation and management of vacancies in different educational levels. |
| Civil registration statistics | Infant mortality | Comparison with reference numbers published by World Health Organization (WHO) | Sanitation actions and breastfeeding |
| Temporary and Permanent crops Vegetation and forestry extraction Sylviculture | Municipal Production | Identify municipal primary production and its production value | Management of production according to the Environmental Fragility |
| Poverty e inequality map | Gini Index | Check the level of inequality | Employment and income generation |

Table 1: Parameters analysed for socioeconomical data of variable C of the Ecological-economic Zoning and considered for this Case Study - Cocoa Coast – Bahia.

3. Results and Discussion

By the analysis and the overlapping variables A, B and C of the environmental planning, a Map of Ecological-economic Zoning (Fig 2) was produced in SIG environment for the Tourist Zone under this analysis. By doing that, five different zones were established for the information framing: (i) zone 1: maximum protection zone – with the frame in which the diagnosis had already pointed out the existing conservation units of high protection, permanent preservation units or areas that were considered with fragility strong and very strong (the variable A). They were considered bio-diversity priority areas; (ii) zone 2: buffer zone or transition zone between a maximum protection zone and a zone for other uses, as established by Federal Law 9985/2000; (iii) zone 3: for rural use of the municipality, due to its rural production, as well as for possible management according to the capacity of land use, where its prioritized for this kind of use the eutrophic soil, mentioned by the Chapter of Environmental Fragility; (iv) zone 4: consisted by urban zone expansion, or controlled use zone through the proposal of APAs (Environmental Protection Areas, under Federal Law 9985/2000), a very common strategy in case of coastal areas, where it's necessary urban expansion control over intensive environmental fragility; (v) zone 5: consolidated urban area, demarcated on map of existing city. The characteristics, permitted use, guidelines and target for the Ecological-economic Zoning proposal is described on Table 2.

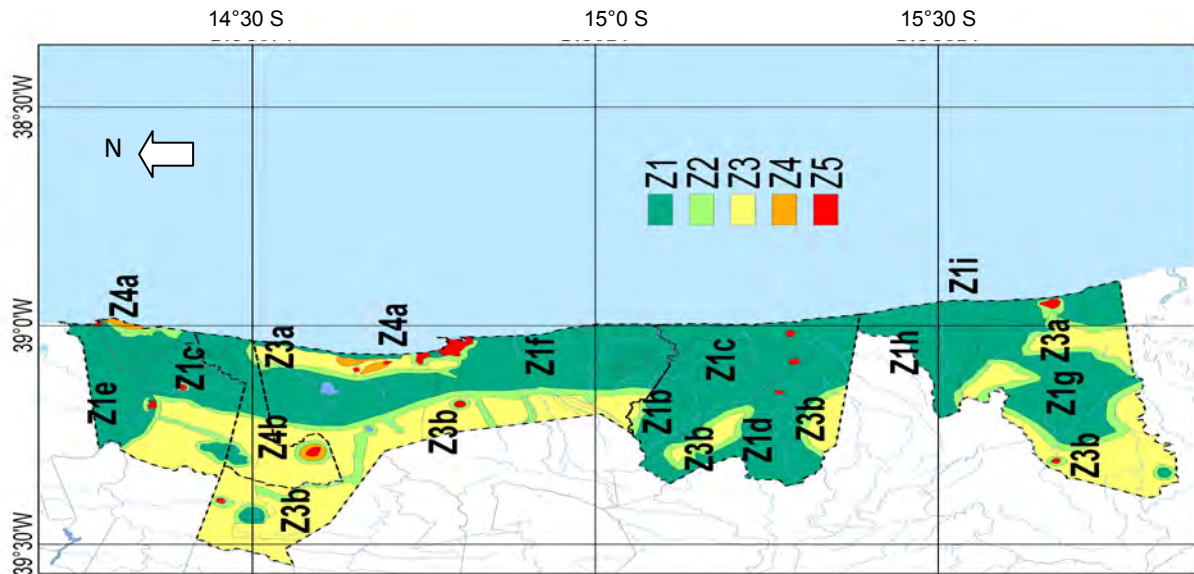

Fig.2: EEZ Map proposed for Tourist Zone of Cocoa Coast, Bahia Brazil.

| Zone | Socioenvironmental | Guidelines | Permitted Use | Goals |
|------|---|--|--|---|
| Z1 | <p><i>Variable A</i> Coastal tableland – Pre Coastal; Red, Yellow Podzolic Soil.</p> <p><i>Variable B</i> Ombrophilous Forest, from dense in advanced stage to medium in regeneration; Restingas (natural coastal vegetation) Mangroves.</p> <p>Presence of endemic species, which have restrict geographic distribution, like <i>Bradypus torquatus</i>.</p> <p><i>Variable C</i> Small human pression due to tourism in the region.</p> | <p>1. Maintenance and extension of Conservation Units aiming the preservation of beauty and nature ecosystem of ecological relevance, defragmenting forest areas and increasing habitat for rare species or the ones being threatened by extinction.</p> <p>2. Coastal Ecosystem Maintenance in its integrity.</p> <p>3. Ensure and protect the style of living and the culture of traditional inhabitants, guaranteeing sustainable use of natural resources.</p> | <p>1. Achieve scientific research.</p> <p>2. Development of environmental education and ecological tourism in accordance with the management plan and the conservation unit category (Federal Law 9985/2000)</p> | <p>1. Expropriation of plantation and rural housing areas with payment of indemnities and in connection with an incentive program for relocating people who live on palm fiber production (<i>Attalea Funifera</i>).</p> <p>2. Elaboration a management plan.</p> <p>3. Full Integrity maintenance of biodiversity and ecosystem.</p> <p>4. Defragment the Atlantic Forest generating ecological aisles in the landscape.</p> |

Table 2: Characteristics, Guidelines, Permitted Use and Goals to the ZEE proposal for the Tourism Area of Cocoa Coast, Bahia, Brazil.

4. Conclusion

ZEE is a powerful instrument for territorial order and planning of medium and small sized areas, however, the lack of an adequate cartographic scale, in association with the lack of updated information from census, allows just a planning project which needs research and visits to the focused area. We understand that, for its accomplishment, not only the Federal Government, but State and Municipal as well, would need a considerable mobilization, in consortium operations with private initiative to prepare the basis for a cartographic material which would enable knowledge, in SIG environment, for definitely provide information about the area preconized by regulations for ZEE in the Federal Decree. Every four years, updated data from socioeconomic census will bring more clear information about the socioeconomic dynamics that the country is experiencing.

It is time now to achieve that the Brazilian Government consider Environmental Planning as a priority, because Ecological-economic Zoning, as an instrument for territorial order, becomes more and more indispensable for the achievement of sustainable and well-balanced development.

IN THE SHAPE OF A HOUSE. Recycling the wastes of the city on the Neapolitan coast

Fabrizia IPPOLITO¹

(1) Facoltà di Architettura Luigi Vanvitelli, Seconda Università di Napoli, Aversa (CE), Italia
E-mail fabrizia.ippolito@unina2.it

Abstract

This contribution refers to a design research on discarded landscapes and buildings in the Neapolitan area carried on within the Laboratory of Architectural Design 1, prof. F. Ippolito, at the Faculty of Architecture of the Second University of Naples [1], on the basis of some previous researches on these issues and place [2]. Testing ground is the Domitian littoral zone, field of inquiry is the urbanization of the coastal landscape and its being mainly made of houses. As in Italy urbanization advances on the coast 30% faster than on the rest of our territory, as 60% of this urbanization is due to houses, as - on the other side - 20% of these houses is empty, testifying that the building process and the consumption of the land are not commensurate with the real inhabiting demands, and 10%, particularly in the South, is illegal, testifying the distance between the planning and the reality of the territory, to work on this city of houses, from the perspective of recovery and recycle, seems to represent an urgency for the requalification of the landscape and for the culture of design. In Varcaturò, Giugliano in Campania, in the past decades a city of houses was born, an urban landscape where every building is in the shape of a house. In such a place, where the nature dissolves itself into built areas and the public space into private space, where an uninterrupted edification produces landscapes of waste, a design-oriented look deals with the houses and urban wastes. A three steps project – project of description, project of strategy, project of architecture – works at reinterpreting this territory and these materials, recognizing the value of waste and imagining actions of recycle and techniques of reinvention. Starting from the houses and getting in-between the houses, sprawl projects work at subverting the sense of what is here.

Key words: sprawl town/illegal housing; urban/architectural waste; public/private; description/project; strategy/tactics

1. Sprawl. The city of houses

Varcaturò, on the domitian coast, is a ghost of urban sprawl. The town of houses that has grown since the 80s from a freeway junction up to the sea is crumbled, interrupted, partially abandoned, and new presences fill in its interstices. After the advance of the cement and the movement of the population from the dense cities towards this coastal town, the territory seems to be in a shrinking phase [3]. Still latent, the city is getting empty, while in what is left from the withdrawing of urban life a landscape of uncertain spaces, uncultivated lands, residual activities and precarious inhabitants is advancing. It's the landscape of remains that urban culture is discussing in these years [4]; it's the mirror of a destiny that many Italian sprawl urbanizations share, blighting expectations and showing original faults; most of all, it's the result of a sum of daily building tricks, which reveal obtuse visions in the long time. If for some years we have been relying on the city of houses, which was born as a satellite of the main urban centres, depending on highways, resulting in a landscape of widespread individualisms counting on their supremacy on everything else, today this city shows its limits and its contradictions. Along with the crisis of an urban form that wastes the land by means

of infrastructures and buildings, there come the crisis of a way of living that produces marginalization and separation by means of enclaves, and the crisis of an urban system that is founded on occasional individual interest, on deregulation, on private appropriation of public space and landscape. Around here, the issues on which the diagnosis of the suburban crisis [5] is founded all over the world acquire specific connotations, traceable in the features of these places.

Varcaturo has nothing special if compared to other neighbouring sites, which are more resounding for better or for worse. It is a common piece of this coast, urbanized starting from a junction, marked out by an axe leading to the sea through the plain, the pinewood and the beach, crossing the Domitiana and Coastal roads and the ruins of the ancient Appia Road. Nothing to do with Coppola Pinetamare Village nearby, well-known as an eco-monster, built for the Americans of the NATO in Bagnoli, protagonist of a complex affair of building speculation and legal battles that went on between permissions and prohibitions up to a symbolic intervention of demolition, emptied of the inhabitants, the locals after the Americans, today committed in buildings again, for the construction of a new port [6]. If a reference to the investigation of these landscapes may be ordinary landscapes studies, Varcaturo stands to Villaggio Coppola as Levittown stands to Las Vegas [7], and for this reason it may have a more general relevance.

This research proceeds from an investigation that was carried out on this same place ten years ago, when urban sprawl, whose devices of growth are set out by a multitude of individual enterprises, was still under exploration in the Italian territory, and when its declension in the Neapolitan places could contribute to demonstrate the false generic of sprawl town and its dependency from site specificities. Around here the town of houses is mostly illegal, it deals with a landscape of dunes and special vegetation, with archaeological ruins, with the sea, with the presence of American settlements and radars. Around here in the 80s there was the expectation that the way of inhabiting that produced the sprawl town would sediment, within a city which was made of sum of houses, fed by the displacement of Neapolitans to north-west, but also by the economic growth, the investment in buildings and the effect on concrete's entrepreneurship of the post-earthquake extraordinary funding. Around here many houses were built outside of the procedures of the Municipality Plan, which is dated to 1981, they passed through three amnesty for infringement of local building regulations, moved through the constraints of building regulations, protection laws, regional landscape plan and military security. Around here, within the game plan of the territory, the matches of the inhabiting took places, being played by variations on a few main moves concerning the construction, the widening, the adaption of the only element of the house. In a game time that is the daily progressive time, which insinuates in the long time of planning, a variety of private players matched against the only public player, slower and more distracted, playing parallel matches, pursuing individual interests, sometimes looking for alliances in order to maximise the advantages. Every so often the game is interrupted for the breaking of rules, the player is eliminated or, paying forfeit, returns with the amnesty. The game moves concern the five steps of the building process, the delimitation, the foundation, the elevation, the covering, the wrapping, and the five correspondent elements, the fence, the ground, the skeleton, the roof, the envelope, being declined in lots of ways, influenced by compromises between specificity and standardization, capable of innovation and rebellion. Every so often some help is needed, such as the imitation of the neighbourhood, the memory of a material culture, the suggestion of an imaginary drawing from time to time on local, modern, exotic or ancient examples, the instructions of the do-it-yourself magazines. The result of the matches' sum is a town made of houses, where the house is the shape of every building, available for hosting any use, delegating to additional signs any specification [8]. To describe the construction of the city as a game, focusing on the house, aims at schematizing the moves of the everyday inhabiting, revealing its tactics [9], in the hypothesis that in this landscape the house can be read starting from the tactics and the territory starting from the house [10]. For effect of daily tricks, the fences are devices of appropriation, of both the ground and the pinewood, devices of aggregation of many houses along a private road, devices of shielding of buildings growing behind the walls; the ground is excavated, increased, moulded to gain cubage, drawn by gardens; the skeleton is prepared for elevations and raisings, it's turned into generic architectures, in the shape of a house, or it's naked, in stand-by; the roof is inhabited, under the pitches or over the floor; the envelope is articulated with fillings of balconies, addition of volumes, variations on a cluster structure reflecting the expectations of growth of the family.

Today these expectations seem to be contradicted. Here and elsewhere these devices, after being investigated, revealed, vivisected and then summarized in the portrait of the landscape of a multitude busy earning cubic metres on nature and on empty spaces, show an unexpected sterility. Here and elsewhere, the territory shows the contradiction of the sprawl model – exemplified by Los Angeles in the literature [11] –, the limits that are implied in the superimposition of an interpreting model to the territory. Here and elsewhere in the South Italy, the effect of a building that went on outside from rules and plans show the ineffectiveness of both a consenting and law-abiding approach – submitted to a revision in the literature –, the limits of an only

legal approach to the territory as it is. While in the last years the urban investigation was engaged in searching for points of view and narrative ways that could be suitable for representing the landscapes of sprawl, being grown in Italy without any care, these landscapes kept on transforming, imperceptibly dissipating as imperceptibly they had grown. The observation, satisfied with itself, risked to get stuck in a mannerism of description, to forget its object and its very reason: catching the mutation in the city [12]. Yet that investigation had the merit of unhinging the interpretation of the territories by zones and quantities, of catching the devices and phenomena beyond the urban form, of promoting a lateral look which is capable of overcoming the pretension of objectivity of both zenith visions and data. Today the same approach, which produced among its side effects the falling in love with sprawl and self-construction, can exercise the same look in following new mutations.

1. Fading. The landscape of wastes

To go back to Varcaturò, and to Italian sprawl town, years after its revelation, discloses a new condition, and maybe also newly oriented interpreting eyes. After the sprawl, the issue of economic and environmental crisis, the urgency of an inversion of tendency and of a project of recycle affect, in their many declensions, the urban debate. The paradigm of sprawl is replaced with that of shrinking, the model of Los Angeles with that of Detroit [13], and the suburbs are indicated as the place of evidence of the crisis and of necessity of repair. The view from inside the inhabiting dynamics catches the processes of abandonment, disuse, and the residual materials of these mutations. The view from above returns overall pictures of the suburbs at their tipping point, succeeding the previous close view's detailed pictures of the materials of the sprawl town in its making [14]. The going across places shows houses for sale, disaster houses, wild gardens and abandoned productive and commercial buildings. The statistics report data about loss of inhabitants, extinction of productive and commercial activities, pollution, consumption of ground. In Italy the warning includes the degradation of the landscape and, especially in the South, the unauthorized building. In this framework sustainability and recycle [15] replace development and expansion, and the densification of the built areas and the protection of empty spaces are suggested as a recipe to stop the sprawl.

In Varcaturò the tangle of unheard expectations and not programmed, in great measure illegal, choices, along with the protracted distraction for this littoral zone, which has been excluded from both a local and a wider planning vision, show their effects. A common destiny binds Varcaturò to its territory, wasted landscape and mass of wastes, place of speculation and illegal actions, of short-lasting visions whose outcomes are already implied in their assumptions. If this landscape can be interpreted, through the houses, on the basis of the inhabiting tactics, the long-lasting vision is excluded from its beginning: the tactics respond to occasional demands and circumstances; they're deep-routed into the present and don't look at the future, so that even in the most immediate future they find their intentions exhausted. Today the inhabiting tricks that animated the matches of building the city of houses stop, suspending the game, in front of their own contradictions.

The houses, which have grown bypassing rules and plans, adopting expedients to conquest ground and volume, are depreciated, penalized by the quality of the contest and the lack of permissions, and turn out to be illusions of real estate goods – two levels single family houses, between 200 and 300 square meters surface, garden, medium-price 1500 euro for square meter, building permission as not granted surplus value, a more and more declining market, besides the crisis because of the uncertainty of amnesty for illegal building and the recent judicial attachments and demolitions [16]- ; the town, which has grown taking advantage of empty spaces, inventing building lands, privatizing roads and hiding behind walls, reports the absence of infrastructures and services, and turns out to be a simulacrum of a real town – lack of primary urbanization works, electricity, hydraulic and gas network; lack of garbage collecting and road maintenance; insufficient services, 1 nursery school, 1 police station, 1 church, 1 bank, 1 postal office, for the number of inhabitants, around 6,000 registered in Varcaturò, around 30,000 on the coast; polluted grounds belonging to the nature reserve of the domitio-flegreo coast, one of the 6 polluted areas on 55 Italian nature reserves [17]; the population, which has grown by individual movements, some of which are clandestine, complains about administrative negligence and asks for local autonomy, turning out to be the latent form of a real community – in July 2009 the Municipality of Litternum citizens' Committee was born, with the goal of a referendum for the autonomy from the Municipality of Giugliano in Campania of Licola, Varcaturò and Lago Patria hamlets, to be merged into the Municipality of Litternum; in the September 2009 the proposal was presented, with more than 5,000 signatures, Regional Council's favourable opinion, Town Council's negative opinion and following swing of opinions; the referendum, which is scheduled for the next Spring, will not be binding [18]-. While the urgency of an urban reparation emerges, the buildings depreciate, the fabric crumbles and the inhabitants bring themselves into question: the houses are available to other uses; the town vanishes

towards another condition, the community goes through abandonments and replacements, and new tactics activate new imperceptible transformations.

In a three steps project, the first step, project of description, collects these observations in a critical map of the places, including spaces, materials, people and uses and representing the fading in its many variations. Some images can work as examples: in the urban core the public space disappears among the fences of the houses; on the main road the density of the commercial street vanishes into the hinterland and coastal landscapes; in the agricultural plains the green dissolves under the buildings, in their turn dissolving into the uncultivated green; the pinewood is eroded at the borders, as well as the Mediterranean scrub, by buildings being engaged in compromises with vegetation; the Roman road, appearing for a stretch, disappears among the houses of a village, which crumble in front of it; the public beach vanishes among the private lidos, themselves disintegrating from North to South, and it's populated with evanescent inhabitants, who follow the seasonal and daily cycles of use of the coast. If fading, by definition, is the effect of a progressive disappearance or appearance of images, the fading, even more than the waste, can be the landscape's interpreting key, which leads to include in the project the wasting process.

Kevin Lynch's interpretation of the wasting as part of the urban life resurfaces, along with his representation of the world without wastes and the world flooded with wastes as two opposite and extreme nightmares [19]. In that interpretation the sprawl town, more easily than other urban forms, can regenerate from its end, thanks to the quantity of open spaces, the fragmented quality of the buildings, the incidence of the connections. This vision, probably more than those of the new regeneration manuals for the suburbs in crisis [20], looks at this town in a perspective of mutation. Another perspective is the reparation, meant as an opportunity for innovation rather than as a re-establishment of lost functions [21]. Densification, rarefaction, grafting, re-naturalization are some techniques of intervention, which work on the existing subverting the relations, re-inventing the form and the sense of town and architectures. The design debate moves between the two opposite intentions of fighting or accepting the sprawl, by turning it into urban centres or dissolving it in landscapes. Re-edition of public spaces and monuments introduce cores of recognition and resistance in the suburban generic [22]; multitudes of additions extensively densify the sprawl town [23]; the ground is a plot for new urbanities that can be obtained by grafts of public micro-spaces in the private town, contaminations of urban fabric with agricultural one, land reclamation turned into landscape design [24]; urban residues and buildings in abandonment are ground for not codified projects and actions from below [25]; interrupted works are monuments, in memory of mistakes [26]. Named *drosscape*, *junkspace* or *third landscape*, the landscape of waste finds its way through the urban culture [27]. Yet the waste is still uncanny in a world that claims for recycle, for an ecological third industrial revolution [28] and a design process that resets to zero the production of discards [29]. The contemporary global call for sustainability seems to go closer to the Lynch's cacotopia, setting against the present world of wastes a future no-waste world.

In Varcaturò, the landscape's weak traces raise questions on its future, which refer to the debate on repairing sprawl, but most of all refer to low definition as a condition of this place [30]. If this territory is neither city nor countryside nor nature, demonstrating the fading of these notions, according to the urban debate, this condition could be a focus for the consideration on the site. And, what is more, if this city is illegal and it is grown up with no common perspectives, illegal housing is a feature that specifies the low definition here. The different perspectives of turning the latent city into a modern one, of working on it with a weak and sprawl approach, of accompanying its wasting away, which have been stated by recent studies on the illegal town [31], could as well concern the sprawl town, which is going through a crisis all over the world, and could all the more concern such a place like this, where sprawl and illegal town are joint. Whether the hypothesis of self-government for this coastal city is approved or not, the hearth of the matter concerns its character and its vision: if it is named city, which idea of city it represents. In this sense the population's internal debate, to be carefully evaluated, may be significant: whereas the demanding of infrastructures and services to the administration fits with the idea of distance between politics and practices that produced the illegal city, the shifting of the debate from the demand of facilities to the proposal of self-government may turn the reflection to an intermediate level between politics and practices and to a much more complex interpretation of the relationship between public and private space.

Within the design research, the strategic design phase, applied on some sample areas, takes as a background the fading of the territory at its different degrees and works on intermediate levels between politics and practices, public and private, open and closed space, nature and building, recognizing fraying, dissemination and contamination as opportunities for the project. Therefore, if to provide with the basic facilities the inhabited core of the town is a necessity, to infill with sprawl public spaces the porosity of the settlements and the textures of agriculture and nature, or to accommodate the lacking services in the abundant abandoned buildings, or to include ancient ruins and new discards in landscape plans, or to relate with each others the residual public spaces of the privatized shore or, finally, to consider the dissolution of

part of the building, imposed by the demolition ordinances, as a process in progress and an occasion to accompany the wasting away are all possibilities to get indications from the existing, giving form to a collective space which can house the fragments of the sprawl town and the desires of the multitude that gave birth to it. In such a frame, the centrality for the urban core, the respect zone for infrastructures, the total preservation for agricultural, natural and archeological areas, set as imperatives, seem to be outdated and, above all, the urban categories they refer to seem to be obsolete. Their fading away, both in the reality of the territory and in the theory of the city, suggests a design scenery where rare high-definition points allow wide low-definition areas.

The low definition concerns architectural design as well as urban design, when architecture deals with variability, incompleteness, lack of means, when it works on time, on accidents, on possibilities, trying to make the most of the least. Recent design experiences suggest an adaptive attitude, which everyday inhabiting landscape unwittingly exemplify [32]. From that landscape, all the more in the face of abandonment and crisis, architectural culture learns the pragmatic and subversive approach, the aptitude for doing with what it has got, imagining what it could become. The project works by steps, bets on a few main things, foresees progression and variation; it feeds on the existing, forces its uses and forms, gaining new spaces and functions by small moves, taking advantages of the spaces of open-endedness of the rules and uncertainty of the plans; it intercepts bottom-up actions, recognizing population as an active multitude. Keeping away from any rhetoric, participation as well as recycle, it faces their issues through the action. It is a tactical project, either not being able to establish strategies, or accepting that strategies are carried out by not prearranged steps.

In Varcaturo the skeletons, the waiting frame structures, the houses that are available for other uses anonymously ask design questions about interrupted work, progressive project, relationship between denotation and connotation, within a context of sprawl uncertainty. In Varcaturo, the city that has been produced by private actions asks questions about public space and landscape, within a conflicting context. In such a context, the tactical aptitude for deviation, dispensation, exception, which allowed the private city to advance at the public city's and landscape's expense by sums of individual moves, could turn into a last resource for the public city itself, constrained to regain terrain by sneaking into the buildings, forcing the fences, occupying disused and empty spaces, aiming at total transformations by sums of single actions.

Within the design research, the architectural design phase goes along with the strategies through punctual interventions, which gather from inhabiting practices the aptitude for varying elements and moves, according to necessities and intentions, so as to restart the interrupted game of the territory's construction with opposite goals. Therefore, the fence, the soil, the skeleton, the roof, the envelope, which were the protagonists of the houses' composition, reappears in countless versions in the composition of spaces and architecture, which, starting from the houses and getting in-between the houses, trace a collective frame. The fence is confirmed, broken, cancelled, as to manipulate the boundaries between open and closed or public and private spaces, by delimiting rooms in the landscape or fluidifying the intervals between the buildings; the terrain is reclaimed, asphalted, cultivated or re-naturalized, worked in its depth, turned into spaces of hybridization between city and nature; the skeleton is naked, partially or completely filled in, repeated, magnified, taking advantage of its elementary structure and its condition of open work in order to accommodate systems of services within architectures turned into a system; the roof is base for controlled additions, container of interiors, last floor, providing habitable spaces and additional viewpoints on the landscape; the envelope is articulated, pierced, shaped, as to insert spaces and performances, converting existing buildings through carrying mutations parasites. Once uncovered the game, the public city looks for its revenge on private city by borrowing its moves.

The documentation of cultural information used as vehicle for regional sustainable development: the case of olive culture

Spyridoula ARATHYMOU

Department of History, Archeology and Management of Cultural Goods, School of Humanities, University of Peloponnese, Kalamata, Greece.

E-mail: pipiar@gmail.com, pipiar@yahoo.com

Abstract

This paper is about a three- year research program funded by European Union and partly by Greek funds under the title: "The documentation of cultural information used as vehicle for regional sustainable development. The case of olive culture". The research is carried out by the author and hosted by the University of Peloponnese, School of History, Archeology and Cultural Management in Greece. It will be realized by the end of 2014.

Olive culture has been part of the Mediterranean culture for centuries and part of the global culture, as well. Olive oil has been a wealth - producing factor of the areas where olive grows. Unfortunately, through time the rest of olive's culture elements seem to vanish, knowledge, practices and techniques of hundreds of years are likely to be lost. Also, the olive cultivation areas face severe financial problems and seek for solutions. The reuse of the elements of olive culture in a new perspective has the potential to give to these areas the solution they look for.

The project's aim is the recording and documentation, in accordance with existing standards, of the whole of the scientific information of olive's culture (recording and documenting traditional and modern methods of cultivation, the olive groves, production techniques, products, production facilities, tools, and written testimonies, local traditions related to olive) in the prefectures of Messinia and Corfu (which includes the island of Paxos and Diapontia Nisia), oil producing areas of the past and present with different socioeconomic backgrounds, and using its results by their representation in electronic environment with open access for the public via Internet and by various methods such as seminars, workshops, study visits to strengthen social and economic development of local communities, but also to their use in areas with similar socio-economic characteristics. As far as it concerns the project's originality, it is the first attempt to document all the cultural elements associated with olive culture in Greece and abroad. It is not only confined to the documentation and promotion of technical culture but combines folklore and intangible heritage with cultural landscape heritage to promote regional growth. Although, the culture of olive is attached to Mediterranean culture, in the World Heritage List no olive oil cultivation areas are included as cultural landscape heritage although vineyards and other cultivations are. So far, across Europe and especially in countries where olive is cultivated, the documentation of cultural elements associated with it is limited to a partial or patchy record of the technical culture of olive such as machinery and production tools, and factories, mills, soap factories as architectural monuments of modern heritage. The olive museums in the Mediterranean countries have documented the technical olive heritage and some of them offer also educational programs for the traditional methods of oil cultivation and production and have historical archives, library and art departments specialized in olive culture. There are also recordings of archival material relating to oil production and the traditional olive oil soap. Occasionally, the production techniques of olive oil and traditional olive oil soap are documented as intangible cultural heritage by official government agencies and scientific instruments. The cultivation methods of olive trees, traditional and contemporary, have not been documented as intangible cultural heritage and the olive groves have not been documented as cultural landscape heritage according to scientific documentation standards, techniques and practices.

This project intends to suggest how areas of these local economies could improve with the help of the total documentation of olive culture. It is the first time that cultural documentation aims at enhancing local economy and proposes development models.

TECHNICAL / SCIENTIFIC OBJECTIVES

- Recording and documentation of all cultural goods associated with the olive in these areas, in accordance with international standards of documentation for each category of cultural goods. The recording will be done through field research.
- Evaluation of the documented cultural information. Methods' design for its dissemination in society.
- Promoting the documented cultural information to society, via Internet. Organizing the documented cultural information in an electronic environment (databases, electronic directories, multimedia, etc.) which will be accessible via Internet for users' information and education.
- Application of cultural information promoting methods (except for Internet) to a variety of socioeconomic groups in order to educate and improve local economies. Possible methods are: seminars, workshops, study visits, conferences, contributing to the content of courses at all levels of education
- Review of the first results from the transfer of knowledge to users

Keywords: documentation of cultural heritage, olive groves' cultural landscape, Mediterranean region

Section

Olive culture has been part of the Mediterranean culture for centuries and part of the global culture, as well. Olive oil has been a wealth - producing factor of the areas where olive grows. Unfortunately, through time the rest of olive's culture elements seem to vanish, knowledge, practices and techniques of hundreds of years are likely to be lost. Also, the olive cultivation areas face severe financial problems and seek for solutions. The reuse of the elements of olive culture in a new perspective has the potential to give to these areas the solution they look for.

This research aims to record and document the whole olive civilization and its use as a factor of social and economic regional growth. It is a long lasting, multilevel and interdisciplinary research which involves information, social, economic and environmental sciences. It also includes tangible, intangible and cultural landscape heritage.

The first innovative element of this research is that it will attempt to record and document, as cultural goods, in terms of cultural landscape heritage, the olive groves of two Greek regions, Corfu (which includes the island of Paxos and Diapontia Nisia) and Messinia, the local olive tree cultivation, production of olive oil and traditional olive oil soap methods as intangible cultural heritage. In 1992 the World Heritage Convention became the first international legal instrument to recognise and protect cultural landscapes. The Committee at its 16th session adopted guidelines concerning their inclusion in the World Heritage List. Although, the culture of olive is attached to Mediterranean culture, in the World Heritage List no olive oil cultivation areas are included as cultural landscape heritage although vineyards and other cultivations are, like the Lavaux Vineyard Terraces in Switzerland, the Alto Douro Wine Region and the Landscape of the Pico Island Vineyard Culture in Portugal, the Rice Terraces of the Philippine Cordilleras, the Agave Landscape and Ancient Industrial Facilities of Tequila in Mexico, the Tokaj Wine Region Historic Cultural Landscape in Hungary and the Viñales Valley in Cuba.

The olive groves of Corfu- Paxos and Messinia have a long history. In Corfu region, their first appearance is lost in time but in the time the island was under the occupation of D' Anjou (1267-1386) the island's olive groves were highly appreciated by the regime although they had not yet acquired the importance they had under Venetian rule (1386-1790) which encouraged the planting of olive trees and rewarded with twelve golden coins anyone who planted one hundred olive trees and so, in the last years of Venetian rule, the island had two million olive trees. Today, it has about four million olive trees. In Messinia region olive groves have a long history, as well. They have been cultivated from ancient times until nowadays but most of the contemporary olive groves of Messinia were replanted after a disastrous fire put by the Ottomans, in the time of the Greek revolution of 1821. Olive groves have been a wealth- producing source for both regions. Unfortunately, in the case of Corfu, a large percentage of the olive groves have been neglected due to the region's tourist oriented economy over the last three decades. Protection of cultural landscapes can contribute to modern techniques of sustainable land-use and can maintain or enhance natural values in the landscape. The continued existence of traditional forms of land-use supports biological diversity in many

regions of the world. The protection of traditional cultural landscapes is therefore helpful in maintaining biological diversity.

It will also be the first time that totally the pre- industrial and industrial heritage related to olive oil, local traditions related to olive and the written documents, such as archival material, will be recorded and documented in these two regions. So far, across Europe and especially in countries where olive is cultivated, the documentation of cultural elements associated with it is limited to a partial or patchy record of the technical culture of olive such as machinery and production tools, and factories, mills, soap factories as architectural monuments of modern heritage. The olive museums in the Mediterranean countries have documented the technical olive heritage and some of them offer also educational programs for the traditional methods of oil cultivation and production and have historical archives, library and art departments specialized in olive culture.

The second innovative element is that the results of this research will be used to promote social and economic growth in these two regions. It will be the first time that documented cultural information will be used to improve regional economy.

The total recording of the cultural goods which constitute olive civilization will be fulfilled with on the field research in the regions of Corfu and Messinia. Information will be retrieved from formal authorities related to the olive cultivation, Technical Chambers, Historical Archives Repositories, private and public, libraries but also from local administration services. The recording and documentation of olive oil mills, soap factories, their machinery and other equipment will be fulfilled according to the international documentation standards for architectural and industrial heritage and with the aid of architects where that will be needed. The recording and documentation of olive cultivation methods in these two regions, as cultural intangible good, will be done with the support of scientific evidence which is provided from authorities such as the Olive Institute in Corfu, from bibliographic and archival material and from the recording of olive tree cultivators' and workers' interviews and the recording of their field work on video.

The recording and documentation of the olive groves will be done with information from formal scientific authorities of the Ministry of Agricultural Development, the Prefectures but also with photographic, topographic and multimedia documentation and the addition of oral testimonies of olive tree cultivators and workers.

The recording and documentation of local traditions related to olive tree will be carried out with the use of archival and bibliographic material but also with the recording of oral testimonies and video recordings of folklore happenings.

As far as it concerns archives, until now, there have not been located olive oil mills' historical archives in these regions but only the historical archive of a traditional 19th century soap factory in Corfu. This research will probably bring to light new archival material but it will surely include archival material produced by authorities related to olive cultivation and exploitation.

The collected material will be classified and catalogued. After that, the methods for its dissemination to society will be named and scheduled. The first step for its promotion will be realized with the creation of an electronic thesaurus which will be available through Internet and a second step will involve educational and information actions.

The collected documented cultural information will be organized in electronic environment in data bases, electronic catalogues, multimedia, etc. according to the international standards for the representation of documented cultural data in electronic environment, which will be available through Internet and in other media such as DVD-R.

This thesaurus will have an immense usability for various user groups such as farmers, scientists, students, researchers, businesspeople and its usability will be multiplied by its electronic form which will be accessible through Internet from the node of the University of Peloponnese. Users will have the chance to search in it with the use of word- keys, by subject, alphabetical, chronological search and have full access to the whole of the recorded and documented material.

The aim for this thesaurus is to be first available in Greek and English and in the future in the languages of the peoples of the Mediterranean as it is estimated that this material will be valuable for them.

A close range educational and information approach of all possible user groups, which can be benefited from the total documented information of olive tree civilization, is vital as it will give them the chance, apart from becoming familiar with the collected material- which can be done through the Internet- to be trained by the team, which conducted the research, for the possible ways they could use this material for the educational, social and economic benefit of each group.

These actions will probably be: seminars, galas, congresses, educational visits, and educational programs for formal authorities which are related to olive tree on how they could use the collected material in benefit of the users, participation at the educational procedures and the teaching material of all educational levels in the regions where the research took place.

Priority will be given to information and training through seminars to the authorities which are related to olive tree and olive oil scientifically and commercially, such as the formal authorities of the Ministry of Agricultural Development, the Commercial and Industrial chambers, the Agricultural cooperatives to inform and train their staff and members, and also to farmers, olive cultivators and producers, olive oil soap producers and all the people working in these fields. In addition, there will be seminars for the authorities of local governments.

The thesaurus' use gives the possibility for the enhancement of activities of enterprises active in agricultural tourism in these regions but it can also suggest the development of new forms of agricultural and cultural tourism in them and in other regions with common socioeconomic features in Greece and in the Mediterranean region, as well. Therefore, educational and information actions will take place, concerning businesspeople of this field.

Besides user groups which are directly involved with olive tree civilization, there is a broader audience to be informed and potentially benefited, in various ways, from this information.

The economies of these two regions have changed their orientation through time and several mistakes have been made on the implementation of new economic activities. In the case of Corfu region, agricultural production and local industrial activity have been vivid until the 80's when there was a sudden turn to a mass and completely anarchist tourist economy. But as, tourist activity has noticed continuous decline since the mid 90's, a demand for change has arisen, to take advantage of the neglected wealth- producing sources of the islands of Corfu and Paxos, which are their olive groves and culture. Tourism as monoculture resulted into the vanishing of local industries, agricultural professions and neglecting the creation of job positions for the maintenance and promotion of the many centuries, rich region's civilization.

The case of Messinia region, has, up to a point, many common features with Corfu- Paxos region. In that region, agricultural production, an intense commercial and industrial activity and also a mild tourist development have taken place until recently. Agricultural production is still vivid and region's olive oil is famous all over the world as it is exported. However, small scale producers face severe financial problems, the region has a quite high unemployment rate and it cannot develop totally its capabilities through various forms of entrepreneurship.

Having in mind this situation in these two regions, the information and training on the research's results of a polymorphic audience such as, new scientists, entrepreneurs seeking to change their business activities, unemployed people, can be inspiring for them and lead to the creation of new economic activities. Proposed information and training methods for these groups are: seminars, galas, and educational visits to olive groves, olive oil mills, and soap industries with the participation of people involved in these fields.

Possible users coming from all educational stages form an audience which has the potential to contribute, in the future, to the change of development policy and is open to information stimulus when these are clearly communicated. Therefore, the proposed research program aims to target to school and university students' user group. Apart from the organization of seminars and educational visits, there will be an attempt to incorporate parts of the research into the teaching material of school and university courses of schools and universities which are based in the regions of Corfu and Messinia, to establish a permanent contact of young people with olive culture.

In the context of the information and training of a broader audience, international scientific congresses will be organized by the University of Peloponnese.

It is presumed that in long time scale, users' information and training will have the substantial results. Therefore, the proposed research aims for a continuous interactive relation with users for a potential improvement of their information and training and the research's results exploitation methods in socio-economic level.

An evaluation process of the first results on how users estimate they have been benefited from the research's results and how they could use them will follow the information and education actions. A recording of these first results will be done via printed and electronic/ on line questionnaires and galas where users will have the chance to present their impressions. This early evaluation is considered of high importance on how the research's results could be used by new user groups, if there will be a changing need in information and educational methods and on how they could be useful for other regions in Greece and in the Mediterranean region

Testing Urban Landscapes

Katrin KOOV

Department of Architecture, Chair of Landscape Architecture, Estonian Academy of Arts, Tallinn, Estonia
katrin.koov@artun.ee

Abstract

In this paper I will analyze the tactical potential of small-scale architectural interventions in urban landscape and illustrate it with the collection of installative projects that have been realized in Tallinn during last ten years.

As dutch architecture theoretician Hans Ibelings has pointed out, adaptive re-use, sustainability and building for demographic decline are the strategies for the coming years in western countries. In Estonia the ultra-liberal governmental policy is combined with the left-wing democratic planning structure. The mismatch of private-public interests has produced a hectic planning practice. While there are no clear big-scale planning visions, several creative people have found other ways to test urban potentials. This small country - with moderate natural resources, small number of inhabitants and harsh climatic conditions, where even simple solutions need more effort - works well as a flexible 'test-field'.

I would like to show how small delicate architectural interventions in abandoned places have changed the atmosphere of the places and created new physical and mental links in urban context. These small material changes bring along much bigger changes in people's values and habits. We may imagine renewing the planning system so it could be more viable when considering with the small successful tactical tests.

Keywords: urban landscape, installation, planning, test-field

1. Marking as spatial practice

Marking places with the installations can be interpreted as our natural biological behaviour. Marking the territory is well known among animals, in order to protect their home territories and food sources. Territorial behaviour aims to avoid more serious battles among representatives of the same species. Sophisticated rituals are carried out daily according to the needs. For human beings the marking has also complex reasons: invitation or restriction, highlighting, surprising, warning statement of the power. Marking is the tool for communication. The fence around the building announces about the territory for the selected persons, white lines on asphalt are regulating the traffic flows, red-and-white tape refers to a danger zone, flag on the moon acknowledges the completion of the mission impossible...

Fig. 1: Marking act of Man on the Moon

The complex structure of the cities produces besides the "normal" marking behaviour also another kind of manifestations. Graffiti is one of the alternative indications, where next to the message there is also important the territorial factor. Norwegian architect Sverre Fehn has written that graffiti is the reaction to anonymity and illustrates his argument with an example from architecture: when modernism cleaned the facades from the ornament and left behind the empty surfaces - buildings "without the faces", then, by the theory of Fehn, urban artists started to cover these surfaces in order to give back the identity to the buildings. The earliest graffiti artists were probably professional sailors who tattooed their bodies: since they didn't have home in the traditional meaning, they marked their bodies as homes. Urban graffiti works also as a social valve - it is an alternative manner to signalize about certain problems, a media form where the author of the message is difficult to identify and for what reason it is possible to express oneself incisively.

2. Strategical planning versus tactical interventions

As many authors have indicated the traditional urban planning system is in crisis and there is need to look for new methods to react adequately to the rapid urban and environmental changes in our cities. Of course there are different local actors in different countries and regions. I will shortly speak about Estonia - a small ex-soviet country that has worked itself up to an equal member of European Union.

On one hand Estonian successful economy has been driven by right-wing liberal policy after the liberation from the soviet occupation, that means less taxes, less administrative obstacles and governmental supervision that has promoted the economical growth. The strategy of "less government" has been working well during the years of transition for the young state and brought along a remarkable economical jump. Former soviet time has been left behind and has become a distant history.

On the other hand many other areas of the society are underdeveloped in the condition of the economical hegemony. Culture, education, social welfare as well as the urban life has not taken part of the blooming, with some exceptions they rather operating in survival mode. Coming closer to the subject - the planning process has been delegated to private developers who can fluently realize their business-plans. This has been stimulating the building market but at the same time brought along greater fragmentation of the cities because of the lack of overall visions. Private developers naturally follow their own purpose to make profit and very often they just ignore the other needs of the city.

Planning system, like the economy, meets the political strategy of "less government". Here that means a constant shortage of well-educated specialists in administration. The system that has been taken over from northern countries requires a large high-level planning office that we simply don't have. At the same time the amount of bureaucratic structures, standards and requirements grows and therefore there is always a risk that the original objective and content will become confused in the supervision of the respective project. Ever more energy is expended in plans as well in architecture to achieve the predescribed standards and exact conformity with procedure, whereas the aspect of content often does not even seem to interest anyone anymore. There are number of institutions that set the rules of the game in their sphere as well as the other interested parties, who argue among themselves to come to the solution that suits to everyone. This is often the content of the planning and the more detailed design that follows. It is as if none of them aspire to a broader and more general view, to building the country and the city. Ideally the municipal planning department should do this but mostly this remains a positive ambition without sufficient institutional power.

[1]

Fig. 1: Street festival in Uus Maailm

Fig. 2: Open air concert in Uus Maailm

After twenty years of independence, we have to ask ourselves: where are the visions of how the state and the city should be built and developed for its people. As a reaction on urban level many grass-root organizations and communities have been activated and started different initiatives of vitalizing the city life. First communities started clearly as reactionary - they were formed mainly for fighting against some arrogant development plan. Later the communities changed to a more proactive groups, started positive programs like for instance the community of the quarter named Uus Maailm ("new world"), formed by the inhabitants of the old wooden buildings' district, mainly younger generation, who are promoting ecological lifestyle, bicycle culture, organizing public events like street market, street festival, open air concerts, etc.

Parallely with communities' human-scale activities there has been always alive the will to promote the visionary spatial thinking at general level among professionals. Content-rich city planning is utmost objective during the education of architects and urban planners and therefore the processes of urban fragmentation have been frustrating to observe. Few years ago the Tallinn's planning department promoted the political vision to turn the city's face towards the sea. That is still the only spatial declaration that has not yet realized but it has brought along many interesting phenomena.

Fig. 3: Map of Tallinn's underdeveloped waterfront

The abandoned coastline in the city has been a unique "polygon" for non-planned activities far before the official statement to broaden the city centre towards the sea. During the soviet time the waterfront was mainly closed. It was the restricted zone, occupied by military structures, prison, heavy industries and closed harbours. When the soviet industries left, the territory got a status of no-man's-land and therefore filled soon with new kind of self-organized life. Local people started to use the wild beach for grilling, promenading, fishing, drive-in sunbathing, dog-bathing - all these were so-called illegal activities but the local government didn't intervene much since the land belongs actually to private owners. In addition the area was also observed and used by artists. Naturally the waterfront has been the subject of studies for architecture students for many years. On this polygon one could observe the viability of the non-planned city-life. Small social groups formed their own territorial rules: fishermen took an old half-drowned wooden shipwreck as their "private" territory and didn't let anybody else on board when they were fishing. Another group - dog owners - gathered there to swim their pets. People themselves stayed at the beach while their dogs were bathing. Naturally some homeless people set their homes in the small caves near the beach and had their fireplace in front of their "door" - this area was also "privatized" like the fishermen's deck.

Fig. 4: Fishermen on the shipwreck

Fig. 5: Unofficial "dog bathing beach"

3. Waterfront landscape as test-field

In earlier years the urban landscape interventions have been mainly small-scale "wild" tests. As one example KAVAKAVA architects arranged a landscape installation named "Found Pleasures" at Kalarand's waterfront. This place offers different pleasures that are not officially proposed but the waterfront is actively used as described above. To see the hidden beauty of the wasteland, visitors have to use their imagination and senses. The area that used to be a fishing factory in soviet time now waits for the new development plan. Until the new developments start to be realized the place continues its wild life as a test-field.

Fig. 6: Fragments of landscape installation "Found Pleasures" 2002 in Kalarand ("fishermen's beach").
 Authors Katrin Koov, Kaire Nõmm, Siiri Vallner, KAVAKAVA architects

Last year brought along the shift in the scale and the span of the promotion of urban installations. Tallinn carried the title of European Cultural Capital 2011. During the other activities city government launched the festival of urban installations LIFT11 that turned out to be utmost popular. An open competition held in autumn 2010 resulted in 129 projects, of which 10 works were selected to be set up in summer 2011 as part of the festival. These site-specific works created at various locations in Tallinn highlighted the specific sites and angles in contrast with the 'postcard' image of Tallinn, addressing local residents as well as visitors. On a wider scale, LIFT11 attempted to break down prejudice towards public art in Tallinn and draw attention to the ample array of opportunities for using city space. [2]

Not very surprisingly a large amount of proposals were offered for the waterfront area. That was even easier to arrange since the city's transportation department had been built a temporary pedestrian road after removing the old rails from the coastline. The new "culture kilometre" gathered together many potential places and buildings: former power plant that is under reconstruction to be transformed into a culture factory, squatted alternative museum for modern art, former hangars for waterplains - now maritime museum, former prison - now unofficial prison museum, former ship-building yard - now temporarily used for modern operas. And between those solid large-scale buildings small and smart human-scale installations were built and several events took place. As follows some examples of the installations will be described that were built along the waterfront.

Fig. 7: Pier installation. Before and after. Summer 2011. Authors Siiri Vallner and Indrek Peil

Pier

The pier located by the Culture Kilometre has weathered and deformed over decades and become unfit for landing boats. However, it would be perfect for sitting, relaxing and having a good time. It can be made usable in its present condition with just a few touches, by conserving and reinforcing the slanting concrete faces and covering them with terrace boards. The boarded surfaces will reflect the shapes of concrete slabs created upon disintegration. This way, a derelict and crumbling object can be revived as part of the modern city space, opening up the seaside area of Tallinn for local people and for visitors. [2]

Fig. 8, 9: Fishermen's Beach installation. Summer 2011. Authors Toomas Paaver, Teele Pehk and Triin Talk

Kalarand

Fishermen's Beach is located on a stretch of shore between the Linnahall and the Patarei fortress, is an improvised beach which has become a popular bathing spot among local people. Regardless of the widespread assumption that the site is polluted, practice has shown the water to be clean and the location naturally suitable for bathing. This is the closest bathing site to the city centre of Tallinn.

In summer 2010, the authors of the installation did a pilot test, setting up a changing cubicle at Kalarand. This marked the place out as a bathing site and the bathers began to use the cubicle right away.

In summer 2011, this urban intervention in public space was repeated on a somewhat grander scale by building a more solid cabin and adding some other elements of a beach, like bench and terraces. The beach area was cleared and the scrub trimmed. Dustbins were provided for the summer season. The seabed of the bathing site was cleared of rubbish and pieces of concrete; water samples were taken and analysis results were posted on a notice board. Regardless of the refurbishments, Kalarand was not listed as an official beach, and people going into the water there were doing so at their own risk. There was no lifeguard service.

These urban interventions like 'sit-or-swim-at-your-own-risk' attempted to draw attention to the plans that concern the entire area and are aimed at developing a large residential and port area there. The residents of Kalamaja contested the proposed plan and it has not been adopted so far. The use of seashore as a beach and public space will not preclude the development of residential buildings or port facilities because that area of land and sea is quite large and holds various opportunities. The use of city space as a beach could also enrich and revive the development plans and help the owner of the property improve the image of the area, the quality of its future environment and its use. [2]

Fig. 10: Linnahall in the year 1980

Fig. 11: Installation "To the Sea". Author Tomomi Hayashi

To the sea

The Linnahall, built for the Tallinn Olympic Regatta held in 1980, was the first and only place offering common people access to the sea within the centre of the city during the Soviet era. The area by the Linnahall used to be closed, and therefore people had to walk across the roof. Nowadays the sea is also accessible from elsewhere in the city centre but the unique location of the Linnahall combined with its architectural design produce a viewing platform for unforgettable experience along with a system of stairs and areas for strolling. The low mastaba-like structure of the building was so designed to preserve a view of the Old Town from Tallinn Bay. The design of the Linnahall, by Raine Karp and Riina Altmäe, still appears fresh and modern.

However, because of poor construction quality and some functional peculiarities, such as the absence of an orchestra pit and the fly tower being too low, the concert hall is in hibernation today, waiting for the winds of change and for investments. The stairs and the roof are still open to the public and the Linnahall continues to be a popular meeting place, especially in the warm season. [2]

4. Different scales and materials

Fig. 12, 13: Temporary Straw Theatre NO99 at Skoone bastion. Summer 2011. Authors SALTO architects

At the same time with installation festival another temporary object was erected not far from waterfront - on top of the Skoone bastion. A relatively small theatre called NO99 built a quite large theatre hall from straw for just one summer. Theatre hall that was built for a specific purpose, programme and location, operated from May to October, worked as a landmark and catalyst for the former military area that has been abandoned for years. The idea of building a theatre-installation that has a meaning not only by its function but also by the idea and material, has been afloat in many heads but this time the young leaders of the alternative theatre Ene-Liis Semper and Tiit Ojasoo made it real. The project was conducted by young architecture office SALTO. The rectangular main volume of the theatre is situated exactly on the same spot as the former navy summer theatre, and one descending flight of stairs of the latter is used as a covered walkway and entrance area to the Straw Theatre. The dramatic appeal of the building stems from its contextual setting on the site and its black, uncompromisingly mute main volume contrasting with a descending „tail“ with an articulate angular roof. And of course one cannot escape the effect of the material – uncovered straw bales, painted black. The Straw Theatre is a unique occasion where straw has been used for a large public building and adjusted to a refined architectural form. [3] For the initiators the outdoor activities were as important as indoor program: the bastion was full of life daily due to the cafe and different playgrounds. This temporary complex wisely made use of the given manmade landscape form.

Fig. 14, 15: Light installation "Garden of Eden". Wilhelm Kühnert's forgotten dendropark in Tallinn. Authors Yoko Alender and Indrek Leht. Tallinn Light Festival 2004

If to look back to the independence years we may see that the tradition of installations has been most vital in the immaterial area: light installations have been built during the yearly Light Festivals for more than 10 years already. The darkest time of the year has been marked with magical light, bringing people outdoors to defy the freezing weather in order to explore the city's hidden values. As one example here is presented the

lighting project named "Garden of Eden" where the passers' eyes are turned towards the old rare trees, that date back to 19th century, a lost garden of Wilhelm Kühnert who was one of the establishers of Estonian forestry culture. With delicate lighting this valuable historical layer of this particular city quarter was revealed. Light has the magical power to change the atmosphere and besides it has distinctive survival meaning for the northern people - it gives light and warmth in the cold darkness.

5. Conclusion

Ideally the cities should be developed in both ways: top-down (by visionary planning) and bottom-up (by local initiatives and temporary interventions) simultaneously. By doing so, there is hope that plans and needs could meet in real life. It is almost impossible to make field tests for the big-scale planning proposals in order to check the solution's durability or the social impact. At this point small-scale installations could be suitable tactical tools for testing some specific part of the planning proposal in minimized or concentrated form. Temporary interventions have proved itself to be especially good in testing the social acceptance. Installations are also economically highly efficient: they can test social, environmental or economical potentials of the particular place by mostly very low cost of the installation itself. On the other hand installations can still remain as independent landmarks that embody the urban freedom. Urban installations are either objects of art, architecture, landscape architecture or design, which are, in conjunction with their surroundings, intended to offer a spatial experience or to comment on the urban environment in a critical or humorous manner. Derelict urban landscapes are perfect test-fields for the site's future potentials and therefore temporary interventions could be used more courageously next to the visionary planning. Only within the continuous dialogue of different methods the content-rich and human-scale urban spaces can be developed.

I would like to end up this paper with landscape ecologist Anne Whiston Spirn's poetical words: the language of landscape is our native language. Anyone with a keen sensibility can recover that language. We are architects of our environment and we need work with people as well as with natural processes to create places that are functional, sustainable and meaningful. [4]

Abstract

Solar heating and cooling technology is a plant engineering technique which uses hot water of solar collectors for building air conditioning during both winter and summer. Recently the interest for this technology has grown constantly especially due to the fact that it allows to reduce carbon dioxide emissions, save energy, and assure a local supply of energy thus more reliable.

A critical point of discussion begins when solar collectors are installed in historical buildings because the protrusion formed by solar panels and mounting structures transforms the shape of the building, thereby altering its architectural aspects. In these cases, respect for historical heritage, protection of the landscape and the employment of renewable energy must be conciliated. As a consequence the design of the installation must be performed in order find out a good balance between technical and aesthetical requests.

In this paper a solar heating and cooling plant designed for the Architecture Faculty of Second University of Naples with the aim to promote solar cooling and heating installations that facilitate the discovery of visual integrations and good compromises between technical and architectonic features is depicted in detail.

Keywords: solar cooling, historical building; architectural integration.

1. Introduction

The energy demand in the residential and tertiary sector represents the 36% of European final energy: 25% for households and 11% for services [1]. This amount of energy is mainly used for air conditioning indoor spaces, heating water, electrical appliances and lighting. The energy demand for heating is projected to increase until 2030 and then stabilize. In contrast, energy demand for cooling is projected to increase rapidly over the current century due to the climate warming [2].

These world energy demand trends are the catalysts calling for the creation of new models in energy conversion; encouraging strategies with renewable energies and higher levels of efficiency to reduce the energy input and pollutants emissions.

With regard to renewable energy sources, a number of innovative renewable technologies are emerging. For example, new building-integrated wind turbines [3], cogenerative solar photovoltaic collectors [4], solar heating and cooling systems [5-8] are currently under investigation both by industry and academia.

Among these emerging technologies, solar heating and cooling (SHC) is probably one of the best choices. A great advantage of such technology lies in the possibility of using solar radiation to provide space heating during the winter and space cooling in the summer, by using a heat-driven chiller. SHC systems are very profitable particularly in summer operation mode, when the maximum demand for cooling coincides with the maximum availability of solar radiation. SHC may significantly contribute to achieve the goals in terms of energy savings, greenhouse gas emissions reductions and increase of use of renewable energy sources, including those goals stated by EU in the Directive 2009/28/EC [9].

A solar heating and cooling system has been designed for conditioning during both summer and winter the nineteenth-century portion, called in Italian “Corpo Ottocentesco, of the Architecture Faculty of Second University of Naples, located in Aversa, a municipality 20 km far from Naples (Italy). The project has been performed also with the aim to facilitate the discovery of visual integrations and good compromises between technical and architectonic features.

The Architecture Faculty of Second University of Naples is located within the Abbey of San Lorenzo ad Septimum. The abbey complex has been built at the end of tenth century along the consular street named “Via Campana” and represents the result of three centuries of history. The church has been raised around 1080: it has a nave and two aisles and shows several stratifications. The bell tower has been rebuilt around mid-fifteenth century as a consequence of the earthquake of 1456. The main renaissance cloister has several round arches positioned over doric columns; it acts as the connection among the different parts of the abbey complex: towards the north there is the church; the garden is located towards the south; westward there are the minor baroque cloister and the eighteenth-century portion at the hands of the architect Ferdinando Fuga; eastward there is the nineteenth-century portion that has been completed during the time when the abbey has been designed as College and Real School of Arts (Figure 1). Additional details regarding the Abbey of San Lorenzo ad Septimum can be found in [10].

Fig. 1: Plan of the San Lorenzo ad Septimum abbey (on the left). View of the nineteenth-century portion of the Architecture Faculty of Second University of Naples (on the right).

In a SHC plant the solar energy required for heating (winter season) or for operating the heat-driven chiller (summer season) is recovered by installing several solar collectors. In case of historical buildings the protrusion formed by solar panels and mounting structures transforms the shape of the building, thereby altering its architectural aspects. The design of the air conditioning for the Architecture Faculty of Second University of Naples has been carried out in order find out a balance between technical and aesthetical requests.

The main aim of the project is to emphasize the respect of local biological cycles adding environmental value thanks to the production of clean energy. The design concept is then developed through the study of natural organisms and their life cycles by integrating all the elements of the SHC system. In this paper the architectural solutions adopted to achieve the best compromise among respect for historical heritage, protection of the landscape and the employment of renewable energy are illustrated and analyzed in detail.

2. Solar cooling and heating plant description

The portion of the Architecture Faculty of Second University of Naples, named in Italian “Corpo Ottocentesco”, is a three levels building containing three classrooms, with a total volume equal to 4533 m³

and a total surface area of 842 m². This portion of the building is currently heated by using both hot water and hot air, while chilled water is currently used as the cooling medium during warm season:

- hot water is produced by an oil fired boiler with a nominal capacity equal to 349 kW;
- chilled water is cooled by an electrically driven vapour compression refrigerating system, with a nominal capacity of 79 kW using R407C (a mixture of greenhouse gases) as refrigerant;
- air is heated up by means of an Air Handling Unit (AHU) with 6500 m³/h as nominal volumetric flow rate.

Water is heated up by the boiler up to a preset temperature and circulated throughout the building by means of a pumps by way of fan-coils, while air distribution into the three classrooms being air conditioned is performed by using air vents at high level.

A new air conditioning system has been designed with the main aims to save energy and reduce greenhouse gas emissions. The design of the system has been carried out in order to get the best integration between the plant components and the architectural constraints. The new proposed air conditioning system is composed by two main subsystems:

1. a solar cooling and heating plant with absorption chiller;
2. a solar cooling plant whit desiccant wheel.

The main components of these two subsystems are:

- two fields of flat-plate solar thermal collectors with evacuated tubes (the first one with an open area of 167 m² and the second one with an open area of 130 m²), horizontally installed on the roof of several hexagonal cells positioned in the garden of the faculty;
- a single-effect LiBr /water absorption chiller of 70 kW cooling capacity;
- an air handling unit with desiccant wheel;
- a peak-up boiler fuelled by oil (one of the three already installed for heating the faculty);
- two hot water storage tanks with different volumes (the first one of 4000 liters and the second one of 2000 liters);
- a cold water storage tank of 1000 liters.

Nominal cooling capacity of the absorption chiller has been defined by estimating the cooling load of the "Corpo Ottocentesco". This estimation has been performed by using the software Thermus [11].

The number of solar collectors has been defined by assuming a value of 0.7 as coefficient of performance for the absorption chiller and an average solar irradiation equal to 900 W/m².

In figure 2 a schematic view of the system during winter operation is reported, while Figure 3 shows the main components of the air conditioning plant during summer operation.

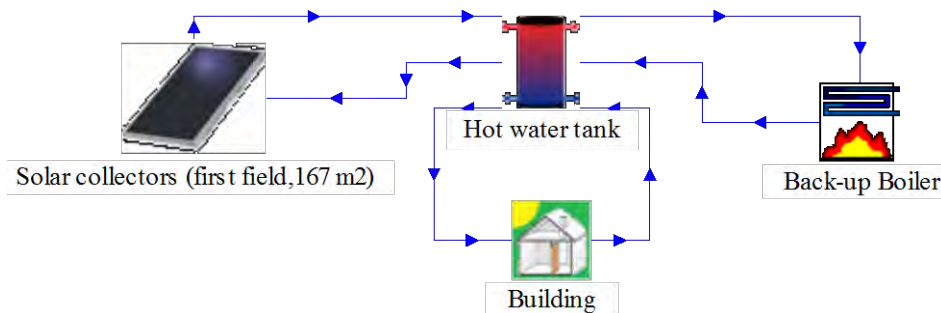

Fig. 2: Schematic view of the system during winter operation.

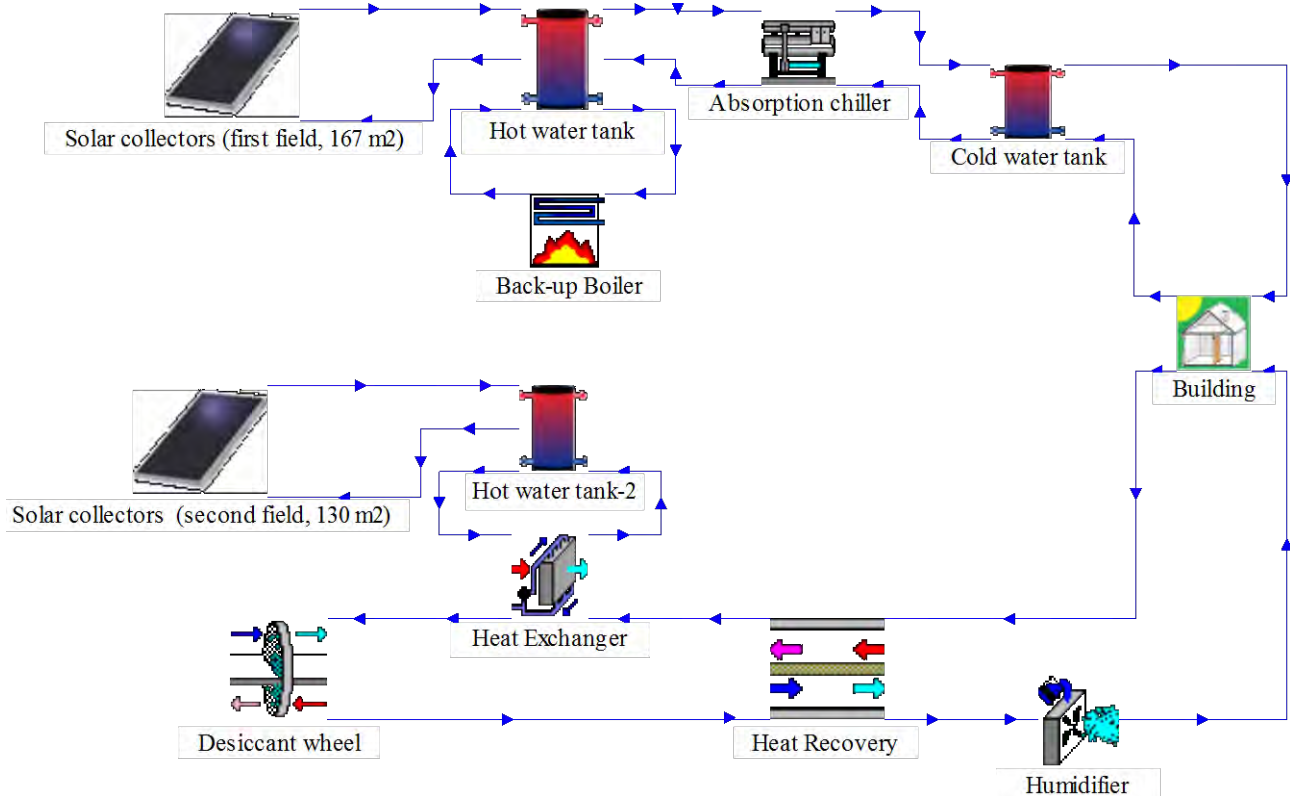

Fig. 3: Schematic view of the system during summer operation.

During the winter the heat recovered from the first field of solar collectors is stored in the 4000 l tank till reaching a preset hot water temperature; due to the fact that the solar energy striking the Earth's surface is poor during the cold season, a peak up boiler has been considered in order to guarantee at any time the desired water temperature in the hot storage. The hot water stored in the tank is then used for heating the building. During the winter both the absorption chiller and the solar cooling plant with desiccant wheel do not operate.

During the warm season, the sensible cooling load of the building is balanced by the solar cooling plant with absorption chiller, while the solar cooling plant with desiccant wheel balances the latent cooling load of the building. System operation during the summer can be summarized as follows:

- heat recovered from the first field of solar collectors and stored in the hot water tank (4000 liters) is transferred to the absorption chiller; when supplied with hot water, the absorption chiller is a system able to provide cold water; the provide cooling power coming from the absorption chiller is transferred to the cold water tank (1000 liters) and then used for balancing the sensible cooling load of the building;
- heat recovered from the second field of solar collectors is used to regenerate the desiccant wheel (regenerating the desiccant wheel consists in removing its humidity). The outside air is dehumidified in the desiccant wheel; it is then cooled in the sensible heat regenerator by the return cooled air before being further cooled in an evaporative process; finally, it is introduced into the building. The operating sequence for the return air is as follows: it is cooled by evaporative cooling and then it cools the fresh air in a rotary heat exchanger. It is then heated in the regeneration heat exchanger by solar energy recovered from solar panels and finally regenerates the desiccant wheel before exiting the installation.

Compared to electrically driven vapour compression bivalent heat pump system, the proposed system can be considered environmentally friendly thanks to the fact that electricity is only used in the auxiliaries (pumps and fans), heat is obtained from solar energy and water is exploited as refrigerant. An energetic, economic and environmental analysis has been performed in order to compare the designed system with the system currently installed and so to better highlight the advantages of the proposed air conditioning plant [12]. The analysis showed that the solar cooling and heating plant with absorption chiller allows to reduce the primary energy consumption by 18364 kWh, the operating cost by 7981 €/ year, and the carbon dioxide emissions by 17685 kgCO₂. Similar results have been gathered by performing the same kind of analysis in relation to the solar cooling plant with desiccant wheel: 47428 kWh as primary energy saving, 5702 €/ year as operating cost saving and 12010 kgCO₂ as reduction of carbon dioxide emissions.

3. Solar cooling and heating plant integration

The new air conditioning system designed for the nineteen complex of San Lorenzo Abbey is located within the rear yard, between the existing ortho and an arboretum quadrangular.

The environmental and perceptual integration with the monument was evacuated: for this purpose a new hexagonal frame structure in a lightweight and precast material has been defined in order to minimize the impact with the ground. The hexagonal structure has been designed with particular attention paid to the environmental and perceptual integration with the abbey and has been made with dry, reversible prefabricated elements, to be assembled on site. In particular, the frame structure of the hexagonal cell is in cold rolled steel mounted in place, ballasted with the ground. Its structure allow avoiding concrete foundations, without any impact on the soil resources devoted to the cultivation of the garden.

Fig. 4: View in context of the hexagonal cells.

The plan of the new system consists of multi-cellular aggregation in hexagonal matrix that runs along the sides of the hexagonal base. In this way it is possible to see pieces of the historical pre-existing building alternating between full and empty spaces. The whole project is designed in order to avoid any obstruction of the view of the abbey, so the texture of the new forms provides a complete visual permeability.

A structure, shaped like a honeycomb, establishing a reciprocal relationship between ancient and modern has been so realized.

The perimeter walls of the hexagonal cells have been made of glass and branch. They allow to glimpse the votive lights in order to weld the religious origin of the ancient building complex with the actual scientific destination of the place. The single hexagonal element consists of a wooden platform placed on the perimeter walls anchored on cement block buried in the ground for a depth of about 40 cm. A hollow central pillar for the collection of the rainwater works with the statically perimeter system. Solar panels have been placed inside the ceiling: in this way they aren't visible from the garden.

One cell has dimensions greater than the other ones because it accommodates the machines composing the solar cooling and heating system.

Fig. 5: 3D model of the hexagonal cell (on the left). Plan of the new multi-cellular aggregation inside the Garden (on the right).

Each cell has a three meter high walls. They are suspended from the ground of about 10 cm. These modular elements can be easily reproduced in other contexts for promoting the adoption of solar cooling and heating systems within historical building.

Finally it can noticed that the project is fully compatible with the historic-artistic monument complex pursuant to art. 20 par. 1 of Decreto Legislativo 22 January 2004 Number 42. It don't damage the distinctive character and material of the site.

4. Conclusions

Solar cooling and heating technology is a solar energy based technique for building air conditioning which is potentially able to reduce carbon dioxide emissions, save energy, and assure a more reliable local energy supply.

In this paper the design of a solar heating and cooling plant for the Architecture Faculty of Second University of Naples located in a abbey complex built at the end of tenth century is depicted in detail.

Taking into account the historical and architectural content of the building hosting the faculty, the air conditioning plant has been designed in order to conciliate the employment of renewable energy with both respect for historical heritage and protection of the landscape. The main aim of the paper is promoting solar cooling and heating installations that facilitate the discovery of visual integrations and good compromises between technical and architectonic features.

Several solutions has been adopted to achieve a good balance between technical and aesthetical requests as the development of a new hexagonal frame structure installed in the garden made of a lightweight and precast material; solar panels have been installed on the roof of each hexagonal cell in order to avoid its view from the garden itself. The whole project is designed in order to avoid any obstruction of the view of the Abbey, so that the texture of the new forms provides a complete visual permeability.

Abstract

This study is the result of an interdisciplinary cooperation among specialists, scholars and different skills aimed at the requalification/regeneration of the archaeological park of Kaukana in Santa Croce Camerina (RG). It is a wide area along Mediterranean which becomes the driving force for economic and functional growth of territory, along with landscape valorisation and environmental restoration.

This area is one of the best Sicilian well preserved late antique period settlement. Over there archaeology and nature merge in a cultural landscape which is unique in its genre and that has been studied by means of innovative cognitive tools (3d laser scanning, photomodeling, and so on) which constitutes the first step towards a conscious territory government.

By acting without big distortions; by supporting the vocation to transformation through actions aimed at the restoration of the past; by qualifying spaces and reinventing green fruiting attractive paths; then the archaeological area becomes a resource, regenerated and inserted into touristic districts, which produces work and both material and immaterial richness.

It represents a regenerative model founded on virtuous values of nature and biological models, which are able to carry out a development "founded on the reduction of the waste of raw materials, human resources, assets". That is a conscious intervention which through the survey, the re-drawing and the analysis of existent places generates less wastes/more life improvement, less environmental impact/ more essentiality.

Keywords: laser scanning, archaeological landscape, 3D modeling, territorial regeneration.

1. Introduction

Franca Restuccia

Today's globalization destroys the history and the identity of places and it causes deep changes not only to society but also to economy and "cultural territories" development. Very often the state of neglecting and degradation of archaeological assets obscures the landscape and environmental values of territories.

Through processes of creative regeneration and new government methodologies these assets and/or sites could be culturally rescued. The purpose is to add more value to regions and places so that they become competitive in the image of the territory and in the promotion of local economic development [1].

By the requalification of spaces and the re-invention of attractive paths of green fruition, the archaeological site can be regenerated without big changes and according to the vocation of place. Moreover as it is embedded into a touristic district, it becomes a resource of work and richness both material and immaterial.

This is a way to provide regenerative patterns based on virtuous values of nature and biological models, which are able to realize a development "based on the reduction of the waste of raw materials, human resources,

assets". Thus it is necessary to aim at coherent and conscious interventions that - through survey, re-drawing and analysis of existent places – create less waste/more life improvement, less environmental impact/more essentiality, less aesthetics/more essence. These interventions contribute to landscape enrichment, to the environmental recovery together with the economic and functional growth of the territory itself.

The archaeological site of Kaukana in Santa Croce Camerina (RG) is a good example of that recovery policy aimed at the regeneration of what already exists. This site is a wide territory along the Mediterranean coast in the area of Ragusa in which archaeology and nature merge in a cultural landscape unique in its genre: it represents one of the best Sicilian well preserved late antique period settlement. It is a place of deep Mediterranean identities, which offers wide opportunities of cultural and economic investments.

Fig. 1: Aerial photography of the state-owned area of Kaukana where the three contiguous areas cut by the littoral road are highlighted in red.

This study is an extract of the cooperation work between the Department of Cultural Heritage of Ragusa and the Laboratory of Architectural Photogrammetry and Survey "Luigi Andreozzi" of the Engineering Faculty of Catania. Through innovative cognitive tools (3d laser scanning) the interdisciplinary study provided the basic elements for a conscious government of the territory. As a matter of fact, this work has been a good opportunity to face with a wide extension and complexity theme due to archaeological, naturalistic and environmental values of the site. Actually this is a park of archaeological interest, a place of attraction and study where the culture inhabits the landscape. The potentialities of the place grant to it an active role in the project of cultural and environmental quality: it could be the driving force for economic and functional growth of territory.

The need to accurately document this archaeological asset and the relations which, during the time, it has established with the natural environment of the park – rich of landscape suggestions between the sea and the Mediterranean vegetation – has required the use of an operative methodology which renovates ways of documentation, perception, analysis, representation and management by using informatics technologies. Indeed, they have been applied renewed "models of doing" able to "catch" nature and built in a unique cognitive model aimed at the project of valorisation and fruition. It is a model of digital synthesis that prefigures the revaluation project founded on the global qualitative change and the identity of the area - as required by the Department of Cultural Heritage who manages and maintains the "hyblean" archaeological park.

The Department plans to organize the area with operative interventions aimed at the quality and sustainability according to the existent resources. The purpose is to have a virtuous recovery of the site; to transform the heritage into a resource in favour of economic development and of cultural growth, avoiding morphological and structural changes of the natural area. That is, to act a reuse that - keeping readable the traces and the memories of the past - will recover them for collective fruition, according to a productive synthesis of nature and history: "less waste/more quality, research and ideas; less waste more ethics/more investments and sustainability".

2. Kaukana project: territorial regeneration between nature and archaeology

Venera Greco

Kaukana was a small village placed in the territory of the town of Santa Croce Camerina (Ragusa) which was used to be very important during byzantine age.

The Greek name (Kaukanae) was used to describe a series of villages in which Kamarina exiles in 258 b. C. found refuge. As a matter of fact, they choose this site thanks to its natural landing places, the fertility of the soil and the richness of water. In 535 A.D. the General Belisario left from Kaukana in the direction of Malta, during its campaign against Vandals [2]. In those years the settlement had an important urban development and its seaport growth in importance until it was destroyed by Saracens. It was an important commercial anchorage, very active between the IV and the VII century A. D.

The cover-up of the coast protected the late roman settlement with a layer of sand so that the walls of the buildings have been almost fully preserved. Today Kaukana hosts a large archaeological park that has discovered one of the best preserved late antique age settlements in Sicily.

The recovered complex consists of 25 buildings of different kind among which a small church (with three naves) which belongs to a burial area. Reported and studied by Paolo Orsi, the complex was brought to light in the '80s by the team headed by Dr. Paola Pelagatti, despite the strong contrasts of the private owners of the land, who planned to build very profitable touristic residences [3,4].

Fig. 2, 3: The remains of Kaukana late-roman age settlement (pictures by Giunta).

Definitely the entire surrounding area was already saturated by a lot of abusive constructions, the so-called "tourist" villages, realized during the building "boom" of the '70s and '80s. The excavations have reported an archeological complex of great value due to the rarity of the temporal dating and of the completeness of the settlement that, even if small, contains all the key elements: the small church, the "emporium", the public space, the stores, the houses, the dock buildings [5].

The peculiarity of being in a recent building fabric, asphyxiated and of poor architectural quality, together with being located in the historic palimpsest of late antiquity and the period of vandals raids, turned it into a main resource/good cultural archaeological and landscape. As a matter of fact, it represents a resource on which it is possible to found the process of requalification of the entire area, which is also enhanced by a beautiful beach recently nourished by the Regional Province of Ragusa.

Nowadays the archaeological park of Kaukana is one of the strategic and focal points of the community of Santa Croce Camerina, that considers it as belonging to his own territory and uses it for the best cultural events of the summer season. Thanks to the conjugation of the protection of archaeological goods together with the landscape one, the common notion of "public green" has been replaced by the specific meaning of identity of places.

The area of the archaeological park belongs to the regional Sicilian state property and it is managed by the Department of Cultural Heritage of Ragusa who has handled in these years the management, the fruition and the maintenance.

Over the last few years, in this area several excavations promoted by the university of Vancouver has been done: the team headed by prof Robert Wilson has excavated some parts highlighting rooms, furnishings and human remains that have confirmed both the dating and the religious cults celebrated in the village, even after it was abandoned [6].

Due to the strategic importance of the park of Kaukana the Department of Cultural Heritage has drawn up a project for enhancing the state-owned area that was financed on the chapter "freed-up Resources" of the previous POR 2000-2006 program.

The project forecasts a series of operations aimed at giving back the area to the fruition according to a clear didactic path that should give to visitors the reading key to interpret the archaeological ruins. This way it is possible to identify the ruins in a wider historic vision reconstructed according to rigorous Scientific criteria and combined with the comprehension of the place, the context and the naturalistic park.

The park completes its natural vocation of public space of the community through the realization of: a small but essential parking at the entrance; wood paths that drive visitors along the archaeological excavations; a space equipped for public open air shows; a restructured roof of the little church. This last offered the opportunity for an architectural reconfiguration that might give back to the public fruition the typological and spatial qualities of the church together with the new lights that emphasize its key role inside the whole complex. Furthermore, the new fence in fiberglass gives a vegetal boundary that partially hides the new roof. Moreover the vegetal component has been deepened too: the dangerous or sick plants have been cut and removed; autochthonous species such as carobs, almonds, wild olives have been re-planted. This way the allochthonous species could be gradually restructured and, during the time, the floristic-vegetal component will get closer and closer to the native one. The scope is to re-construct a piece of the historic landscape, which is of great value and unfortunately now it is readable only in few fragments. Moreover, in the didactic indications large emphasis will be given to the archaeological and historic components as well as to naturalistic and vegetal the ones.

Fig. 4-5: The renewed roof of the little church merged with the vegetation (pictures by G. Manganello).

3. Less waste/more research for the knowledge and documentation: the project of the archaeological park of Kaukana between perception and dimension.

Mariateresa Galizia

The enhancement project of the state-owned area of the park of Kaukana is part of a regenerative policy focused on investments in local cultural heritage.

The planning intervention drawn up by the Department of Cultural Heritage of Ragusa is mainly founded on a plan that counts "less waste/more quality of life and places"; a plan where culture is the driving force for places development, saving them from devastating speculative projects.

The scope is to have "less environmental impact/more environment requalification" in order to improve economic, social, environmental and cultural forces that could give back this area to local inhabitants and to tourists.

The careful and accurate action of the Department of Cultural Heritage required a rigorous survey of the site aimed at "more knowledge and documentation/less imprecision" into planning choices.

The characteristics of the site – based on the indissoluble relation between landscape and archaeology – required a kind of survey aimed at the project of reuse of the park. This survey should be able to catch and represent, in their shape and measure, the late-roman settlement together with the natural features that during the centuries have modified the state of the places.

The main goal of the planning intervention is to give back to the community a proper interpretation of a piece of history told through the archaeological ruins as well as through the traces of an historic landscape with a peculiar floristic-vegetation component.

As a matter of fact, the archaeological park represents a wide and diversified presence of the human intervention and it's the memory of the changes undergone on this characteristic area of the "hyblean" territory. Therefore, there is the need to analyze and interpret the hierarchy of the elements which characterize the place – terrain morphology, autochthonous and allochthonous vegetation, the constructive tools – in a unique model of representation through which it is possible to properly identify the paradigms/models, natural and not, of the hyblean archaeological area. The study has been an applicative experience aimed at the creation of a possible "extended museum" according to a settlement connotation on which it could be possible to develop significant disciplinary elaborations (archaeology, architecture, history, conservation, geology, economics, agriculturalist).

The Department of Cultural Heritage of Ragusa required a cognitive survey which would combine and support the planning choices focusing both on the recovery of the preexistences and on the new project of fruition of the park as resource/cultural assets, archaeological and landscape. This process of requalification has economic and cultural effects on the whole ragusan area.

We choose to use 3D laser scanning methodology in order to obtain an integrate representation made of analysis and measurements, survey and representation. Thus, a survey appropriate to understand and document the object in its completeness: from the morphology (territory/altimetry) to the geometry of the archaeological complex, to the topology of elements, to the state of conservation of the stones of the settlement.

The 3d laser scanner survey provided a product/model of the surveyed reality through which it is possible to carry out a diachronic and synchronic reading and to convey an analytic and synthetic evaluation already during the survey phase. A 3D model objective – inspected in the virtual space of the computer where it is possible to intervene and operate with subjective evaluations - has itself the fundamentals of the project.

Fig. 6-7: Views of the cloud of points near to the remains of a house (on the left) and of the little church (on the right).

As a model of representation, it is a media of exchange of visual feelings and spatial descriptions and it allows to be observed according to the "perspicere" of the tradition. The coexistence of the perceptive feature and the metric-objective one represents the innovative component of the digital survey that allows, thanks to data correlation, the integration and the interaction of the specific disciplinary expertise.

This way the role of the traditional graphic representation - seen as interpretative media of the different languages and specialist expertise involved in the planning activity – is placed side by side to the model of digital synthesis. Through the model the following ideational phases of the planning process, the new shapes and the new volumes are inserted into the virtual scene of places, embodying the 3D digital space.

The visualization of the model – that for its intrinsic potentialities enriches the process of scientific discovery because it improves the hidden interiorities of the place – allowed us to transfer all the planning reasoning into digital form [7].

The elaborated product is not only a simple prefiguration that relates drawing and design but also a manipulable system that simulates the reality simultaneously to the work of the designer.

This model embody a hierarchic structure which allows, in the planning phase, a dynamic approach which goes from the critical analysis to the visual impact of the intervention, to the simulation of alternative hypothesis for restoring the materials and the vegetation. Moreover, the representation by means of 3D digital models gives the opportunity to create a "virtual museum" which has its dimension and which is able to host the whole archaeological site according to an efficient and attractive interdisciplinary didactic path.

The use of 3D scanning in the field of cultural heritage contributes to the elaboration of a new communicative and visual grammar which allows to combine the cognitive rigor of the metric investigation with the need to be an effective tool for understanding values, as well as to convey the meanings of the site making easier the integration among culture and economics, tourism and territory development [8].

Thanks to the processed model it has been possible to activate the project of requalification of the park that – preserving the memory of the past and the respect of the nature – would develop more growth and, at the same time, “less impact on the historic/cultural, floristic/faunistic, socio/economic environment”.

Fig. 8-9: Suggestive representations of the model among shape, measure and perception.

4. Less waste/more knowledge of Hyblean archaeological landscape: survey and representation of the archaeological park of Kaukana

Cettina Santagati

The archaeological park of Kaukana stretches for about 3 hectares and half into the construction fabric built during the economic boom of the 70s and 80s.

The ruins of the late-roman settlement are plunged into a thick woody density (about 1170 trees among autochthonous and allochthonous species) in an indissoluble union between nature and archaeology generating a cultural landscape of remarkable historic-naturalistic value.

The knowledge process of this archaeological area – nowadays fragmented by the littoral road into three adjoining areas, one of them along the coast – required a selective methodological approach, alternative to the traditional investigation methods. As a matter of fact, the survey of the site has taken into account the archaeological emergencies issues together with the naturalistic element in order to develop a requalification project of the park aimed at “less wastes/more knowledge” by planning fruition and enhancement paths along the ruins and the green.

It has been investigated on the field the 3d laser scanning technology which is, until now, the most suitable for measuring and documenting the reality in terms of acquisition speed, quantity and accuracy of measured data and capacity of providing, in real time, the 3D representation of the surveyed object [9,10,11].

The Time of Flight 3d laser scanner HDS 3000 by Leica Geosystem, belonging to the laboratory of Architectural Photogrammetry and Survey, has been used.

Through a conscious pre-knowledge of places, some innovative operative protocols have been tested on the field. That was essential to fully understand the complex and multiple issues of the cultural asset we were about to study and of the whole environment, anthropic and natural, to which it belongs.

The procedural logic, experimented and adopted during the data acquisition steps, supplies to the peculiarities of the site, to the need to document the trees, to integrate and to geo-reference the surveys of future excavations. It has been conceived and arranged an almost regular grid of station points (34), arranged at about 30-50 mt one from each other, so that each station is connected to the previous and the next one. This way, besides a good overlapping between the scans, a better error compensation in the following phase of the model alignment is granted.

In the absence of well recognizable reference points, the chain between each station and the following is assigned to a set of 3D targets (69 polystyrene spheres with 12 cm in diameter) univocally identifiable and well visible. The targets are uniformly arranged in relation to the station points so that from each station point it is possible to acquire at least 4 targets in common with the direct adjacent stations.

The choice to use polystyrene spheres instead of pre-calibrate 3D targets (more expensive) has been based on some tests performed in our laboratory. These tests gave good results about the alignment of adjacent stations. The only condition is that a redundant number of spheres should be used so that it is possible to balance the error due to their un-calibration [12].

Fig. 10: Experimentation on the field with 3D spherical target.

Particular attention has been paid to the visual connection between the passage stations from one area to another one and - even if adjoining - they are cut by the littoral road and the surrounding buildings: thus, intermediate stations have been planned when the points were too far.

The in situ survey for each station provided: a fully 360° scan with a density of 1 cm to 15 mt; a thickening in presence of the archaeological ruins and the 3D targets (4 mm). In total, 34 scans have been performed and 185 millions of points have been acquired.

Before merging the overall model, raw data have been cleaned and spherical targets have been recognized and identified by creating, in the embedded software, the corresponding spheres (through proper fitting algorithm) and by assigning them an ID label.

The assemblage of the 34 scans into a unique reference system - in order to have a close mesh of connected scans - has generated 77 chains (cloudmesh).

The alignment error has been reduced to 1,5 cm by optimizing the computation parameters. This result can be considered more than acceptable because of the wind which introduced a strong disturbing element in the survey of trees leaves (essential for an accurate documentation of the foliage overall dimension). Moreover, considering the required scales of representation (1:200; 1:500) this value fits the graphical error.

The obtained 3D model is a digital document that holds the morphological, geometric, natural, environmental and perceptive characteristics of the homologous real model but only with a later manipulation-interpretation it might become an intelligible space.

The overall model constituted the base for the following elaborations aimed at obtaining a full documentation of the condition of things. Thus, they have been represented: plani-altimetric relief of terrain (by contour lines at each 25 cm), the ruins of the settlement, the arboreal species (localization, foliage overall dimension and denomination), the walls, the fences and all the elements useful for the comprehension of the spatial and

environmental contest of the archaeological park and very important for the enhancement project of the state-owned area.

Finally, to document the plani-altimetric relations between nature and built area –essential for the project of fruition of the park – they have been performed some sections of the model aimed at the elaboration of representations which give the perception of the state of places.

The digital survey of the park has constituted a valid analysis tool for the comprehension of the cultural, natural and landscape worthiness of places, allowing a “less static/more dynamic methodological approach” to the regeneration project of the Hyblean territory.

Indeed, the possibility to be able to extract at any time new information, to compare with the planning solution being formulated, allowed a better control of the project through “less wastes/more quality choices”.

“Less randomness/more ideas” would contribute towards the development of a sustainable project based on the strategies of enhancement of the archaeology and of the related landscape.

Fig. 11: Plan graphical restitution of the archaeological park where is highlighted the project of survey.

Fig. 12-13: The archaeological landscape between natural and built environment.

Fig. 14-15: The remains of Kaukana settlement in the environmental context of the park.

Abstract

Lack of values and sloppiness characterize our territories, even if they are full of cultural resources, as in Enna. A spread heritage often left to itself, no longer or only few integrated into the active life of places. However, dispersed in a landscape of rare beauty, significant examples of an important chapter in the Sicilian history, connected to the historical exploitation of its large sulfurous deposits, rise. Among these, the Floristella and Grottacalda mining site, located not far from the UNESCO World Heritage site of the Villa Romana del Casale, is one of the most expressive examples of industrial archeology in Southern Italy. In this area, still visible and dramatically evocative are the signs of several ages as well as the systems and methods of mining and sulfur melting. Only partially located within protected enclosures and managed by a park governing body that should take care of its safeguarding, this place appears quite "distant" from people who do not "recognize themselves" in it. Nevertheless, if properly protected and promoted - i.e. in the framework of an eco-museum structure - and connected to the territory; when studied for scientific and educational reasons, in close collaboration with the community and in synergy with the Institutions, such heritage would be a very useful tool for the reinforcement of identities among the population. It will also help to increase cultural and environmental heritage awareness, collaborating for its preservation.

Parole chiave: cultural heritage – industrial heritage - eco-museums - Sicily

1. Introduction

Looking towards the existing city - in general, fully built, dense and chaotic - the gradual fade of those values that give meaning to a physical location, allowing its transmission to future generation, is becoming increasingly evident. This loss of identity can be seen in many historic cities, often characterized by atopic landscapes in which stand contemporary edifices built according to homologating processes, unrelated to the morphological and/or constructive relationships with the environment and the permanence of memory. Moving away from the old town, the sense of disorientation is even more understandable: plunged in the urban sprawl, extraordinary signs of the past remain silent and solitary. Used also in relatively recent times for productive purposes and finally forced to abandon the old tasks and the original functions - they are looking for new opportunities to transform and adapt to contemporary needs. These industrial areas, now neglected, deserve to be rediscovered, restored and reconnected to the real world, because they are expression and reflection of those technological, economic and social values that have characterized the so-called "machine age"; of that culture of work that has deeply influenced the course of the 20th century, providing a substantial contribution to the development of human civilization.

Nowadays, they represent the promise and the challenge of intervention possibilities to be undertaken for the sake of future generations [1]. They can also be considered a response to the needs of adaptability and flexibility, increasingly rare in highly structured cities, often degraded, crystallized and congested.

Considered as "empty" spaces because lacking their primary function, they are instead usually "full" of architectural artifacts of a certain local historical significance; rich in symbolic values, meanings, traditional practices and informal uses [2]. These marginal realities actually possess a heritage of great interest: they are a vital resource as their recovery would allow to not use more open areas; in addition, usually already equipped with urbanization works, they are easily accessible and well connected to existing infrastructure system. The return of these spaces to the city may therefore constitute an important opportunity to reshape the urban fabric in which they are located, helping to mend the fragmented peripheral tissues, partly compromised in recent decades by an uncontrolled urbanization [3].

In Sicily, currently in a state of "almost resigned standby" the landscape of sulfur mines, after having fed both the economy of the region and the inspiration of its poets and writers is waiting - as most of the submerged assets of this land - to be unearthed and, above all, valorized as a place of extraordinary individual and collective memory.

2. The important role of mining industry in Sicily

The provinces of Enna, Agrigento and Caltanissetta are the most important and largest areas concerned by the ancient production of sulfur in Sicily. If between the 19th and 20th centuries the parable of the practice of sulfur extraction begins and ends, its history, however, has ancient origins and an evolution strongly linked to the succession of rulers and the resulting political control in the island. Since the Bronze Age (2500 B.C.) an intense activity in the field is, in fact, documented. It reaches its climax at the end of 18th century when the Sicilian sulfur cycle became fully part of the chemical European industry. The consequent need to recover the sulfur in large quantities led, in 1808, under British protection, to the decision of government to give Sicilian aristocracy, the permission for the subsoil exploitation. The opening of mines, begun at the time of British occupation during the Napoleonic wars, then gave life in Sicily to a particular industrial revolution that progressed in parallel to the contemporary English and French experiences [4]. The sulfur produced will be requested from the European market, especially by those nations, as the basic element of the transformation processes in the emerging chemical industry. Because of this, between 1830 and 1835, the number of *cantari* (tons) exported, doubled rising from 380,000 to over 660,000. In 1835, the most of exported sulfur will be directed in Great Britain (325,793) and France (262,774); the remaining amount will join other northern European countries and the United States of America.

However, Sicilian mining was characterized by a high labor exploitation, especially among children: the so-called *carusi* (as recorded in Pirandello's literature, for example, in *Ciàula scopre la luna*). Boys aged between six and fourteen years for a few handfuls of money, were handed over by their parents to the *picconieri* (pick-axe workers) to be used by them to bring to the surface the sulfur ore extracted. Numerous were the laborers who preferred to leave the camps to work in the mines, even in inhuman conditions; the exodus from agriculture was important and greatly influenced the fall in cereal production of large landed estates. Although the establishment of a great "industrial proletariat" for those times (the first statistics, dating back to 1860, show the presence of a job working in the mines of approximately 16,000 units) the "exploitation" of sulfur was a mechanism in colonial style. The whole raw product was destined for foreign market and mainly sold by foreign operators, mostly British, who also took care of credit aspects ensuring a prepayment on delivery.

Such a race to low-cost production often led to overproduction crises which the Bourbon government, in 1835, tried to stem, by entering into a contract with the French company owned by the industrial Aycard and Taix. Thus opening the way for the foreign capital to obtain concessions for the purchase and sale of sulfurous Sicilians deposits. This agreement committed for ten years the company to purchase all sulfur produced in Sicily at a set price. The production had to be contained within certain limits, but they ensured the immediate payment of half of the sulfur delivered. In addition, the Taix & Aycard C. had promised to build a local industry for the preparation of caustic soda and sulfuric acid, and to build sixteen miles of roads per year [5]. In 1840, following the English dealers protests who accused the government of Naples having specifically guaranteed a corner for France, the contract was terminated and with it the ambitious project of creating a Sicilian chemical industry vanished.

In 1850, the discovery of *oidium tuckeri*, a fungus that causes powdery mildew of grape, the demand for mineral increased, making Sicily a leader in the mining sector. A role that it held until the early 20th century and that was closely linked to the strong atmosphere of renewal that concerned Sicily after the unification of Italy until the end of World War I and again between the 1920s and 1930s, especially in the transport and development of regional rail [6]. Depending on the needs of the sulfur, the major mining centers of the island were connected to the main Sicilian ports, then creating the so-called "sulfur-ways".

The crisis in the Sicilian sulfur industry began in the late 19th century with the introduction of the Frasch process, a method of mining deep-lying sulfur named after its inventor - used in U.S. mines with consequent

vertical reduction of market prices. In 1896, in an attempt to reverse the negative trend, Sicilian producers decided to form the Anglo-Sicilian Sulfur Company, promoted by British entrepreneurs and Ignazio Florio, the heir of one of the largest Italian business dynasties of the time [7]. This allowed to stabilize the prices of sulfur and large mines improved facilities and increased the equipment, thanks to the arrival of technical and entrepreneurial middle class from northern Italy. The attempt, however laudable and delivering good results, failed after only ten years: the pressure of American competition meant that the price of sulfur drastically lowered.

Later, the beginning of World War I made it increasingly difficult to supply the mineral causing that sulfur American grabbed much of the world market. The ensuing crisis period affecting Sicilian industry became serious in the 30s, when the global economic crisis strongly penalized the sulfur mines in Sicily until the total collapse of output during the second conflict. The Sicilian sulfur production recovered slightly after 1943, when the war ended and only until the early 1950s, a period in which America, engaged in the Korean War, channeled into the war industry, all its resources.

However, the subsequent revival in U.S. industrial production raked again, all the markets; the competition by then too strong, led to the final decline of the Sicilian sulfur industry and to the gradual closure of the mines.

Since the mid-80s, these places, whose importance for Sicily, the associate territories and people is unquestionable, set off for tragic destinies, made of abandonment and desolation. The economic speculation, the forced removals of these important expressions of the economy and culture of this land, caused the subsequent deletion of expressive traits of its cultural identity that only much later, people will try to reconstruct.

With the Sicilian Regional Law n. 34 of 1988 finally closed, in Sicily, sulfur mining production. In the aim of preserving the memory of the mining industry and culture in the region and to preserve and protect, at least in part, the unique environmental heritage and industrial archeology of sulfur, personages from culture, trade unions and other representative sectors of the society and politics, worked in order to Sicilian legislature approves another law, the n. 17 of 1991, who identified some mines and mining sites to be transformed into mining parks, regional museums of the mines and mine-museums.

In the three major sulfur provinces were chosen for this purpose, the following mines: Gessolungo, Trabia-Tallarita and La Grasta in Caltanissetta; Ciavolotta and Cozzo Disi in Agrigento and, finally, Grottacalda and Floristella in Enna, one of the most expressive settlements of industrial archeology in southern Italy.

3. The history of place

The Floristella and Grottacalda mining site is located in a large area on the outskirts of the town of Enna. Surrounded by a remarkable landscape, it forms an equilateral triangle with two other important polarities: the Pergusa Lake and the Nature Reserve of the Ronza (Fig. 1). The mining site is also located in a basin where cultural and environmental heritage of international interest seat, such as the Villa Romana del Casale in Piazza Armerina and the excavations and the archaeological museum of Aidone, where the famous Venus of Morgantina, returned in 2011 from the Paul Getty Museum in Malibu is hosted. Until 1971, the mines areas were crossed by the disused railway Dittaino-Piazza Armerina-Caltagirone which stopped for the traffic of goods and workers in Mulinello, Floristella, and Grottacalda Valguanera (Fig. 2). Next to the now disused Grottacalda station, 647 meters above sea level, there is a forest green that extends over 1.5 km.

The complex brings together two abandoned sulfur mines with a total surface of 400 acres: of these, one half, the core of Grottacalda is a private property and the other, the nucleus of Floristella, is owned by the Sicily's Regional administration (fig. 3).

As documented by the archives of the Royal Corps of Mines of Caltanissetta, Grottacalda started its mining activities in 1815, even if the sulfur research in this area is thought to date from a period between 1700 and 1750 [8]. Sebastian Mottura, creator and first director of the first Mining School of Italy, founded in 1862 in Caltanissetta, traveling between 1868 and 1875 to design the first official geological map of Italy commissioned by the Government, when surveyed areas in central Sicily, wrote that the *solfara* (sulfur mine) *Galati* in Grottacalda was one of the oldest in Sicily. The land belonged to Romualdo Trigona, Prince of St. Elias, who in 1886 granted the right to carry out extraction activities to Trevelia & C company maintaining it for several years. In 1919 the *Società Solfifera Siciliana* acquired the concession for extraction and, subsequently, after its fusion with the *Montecatini - Società Generale per l'Industria Mineraria e Chimica* (later *Montedison*), a perpetual license was required and granted in 1943. The events immediately following the war caused serious problems in the ordinary development of activities. Due to the lack of electric current, it was impossible to perform the mine drainage water procedures. A few years later, the Montecatini decided to abandon the industry and to convert it in an agriculture business, dividing the area into several farms, of which still remains some witnesses on the façade statements of certain buildings.

Fig. 3: The mining site of Grottafaldia and Floristella and its cultural heritage (courtesy by Alessandro Ensabella).

In accordance with an agreement established between the company and the Grottafalda's miners to exploit the high areas of the mine, activities continued until 1963, the year of expiration of the concession. Of this important mining activity (among the largest in Sicily) now remains a vast as degraded heritage: castles in masonry, concrete drop structures located near the extraordinary Mezzena Well (Fig. 4 and 5), the so called *Pozzo Grande* built in 1868, the *calcaroni* (masonry furnaces), several buildings, formerly used as housing for the miners and the administrative staff, the former power station, a cinema, the buildings of the former railway station. Recently, some of these buildings have been converted to farm holidays structure by the current owners [9].

On the other hands, with regard to the mine Floristella, the permission opening was granted on April 11, 1825 although the extraction of sulfur happened even earlier, after the discovery, in 1791, of the method of manufacture of soda obtained by treating with sulfuric acid, the common salt. This field was one of the most important mining district of Caltanissetta, not only for its productivity but also for the quality of the sulfur that was extracted: so high as to constitute a standard of excellence in the market.

The mining area of Floristella preserves the typical landscape of the Sicilian *zolfiera*. Like a great open-air museum, the huge mining complex provides a true "stratigraphy" of different eras and related systems and techniques of sulfur mining and smelting. Inside, in fact, are present and clearly visible countless galleries and about 180 *discenderie* (shafts) from where the sulfur was knocked down by the traditional pick to be then transported to the so-called *calcarelle* (a sort of circular ditches with a 1.50-2 meters diameter with an inclined plain so to allow the casting of the molten sulfur towards an opening called a *morte* - death - where it solidified) that are still preserved in good condition, near wells and galleries. It can also be seen what remains of industrially masonry furnaces, several examples of the so-called Gill furnaces (invented in 1880 by Robert Gill), of castles complete with winch (the oldest dating back to 1868), in addition to the ruins of service buildings arisen in the vicinity of the wells (nursing, accommodation for the miners, including the room used as a recreational club for workers).

On a hill stands the imposing *Palazzo Pennisi*, former residence of the owner family, which dominates the entire mining area of Floristella of which it represent the real heart (Fig. 6). Built between 1870 and 1885, initially only until the ground floor by Baron Pennisi, nobleman from Acireale, it was intended as a summer residence for the family. The *Palazzo* was later raised to two other plans to meet the need for accommodation of the mine manager and employees, and for setting up office facilities. It was designed to be an impregnable fortress: unable to be taken by the miners in the event of strikes and riots. For this reason, the numerous openings were equipped with louvers and inside - in addition to housing, offices, chambers of operation, an octagonal chapel, the coal cellar, barns, cellars - there are some secret safety exits that, through the cellars and two small galleries, allowed to escape from the Palace in the ridge below. The magnificence of the building and its architectural value, generate a kind of contrast with the austerity of the place, providing an immediate and exciting image of what should be the extreme social gap of that time.

Fig. 4: The Pozzo Mezzena.

Fig. 5: Laser scan 3D of the Pozzo Mezzena.

Over the years, and with the exponential growth of mining industry, the building became the headquarters of the mine until its definitive closure. Following its sale, the building has long been abandoned. Because of its poor conditions, urgent consolidation works have been recently carried out, looking forward to finally be restored to one day be transformed in a museum of industrial archeology. Worth mentioning are also water catchment system structures situated therein, the millstone of the Pennisi's family and the so-called *via del mosto*: a trail, originally built for the purpose of enabling a quick connection between the winery and the Palace, flanked by an ancient gutter made by Sicilian tiles who brought the must to fall directly into the cellars.

4. Prospects for the future

Floristella was one of the last Sicilian mines to close the door in the late 1980s. The abandonment of structures, however suddenly happened, led to a period of great destruction, vandalism and theft that have largely compromised an unique heritage, consisting of buildings, equipments, warehouse stock, often irreversibly damaged or disappeared. To overcome these problems, unfortunately common to all Sicilian sulfur mines, regional government promulgated on May 15, 1991 the law n. 17 that established in this area, the *Ente Parco Minerario* (Park Mining Authority) in order to defend and protect the natural and human landscape. By taking appropriate safeguard measures, this tool would be able to stop the degradation of this rich set of cultural assets. Nevertheless, despite the commitment of its administrators, it has not allowed to completely prevent the rapid destruction and decay processes that characterize today a large part of the former mining site. If a number of "recovery, protection and restoration" actions were executed in the Park, and as much are foreseen (waiting for funding), an objective data is source of concern: the almost total indifference of the local population who do not know, do not understand it and/or it does not recognize itself in this place. In part, privately owned and difficult to reach due to the absence of practicable roads and to the presence of fences, the goods of this important industrial heritage, now fragmented, seem to move towards the complete annihilation and with them the memory of the place and people who have populated it. Not taking advantage of special attention from architectural critics or the interest of younger generations, this site lies unexplored and isolated, although it deserve to be recovered.

In recent years there has however been an increasing interest in the requalification and valorization of the Sicilian dismissed sulfur mines, which occurred mainly at the institutional level. This renewed attention is now accompanied by the possibility of developing reasoned and concrete actions of protection and promotion. They would certainly be helped by the presence of the *Parco nazionale geominerario delle Zolfare di Sicilia* that a regional bill proposes to establish. This initiative aims at strengthening the provisions ensuring the defense of the extraordinary industrial heritage of Sicily and to implement that "subsidiarity" principle that appears necessary to allow the enhancement of the specific cultural, economic, historical and natural values of the social and territorial realities involved.

In Italy, the experience of Geoparks has now reached a good level of maturity, in particular, with the creation of the Geo-mining Historical Environmental Park of Sardinia and the implementation of other important initiatives that merit to be studied and investigated. The meaning and the cultural contents of these realities are by now concrete matters of record which a proper management policy of the historico-morphological resources of the territory would necessarily refer to. They reflect an interest no longer being limited to the respect and recognition of the natural values but that is part of the broader concept of "cultural heritage". To the deep meaning of nature to be preserved is thus added the need to also consider the value of human presence and that of all the signs of working activities and land transformation connected to it. In this context, the concept of cultural heritage has gradually freed from the aesthetic values to include today the social aspects, even the intangible or virtual ones, once considered exclusively the subject of specific and exclusive studies [10; 11]. This should not be understood as a new complication, but, on the contrary, the testimony of a broader and generalized awareness of the meaning of human presence, of the role of the work, which could become a powerful catalyst capable of triggering processes of growth and improvement of the quality of life in the concerned places.

The establishment of the *Parco nazionale geominerario delle Zolfare di Sicilia* is part of this worship process and is focused on the idea to create a *museo diffuso*, a kind of extended museum at regional scale, really considering the whole island as such, seeking at improving natural and ethno-anthropological qualities.

Will this project (clearly top-down based) achieve the results aimed by Politics? Will it succeed in facilitating the rediscovery of that authentic local culture that is needed in order to preserve and affirm people's identity and to highlight the differences for the purposes of an overall socio-economic development?

Probably not, unless of first rebuild the "reasons" of such settlements, giving them a "sense", at present lost. This, in the conviction that only what is understood and of what are known the true motives and

Fig. 6: Palazzo Pennisi.

meanings, can be properly maintained: "in a few words, the history that is deposited in them that, through the memory of each of us can be passed on to others because they make appropriate use" [12].

Only by implementing forms of coordination referring to the complex system of natural, cultural and landscape values of the individual local entities, based on a specific relationship with the existing institutional protection instruments and in close connection with local people and research entities located in the area, such as universities, these places will become very important resources for the territory and its community.

In this context, it may be useful to have recourse to the concept of eco-museum, actually a pretty well established reality at international level but that only in recent years has come into common usage in the Italian context [13]. On the basis of the eco-museum approach, the territory should not be considered as the physical place where monumental isolated elements are located, but as a complex system of goods and people that interact to compose the whole structure. The desire for innovation, born from the belief that museums should not just collect, display and tell the story of objects in them stored but talking about people and ideas, has contributed to the design of new organizational systems aiming at retracing and describing the history of physical contexts, places and landscapes of the spirit, facts, atmospheres, works, legible forms, all also signs of a past history. The eco-museum can be seen as the possibility that the museum's idea could be extended over an entire area, involving in the process the population, finding a new sense to old settlements, obsolete objects and methods, reusing them for new productive and cultural purposes: "It is, in particular, for the local population that the eco-museum should be established. So that they would recover lost traditions and, simultaneously, preserve cultural heritage - tangible and intangible - and the environment, promote sustainable social, recreational, touristic development and through it, valorize resources and create new or more skilled jobs [Boriani]. The success of these initiatives, however, highly depends not only on economic factors, will and management abilities, but also on the quality of the restoration, reuse and enhancement activities carried out on the goods involved in the projects or thereto related. To this end, it is essential to focus on the issue of conservation of anthropological, natural, environmental, landscape, historical and architectural characters in the area, starting from (finally!) implementing those basic processes of direct knowledge (metric, material and environmental) directed not only to the buildings of major importance but also to the so-called "minor" heritage often, still, incorrectly underestimated.

5. Conclusions

These are the principles that should motivate the material and spiritual rebirth of the Floristella Grottaacalda mining site and with it the whole territory. In an era dominated by changes brought on globalization processes and on the increasing risk of homogenization, the only possibility of distinction and self-affirmation of different places should be entrusted into the recovery of their identity. Only by the endogenous strengthening of these characters it is possible to find the reasons of a desirable self-healing.

Since some time on, the presence of many urban and peri-urban "empties" characterizes most Sicilian big cities. Areas mainly resulting from industrial decommissioning processes, remained largely ignored by the urban development strategies that, at least until the mid-90s of the last century have preferred new forms of expansion, mainly directed to the residential sector [14]. These pieces of land, made unproductive for purely economic reasons and now emptied of meaning, can become, if properly rehabilitated, the ideal places where osmotic processes between past and present, human activities and nature; between the man and the city where he lives and in which he should be able to identify and find himself, would be reactivated. These

sites could serve as a stimulus for a re-evaluation of the city as a whole, reconsidering years of segregation and zoning policies, reactivating virtuous processes of local governance aimed at rehabilitating the many wounds inflicted on the landscape, places and people's identity.

It seems clear that the economic and cultural recovery has now become necessary and urgent in order to allow the reuse of these areas for productive and social purposes, allowing their re-appropriation by the local population which has the legitimate right of consumption.

Le *tanneries* di Barjols: uno spazio costruito da reinventare

Laura BLOTTO

Dipartimento Architettura e Design, Politecnico di Torino, Italia
E-mail: laura.blotto@polito.it

Abstract ID034 The *tanneries* of Barjols: a space built by reinventing

The spectacle of abandoned factories is a fairly common phenomenon, the old factories reduced to empty containers become places of memory, evidence of intense and sheer hard work, which for centuries has involved generations, distorted and modified through the initiatives of individuals, the environment and the territory. Although apparently they all look alike, on closer inspection they reveal different realities starting in the places in which they live, their winds along the water supply sources and their planimetric and typological development and who do not respond to the same quantitative and qualitative parameters.

Certainly these buildings define and confer, with their silhouettes, the identity of a territory.

The case examined has focused attention on the reality of a post-industrial town in the central Provence where the activities of Tanneries have influenced over a long period of time the life and choices of a population. Faced with this scenario, composed of disturbing manufactures abandoned, but still present and very close to the heart of the local people, one wonders what will be their future, we will investigate the measures taken and what the intentions are planned with a view to sustainability global.

Parole chiave: Barjols, fabbriche, riconversione, ambiente

Lo spettacolo delle fabbriche abbandonate è un fenomeno piuttosto frequente, le antiche fabbriche ridotte a vuoti contenitori diventano luoghi della memoria, testimonianze di intenso ed alacre lavoro che per secoli ha coinvolto generazioni di famiglie, stravolto e modificato attraverso le iniziative dei singoli, l'ambiente e il territorio. Anche se all'apparenza sembrano tutte eguali, a ben vedere esse rivelano realtà diverse a cominciare dai luoghi in cui sono inserite, il loro snodarsi lungo le fonti di approvvigionamento idrico ed il loro sviluppo planimetrico e tipologico che appare diverso nei parametri quantitativi e qualitativi. Certamente questi fabbricati conferiscono e definiscono, con la loro silhouette, l'identità di un territorio.

Il caso preso in esame ha focalizzato l'attenzione sulla realtà post-industriale di un paese della Provenza centrale dove l'attività delle *tanneries* ha influenzato per un lungo lasso di tempo la vita e le scelte di una popolazione. Di fronte a questo scenario composto da inquietanti manufatti abbandonati, ma pur sempre molto presenti e vicini al cuore della gente del luogo, ci si domanda quale sarà il loro futuro, si indagherà sui provvedimenti adottati e quali intendimenti sono previsti nell'ottica di una sostenibilità globale.

Fig. 1 - Immagine d'insieme delle tannerie di Barjols (foto di L. Blotto)

Situato alle porte dell'Haut Provence, nell'alto Var, il comune di Barjols è l'epicentro di un cerchio di interesse i cui estremi si identificano nei poli di attrazione di Marsiglia, Tolone, la Costa Azzurra e il Parco Naturale Regionale del Verdon. Esso si trova all'incrocio dei grandi assi di comunicazione di Aix-en-Provence – Nizza e Marsiglia – Sisteron. Si presenta come un villaggio tipico della Francia del Sud, con un centro storico attraversato da ripide viuzze che sfociano in piazzette ombreggiate da platani centenari e le sue fontane disseminate sul territorio che costituiscono motivo di interesse turistico.

Barjols deve la sua notorietà alle concerie già presenti dall'inizio del XVI Secolo, le quali hanno costituito l'unica risorsa economica del paese fino alla seconda metà del Novecento.

Esse sono ubicate in un vallone all'ingresso del paese e si snodano lungo il corso del torrente Fauvery, il loro stato di abbandono offre ai visitatori un'immagine del luogo molto negativa pur essendo inserite in un contesto ambientale naturale rimarchevole.

Lo sviluppo planimetrico del paese è orientato da est a ovest, nel quartiere delle concerie si osserva una dilatazione della scala delle particelle catastali. In pianta è ben visibile il contrasto tra i due spazi urbani: il centro storico e la zona delle *tannerie* sono addossate l'una all'altra, semplicemente separate da un muraglione di sostegno.

La questione della riconversione di queste strutture è complessa ma essenziale per lo sviluppo di Barjols. Si rende necessario, anche in funzione dell'estensione del sito un progetto globale dell'intera area che la ridinamizzi e la restituisca agli abitanti.

Passando quindi ad un'attenta analisi della situazione attuale, emerge che il quartiere è composto da quattro fabbriche principali che appartengono alle famiglie Vaillant e Plauchud, con una superficie variabile dagli ottomila ai diecimila metri quadrati ciascuna. Per via delle differenti date di costruzione, aggiunte e riadattamenti, si osserva una disomogeneità architettonica che fa pensare ad una mancanza di logica costruttiva. La difficoltà di lettura dell'intero complesso industriale è accentuata dalla forte pendenza del terreno.

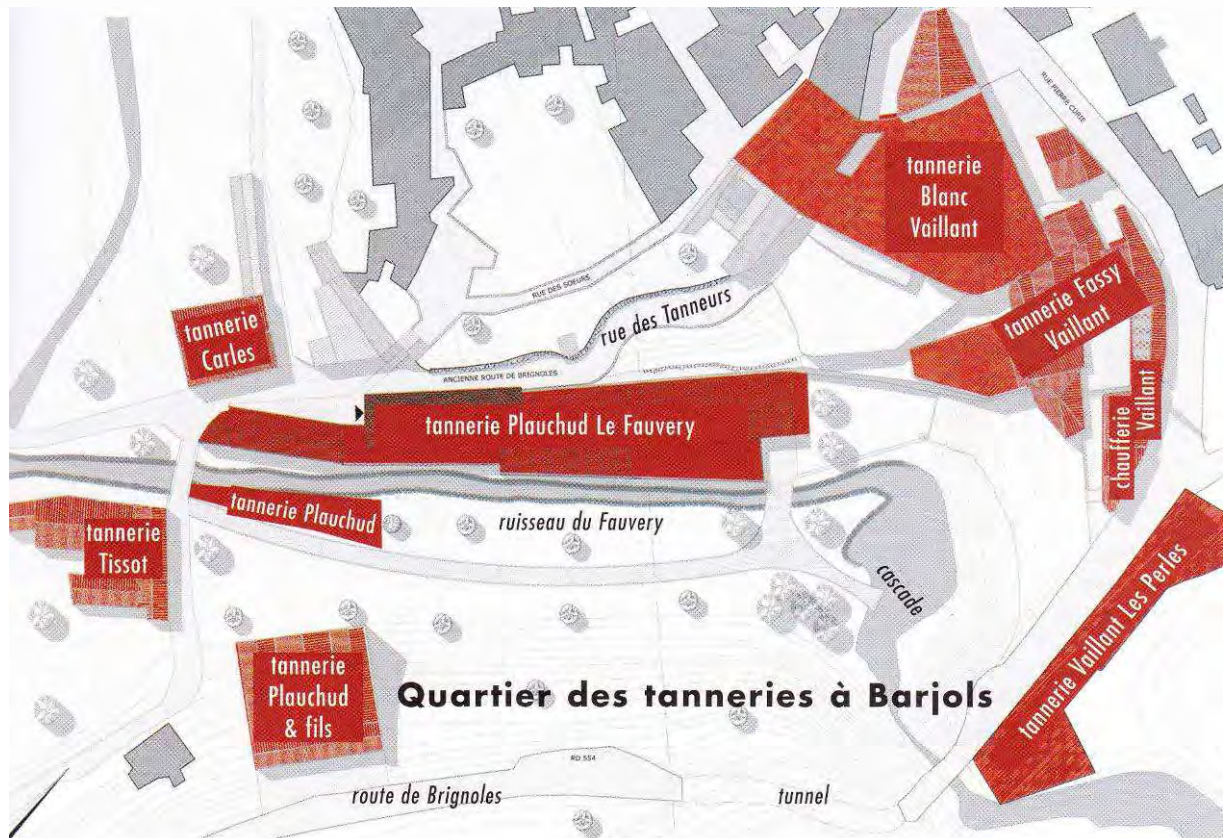

Fig. 2 - Piano del quartiere delle concerie redatto dall'Arch. Nicolas Coquillas

Provenendo da sud sulla strada dipartimentale di Brignoles ed oltrepassato il tunnel all'imbocco di Barjols, ci si ritrova su uno strapiombo dominante le *tanneries*, che si rivelano come un intreccio di volumi incastrati gli uni agli altri con una tessitura estremamente eterogenea.

Le *tanneries* Vaillant sono di proprietà privata e fanno parte del Patrimonio industriale nazionale. Il fabbricato si sviluppa su più piani in verticale con ampi spazi atti ad accogliere il voluminoso apparato della lavorazione. Come per tutte le altre concerie questo sistema costruttivo è in funzione alla successione dei trattamenti che dovevano subire le pesanti e voluminose pelli. Il tipo di lavorazione si basa esclusivamente sull'acqua per le diverse operazioni. In mancanza di spazio si è dovuto ampliare e ricostruire sulle preesistenze, così le nuove trame di pilastri in cemento armato si sono sovrapposte ai vecchi muri tradizionali.

Le nuove concerie Plauchud & fils sono ubicate nella parte bassa di Barjols, si presentano in buono stato e non necessitano di misure conservative. Per contro le dimensioni e l'impatto visivo male si integrano nel contesto paesaggistico. Costruite dopo la II guerra mondiale, all'incirca nel 1950, dovevano contenere tutte le fasi di lavorazione, per cui ne risulta un edificio di gigantesche dimensioni che domina l'intera zona. Il vecchio complesso Plauchud è situato lungo il torrente Fauvery ed attualmente è in parte occupato da artisti ed artigiani. La sua divisione in lotti operata dall'amministrazione comunale nel 1980, ha determinato numerose modifiche plani-volumetriche e di distribuzione interna, conferendo ulteriore eterogeneità alla costruzione. Addossato al muro di sostegno orientale del centro storico ha subito durante il XX secolo numerosi rimaneggiamenti effettuati su una pianta settecentesca.

Attualmente, in gran parte, queste fabbriche si presentano in grave stato di degrado e abbandono e ci si domanda quali possano essere le strategie di recupero, rifunzionalizzazione e riconversione di quest'area dismessa, ma con enormi potenzialità soprattutto in termini di spazio e valori intrinseci di memoria storica, territoriale e culturale. Alla voce "manufatto storico" che qui ci interessa il vocabolario parla "un oggetto fatto dall'uomo e realizzato in altri tempi spesso con altra destinazione e finalità, appartenente ad una realtà oggettivamente accertata e alla storia quale seguito di avvenimenti" sul territorio antropizzato.

Il monumento storico rappresentato dalle *tanneries* di Barjols può e deve essere esaminato secondo i parametri della sua storia delle vicende pregresse, della spazialità originaria, della collocazione sul

territorio, della durata temporale delle sue funzioni primordiali e di quelle diverse assunte nei secoli. Di fronte alla necessità di recuperare alla piena funzione un concreto manufatto storico, per lo più – come già si è detto – in condizioni di degrado per la perdita della propria funzione originaria -, occorre un indispensabile processo di riplasmazione della infinita offerta di spazi interconnessi dei quali non debbono venire alterati i rapporti, se non con la massima cautela e in misura tale da non sconvolgere assolutamente l'effetto della spazialità globale.

Le vestigia, le fabbriche, macchine, archivi ed attrezzi sono testimoni insostituibili delle condizioni di lavoro e del modo di vivere di un'epoca e rappresentano un valore patrimoniale nonché didattico. In ragione del loro passato prestigioso, del loro carattere estetico e del loro valore simbolico un certo numero di edifici meriterebbero di essere valorizzati. E' proprio attraverso lo studio dei valori intrinseci ed un approccio rigoroso che si potrà intervenire sulle antiche concerie di Barjols.

In merito al tema della riconversione constatiamo come spesso magazzini, mercati coperti, caserme, fabbriche edificate ai fini della produzione industriale o commerciale si siano trasformati ed adibiti a nuovi usi anche mediante l'intervento di un determinato movimento artistico e cittadino, nato dall'incontro tra gli spazi abbandonati e l'impegno di artisti.

Nel paesaggio urbano in Europa dalla fine del XX secolo molti dei luoghi simbolo di un'era industriale hanno cessato la loro ragione d'essere e si sono trasformati in vuoti contenitori. Attraverso la creatività artistica e culturale, la popolazione locale, mettendo in opera le proprie competenze, ha riqualificato queste aree di memoria trasformandole in spazi di lavoro orientati a tutte le discipline artistiche, ateliers, luoghi di incontro e svago. Si è resa possibile una formidabile inversione di marcia nell'utilizzo di questi fabbricati, altrimenti destinati ad un inesorabile declino, avviandoli ad un futuro di rinnovamento. Questi nuovi centri di cultura rappresentano i simboli di un'evoluzione positiva e costruttiva del territorio, questi luoghi fortemente intrisi della storia di un mondo in movimento sono diventati "i nuovi territori dell'arte", le "artfactories" del legame tra creatività artistica e creatività sociale, essi sono il fulcro delle riflessioni sul ruolo dell'arte nel contesto della nostra società.

Fig. 3 – Le tanneries Plauchud sul torrente Faubery (Foto di L. Blotto)

Fig. 4 – Sviluppo verticale anni cinquanta – sessanta (foto di L. Blotto)

Il caso esaminato di Barjols si inserisce nel contesto, ormai piuttosto frequente a livello europeo ed extraeuropeo, di riconversioni di manufatti dismessi. Tra gli innumerevoli esempi di riconversione ricordiamo la UfaFabrik di Berlino, dove negli antichi locali della Compagnia cinematografica UFA, su un'area di 18.500 mq. ha preso vita un'associazione a scopo non lucrativo che si occupa di musica, danza, teatro, circo, comunicazione e percezione visiva, cinema, formazione artistica, e progetti ecologici.

Ed ancora l'Échangeur a Fère-en-tardenois in Francia (ex magazzini di cereali), l'Hangar di Barcellona (ex depositi), il Centro K@2 Liepaja in Lettonia (ex quartiere militare), le Fonderie Darling di Montreal (Canada) ed infine la Friche de la Belle de Mai a Marsiglia, antica manifattura dei tabacchi dove su una superficie di 45.000 mq. la struttura polivalente e pluridisciplinare ospita tre sale di spettacolo, uffici, cybercafé, gallerie d'arte, scuole di danza, 18 ateliers, bar e spazi modulabili.

Se però confrontiamo la struttura di Marsiglia a quella di Barjols, si constata che non ci sono similitudini sia per quanto riguarda la forma architettonica che per quanto riguarda il contenuto del progetto, oltre che la differenza di scala a livello urbano e della popolazione residente. Inoltre, a Barjols le vecchie concerie presentano la particolarità di offrire più fabbricati contrariamente a la Belle de Mai, ed agli esempi citati che si concentrano in un solo blocco. Inoltre queste concerie appartengono per lo più a diverse famiglie di imprenditori, da qui la difficoltà di portare avanti un progetto sostenibile condiviso da tutti. Soltanto le fabbriche Vaillant, dopo la cessata attività, hanno cercato di inserire nell'area degli artigiani, soppiantati verso la fine degli anni ottanta da un gruppo composto da una trentina di artisti che pian piano hanno organizzato i loro ateliers riabilitando l'immagine del luogo. Gli abitanti, d'altro canto, sono grati a loro per aver conservato il patrimonio architettonico e di non averlo snaturato nell'opera di restauro, inoltre grazie al loro lavoro e ai contatti esterni si è inserito Barjols in un reticolo più vasto di immagine culturale del paese, supportato il tutto da una attenta divulgazione tramite internet.

La loro presenza ed attività di recupero culturale e formale si è focalizzata con successo solo su una parte dell'intero complesso. Dopo questo primo lotto di interventi si guarda con entusiasmo e determinazione, non priva di cautela, verso il futuro delle *tanneries*.

Fig. 5 – 6 L'alimentazione idrica delle tanneries e le cascate del Fauvery (foto di L: Blotto)

Osservando da vicino, passeggiando tra questi vuoti contenitori, sbirciando all'interno, ci si accorge che c'è sempre qualcosa da scoprire, soluzioni architettoniche che non mostrano mai lo stesso aspetto, ma cambiano ad ogni passo, uno spazio dinamico che suggerisce idee e progetti.

Tra gli studi presentati ritengo di particolare interesse quello degli architetti Elise Michel e Nicolas Coquillas relativo alle conerie Plauchud. Il tema affrontato è quello museografico e si esplica nell'Ecomuseo delle *tanneries* e la *Maison de l'Eau* che investono due settori differenti ma complementari tra di essi. Il progetto per utilizzare al meglio le qualità dell'edificio si organizza in tre comparti di cui due dedicati ai musei ed il terzo è costituito dai servizi destinati al pubblico e agli spazi di circolazione e parcheggio.

L'elemento acqua è il filo conduttore che ha caratterizzato e accompagnato tutta l'evoluzione storica di quest'area sin dai tempi remoti del Medioevo quando lungo il torrente Fauvery, su impianto monastico, si stabilirono le conerie le quali, a loro volta, si moltiplicarono fino alla saturazione degli spazi esistenti. La sua presenza costituisce un valore aggiunto in positivo nella lettura di questo paesaggio: sgorgando a nord di Barjols, il corso d'acqua forma delle rumorose cascate che si immergono in un piccolo laghetto dall'aspetto un po' selvaggio per poi dileguarsi a valle dopo aver lambito i fabbricati oggi abbandonati. Valorizzare questo elemento così vivo in un contesto ridotto al silenzio, con l'istituzione di una *Maison de l'Eau* significa non solo sottolineare il valore della sua utilità e impiego, ma soprattutto dare nuova immagine sia al sito industriale che al contesto generale.

Molto lavoro è stato fatto ed il percorso è ancora lungo, ma appare evidente che esigenze ed interessi dovrebbero convergere verso una ricerca nei confronti del "patrimonio", sia esso contenuto che contenitore, ambientale paesaggistico. Le metodiche di gestione è necessario che siano coerenti nel raggiungimento di un rapporto sia pure dinamico per la mutazione del contesto culturale ma sempre protese all'istanza di conservazione. Diventa importante dunque saper cogliere in ogni fase del processo intrapreso quelle che possiamo definire duttilità prestazionali dei singoli elementi, vagliando presenza e valori delle potenzialità ancora latenti o appena timidamente emergenti: le più difficili da definire con esattezza ma forse le più delicate e importanti.

Possiamo dire infine che ogni ricerca ricostruttiva, dalla più libera e possibilmente alla più rigorosa deve tendere a creare un sentimento emozionale tale che le orme e la memoria di un passato ritornino in tutta la loro complessità ed estensione con vitalità quasi virtuale.

The design of the urban centers of the Amalfi Coast

Maria Archetta RUSSO

e-mail: mariaarchetta.russo@unina2.it

Abstract

The Amalfi Coast is made up of towns having different organisation, more or less in contact with the sea. While to the west of Amalfi agglomerations consist of centers located at different altitudes, often on top of coastal cliffs, the city and the east side are arranged at the mouth of streams, on sandy shores, and take advantage of the same side of the valleys, with houses on the hillsides, served by flights of steps, sometimes extremely steep. The main elements are represented by small villages, gathered around a church and connected by pedestrian streets, almost always stepped in to bridge the existing soil, arranged in terraces. Centers in the east, the narrowness of the implant site has produced the initial welding sets, resulting in a compact urban structure, however, in the western and interior areas, the different terrain and the absence of constraints have allowed the preservation of isolated small centers.

The conservation of this unique environment, recognized World Heritage Site, cannot ignore the preservation of the ancient urban structure of the Amalfi Coast.

Parole chiave: Amalfi Coast, village, road.

1. Environmental features

The territory of the Amalfi Coast is marked by high, jagged mountain peaks, interspersed with deep valleys in which flow streams to torrential regime. It overlooks the sea with breathtaking cliffs, here and there interrupted by short sandy coasts.

Through painstaking work, between X and XIII century, the soil, originally much steeper, was tilled and terraced, obtaining narrow strips of land, contained by stone walls, which allowed agricultural development. The work led to the transformation of the environment in a hospitable context, creating at the same time, a system for the control of irrigation water. A dense network of roads, mainly tiers, was drawn, providing the overarching framework for urban settlements, in the full merger of the natural landscape with buildings [1].

The same principle of the terraces was adopted for buildings that, resting on a lower level, develop in height, becoming thicker as that the withdrawal of the slope allows the expansion of the sub-base.

The different villages, of medieval origins roughly contemporary with the aforementioned large territorial transformation, are placed both on the coast, and inland areas, at different altitudes between them.

Celebrated for their beauty and panoramic views, and especially for the valuable historical and artistic heritage preserved, they are the result of ingenious adaptations to tectonic conditions often prohibitive and of maximum use of scarce resources available. Each one is a unique example that, although in different combinations, modulates a common matrix. Originally a small group, formed around a church and attested on a road that provides internal communications and, prolonged, as with other centers more or less close.

By examining the different areas it can be seen that, as far as the coastal areas, agglomerations west of Amalfi - Positano, Praiano, Furore and Conca dei Marini - are located at the top, above the cliffs that plunge into the sea. Instead, the cities the eastern side - Atrani, Maiori, Minori, Cetara, Vietri - are at the mouth of streams, beaches and looked forward to using the system the same sides of the valley where the waters flow. The narrowness of the sites has resulted in the progressive welding of primitive aggregates, giving rise

to compact settlements, in which the housing, distributed over the strokes made smooth and attached to the heights, overlap one another. Instead, if there are no constraints to the expansion, there are different villages, more or less apart, as in the villages of Amalfi, in the municipalities of the western slope and in those mountains of Scala, Ravello and Tramonti.

As we anticipated, the connective element of this complex system is the road texture, developed together with the redefinition of the territory operated in the Middle Ages. The routes, remained almost unscathed through the first half of the nineteenth century, assured communications within the Coast and outward, to the area of Naples and Sorrento, the Agro Nocerino-Sarnese and at Salerno. In the rough paths, passable only on foot or by mule, to recognize a hierarchical role: the main, delineated using the lowest possible lines of lesser steepness, welcome secondary steep slope, almost always steps, which extend up to furthest reaches of the settlements.

Despite the many alterations of the original topography, produced over time by natural events such as landslides and floods, or the construction of roads suitable for vehicles started in the early nineteenth century, you can still read the old distribution which overlapped and joined by the modern stage. The new routes are cleared, interrupting and overlapping in many of the earlier, and have completely subverted the traditional approach to the territory with their pace on the edge of the coast, galleries, winding roads and bridges to overcome mountains, hills and valleys frequently [2, 3].

The area is served by the national road of the Amalfi Coast n. 163 and n. 366 of Agerola, whose trace has a major influence on the original urban design, with deep and irreversible upheaval in some of the countries traversed. The first, which runs from east to west along the coast, joined in the first half of the nineteenth century, Amalfi and Vietri, last quarter, with Meta di Sorrento and Positano, in the same section was begun the latter 'other, direct from Amalfi agerolino plateau and from there to Castellammare, only ended in 1930.

The economy of this discussion only allows a rapid excursus on the organization of individual centers, each of which deserves a long and detailed examination impossible here. Therefore we will focus especially on the common characteristics and distinctive features present in each of them.

Fig. 1: Amalfi.

2. Amalfi and the eastern side

The image of Amalfi is emblematic of the towns eastern side of the sea, which summarizes all the features, interpreting them in the most noble and complete. The view from the sea shows the similarity of their system, strongly influenced by the size of the valley in which are situated: very close to that outlined by Dragone Atrani, wide to Maiori, where Reginna expands increasingly in descending Tramonti [4].

The former capital of the Duchy stands in a majestic setting, surrounded by high jagged peaks: Mount Aureo east, crowned by the Tower of Ziro and ending at the sea in Cape Atrani said, improperly fitted the tower called "Saracen", to impassable west and rugged peaks, steep, which seems to cling to the complex of the Capuchins, now a hotel. Behind the beach, separated from the mouth of Canneto, stood the village, located inside the gorge for the full depth of the stream and collected on the side slopes, the East dominated by the long colonnade of cemetery monuments - the largest nineteenth-century architectural creation of the Coast - culminating in the opposite quarter Vagliendola, who closed the city from this side. The shape of the blocks is determined mainly by the need to adapt as best as to the orography of the land and enjoy the most advantageous exposure. The narrowness of the site generates an aggregate very concentrated - at first sight, chaotic - in which the volumes are superimposed along the slopes that line the main road, creating small neighborhoods interspersed with forest and terraced by sharp jumps and natural. In a well articulated together play a vital role connections, trust in the way hierarchical connotation. The central axis, which crosses the city from the ancient north gate to the cathedral, was obtained between the thirteenth and fourteenth century with the coverage of the stream, defining the main director of commercial expansion, the new route roughly parallels that replaced the old, satisfying the lines of lesser slope, running toward the north, at higher levels. Dark, winding stairs climb up the sides cross the hills, often becoming galleries underpassing buildings, reaching the highest areas, even reaching to the neighboring centers.

This network, which includes monuments of great importance - on which this is not the place to linger - and small buildings, is dotted with Medieval, Baroque, nineteenth and early twentieth century and even more qualified by the recent discovery of structures traced back to Classical times.

In the dense urban network remains the original appearance of Amalfi, on which we have settled the next steps, to this day. Unlike most of the common neighbors, thankfully, modern infrastructure was affected only on the band immediately behind the coast, leaving almost unchanged the back, though seriously disturbed by tampering or by altering and incongruous growths contemporaries.

Eastern centers reproduce on more or less reduced scale the same structure. Atrani, which follows, enters the valley of the Dragon, which, extending to the north, separated from Ravello Scala. The agglomeration, enriched by important artistic and architectural emergencies, draws further suggestion by the presence in the field of higher rock chapels and large natural cavities. Unfortunately, it is irreparably altered the sight overboard with multiple spans of the viaduct on which the carriage passes, erected on the beach, in the first half of the nineteenth century, to connect the logs of road from Amalfi and Minori.

Continuing his journey, the artery bursts in Minori, cutting through the western area and proceeding parallel to the beach, up to the altitude of which stands the tower Mezzacapo ledge that marks the border with Maiori. The original village stood on slopes, almost perpendicular to the west. Behind the coast lies the

Fig. 2-3: Atrani.

Fig. 4: Maiori, plan 1848.

Fig. 5: Maiori, plan today.

important archaeological site of Roman villa, not far from the basilica of St. Trofimenia point of convergence of the old pedestrian from small villages, to the high position and the rugged terrain and convoluted, retain most of their plant. Instead, in the valley, the national road has driven following settlements, encouraging, especially in the second half of the twentieth century, a mainly speculative housing.

The contiguous Maiori, second city of the area after Amalfi, extends over a wide area facing a long sandy beach, enclosed by headlands, each with a tower - the western transformed into the castle Mezzacapo, the East called 'Normanna'. In the middle of the beach leads to the Reginna, who, descending from Tramonti, divided the territory for the full depth, drawing on the sides of a flat band, which expands more and more, as it approaches its mouth, until, in last sector, roughly the width of the beach.

The first settlements were on the banks of the river - around which, in the northern areas there were numerous factories - and on the steps that wound along the side slopes, the West topped by medieval Church St. Maria a Mare. Large architectural complexes are still present, both religious and civil, facing the last stretch of the river, whose coverage generates a kind of long square, condition almost unique to the Coast. The interior and the sea areas now saturated with buildings, most of which show recognizable interventions of the last half century, which concluded the work of urbanization of fertile arable land between the houses and the coast, started to mid-nineteenth century, together with the stock, with a workforce program by architect Pietro Valente. The idea, a real town redevelopment project the image in order to demonstrate the economic Influence experience, led to the revision of the western sector, drifting the mother church and reversing the orientation, opening the entrance to the valley, above an imposing staircase that emulates that of the cathedral of Amalfi. Being into the valley, the village becomes more and more scarce, giving way to numerous plants, both served by modern provincial road Maiori-Chiunzi, which runs on the eastern edge, is the stretch that goes on the opposite shore, coinciding with the way driveway of age Bourbon, Tramonti direct and Sarno Valley, then abandoned, opting for the route along the coast to Vietri. At the high, you will find the villages of Vecite and Ponteprimario, perched in the foothills overlooking the gorge, on the border with Tramonti.

The small fishing village of Cetara, distorted by today's port facilities, forward sinuously into the gorge defined by the stream, covered in the urban section, which ends on the beach, dominated to the east by the Angevin tower, increased age viceroy. On both sides of the river, there are the most ancient areas, between the eastern and defensive garrison church of S. Peter, from the western plot thinned, gathered around the former convent of the Friars Minor, now Town Hall. The road runs behind, above the main road with a bridge and creating a striking effect to almost touch the majolica dome of the church adjacent to the communal house; but unfortunately not as pleasing buildings are decidedly out of scale, which rise on its margin.

Vietri sul Mare, which marks the edge of the Coast, lives a unique condition, related to the proximity to the

Fig. 6: Cetara.

Salerno, the large number of these industries and, especially, its position central to road, rail and sea networks. It is placed in a spectacular location on a sort of plateau, contained by high walls that plunge into the sea and Molina in the river - which flows to the west - to the mouth of which lies the village Marina, on long beach, protected by towers of Albori, of Marina and of Crestarella. While treating the common characteristics of the countries considered so far, starting with the picturesque, perched in the most high and dotted with domes, bell tower and buildings with facades ornamented with elaborate baroque plaster, has expanded wildly downstream, resulting in an aggregate compact that covers the entire slope.

3. The western side

Starting again from Amalfi Coast to the west of the section, we can easily see the complete change in the topography. Beyond the valley of the Blind - the deep depression that closes the city from this side - extending the five fractions, Pastena, Lone Vettica Minor, located atop high cliffs overlooking the sea, and Tovere and Pogerola, in the mountains. Except the latter, which is accessible from the trail that climbs the gully or directly from the city center, the villages have a plant in a line on road Maestra dei Villaggi, the most

Fig. 7: Vietri.

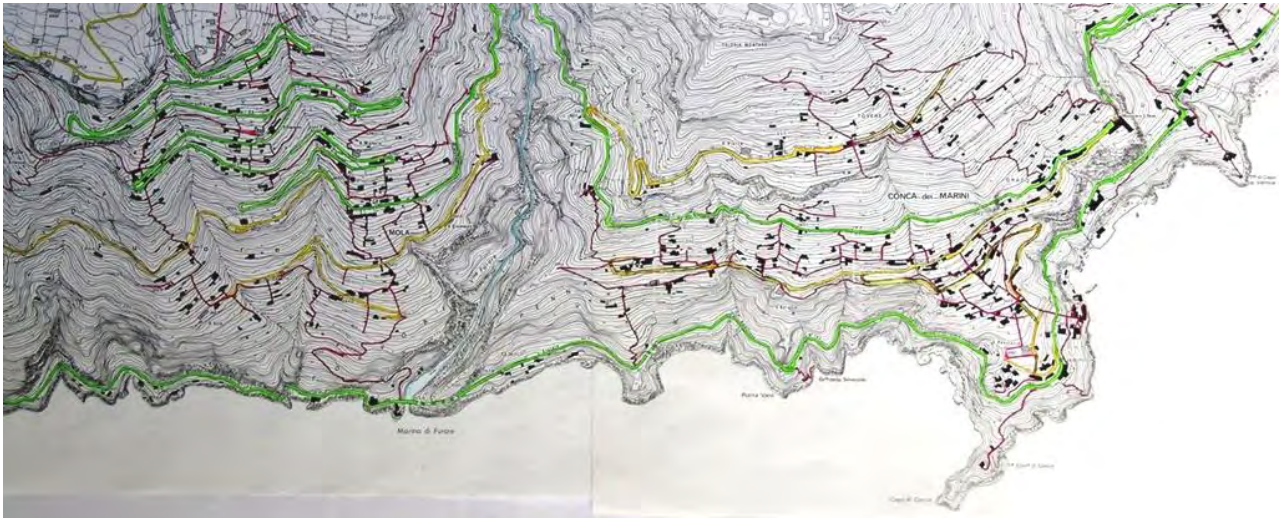

Fig. 8: Furore, Conca dei Marini and Tovere (Amalfi), plan.

important medieval road this side, on which stand the greatest architectural episodes religious and civil [5]. The road winds with ramps, curbs and rare flat sections, complying as much as possible the lines of lower slope and, after crossing the maritime towns, shall be directed to Tovere and from there to Agerola. It brings together on steep routes, which cut perpendicular to contour lines, from the mountain and the coast, stretching up to the furthest reaches of the settlement. Even here, the plot is still legible traditional road, despite multiple impairments introduced by vehicular arteries, first of all, the Amalfi-Agerola, which penetrates Vettica Minor with straight line segments and curves.

Those villages have mainly concentrated on the main road blocks and lower transverse or parallel in some cases, denoting the linear form is typical of this area.

The first one, Conca dei Marini, repeats the same orography. Arranged according to an ancient chronicler, "on the face of a steep mountain", is bolted to the north by high cliffs, steep cliffs to the south and from east and west by deep valleys. The conformation fostered the creation of small groups scattered in the most hospitable (m 180-280 above sea level) and a tiny nucleus of the sea, where he was a natural harbor, until the mid nineteenth century among the few sheltered harbors near Amalfi [6].

The town assumed an elongated configuration on the edges of the road - now almost entirely made carriage - which, by accounting for the slope, through the whole municipal area from east to west, receiving from the upstream and downstream laborious steps, called "petigni" and touching around which the three parishes in the Middle Ages settled urban cores: St. Maria of Grado - be abolished and incorporated at the end of the seventeenth century in the conservatory of St. Rosa - St. Antonio and St. Michele Arcangelo. The walk, starting from the far east of Grado, placed in the highest, was heading west to Penna, bordering Furore. About half of the course, met the square of the Elm, the only open space land, from which started the link with the largest settlement, extended on the promontory called "Vreca" and relating to the fourth parish, St. Pancrazio. From there, it branched off to the Cape, where later was erected the tower, Viceroy, and from the Navy. Fortunately, the Amalfi-Agerola interferes little with the villages, and remained almost as high, however, has made the village Grado, once the most isolated and inaccessible, accessible directly by car.

Furore extends west, beyond the deep ravine where the stream flows Schiattro, which flows into the famous fiord, on which, in the late nineteenth century, was built the bold single-span bridge of today's SS. 163. The soil, which rises from the sea to share about 600 meters of the plateau of Agerola, is characterized by an exceptional southern exposure and a strong steepness, which makes it extremely difficult journey [7].

Despite the deep changes brought about by the Agerola-Amalfi, you can still recognize the old distribution scattered in small sets, which is associated with that of last century, set along the road and in the immediate vicinity, as far as possible in order to facilitate the approach [2]. From the few houses at the mouth, the steep staircase climbs the ridge to about 300 meters, after which it divides into two branches. The first goes north and then west to the houses surrounding the church of St. Elijah (about m 250 above sea level), continuing to the north with steep straight lines and zig zags, orthogonally facing the ascent to below Agerola. The second was the same way the slope, leading to the three villages belonging to the churches of St. James, St. Michael and St. Maria of Pieta, linked by narrow longitudinal parallel and continues up to the plateau.

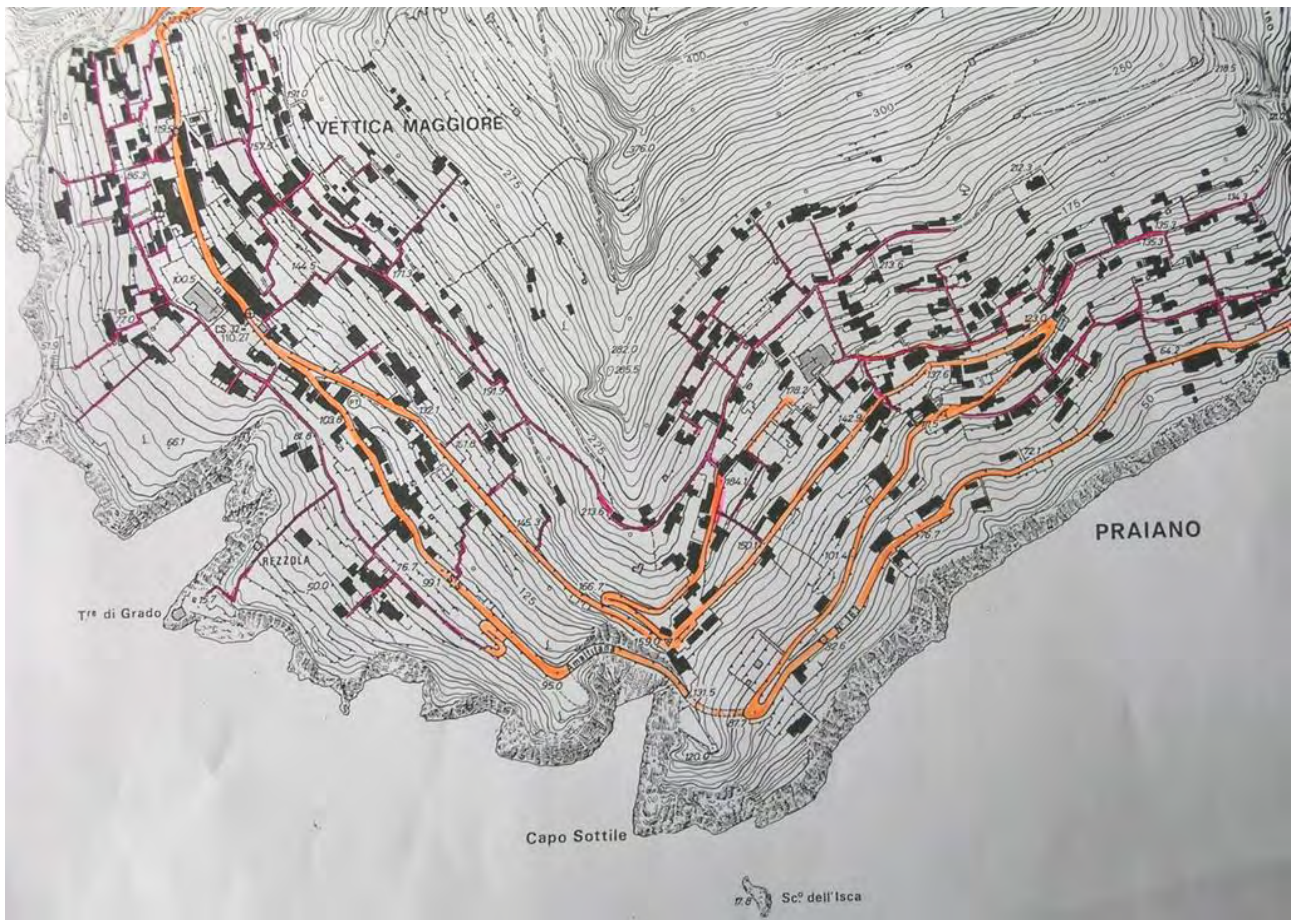

Fig. 9: Praiano, plan.

The following villages, Praiano and Positano, fall into a different type, being distributed on the slope next to vertical relationships, without reaching the compactness of the East.

The first consists of Praiano and Vettica Maggiore, which are arranged on both sides of the promontory which ends at the sea with the Capo Sottile, and are therefore directed to the east and west. Praiano, situated at higher levels (between m 70 - 220 approx.), lapping just downstream from the highway 163, along which line the more recent expansions. The country, through the whole extension of a road that leads to the square in front of the parish of St. Luke, is divided into two groups belonging to the church just mentioned and in S. John, to the south-east.

Following the slope, the town is spread across multiple arrays, which make up a very compact, but highly organized and served as a link to terraces, which cut a 90° contour lines. Similar organization is found in Vettica Maggiore, which is between 70 and 170 meters, coming from the leading edge of the coastal cliffs. The village, whose center is the parish of St. Gennaro, is penetrated by the SS. 163 for its entire length. Roads that take advantage of the lower slope, connected by straight perpendicular uncomfortable stairs, connect the buildings, located at different altitudes.

Positano, however, extends along the gully, which acts as the main road. The eastern side, which goes on the beach called "great", is more gentle and welcomes homes nearly 100 since the height occupies; the opposite sides of the small hill that rises between the beach and the center of Fornillo, extending to the summit (222 m approx.).

The primitive set-up, even if it is not disturbed by the state road, that the perimeter upstream with a sinuous path, however, appears varied by transformation into carriage of some old tracks. Nevertheless it is still identifiable the ancient road pattern, which sees the main longitudinal streets, connected by perpendicular secondary ridges that climb up to the summit, to serve the residences, the bedrock upon himself, constantly changing direction.

Fig. 10: Positano.

4. The mountain towns

The inland villages are covered by other types, being composed of scattered groups of very large territories, for different altitudes.

From the northern area of Amalfi a winding ascent to the top of the ridge overlooking the valley of the Dragon, on which stood Scale, consisting of an aggregate principal and several villages, which are arranged longitudinally from north to south, on roads which follow as much as possible the level curves, with buildings upstream and downstream. The first group has met Pontone, whose soil, markedly steeper, a plant uses to wrap around the ridge, on whose southern limit emerge from the impressive and spectacular ruins of St. Eustace to 275 m s.l.m. The laborious steps continues northward, passing the 100 meters that accompany the tiny village of Minuta, gathered around the Church of the Annunciation.

From here continue up to the largest center (m 400 approx.), aligned along the fairly flat - now made passable to cars - that leads to the Cathedral of St. Lorenzo, one of the major emergencies of the Amalfi coast. The trail continues up to hamlets S. Peter and S. Catherine, gaining about 450 meters, after which, back toward the south, with trends roughly parallel to the center, reaching Campidoglio to over 500 meters, and meet at the junction of Minuta.

The environment is highly suggestive of the presence of churches and medieval buildings, some still adorned with traces of inlaid stone decoration and Arab baths. Among them stand the palaces Mansi-d'Amelio, Verone, Romano, D'Afflito, the Bishop's House and other anonymous remarkable episodes of Pontone [8].

Ravello, overlooking the other side of the valley, reflecting a different condition, with nuclei aligned along the direct routes from north to south and east to the sea and to Minori. The largest town is situated on a plateau about 350 meters tapering on top of a massive rocky outcrop rising from the valleys of the Sambuco and the Dragone, in which almost vertical walls there are interesting phenomena that give rise to numerous karst

Fig. 11: Amalfi, Atrani, Scala, Ravello, plan.

Fig. 12: Tramonti, area Pucara-Polvica, plan.

caves. Gathered around the cathedral, is famous for the presence of emergencies religious art - churches and convents - and palaces of the Middle Ages, the most important of the Coast - as the known Villa Rufolo - that stand out with their wheels in town. Still retains its original shape from elongated oval, with only pedestrian streets, ending on the sheer cliff on which stands Villa Cimbrone. The context is qualified by the widespread presence of ancient structures in which are preserved, even more than in Scala, inlays, elements of plunder, Arab baths, etc.. Long flights of steps, perpendicular to the contour lines branch off to the north or down to the sea, embracing the different fractions on their edges.

The natural continuation of Maiori, in the basin Reginna, consists of Tramonti, the country from the analogous ancient origin but characterized by a consistent picture late Renaissance. The municipality covers a vast territory, with alternating steep share with others of moderate steepness, with a complex and unusual combination, being composed of thirteen villages more or less similar, arranged in extremely varied, almost in opposition to those seamen, neighboring Maiori, others that go to 800 meters of altitude crossing Chiunzi. Smaller agglomerates, usually modest in size, ranging from south to north on both sides of the valley through which flows the river and its tributaries, forming small villages organized around a church, using roughly flat areas and connected by a dense network of streets, largely increased in the late nineteenth century, today, made almost entirely vehicular, evening the modest inclination [9].

The position on the heights overlooking the gorge creates amazing effects in some places, green for nature - the forests, which take over as you go up - the waterfalls that are followed and the remains of old factories,

which the driving force derived from the water, finally abandoned after the flood of 1954, or converted to new uses. The lack of territorial constraints has allowed the persistence of the initial isolation of the villages, although the provincial road Chiunzi-Maiori - remake of half a century ago, the stock drawn at the end of the nineteenth century - is abnormal, the last director of expansion [10]. Numerous episodes of strong suggestion, is religious in nature - such as the Cave Chapel of St. Angel of Gete and the church of St. Elia of Paterno - that civil presenting buildings among the most qualified of the Coast to the Late Renaissance, which is noted between the houses of Conte and Pisacane in Pucara and Cardamone to Gete. The centers of the western slope wind along the primitive road that traced after 1811 it was abandoned about twenty years later, continuing from Maiori along the coast to Vietri.

As it can be seen from these brief notes, the preservation of the ancient urban structure of the Amalfi Coast was largely ensured by the almost total isolation in which the area lived until the mid nineteenth century. Since then, a series of modernization initiatives, increasingly linked to tourism and increasingly compelling, has put a strain on survival of the original urban structure. The conservation of this unique environment, recognized World Heritage Site, cannot ignore the value of all its components, first of all the design of towns that populate it, which merges inseparably with the celebrated natural features and landscapes. It is hoped that this reflection may be the input to operate in this regard.

Cuma Archaeological Park: a communication strategies to improve public enjoyment

Mara CAPONE

DICATA, Architecture, University of Naples Federico II, Naples, Italy
mara.capone@unina.it

Abstract

The ancient city of Cuma is one of the most important of the Phlegrean Fields. It was the first settlement of the area chosen for its strategic position. Today, the appearance of the area is very different from what it looked like in ancient times, in fact natural and anthropic actions have modified landscape over the centuries. The objective of the communication project is to promote knowledge of Cuma Archaeological Park and to define a new way to enjoy Archaeological Heritage for a large audience.

The archaeological finds are generally only a "piece of matter" and to reduce the communication gap we can reconstruct what is missing.

The use of digital media and 3D modelling opens new perspectives in archaeological research, it let us to document the passage of the history, but it raises new questions about the way of representing the archaeological heritage.

The branch of representation is called into question, especially for issues related to visualization of 3D models and design of the structures of knowledge. Animation is always been the best way to show the evolution over the time of monumental buildings and landscape but it is lack interactivity.

We think that 3D PDF could be an user friendly interface to access additional information. So we are testing the possibility to use 3D PDF to improve the access to cultural resources to all users, and to improve the exploration of 3D model.

Keywords: Virtual Archaeology, 3D PDF, 3D modelling, Representation, Archaeological landscape

1. Cuma and the ports system in the Greek and Roman age.

The ancient city of Cuma is one of the most important of the Phlegrean Fields. It was the first settlement of the area chosen for its strategic position.

Cuma is the oldest archaeological sites and it is the oldest Greek colony in Italy, today, the appearance of the area is very different from what it looked like in ancient times and it is very difficult to understand the meaning of archaeological finds from different eras.

The first Greek colony of Kyme took place on the hill, where the Acropolis had the role of stronghold and sacred place of the polis.

During the Archaic Age the Acropolis takes on a monumental look, in fact, the two known temples, one in the lower terrace (dedicated to Apollo) and the other in upper terrace (known as Jupiter's temple) are dated to the end of VI century. B.C. The construction of the wall fortifications of the acropolis dates back to the ambitious political projects of Aristodemus. In this period the city borders reached the maximum extension and this is proved by the discovery of some remains of fortifications still existent.

According to the theory of archaeologists the wall fortifications encircled the Acropolis, the hills on the west side and the area of Monte Grillo on the east side. The southern wall fortifications followed a line on the southern side of Monte Grillo and on the north side they separated the city by low marshy plain of Licola.

The urban development of the lower city, the center of city life, begins in the Samnite Age (IV-III century. BC). In this period are certainly built the temple which will be the Capitol (III sec.) and other buildings, not a sacred character, such as the so-called Central Thermal Baths (III-II century BC.) [1].

During this period, the Samnites put in place a plan of adjustment of defensive fortifications to meet the demands caused by the difficult coexistence of Samnites and Romans.

In the Augustan age, Cuma lived its heyday. Cuma played a major role in the troubled events that accompanied the transition from Republic age to the Empire, the aspect of the ancient city, that looks like to the modern visitor, is determined to the massive works built in this period: here, in the period of civil wars, Octavian, the future emperor Augustus, had its base.

In Greek and Roman times the importance of Cuma related to the strategic role assumed by the Port.

In ancient times, the Phlegraean area, characterized by volcanic craters and a coastline with deep bays, was considered a safe harbor. Both in Greek and in Roman times, the port of Cuma was located in a natural bay, near the center of the city, in an area morphologically perfect.

The analysis of the sources shows that the Greek port was located on the north side of the Lake of Fusaro, where it was in direct communication with the sea .

The Greek port was gradually disappeared for the silting up and the bradisism phenomenon that modified the coastline over the centuries. Today, the ancient coastline is covered by vegetation, and from the top of the Acropolis it's possible to see the sign of the ancient bay.

On the north side the coastline is characterized from a long and straight beach, which separated the sea from the lagoons and lakes there were inside of territory, as we can still observe.

Today, there is the Lake of Fusaro within this natural dam, the ancient swamp Acherusia, formed after the movements and pressures related to the arrangement of the Mediterranean basin during the third geological era.

Piaget [2] hypothesized that there were two ports in Cuma in Greek time, one was located in the bay on the north side of the lake of Fusaro and the other one was under the acropolis (Fig.1). This place was used from Agrippa, admiral of the Roman fleet, to built the roman port.

In fact, in 36 d. C. the admiral Agrippa took charge of operation against Sextus and so he needed a naval base in the Phlegrean area.

At first he placed the naval base in the Lake of Lucrino, that was very different from what appears now, because it was more extended than now, but the lake was not deep enough for Roman ships and so Agrippa used it for military training only (fig. 2).

Moreover, unlike the Lake of Fusaro, the Lake of Lucrino was separated from the sea by sand dunes exposed to sea currents and to winds. For this reasons, Agrippa decided to place his naval base in the Lake of Averno, called Porto Giulio, and he built a canal to connect it with the Lake of Lucrino.

Porto Giulio and the Lake of Lucrino were entirely occupied by the shipyard and training military activities and so it was necessary to find another place near to Porto Giulio, for these reasons Agrippa decided to use the ancient Greek port of Cuma [2].

He built a connecting tunnel between the Lake of Avernus and the city of Cumae, called Cocceus Cave, and a tunnel under the Acropolis, the Roman crypt, to create a link from the acropolis to the beach.

Agrippa addressed the problem of the silting up of the Cumae ancient port and he dug what it was covered over the time. Later he built a connection canal with the lake of Fusaro and closed the original entrance of the sea with a pier (Fig. 3).

At the end of the war against Sextus the port had no more reason to exist. In fact, in the Gothic period of Justinian, Cuma was only a well-fortified place. The Roman naval bases were reorganized in others places and the port of Cumae was completely destroyed: the sand transported by the wind into the area and the phenomenon of bradisism were the reasons of the total destruction of the two ports. The agricultural settlements have erased the traces of its existence over the time.

The choice of the study case allowed us to address a number of unusual issues especially related to reconstruct of archaeological landscape, very different from what we can see now, to develop a strategy to communicate the story of the place and to define a different level of enjoyment of archaeological heritage.

Our work is to translate into images, an iconic language, what is traditionally communicated using written language to improve the public enjoyment.

Fig. 1: Greek time, a. satellite image, b. the reconstruction hypothesis by Paget, b. overlap Paget hypothesis/present

2. A communication strategy to improve public enjoyment

The translation of scientific data into popular data is one of the problem that we have to address to correctly define a communication project. The aim is to understand the meaning of the archaeological finds, to reconstruct the archaeological landscape and the relationship with the existing landscape.

The spread of archaeological knowledge is very important for citizens, first users of cultural heritage. To have awareness of the role, that citizens can play in conservation and valorisation of the territory where they live, it can be more powerful than any law to preserve the archaeological heritage.

From a methodological point of view the stages that characterize a communication project designed to increase the value of archaeological heritage are: analysis of the sources, data acquisition in archaeological sites with different technology, data processing and the definition of the communication project.

We are more interested in the theoretical framework for defining the communication project than to the problem related to the acquisition methods and data processing.

Message can generally be decomposed into two components *content* and *media* and to develop an effective communication project it is very important to know the information you have to send (content); only in this way you are able to operate the simplification necessary to provide an accurate information and to select the appropriate media (form of communication).

In our case the content to transmit is the story of a place, Cumae, transformed over the time from nature and human actions. The selected *media* to transmit information is digital media and the *recipient* of a communication project is a non-specialist audience, so it is necessary to submit all disclosures to help them to decode the "sign" are still present.

Fig. 2: Roman time, overlap Paget hypothesis to present look

We think the "virtual rebuilding" can help to understand the meaning of archaeological finds and the most important problem is to define *what* to rebuilt, *how* to represent the reconstruction and what technology to use.

The archaeological finds are generally only a "piece of matter" and to reduce the communication gap we can reconstruct what is missing.

The use of digital media and 3D modelling opens new perspectives in archaeological research, it let us to document the passage of the history, but it raises new questions about the ways of representing the archaeological heritage[3].

The use of 3D models to represent hypotheses of reconstruction is a powerful tool that promotes communication and dissemination of cultural content to a wide audience.

The 3D models allow us:

- to access to monuments at risk of damage, and therefore closed to the public;
- to document what the history has erased;
- to create new way of enjoyment of archaeological heritage without boundaries, in a virtual space;
- to obtain a dynamic view, from different points of view in space and time;
- to build an information system where we can access to data collected;
- to organize a database linked to the models and to territory[4].

In this field there are some different issues to deal and some needs to fulfil:

- we have to solve the problem of the credibility and validity of reconstruction models of object, monuments, sites or landscapes partially o totally modified or destroyed, and virtually reconstructed based on archaeological interpretation;
- we have to define a communication code to show the traces of philological work in 3D model to show elements corresponding to reality from hypothesis;
- we have to chose what kind of representation to use: structural or hyperrealistic
- we have to design the interface for an interactive use of the models.

A problem often overlooked is the difficulty that the *end user* meets by using technological tools.

Sometimes, we used very complex systems and the interface isn't *user friendly* and it is very difficult to understand for those who are not familiar with technology. In fact, we aren't willing to spend our own time to learn how to use a tool that is only a means to acquire further knowledge. Moreover, a user, who feels inferior, backward or inadequate respect to the proposed product, irritates and he renounces to use cultural product.

Therefore, the interfaces must be designed with particular regard to the users, by ensuring their intuitiveness and limiting as possible the technology interference.

3. The rule of representation

To define a communication strategy for enjoyment of Archaeological Heritage it's very important to work in a multi-field team of experts made up of architects, archaeologists, computer specialists and communication experts.

Fig. 3: Roman time, a. satellite image, b. the reconstruction hypothesis by Paget, b. overlap Paget hypothesis\present

The reconstruction does not represent the unique final result but the aim is to define an open system which can be further developed or improved.

The area of representation can play a key role especially in matters relating to the visualization of 3D models and the design of communication systems.

We have to address two fundamental issues: the first is related to the definition of a communication code appropriate to the *receiver* and the second, no less important question, is how to make clear in visualization of the 3D model the reconstruction hypothesis.

The concept of communication requires the transfer of information from a *transmitter* to a *receiver*, to do that we have to use a *code* and a *medium*.

We mean for code all the signs that make possible a communication and it is important to use signs that are able to send the meaning correctly.

The communication must respect the cognitive process which occurs by incorporating the sign with the knowledge previously acquired or deemed necessary. In the case of Archaeology the sign is always an iconic one, and additional information needed to understand this sign has traditionally been transmitted using a verbal language into written form (panel) or oral (audio guides or guides) [5]. In the first case we obtain a communicative stress because we have to decode either the iconic sign and the verbal one, and so we force the viewer to "read" or to "look". In fact the viewer has to switch between modes based on a cognitive analytic process to another one of gestalt kind. The result is that the viewer has to leave one of the two cognitive system. Of course, the conflict is less if verbal information are transmitted orally in a conversational way. This conflict can be eliminated by using a visual language and minimizing the verbal comment that "separates" us from the sign.

So, an efficient communication system for archaeological heritage is based on using of an iconic code.

Regard on this question we are involved in discussion about the kind of representation, when we have to use a realistic image and when we have to use a conceptual one.

In fact a lot of communication projects are based on the simulation of reality but we think that the main aim is not only Virtual Reality, rather than the representation of knowledge and the Reality is just a part of it.

So, we think that is very important to define a code to communicate "uncertainty", to emphasize the difference between real finds or landscape and the hypothesis of reconstruction and so full range of 3D visualizations options must be considered, photo-realism or structural visualizations.

In any case, a winning strategy is to simplify: to give a clear message, and then universally readable, it doesn't mean to make obvious what is complex but it means to remove everything is not necessary to give accurate information rather than complicating with adding information.

The use of 3D digital models is one of the best way to show the reconstruction hypothesis.

We can use 3D models to produce:

- images
- animations
- 3D PDF
- 3D database
- virtual reality

Fig. 4: 3D model, a. Greek time, b. Roman time.

Static images can be used to make photomontages whose aim is never to achieve a photorealistic simulation of reconstructive hypothesis but rather to contextualize it in the real landscape. The contextualization represents a key element that allows to spread the cultural content in an adequate way.

One of the main innovations offered by digital technology is the possibility to interact with 3D models independently from software used to produce them .

It is possible to generate a 3D PDF from a 3D modelling program and interact with it using Adobe Acrobat Reader, put it in a presentation in Power Point or in a PDF text [6].

The aim is to explore the communicative potential arising from the possibility to interactively explore the 3D model. Interactivity gives the user a level of knowledge certainly different from the video or the images that show the object. The experimentation in this field is to produce models where it is always possible to recognize the datum from the hypothesis by using different forms of visualizations.

3D models can become a *user friendly interface* to access other information related to it, through the three-dimensional display system. It is possible to visualize different views of the model, you can link them to text or some other information, such as images photos and so on.

It is possible to generate a 3D PDF establishing different types of visualizations (opaque, transparent, wireframe ...) that can be easily viewed by the user using Acrobat Reader. 3D PDF isn't a photorealistic model but it allows the user to acquire a greater awareness through the interaction with the 3D model.

4. A dynamic representations.

The possibility of representing motion images is one of the most important innovations linked to the use of digital media. The animation is a very powerful narrative tool that allows us, through the conscious use of different visualizations options of the 3D model, to explore the 3D model visible characteristics and to go beyond what is visible in a dynamic way, revealing the structural characteristics of buildings and landscape.

Video is the media best suited to communicate Archaeological Heritage because it offers the possibility to combine, thanks to technological development, real elements with virtual reconstructions and contextualize the findings in space and time.

To produce the video we can mix static images with animations appropriately designed, to transmit the cultural significance of archaeological finds.

In a video we can hybridize different systems of representation, static images in filmed sequence to make clear the relationship with the current landscape, animations to represent the dynamic transformations of the site over the time.

Communicate the cultural significance of the place and not just represent it, to relate the reconstructive hypotheses with sources to make explicit the path and assess its reliability.

5. Case study: Archaeological Park of Cuma

The Archaeological Park of Cuma is characterized by the presence of finds from Greek and Roman times, the layering makes reading very complex and understanding of finds very difficult, now panels placed along the tour show the meaning of them.

First of all we analyzed the documentary sources, the studies of archaeologists and reconstructive hypotheses, so we defined the content of communication project.

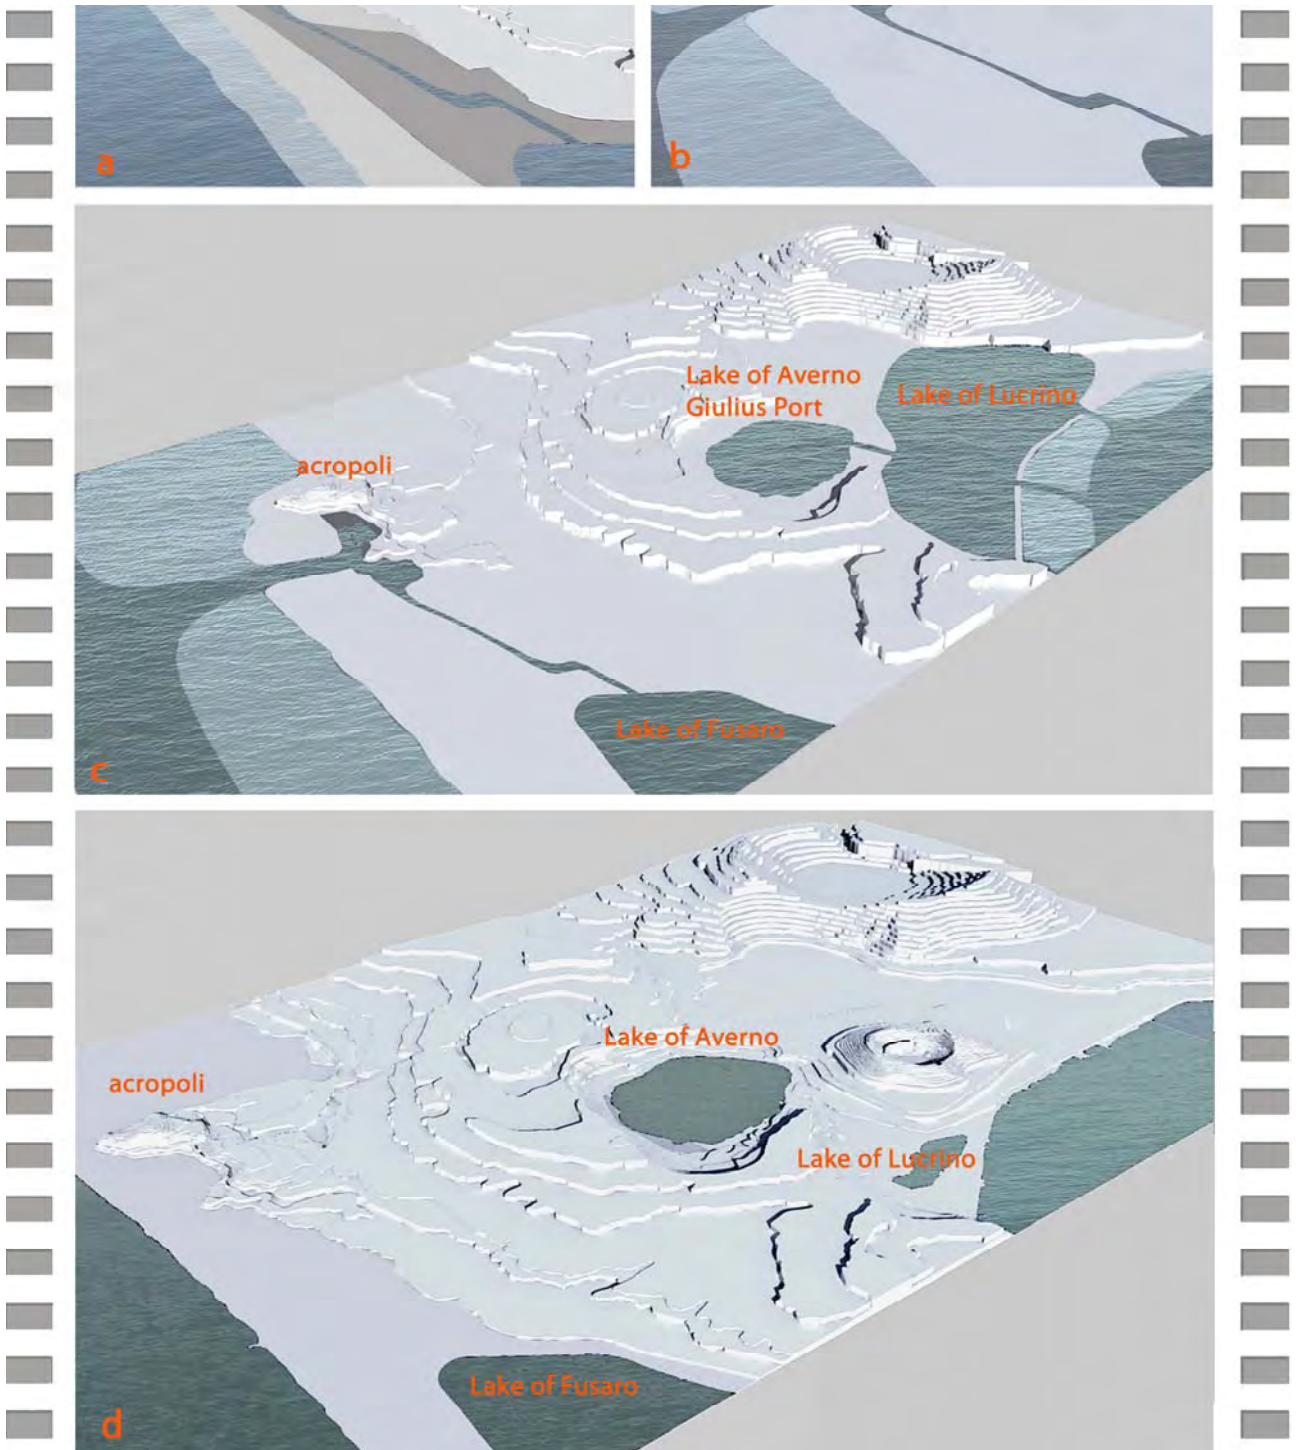

Fig. 5: A dynamic representation of landscape to show evolution over the time. a. zoom on the Lake of Fusaro in Greek time, b. zoom on the Lake of Fusaro in Roman time, c. landscape in Roman time, d. current landscape.

We identified three key issues: the representation of territorial transformations, the representation of urban transformations and the representation of the monumental buildings transformations.

In the first part of the work we dealt with issue of the Cumae's ports and the transformation of the territorial system. The hypothetical reconstruction is mainly based on the interpretation of Piaget, he summarized his hypothesis about the configuration of the Greek port and the transformations in Roman times in a series of sketches.

Fig. 6: Acropolis of Cuma

Overlapping the Piaget's schemes to the aerial photo we can reconstruct the main territorial changes and compare them to the present look (figg. 1, 2,3).

Based on this information we built a 3D model of the territory during Greek and Roman times and the 3D model of the territory how it looks today.

The comparison between three models allows us to show the spatial transformations of the area study.

One of the problem to solve is the exploration of the model of a large part of territory, static images aren't enough to show the transformation of landscape because it is too large and too complex.

Animation is the best way to solve this problem, in fact video allow us to visualize the 3D model from different point of view, in different ages in a dynamic way and it is possible to use static images mixed to some others sources such as photo, iconographic sources, but in a video lack interactivity (fig. 5).

A new way to explore 3D models is the possibility to interact with the 3D model, to do that it is possible to use a 3D PDF files

3D PDF is very convenient when the object is too large or too complex, when we want to show evolution over long period of time of cities or landscape. If we reconstruct landscape the amount of 3D data that we'd like to visualize exceeds by far the capabilities of the complex user.

So, we can cover all 3D visualization using 3D PDF and video files. The use of 3D PDF let us to link to 3D model some others data.

There are some other providers that use other technology based upon WebGL supported by Chrome Firefox and Safari but we are interesting in 3D PDF because it is supported by Internet Explorer.

In fact, 3D PDF file is [7].:

- available on every computer platform system;
- easy to use;
- readable on all computer by Acrobat Reader.

Now 3D PDF can't be used on mobile device but it will possible in the next.

We are testing the possibility to use 3D PDF files to public on web 3D resource linked to the Archaeological park of Cuma and its use in cultural heritage application. The new communication strategy will let us to spread the results of our research on web to improve public enjoyment and to show the landscape and monumental buildings evolution of Cuma over the time.

From a methodological point of view the most important steps of our workflow are:

- to convert 3D model in a 3D PDF file;
- to define a visualization code by texturing and mapping;
- to link information to 3D model by layering, named views, action and so on[7].

First of all we are testing different methods for texturing [8].:a 3D object to define a visualization code and to choose the best way to spread cultural content for a wide audience. To link information to 3D model using a 3D PDF file we are testing layering options [7]. In the conversion process from 3D model to 3D PDF file it is to improve to show landscape's transformations by turning on and off the part of 3D model that represent landscape in different ages. We are going to use this method to compare 3D model of archaeological finds of monumental buildings with their virtual reconstruction hypothesis. To do that we had to structure the 3D model in layers related to the transformation process from Greek and Roman time to current time.

Fig. : Antro della Sibilla, Cripta Romana

Another important possibility it is to guide the user and to link, for example to a text, some particular views to visualize the object in a certain way to emphasize some property of it. We created special named view such as top, front, left right in perspective or in orthogonal mode, to improve the public enjoyment of 3D model by interactivity. We decided to show the model not only in a render mode, where the hidden lines are invisible, but we chose to visualize the model showing its structure.

We carefully planned the named views that we considered more useful for visualization and interaction.

We are testing the best way to link to 3D PDF file some other information to compare the original look of Cuma's monumental buildings and landscape with they look today.

We have done this by using action options, they let us to create a conceptual link between 3D model and some other information. We think this is an useful alternative to classic animation. However, this kind of representation is a dynamic one, in fact, when we change from one named view to another, the 3D PDF visualization mode automatically creates an animation[7].

There are a lots of benefits to use actions, first of all we can update and expanded the database linked to 3D model in an easy way and we improve the access to 3D exploration of the model for people who no experience of 3D.

So, one of the most important target of our research is to test a new strategy to improve public enjoyment using 3D PDF files.

Another problem to solve is to simplify the 3D model to create 3D PDF file. We have to reduce the complexity of the 3D model choosing details, texture in an adequate way.. The target is to have a 3D model file not too large without losing its communication characteristic. In this case it means that less could be more.

6. Conclusions

The videos represent one of the most powerful tools to communicate the story of an archaeological site.

Animation are always an alternative for visualization of 3D model but lack interactivity.

The availability of platform such as the iPad and iPhone has improved the way we deal with digital data.

We think that 3D PDF could be an user friendly interface to access additional information such as text, photos, iconography and so on. So we are testing the possibility to use 3D PDF to improve the access to cultural resources to all users., and to improve the exploration of 3D model and linked sources.

7. Acknowledgements

I'd like to tank Daniel Pletinckx, Euopeana CARARE, Visual Dimension bvb, Belgium, who brought 3D pdf and its use to my attention.

Road Infrastructures: methodological approach for the research of value added.

Michele CULATTI

Phd at Department of Structure Engineering, Faculty of Engineering, University of Trento, Italy
michele_culatti@fastwebnet.it

Abstract

Even though the treatment of road infrastructures (bridges and roads) assumes the subject of quality as a goal, it is rarely developed in a propositive way. Among numerous forms of quality, there should exist a technical performance quality level which infrastructural promoters and supporters aim for, there is also a perceived quality which is hard to detect because of, in some instances, its intangible value. When comparing road infrastructures that are typologically homogeneous, one realises that during the planning, the dominance of the technical performance quality leads one to think about a value subtracted from the territory, determining an overshadowing of the perceived quality. Nevertheless, when observing the best planning results, it turns out that the perceived quality can assume different forms amongst which is "conceptual quality". Should this latter one be defined as a *whole of value added deduced from the connection of components within the plan and the territorial context*, it enables the project to satisfy a series of requirements not directly requested by the performance goal but essential for the function of the infrastructure. A methodological approach can take place in order to define this value added approach which provides the appraisal of already existing road infrastructures according to its fruition, thus the form-function perception and its meaning (or importance or significance). All of the subjects arising from the perceptive reading of the projects, can provide a sort of checklist which is useful to support the improvement phases of new infrastructural plans, determining the composition of value added and place renovation.

Key words: infrastructure quality, value added.

1. Quality forms of infrastructures

In times of restricted financial resources and in vulnerable territories which arise because of objections to a planning proposal, the growing quality required of linear road infrastructures (urban and extra-urban roads) and all types of bridges and their relationship with the immediate environment, focuses the attention on the evolution of the meaning of road infrastructure quality. There has been an evolution in the road infrastructural plan, from a quality addressed only to the plan which has as technical-performance goals, to a quality relating to the environment where qualitative criteria refer to the environmental protection, specifically environmental impacts and more recently or landscape ones. Yet, what is lacking is a quality external to the plan, concerning its relationship to an urban and territorial context used by the community. This is due to many factors: on the one hand a cultural "emptiness" which has its roots in the history of Italian infrastructures during the post second world war period. On the other hand, a normative "emptiness" which will be analysed later. In addition, the determination, measurement, and evaluation of the road infrastructure quality during its many phases, such as planning, getting into operation, maintenance, and their relationship with the environment, can be detected through complex quality-quantitative indicators. Then again, the quality of the work which complies with the function in the context and its interaction with the fruition, is too often without a far-reaching concept that leads to the discussion about the meaning for the community of

having an infrastructure in a certain territory. To state it more exactly, the expression “conceptual quality” appears in the Italian regulation for public works (D. P.R. 544/99 and further modification – Art. 46 Verification of the preliminary plan [...] 2 . The verification aims to ascertain the *conceptual quality*, as well as the social, ecological, environmental and economic quality of the chosen plan solution and its conformity to the specific functional, performing, technical dispositions enclosed in the preliminary plan document, and it aims to optimise the chosen plan solution). However, because the expression “conceptual quality” is never defined, its plan application has always turned out to be generic and of little meaning. Recently, the D.P.R. 05/10/2010, n. 207, regulation of enforcement and actuation of DLgs 12/04/2006, n. 163, about public works, under “verification of the plan”, the expression “conceptual quality” has disappeared and has never been substituted by any other parameters referring to the external quality. This situation has determined a normative “emptiness” which limits a documented consideration and represented in *genius loci* with the risk of increasing the existence of infrastructures lacking in an intangible as well as indispensable quality. Thus, the intention to grasp this “conceptual quality” as a way to reflect about its meaning, becomes concrete in order not to lose the comprehensive awareness which is able to improve the harmony in the infrastructure-human being connection.

2. The appraisal of the projects: a survey

To better understand how added values exist in a road infrastructure, it is necessary to dwell upon the features which are part of the complex connection between the plan and the territorial context. The main features of such correlation are: the *user*, who perceives the road infrastructure work and its context according to a specific cognitive process, the *work* (roads and bridges) and the *territorial context* (the plan area). To start with the first feature, the human aspect is included in those environmental factors both biotic and abiotic though with an interpretation addressed to the protection. Should we consider the human aspect from an anthropocentric point of view, which has to do with people’s everyday life, this aspect assumes many different connotations depending on who uses those road infrastructures, through its perceptive and interpretative faculties, becoming thus the *user*. According to this point of view, the *user* becomes the most important for both using road infrastructures and for living with them. From a cognitive point of view, the *user* stimulates a perceptive as well as a representative process which produces an evaluation – positive, negative, indifferent - regarding all that activates our attention. Briefly, “the perception is always part of valuation criteria, - more or less self conscious, intuitive or automatic – which becomes the appreciation about the shape, meaning and function of something”[1]. Even though the shape, function, meaning and features of the object refer to the cognitive activity of the user and according to psychologists they are interrelated, in this survey they are separately analysed and seen as an interpretation key for infrastructures. As far as the perceived shape is concerned, there are two main categories: the first one belongs to the context, be it territorial, peri-urban or urban. The second one regards the road plan as a linear system of roads and bridges. The growing awareness about safety measures and acoustic impact meant to reduce road accidents as well as human and biotic impacts, leads both the designer and the buyer to incorporate safety measures such as increasingly higher guard-rails and sound proofing barriers which make the infrastructure look like an enclosed lane. Consequently, it happens that the technological structures of roads and bridges dominate over the road and bridge shapes. From the point of view of perception, when the work is finished, its shape can either be lost in its context or become more prominent but it is always inescapable within all that surrounds it. The perception of the work shape is always incorporated with its context. The second feature, the function, is also to be considered in a different way. As far as the work is concerned, the function is the reason of a road infrastructure’s existence which allows the transport of people and animals or the clearing of an obstruction in the case of bridges. Culturally and strategically speaking, the large quantity of infrastructures in our country is due to the maximization of the means of transport and to safety measures. There is also the function relevant to the area, such as the rural or urban one, with different ways of connection with the road infrastructure. The third feature, the meaning, described as “the content of any means of communication as it is translatable into concepts, notions, references”, or as “importance of a fact, in consideration of the reasons which have motivated it and their possible consequences”, leads one to understand that both a territorial context and a road infrastructure can have many meanings. A bridge, with its formal and chromatic features, can be the main symbol of a town, for instance the fourth bridge in the Canal Grande, Venice, by Santiago Calatrava or the highway access in East Padua where the former is an outright monument, the latter an access to the town. In the same way, agricultural land means not only the production of bounties of the earth but also the representation of cultivation techniques, an urban context can

Pic. 1 and 2 Fourth bridge on the “Canal Grande” in Venice (2008) and new junction in Padua near the motorway exit “Padova Est” (2008)

be the place where you live, eat, sleep, work, that is the place where different human relationships happen. (It is necessary to point out that the subject of the *place* has been examined by the anthropologist Marc Augé who talked about the Non-Places, giving a representation of many infrastructures; though this is not part of this essay, it is important for the consideration of the *meaning of the context*). So far said, when the road infrastructure is in its context, shows itself through its shape, it becomes the carrier of a function (means of transport) and of a meaning (the way to reach a place or clear an obstruction either natural or artificial). At the same time, it can give the opportunity to enjoy a view or to go across, probably with some distaste, a degrading urban site. The working of the function, shapes, and the meaning of the road infrastructure plan means to interact with the shapes, functions, and meanings of the area. Should such plan be properly done, it can create added value, emphasizing the conceptual quality. The infrastructures are usually associated to their use (means of transport) though the “shape” and “meaning” are often left aside, with the consequence of a degrading of the urban site. Thus the conceptual quality, seen as a value added, is characterised by the increasing of the *function* and the *meaning*. According to this opinion, it stands to reason that relational, identical and symbolic factors come into play and even though they seem intangible, they are necessary in order to have a planning awareness. In terms of *shape, function, and meaning*, it can be affirmed that the added value occurs when one or more of these factors are deepened and go beyond the plan’s main purpose, which is generally connected with the utility idea. In other words, each time a road infrastructure shape doesn’t follow only functional needs, but also the meaning of the plan in a territory, then you can find the perfect circumstances to have a value added. At the same time, the creation of added value happens when, besides the function of the plan, there are other factors which add more levels of functions to the plan, such as the way to use it. If the purpose of the road infrastructure is a technical-performing one, it is when the shape, the utility and the meaning both of the plan and the context are taken into consideration that we can have a double level of added value: the interpretation of solving a transport problem and the interpretation of an urban site lived by the users.

2. An example of reading according to *shape, function and meaning*: the bridge on Taglio channel in Mira (Venice)

1) Description of the intervention reason

The “Passante of Mestre” is an infrastructural work which totals app. 32 Km and has seen the realisation of numerous bridges, overpasses and underpasses. One of the necessary bridges to guarantee the road continuity is the crossing of Taglio Channel.

Pic. 3 Territorial context of the intervention area – aerophotogrammetric view

Pic 4 Left: positioning of the bridge in respect of the built-up area. The purple color shows an area which will become a park and is connected to a green area in the centre of Mirano through the passage under the new bridge. Right: section, planimetry and prospects.

2) Description of the territorial context.

Shape: the context is a level district mainly agricultural where some industrial areas stand out. The bridge is near the banks of Taglio Channel, which connects Mirano and Marano.

Function: Taglio Channel is an old good transport infrastructure waterway: a channel that, because of functional needs and due to the flatness of the district (Pianura Padana) crosses the territory with a linearity that is the most constant and recognizable feature in such context. On one of its banks there is the road which connects Mirano and Mira, on the other there is a cycle-pedestrian way which is used to the utmost by the local people to go for walks.

Meaning: the historical value of the channel, besides the fact that it has turned into a place where people spend lot of time at, has assumed a collective identity which will be surely menaced by the impact the visitors will produce in such context.

3) Description of the work and possible alternative solutions

Shape: the bridge is 80m length. It has three bays, two side ones of 30m. and a central one of 40m., it is 35m. wide, with two carriageways, each of three lanes. It has an almost entirely steel structure, with glass sound proofing barriers and its characteristic is the built on the Taglio banks, making it not too high. In addition, the road continuity of Left Taglio and the cycle-way of Right Taglio have been kept, making them pass along the banks to go under the bridge. The bridge fabricated in metal, with the front made by a series of inclined bars with the function of hardening the core of the longitudinal girder.

Function: the bridge has a double function. The main one is the continuity of the "Passante di Mestre" with the crossing of Taglio Channel; the second one is the continuity of the road which goes along the Taglio

Channel under the bridge. The bridge is also situated near a redevelopment area which will become a park and is connected, through a cycle-pedestrian way, up to the Park "XXV Aprile" sited in the centre of Mirano. Meaning: the bridge, meant as a crossing of the channel by the road, has been interpreted as an element of the landscape with its own role and identity but at the same time it is part of it through the connection between the elements present in the context. To find out the role that the bridge should have in this context, we have analysed the landscape, isolating some elements in order to discover the mechanisms which regulate their connections. We have imagined what impact the structure could have and from which point of view it was better to view it. The result of these studies has led to the insertion of the bridge between the banks, where there are already existing strips of green (poplars, small woods) near the bank, so that the sight of it from far away makes its dimensions appropriate to the context. As one approaches the bridge, gradually descending the banks, exactly when the bridge is showing its real and unavoidable dimensions, one's attention is drawn towards a green area near the motorway which works both as a mitigation of the motorway itself and as a facilities area for rest and leisure. It also includes a small refuse which will be renovate. The bridge is also inserted in its context according to the following consideration: there is a daylight landscape which we are used to taking into account according to our cultural dimension, however there is also a night landscape to which little attention has been drawn especially those structures which are a reference point for the community, such as bridges. In a certain context, the visibility of the bridge at night contributes to create an extended landscape portion which can be coherent with the daylight view, depending on the artificial lightning. During daylight, the movement of the metallic bars, perceptible as an alternation of recess and protrusion, creates a play of light and shadow that gives depth to the front, reducing the visual impact. Even from the very first planning phases, the depth effect was kept also in the night-time view. Just like in the negative of a picture, during the night the play of light and shadow has been achieved bringing out recesses and protrusions through lights put inside the many inclined bars which make the front of the bridge. The artificial light emphasizes the presence of the bridge in the dark background of the night, creating a recognizable reference point in the same way as it happens during the day.

Results:

a) Interpretation of the means of transport solution:

Clearing of the barrier given by the Taglio Channel, so as to have a transportation continuity thanks to the new infrastructure "Passante of Mestre".

b) Interpretation of the territorial context

The features of the bridge are connected to its functions which is both the crossing of the Taglio Channel and a reference point for the continuity of the road network. It has been thought that the perception of motorway drivers, given their speed and consequently lack of attention to the landscape, should have been of a more abstract sort: the crossing between the roads of the Passante and the Channel is a clear sign perceptible even at speed, thanks to the curves of the extrados of the girders. The plan has also taken into account the night landscape through the artificial light.

c) Added value

i) The lightning of the bridge has been taken into consideration as a form of night landscape continuity.

ii) Keeping of the road continuity under the bridge and connection of two homogenous functional areas.

iii) Concealing of the traffic in relation to the visibility of the bridge.

iv) Bridge visibility due to its proximity to the park, whereas the traffic will be hidden by the structure's height.

v) Arrangement of the residual areas due to the achievement of the new road and of the conditions for the creation of a park.

3. An indicator list of conceptual quality

From the reading of the relationship between the work and the context which are applied to a wide number of road infrastructures, it is possible to take out those themes which have contributed to the creation of added value and make a list of some indicators of general validity.

In the same way as in the procedure for the writing of the SIA (Study of Environmental Impact) where there are some checklists proposed as questions, here it is a checklist with the transposition of added values into arguments which can be treated also in other planning cases. The indicators have then been grouped together taking away the repetitions, in terms of shape, function and meaning. Of course, the checklist below does not exhaust all the possibilities for the creation of added value, however it can be considered as a reference point for the checking of the plan external quality.

Shape:

1. *Bridge dimensions and shape:* Either in the overpasses and in the bridges, is it necessary to keep a reduced deck dimension in order to minimize the visual impacts? Has the bridge typology been studied together with construction techniques which allows a drawing able to keep a reduced deck dimension?
2. *Context shapes:* Does the bridge/road take into account the functions and shapes of its surroundings? Is it in connection with them?
3. *Visibility of the infrastructure and by the infrastructure:* Have the various alternatives been evaluated about the bridge/street positioning in relation to its view from the bridge/street and of the bridge/street? Can the bridge/street offer optical cones towards worthy landscapes and at the same time conceal the view of the traffic?
4. *Formal coherence between the product and the context:* Is it necessary that the bridge/street drawing follow a formal coherence with the other elements of the territory?
5. *Lighting:* How does the bridge/street work at night? Is there any lighting which shows its presence, enhancing its shapes? Does the night lighting give a formal result which is coherent with the day-time view?
6. *Vehicular traffic view:* Is it necessary to conceal the traffic view of a bridge/street?

Function

1. *Flexibility:* In the future, can the bridge/street be enlarged in order to achieve new traffic needs?
2. *Economical contest:* Does the bridge/street take into account the economic development of its surroundings?
3. *Interchange:* In the network nearness, is it possible to exchange the various transport ways?
4. *General economy:* Is the working of a road infrastructure compatible with the structural needs of the population budget?
5. *Interdisciplinary program:* Do the program documents grasp the potential and vulnerability of the territory functions, shapes and meaning both on a great extent and on a local rank?
6. *Traffic category:* Does the bridge/street take into account the different traffic categories?
7. *Functional intersections:* Which functions do the bridge/street seize? For instance, if in the nearness of the bridge there is the possibility to create a park, can the bridge have functional relations?

Meaning

1. *Characterization:* can the succession of overpasses with similar features be the expression of the stereotyping of a road?
2. *Identity:* Which images of the territory are possible after the infrastructural intervention? Which territory's identity is possible after the infrastructural intervention?
3. *The symbol:* Does the bridge/road have a symbolic value?
4. *Renovation:* can a bridge/street renovate places?
5. *Doorway/access/transit:* can a bridge/street express, where it is necessary, the access to a town? Or as the crossing of a place?
6. *Limit:* can a bridge/street be a geographic reference point which marks the crossing from a territory to another?
7. *Grades:* Are there any recognizable functions in which the bridge/street is in connection with? Which grade of function is recognizable?
8. *The old and the new:* in case of a functional adaptation of an old bridge/street, are there any rules which regulate the old and modern relations? Will the intervention be on both sides or on only one? Will a reversible technology be used? Will there be a hierarchy to highlight?

4. Results

The infrastructural road plan can be the chance to create a conceptual quality which is able to establish a relationship between the functions, shapes, and meaning of the road/bridge and the functions of the context. Supposing to define the "*conceptual quality of the infrastructural roads as a whole of value added deduced from the connection of components within the plan and the territorial context that enables the project to satisfy a series of requirements not directly requested by the performance goal*" [2], it stands to reason that the conceptual quality can differ in many ways and can be expressed through a multiplicity of meanings. The followings are to be underlined.

The determination of a conceptual quality is a cultural fact.

The conceptual quality of a road infrastructure is the result of the communication between the client and the designer; it is territory knowledge; it is multidisciplinary or better trans-disciplinary, as it follows a process of mutual exchange and of mutual enrichment between the designer and the client as well as it tries to catch the population requests. The infrastructure, characterized by a higher grade of conceptual quality, will be

able to synthesize coherence between the functions of the road and of the work and the functions of the territorial context through an architectural plan which is able to interpret the meaning of the places. The conceptual quality of a road infrastructure is the organization of the place density variation and the competence to use it; it is the chance to handle the threshold between road infrastructure and context, where identities are attested and differences are reinforced, at times belonging to the world of the street, at times to the world of nature (it is necessary to think about the noise barriers obtained through the insertion of greenery or to the technological barriers through sound proofing panels).

The conceptual quality is the chance to re-organize the space where the plan documents haven't been able to grasp the value of the places.

The conceptual quality consists also in foreseeing the variation of the territory functions and of the infrastructural network which can happen within time.

The conceptual quality is the approval of several points of view which are able to outline the complexity of the relationship between the infrastructures and the territory; it is the analysis of the depth of time and the depth of field which allows one to perceive both the street and the landscape with a reduction of the contradictions, where not only the travel acquires a meaning, but also the parking and the stopping off.

The conceptual quality also consists in the power to detect the area where an economic development is possible, through the connection of the road infrastructure to the territory's functions; thus, the road infrastructure can be seen not only as a centre of attraction of the traffic, but also as a centre of attraction of tourism and economy. Last but not least, the road infrastructure can be the place where new landscape plans materialize.

The conceptual quality needs to be examined, studied, explored and represented. It deals with the close examination which can be found in other disciplines amongst which there is psychology, landscape, geography, representative, anthropology, sociology, urbanity and of course structural and architectural ones.

Abstract

Urban productive landscape is a process of production in urban green space, which involves production of vegetables, herbs, ornamental flowers and fruit trees. The production process begins from small units in private yards, to the larger scale in the farm lands. Productive landscape is beneficial to the society and people.

Agricultural lands in southern Tehran have been selected as case study, in order to be reorganised hence, part of these agricultural land is selected to be designed, in local scale. The selected site is considerable from two main aspects, firstly, the residential fabric which is penetrated in to the agricultural land, caused various types of pollution in the environment, and secondly, its establishment in the southern edge of Tehran.

Increasing conversion of agricultural lands to residential and industrial construction occurred, while the importance of productive landscape has been ignored in the selected site. productive landscape's restoration, will empower various changes in residential fabric, it improves social interactions and it will restore and enhance environmental quality.

Urban productive landscape is capable to empower and improve the environmental, economical and social aspects of the city. It will revitalize natural and cultural landscape and it will improve the interaction in between man and nature, as well. Preservation of productive landscape as an urban land use is periphery requirements to create a sustainable landscape. Thus, productive landscape describe as a conversion, from an entire consuming green space to a productive green space.

Therefore, the paper will discuss productive landscape design as solution to work out issues within this particular site.

Keywords: productive, landscape, agriculture, southern Tehran, design

1. Definition of urban productive landscape

Urban productive landscape is the process of producing agricultural goods such as vegetables, legumes, mushrooms, even meat and dairy products, within the city or its suburbs. These products may also include medical plants, shrubs and ornamental plants [1].

Urban productive landscape is defined by the specific requirement and necessities in different urban regions. The main purpose of urban agriculture is to plant and produce food through simple procedures despite limited facilities [7].

According to the above definition urban green productive landscape can be regarded as specific urban land use which in turn may include private territory such as one's backyard or it can consist of larger scale functions namely parks, urban green spaces, travel and recreational spaces. Urban policies regarding

productive landscape design restrict urban fabric transformation, yet it will restore urban open spaces through multifunctional landscape [1].

In order to change urban landscape, Urbanites' life style and the urban policies need to be reconsidered, that could be achieved through different interaction with urban green space. For example, residents will begin to cultivate fruit trees, variety of vegetables and ornamental flowers by working on the fields.

2. Urban productive landscape significance

Landscape is not only a field for human activity but it is a field of visual perception and it associated with all human senses. Aesthetical, perceptual and emotional characteristic of landscape could be experienced by all man's senses [2]. Various plant species, in the adjacent parcels, with different textures, colors, sizes and fragrances during different seasons, will stimulate human senses and it will create a different experience for the residence in the urban landscape. Different plant species with diverse rate of productivity causes urban landscape to continuously change, hence, urbanite's life quality and their contact with the urban environment will be affected by these alternations.

Breeding agricultural crops in local scale urban green space is a creative opportunity, in that unique ideas of design and management are practiced within the city, while, any two productive lands are not adorned similarly. People central urban productive landscape provides a different method of design and management which includes various individual reactions, and is not achievable through static comprehensive plan.

The urban productive landscape is able to gather people, revitalize missing sense of society, act as a source of education, and it provides opportunity for the public participation, which in turn leads to local economic development. People will be bounded to their environment through agriculture; they will become sensitive and curious about environmental pollution and consumption of their local resources. Moreover by educating urbanites with necessary skills, they will be able to manage their own local environment [1].

Urban productive landscape is a conversion of the urban landscape which is significant not only due to its physical characteristic, but also due to concepts of productivity and memorable experiences. What has been manifested in urban landscape is a sense of place, which is achieved by means of public involvement. Productive landscape inspires memorable mental images through Public participation in the process of breeding crops in different season and various days of the year.

Urban productive landscape distinguishes local differences in each region, which could be seen as distinct types of planting as a result of different cultural choices. Different plants grow in different climate, therefore the planting season is important and need to be considered in productive landscape [4].

Another significance of urban productive landscape is moving towards sustainable environment .Due to the lack of resources, landscape designers are required to reconsider their consumptive perception in order to design urban green spaces [3].Urban green space could be designed based on productivity rather than energy consumption. Since it supplies urbanite's required products within the city or in the suburbs without the need of transportation, it will provide job opportunities as well [1].

3. Urban Productive landscape planning, a case study of Tehran Southern agricultural lands

Tehran's nature is vast territory in between Alborz Mountain and central desert; it is limited to Alborz height in the north. Mountain located in the east and the sought east edge defines its territory in the east. And the residential cores and the cultivated lands occupied west's and south west's lands (Fig.1).

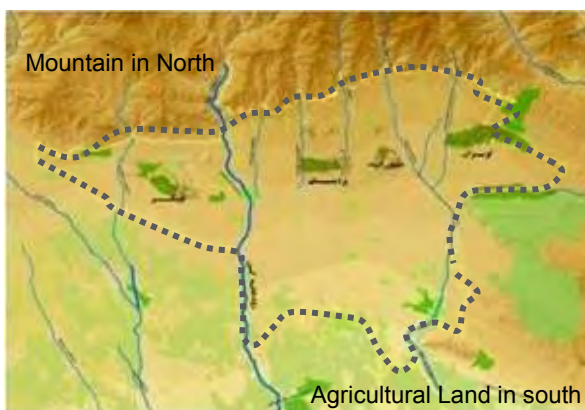

Fig.1: Tehran natural structure

3.1. A brief history of Iranian productive landscape

Throughout different periods of time gardens have been deemed as sacred places, where techniques of farming and gardening had been practiced. Survival of ancient Iranian cities depended on the presence of gardens, at the city's entry [6]. In ancient times cities were regarded as garden-city in that farming and agriculture were an inseparable feature of those cities.

The city was surrounded by large scale farmlands that reduced into private courtyard when entering into the city core. Farming is part of Iran's economical and production system, which promotes self-sufficiency. Iranian cities have lost their identity during years and they sought to imitate western culture, hence farm land had been replaced by parks during centuries.

Tehran is surrounded by agricultural lands and gardens (Fig.2). The city's wall was removed in 1270 for the first time and it was expanded in four directions. As the city developed a remarkable part of it remained in the form of gardens, farmlands and green spaces. And the new developed city spreaded out to fertile fields in the outskirts [5]. The Gardens gradually transformed into roads and buildings without any visual and conceptual harmony (Fig.3).

3.2. Site inventory and analysis

Tehran's agricultural land, is both located within the city and in the city's outer range. Productive landscape in the outer range considered as rural area and were designed according to a specific structural plan (Fig.4). The inner lands are located in three different regions and they have been structured according to their specific regional policy plan (Fig.5). Hence, there is not a coherent and unified approach regarding agricultural land design in Tehran.

Although an urban freeway acts as a border in between the metropolitan and the rural area, there is not any hierarchical process to segregate the rural and urban area. Due to Lack of integrated approach to agricultural land design and planning, agriculture as an important urban function is neglected. This leads to unauthorized construction, destructions of agricultural land and exploiting agricultural lands for other uses.

3.3 Proposed productive landscape's arrangement pattern in the selected site (regional scale)

Converting agricultural lands and gardens into urban and industrial land use, leads to environmental and economical consequences, which is threatening to the productive landscape's preservation. Therefore the importance of productive landscape development and preservation are as following:

- Tehran's southern agricultural lands perform as a visual land mark on entrance to the city.
- Urban gardening and agriculture revitalized the native landscape and is considered as Tehran's valuable heritage.
- Sustainable approach, accentuate productive landscape preservation and development.
- Productive landscapes are urban ecological zones, and their preservation, will strengthen biodiversity and the life cycle

Fig. 2, 3: Tehran map in 300 years ago, Tehran map in 200 years ago

Fig.4, 5: Agricultural lands located in Tehran's outskirts, agricultural land located within the city

Due to the importance of natural and productive landscape within the city and in the suburbs, various solutions have been presented, in order to integrate the urban development and the surrounding nature to protect and preserve green spaces and productive landscape.

A key objective of Tehran's productive landscape design and planning is to create a unified environment which is coherent internally and it conducts a seamless transition from natural environment to the urban environment. Through implementing this method productive landscape penetrated in to the urban context through a hierarchical process.

The specific characteristic of this design is to concern the economical, cultural and environmental importance of productive landscape. Moreover agricultural activities will be implemented as part of urban life and unauthorized construction prohibited in the agricultural lands (Fig.6), as result:

- Existing agricultural landscape at the city edge provides the opportunity to revitalized productive landscapes in the city. The agricultural land and gardens are territories where developed rural landscape penetrates in to the urban context.
- The agricultural lands located at the terminal point of the three (south to north) axis and the productive landscape enters through these channels into the city.
- Three agricultural zones linked together through development of green productive network that generates green productive zone in southern Tehran.

In this respect, to achieve this goal, long-term planning is required in order to improve environmental conditions to change the polluted land use.

Fig.6: Proposed agricultural landscape development pattern

4. Productive landscape design in neighbourhood scale

As stated above, based on landscape preservation's significance, agricultural lands and gardens in southern Tehran have been selected for the present case study. The main aim is to design and reorganizing the selected site which is surrounded by urban freeways both in the south and in the north. It should be mentioned that the site area is 140 hectares.

The selected site is located in the southern edge of Tehran, and it acts as a medium between the residential fabric and agricultural land in the south. The social and cultural factors and the visual characteristics are inappropriate, in this area (Fig.7).

This study intends to implement, productive landscape design as the proposed solution in order to work out issues within this particular site. The discussed issues consist of two aspects. Firstly, the internal aspects include" solving productive landscape problems that are associated with the residential context ,appropriate quality and integrity of the landscape ,appropriate accessibility and establishment of infrastructure facilities. Secondly, the external aspects include" creating strong linkage between productive landscape and the whole perception of Tehran and improving its functional role (Fig.8, 9, 10). Therefore, the following objectives are suggested:

- To define the site's functionality in both North and south
- To create an appropriate interaction between the two sections
- To design northern sectors in local scale and in relation to residential context
- To design southern sectors in regional scale, and to meet the needs and requirements of tourists and visitors

Fig.7: Inappropriate social condition in the site

Fig.8, 9, 10: Design approach (external and internal aspect), residential context penetrate into agricultural land, agricultural land in south west entrance

Appropriate interaction among urbanites and designed productive landscape, improves the quality in residential sectors and it encourages, urban landscape's revival in the district. Productive landscape's preservation is a process of quality reproduction, which integrates old and new values. And it protects natural relations among man and his environment; also it is an attempt to achieve local identity. Additionally, the productive landscape is capable to provide job opportunities and is a solution to social and economical challenges.

The overall population of the designated area is 8524 people, where 75% are the employed population and 16% are unemployed, hence 1022 people are active job seekers. Each hectares of productive landscape, is able to provide required vegetable needs of 200 people [8]. Since 60 hectares is under cultivation, the required veritable amount, for 1200 people is already provided, despite the fact that this amount is greater than demand (Fig.11).

Based on the calculations, 246 people could work on the areas under cultivation, although other occupations such as greenhouse transplanting, nursery maintenance, agricultural education, local recycling management, sales production management and monitoring livestock, are also available.

Considering the fact that 4.1 people can work on one hectare of land, 2500 m² can be cultivated by one farmer. Farming on an agricultural land with the area of 2500m² is profitable and could be regarded as their main job [8]. In smaller scale; agriculture activity is a part time job which supplies family food necessities.

4. Proposed productive landscape's land use, in neighbourhood scale

Based on the site's potentials, proposed land use has been designed (Fig.12). The entire site is a garden city; the northern part is designed in a local scale, and moving towards the southern edge, urban functions are implemented. Therefore, parcel size is becoming greater from north to the south and the land use will gradually meet local needs to greater urban requirements (Fig.13). The General approach is to design and plan based on productive landscape which distinguishes the designed site from other urban communities.

Fig.11: Excess of product over demand in the site

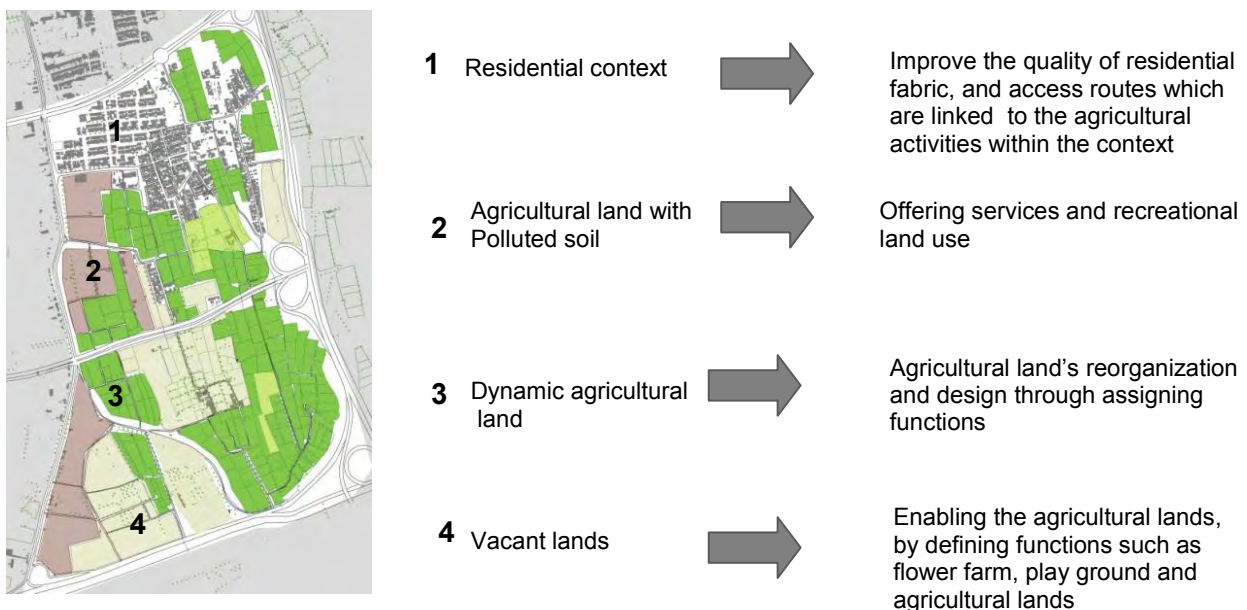

Fig.12: Proposed function related to the site potentials

To achieve the concept of garden-city design, urbanites and municipalities should be educated to become aware of the importance of productive landscape's revival and to motivate public involvement. Site's Implemented plans, are applicable models in other part of the city based on their required specific characteristic. By implementing the concept of garden city in productive landscape, preservation of energy resources, environmental sustainability and environmental management will be achieved through public participation.

Due to the site's potentials, following land uses are proposed:

Family farm : low density residential complex will be built in the site's west-east axis, and it will hold population of almost 1200 people in the area. According to published statistics, family size is 3 to 5 person in this area (4person in average). Each hectare of land can supply the required vegetables for 200 people; therefore to accommodate the needs of 600 people three hectares of agricultural lands should be allocated. Consequently a family of four will need 200 square meters of land surface to supply their own required fresh vegetables and to become self-sufficient .As a result 10% of food expenses will be saved in the family.

The proposed plan is, to maintain agricultural land adjacent to residential complex functional. The Agriculture land will become as garden for the residential units and the residents will farm in private space surrounding the residential areas (Fig.14).

Fig.13: Scale conversion and landscape diversity from urban farm to private garden

Fig.14: Proposed designed area for the family garden

Allotment garden: is designed for the purpose of providing job opportunities and also as a source of income for the residents. Due to land limitations, it is estimated that 35 persons will be employed in the community. Allotments farms evolve among the residential blocks (Fig.15). The remaining agricultural lands located in between residential complexes would be allotted to the residents. Allotment farm land is a manifestation of private garden in the public area. This will incorporate resident's individual characteristics so that residence will become designers of their own green spaces. Thus Landscape features are constantly changing while different owners will change field structure each year (Fig.18).

Neighbourhood farm: includes child play ground, places where residence spends their leisure time, sport fields and green productive fields. 2/5 hectares is devoted to play grounds and sport field, with the intention of employing 20 people, agricultural lands with the area of 1 hectare is provided (Fig.16). Hence, neighbouring farm is a public garden for everyone, where agricultural landscape and recreational spaces are integrated (Fig.19).

Farm-institution: includes educational, religious and health care centers in the selected site. These institutions have the ability to interact effectively with the productive landscape. Agricultural education could be considered as part of school's curriculum. As a result adjacent agricultural parcels become part of school yards where teachers and farmers guide students to cultivate crops, in action. Similarly religious institution, perform training courses to educate volunteers urbanites. Such approach is the agricultural landscape's management through public and private sectors' participations, while it increases sense of responsibility toward surrounding green space (Fig.17).

Fig.15: Proposed design area for allotment garden

Fig.16: Proposed design area for neighborhood farm

Fig.17: Proposed design area for farm-institution

Urban farm: it is located at the site's southern edge, the urban farm contain agricultural lands, which includes agricultural facilities (storage) and resting areas for the urbanites. Total areas of the southern part is 60 hectares, 8 hectares of which is not appropriate for the cultivation due to soil pollution, and its estimated to provide job for approximately 190 peoples in the urban farm (Fig.22). Urban farm is designed in regional and urban scale, is located adjacent to urban freeway with the intention of providing the required needs of transits visitors, Such as tourist or travelers. It's preferable for the urban farms to be managed by the local residents so that they would be able to host the travellers and tourists (Fig.20).

Bazaar garden: is supplying Direct, fresh healthy production. Bazaar gardens, will offer the farmers the potential of directly selling their products in local market (Fig.21).

Fig18, 19: Allotment garden, neighborhood farm

Fig.20, 21: Urban farm, bazaar garden

Fig.22: Proposed design area for urban farm

5. Conclusion

Restoration of biodiversity is an important benefit ,which is derived from productive landscape As result, various species of plants entered to the urban green space, various form of life cycle has been formed.

Urban productive landscape encourages people to learn new life style in the hope of increseasing their self confidents, in addition to food production. Crops production in the urban context encourages community members to work and to produce collaboratively for achieving a unique and common goal ,without any discrimination. Furthermore, public health will be enhanced by working on the farm lands.

It is worth mentioning that if the cost effectiveness of productive landscape can be demonstrated the restoration of which is more likely. For this reason a remarkable percent of the population will consist of farmers who will produce urbanites' agricultural needs resulting in the self sufficiency of the city.

In the selected site, agricultural lands and community landscape are integrated. This involves a hierarchical process of development from private space to public areas in the city .Agricultural landscape offers various land use and identity in form of urban farm, neighbouring farm, allotment gardens, family farm, and productive landscape will become part of urbanites lives.

LANDSCAPE OF NEW ENERGY

Alessandra PAGLIANO,

Dipartimento di Configurazione e Attuazione dell'Architettura, Facoltà di Architettura, Università degli Studi di Napoli "Federico II", Italia
pagliano@unina.it

Abstract

The domain of technical knowledge has led to a deconsecration of the beauty that traditional cultures associated for centuries to the landscape, so allowing selfish and indiscriminate use of it, and therefore abuses: contemporary landscape is covered with all sorts of infrastructures, arbitrary in shape, location and size, without any reference to the image of those places.

Barely tolerated by virtue of their necessary function, mobile repeaters, antennas and iron pylons of the power lines are domineering presences, unable to interact with the landscape.

In the same way, it was shown that, although in general there is a substantial support to renewable energies, local communities often perceive them negatively because the installation of such systems is greatly impacting on the landscape. The strong perception of the solar panels is now the biggest problem.

This paper addresses the problem of a visual integration between infrastructures and landscape, based on morphological elements, color and materials, with a particular attention towards new technologies for the production and distribution of energy, both traditional and photovoltaic, focusing on contemporary research of companies that base their philosophy on the desire to combine innovation, technology and design for sustainable development of energy production and transmission networks, in respect of the landscape. In particular, is here presented a new method, based on perspective studies, that allows to place the new infrastructure in accord to the shape of landscape.

Parole chiave: landscape, perception, perspective, infrastructure

1. Infrastructures and landscape: a different point of view

The aspect of a place is determined by its consistency of expression, by the complex units of meaning, both symbolic and aesthetic, that characterizes unequivocally that piece of land. A set of characteristics defining the irreducible singularity, the specific physiognomy of the place, its recognizable expression, are signs not reducible to pure aesthetic appearance. Do not forget, in fact, that same area, same as in morphology, climate data, vegetation, geological structure, etc..., can be interpreted in diverse ways by different cultures: the objective data of the geographic lands set only the conditions of a possibility that can come, within certain limits, emphasized differently, depending on the culture of the society that takes that land as its own landscape.

The multidisciplinary considerations of recent years about such issues have led at last to distinguish, and specifically characterize, terms and concepts such as "territory", "land", "environment" and "landscape", which are not synonyms: in particular, the definition of landscape provided by the European Convention (2000) clearly specifies that landscape is always a cultural construct, related to the sensitivity of the perceiver, while the term "environment" thus defines an objective natural and ecological condition.

In particular, the Convention of the European Council extends the concept of landscape to all places, thus overcoming the traditional aesthetic sense, certainly reductive, and so defining it as the place and the

irrepressible expression of a cultural identity. Every landscape, both natural and cultural, both excellent and degraded, represents a life framework for the affected population, which has a profound effect on the quality of life.

In this perspective we emphasize the importance of the coherence that every territorializing act must have to not potentially dissolve the unity of expression of the place. When a series of inappropriate interventions, and dissonant transformations takes place on a land, the image of the landscape related to these places end up to be gradually unreadable, with the consequent failure of recognition by the community. This produces consequent effects of further deterioration, such as vandalism but also disintegration and social distress.

Much of the responsibility of the irreversible destruction or degradation products on our contemporary landscapes is a consequence of the indisputable primacy of economy, ideology conceived as an immediate profitability, regardless of intangible meanings like beauty or preservation of memory, and myopic in respect of long-term effects of today's actions.

The domain of technical knowledge has led to a desecration of centuries-old aesthetics culture of nature and landscape, allowing self-centered and indiscriminate uses of it, and therefore abuses: our contemporary lands are covered with all sorts of infrastructure, settled with arbitrary shape, size and location, without any relation to the image of those places, stratified for centuries.

Heroic symbols of modernity in the first half of the XX century, the infrastructure has today become the mainstream support for a process of technical and technological upgrading of the territory to the needs of our contemporary society.

Barely tolerated by virtue of the essential function performed, the mobile repeaters, antennas and pylons of power lines, is an arrogant presence, unable to communicate with the landscape.

In a similar way, it was demonstrated that, although in general there is considerable support for the dissemination of renewable sources of energy, at the local communities often perceived negatively the installation because of their strong impact on landscape.

Like everything related to the physical modification of a territory by man, the infrastructure must necessarily go back to be a topic of architecture.

An urgent and necessary discussion can be carried out from understanding the progressive distance that is currently emerging from the infrastructure projects, on one side, and the tradition of urban design on the other. The principle of identity and recognizability of the infrastructure plan, that provides to prefigures the degree of compatibility and transformability of a territory, must necessarily be acquired awareness by the designer: what pertains to the perceived size of the landscape must plays a decisive role in the plan, like the functionality, cost and safety of the works: the infrastructure design must adapt itself to different landscapes traversed, as an essential prerequisite for assessing the quality of a plan.

2. Landscape of new energies

The research for a balance between energy needs, the landscape and the environmental safeguard, has recently characterized a new line of experimentation for Terna S.p.A., company responsible in Italy for the transmission and dispatching of electricity on the grid at high and highest voltage throughout the country, in finding appropriate solutions to ensure the country the power it needs with optimal reliability, cost and environmental sustainability.

They have adopted several methods of modern bioengineering, by exclusive use of native species of bushes and trees, to mask the sites of power stations, especially of new edification, as well as the attempts to camouflage the pylons of power lines. All these expedients, however, clearly indicate how much unrelated the infrastructure is into the landscape. The reasons for the dissonance between landscape and infrastructure are often structural and irreconcilable with the simple mitigation measures.

Terna S.p.A. has also recently cast an interesting competition for ideas, to conceive and to plan new pylons, with low environmental impact, by combining innovation, technology and design for a sustainable development of the transmission grid, in order to satisfy both the needs of the electrical system and the respect of the landscape. In fact, the functionality may be declined in various forms through the aesthetic research, such as happens with the new high-voltage pylons which are intended to renew progressively kilometers of old high voltage power lines.

The high-voltage pylons are perhaps the most difficult objects to be reinvented in the name of creativity; hardly tolerated according only to their utility as scars in the landscape, in this perspective are reinvented as landmarks, proud signs of modern technology able to dialogue with the land forms, in order to contribute to characterize the image of those places.

TERNA – Lodi-Maleo

Fig 1: Terna new proposals for electrical infrastructure, photographic simulation of mitigation for a new power station construction, by the acts of congress: *Environment, landscape and infrastructure*, Rome, October 2009.

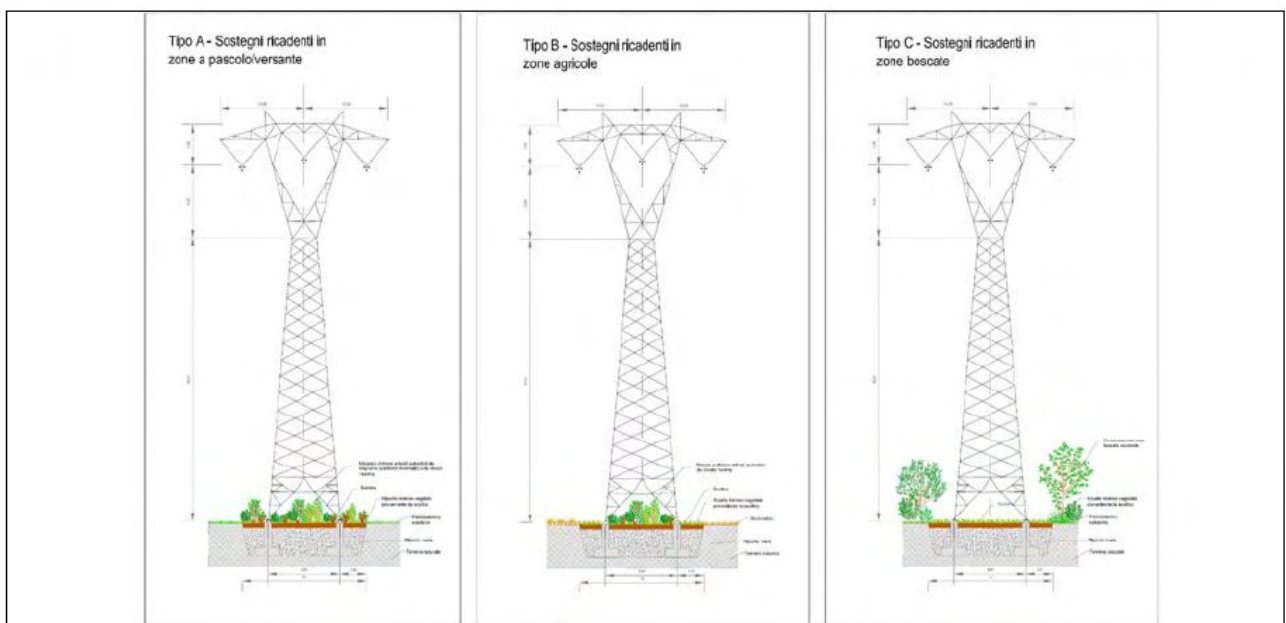

Fig 2: Terna new proposals for electrical infrastructure, solutions for pylons, by the acts of congress: *Environment, landscape and infrastructure*, Rome, October 2009.

The competition titled Pylons of the future, banished by Terna S.p.A. in 2007, was won by the Studio Rosental, leader of the group composed by the architect Hugh Dutton with the companies Cegelec Centre and Gozzo Equipment.

The new generation of support, after *Monostelo* (which has the pylon base of only five square meters) and *Foster* (named after the architect Norman Foster, who designed them for the power line recently built on the hills of Scandicci, near Florence), is intended to progressively renew miles of old high voltage power lines from one side to the other of the peninsula.

Lightweight but resistant, flexible but stable the *Rosental-Dutton* pylons are inspired by the shapes of trees, but using advanced materials and according their design to the attempt to reduce high contrasts, even between light and shadows.

3. The landscape design as an instrument of analysis and prediction of the transformation

On the basis of the considerations so far reported on the contemporary landscape sensitivity in the infrastructure design, the development of a scientific methodology for assessing landscape impact is the product of a series of researches I have conducted experimentally during the last years, on a large number of case studies, scattered throughout the country, whose aims is to provide Public Administrations an important tool to read the landscape.

In fact, is important but not enough, to design new shapes for pylons if their disposition will finish to ignore their strong relationship with the forms of the surrounding areas.

The objective was to formulate particular tables of visual impact, specific to each category of large infrastructure, such as roads, grids for producing and distributing energy, telecommunications towers, etc...

The main purpose of these guidelines was to direct the designer in taking conscious choices in order to avoid the major critical points in each individual category of works. In terms of approaches, our guidelines aim to prepare active policies based on the correct identification of the those values that we must be preserve or implement by the infrastructure, through the transformation induced.

We provided to create a sequence of images and tables, an iconographic repertory with operational instructions, that offers an open path to multiple uses, not as an abstract methodological protocol but as a tool to allow the designer to find the most suitable approach, leaving him the task of identifying the best solution, with respect to a given problem in a particular area. They play an interpretation service of landscape, identifying features of those recognizable signs which contribute to form the image of those places, adaptable to different situations, so having a guidance function, especially during the preliminary draft, because they facilitate the identification of problems and suggest new interpretations of landscapes.

In the images presented below, the first table intends to lead the designer in the analysis of the landscape most recurrent forms, providing graphical examples of simple interpretation in order to correctly analyze the condition *ex ante*, to be compared to the situation of the same place *ex post*.

Fig. 6: An iconographic repertory of the most frequent and recognizable forms in the landscape, images of Fulvia Riccardi.

Fig. 7-8: Natural examples of REGOLARE - ORDINATO (regular - ordered) and CASUALE (accidental).

Fig. 9: An iconographic repertory of the most frequent and recognizable scale of relationship between built elements and landscape forms.

Fig. 10-11: Real examples of EFFETTO RIPETIZIONE (Repetition effect) and FOCALIZZATO (focused).

Figg. 12-13: In the first example is represented a infrastructure in a decentralized position respect to the point to which the lines of the road focus the attention. In this case is possible to implement simple measures to mitigate the visual impact, on the contrary of the second scenery in which the presence of a tall element is perceived as a strong presence, whose impact cannot be mitigated with bushes and trees. The dominant position suggest the designer to adopt a suitable shape for his pylon or tower, in order to create a new landmark, whose aesthetic aspect could implement the value of the transformed landscape. Images of Fulvia Riccardi.

4. A question of point of view: landscape and perspective drawings

In order to analyze, evaluate and foresee the visual effect caused by the inclusion of a new infrastructure perspective drawing must once again become the preferred method of representation, due to its similarity with the visual Images physically perceptible by the human. You cannot assess the forms of landscape analyzing a plan or orthophotos, however useful in the organization of the territory, whose point of view is infinitely far away, and thus inaccessible. Landscape is strongly characterized by its visual dimension that needs to find a correct representation.

Camillo Sitte meets Robert Venturi at Berlin Südkreuz

Jorg SIEWEKE,

School of Architecture - Landscape Architecture Department, University of Virginia, Charlottesville, USA
sieweke@virginia.edu

Abstract

How can a peripheral high-speed transit hub be reconsidered as a collective public space. Sitte's idea of significant gathering places is scaled and accelerated in Venturi's spirit of flows to contrast the romantic replica of the European city with a contemporary dimension of trade and commerce. The proposal of a hybrid space that, is on one hand based on the urban planning tradition of bracketing space by means of a coherent geometry of place (Camillo Sittes' European city) and, on the other hand, attempts to civilize the neoliberal "space of flows" (Venturi's Las Vegas): an open square measuring eighteen hectares bridges the beltway and creates a pedestrian path from *Berlin-Südkreuz* train station to the adjoining residential and commercial neighborhood. The center of the square creates a void measuring 800 by 225 meters, dramatizing the surrounding traffic flows. The crucial idea is to update the place of exchange, of trading, of action. The proposal suggests a market square for the twenty-first century that does not negate the dimensions and speed of recent flows, but rather embraces and civilizes them. *Südkreuz* is dynamic; a programmatic *passé partout* frames already existing as well as anticipated future uses.

Keywords: Public space, urban design, periphery, beltways, public infrastructure

How can the idea of public open space of an inner-city market square be translated to the world of motorways and big box real estate? The paper critically discusses the recent development and offers an alternative hybrid derived from both, Sittes' and Venturis' ideas.

Whereas in the center of Berlin the historical layout of the "European city of the flâneur" is being reconstructed with great care, on its outskirts things are happening on a sizeable scale and at a different speed. The rift is found just a few meters south of the compact neighborhood of James Hobrecht's *Schöneberger Insel*. *Südkreuz* is an essential rail-hub in Berlin with great potential for development. The ring expressway, the beltway line of the commuter railway, and the new high-speed train connections form the infrastructural backbone for this highly dynamic site. Due to the late insertion of the hub, the *Südkreuz* site is spatially isolated from its immediate urban environment. Enormous corridors of infrastructural corridors slice through isolated residential and commercial neighborhoods - typical for peripheral milieus. Ideological antitheses of the urban condition are colliding here that can best be illustrated by comparing Camillo Sitte's and Robert Venturi's concepts of the city.

Sitte can best be characterized by the concept of *places*, meaning sites of identity and living, framed spaces with perhaps irregular structures but with recognizable boundaries marked by stability. These places are suited to lingering; they are "gathering places under the open sky" with a "strong influence [...] on the human soul." [1] By contrast, in his analysis of the Las Vegas Strip [2], Venturi stands for flow, for places of

movement marked by symbols of passage. Venturi's city is a neoliberal one; its symbolic architecture in the "space of flows" [3] is primarily perceived from a moving car.

The predominant ideology of preserving the morphology of the nineteenth century city excludes its manifold contemporary everyday aspects. Often the infrastructure of our time is neglected hidden or pushed to the margins. The urban space should be protected from being drowned by the rush of automobile traffic. For example, the delivery of goods to the "marketplace" on Potsdamer Platz was buried, at enormous expense, in five underground levels, along with the Tiergarten-Tunnel. The proposal to connect the Südkreuz train station discussed here⁴ is an effort to update these two approaches; it suggests the ideological antithesis of *places* and *flow* as an opportunity for hybridization. Until now each of these antagonistic concepts of space negated the other, avoiding the negotiation of their boundaries—and hence any chance of finding the symbiotic potential of its antithesis. The plan presented here, by contrast, strives for an innovative interface that is sufficiently open to integrate the "space of flows" without neglecting the "sense of place" that living in a neighborhood makes desirable in the first place. Sitte's idea of the importance of places as architectural gathering places is scaled and accelerated in Venturi's spirit in order to contrast the romantic replica of the European city with a contemporary alternative that today opens up onto the flows.

The proposal [4] of a hybrid structure that, is on one hand based on the urban planning tradition of bracketing space by means of a coherent geometry of place and, on the other hand, attempts to civilize the neoliberal "space of flows": an open square measuring eighteen hectares that bridges the beltway and creates a pedestrian path from Südkreuz train station to the adjoining residential and commercial neighborhood. The center of the square creates a void measuring 800 by 225 meters, dramatizing the surrounding traffic flows. The crucial idea is to update the place of exchange, of trading, of action. The idea is to create a market square for the twenty-first century that does not negate the dimensions and speed of recent flows but rather embraces and incorporates them. Südkreuz is dynamic; it is captured architecturally in a programmatic *passee-partout* that serves to frame already existing with further anticipated patterns of use.

Negotiation between these programs, provoking their confrontation, collision, rather than discretely avoiding it, characterizes the principle of the urban condition. Imagine the people returning home from the southern lots of the garden colony offering their fruit and vegetables on the parking lot of the Moebel Kraft furniture store. IKEA customers cross the square as they bring their purchases home from the market hall on the circle line of the commuter light rail. The residents of the Schöneberger Insel neighborhood fill the arches under the railway with day-care centers and cafés à la Savignyplatz. LIDL can fit into this *passee-partout*; we have already accommodated its need for space, including open parking spaces meant to suggest open cash registers. The needs of the residents for their everyday living environment ensure the square will be lively. The collective activities civilize the "space of flows". The headstrong appropriation reacts to a wide variety of speeds and dimensions and suggests Südkreuz to transform from a peripheral transfer hub to a lively urban place in a metropolis. This reconfiguration allows connecting the seemingly incompatible. Rather than discretely avoiding opposites, their encounter is seen as an enrichment. The inclusive approach avoids the museum quality and stagnation of Sitte's idea of the city and civilizes through daily negotiation Venturi's "space of flows" against its un-aesthetic neglect.

Abstract

The lack of a deep sense of responsibility and respect for the distinctive features of place, to which the production of practising architecture must make reference, very often produces designs of compositional morphologies that are not fitting and inadequate to the geographic nature of the *topos*, with heavy repercussions of environmental degradation on the sustainable ecosystems.

The entire apparatus of signs that the territory manages to express must be constructive and strongly determining in the definition of the strategies that should guide and support the whole procedure of the stages of creative thought.

In this sense, proceeding from the first intuitions that have come about through the accurate representative transpositions on paper, the entire successive process revolves around the compatible *ratio* with the eco-sustainability of the place, that unites the planned intervention with the area of land.

The materialization of innovative modernity, through the volumetric control of the parts and in relation to a framework of systemic congruence, is realized in a *frottage* of iterative relationships between what is full and its contrary.

Accordingly, given the close bond between design and plan, precisely that we are today experiencing a moment of profound instrumental changes, the complexities of the outcomes of innovative designs, seen within the evolution of the creative processes, become qualities to investigate and understand, in a systemic way, with an introspective eye.

Keywords: Environment, *Topos*, Morphology, Sign, Sustainability

1. The design-concept process and the signic imaginary as impulse of the creative act (M. Liuzzo)

Today more than ever, the life of the human species is conditioned, besides by the course of natural phenomena and impact of forces of a higher order, by consequences that are not always governed by political-decisional logic, which, from the global to the local and individual scale, are unfortunately not always accompanied by a conscious assumption of responsibility.

Inevitably, at the manifesting of needs and requirements, in the first instance Man resorts to instinct and cultural resources, able to trigger that logical-ideational process taking place in the complexity of the articulate functions of the brain.

Here, a fascinating and to a certain extent still mysterious, organizational structure is housed, made up of different interacting reticular areas, heading up on one hand a logical mind, situated in the left hemisphere, rational, sequential, mathematical, that organizes information and communications, and on the other, an emotional mind, that occupies the right hemisphere, irrational, intuitive, creative and oneiric. [1]

Fig. 1: Ideational accelerations of the creative process. Zaha Hadid, *Parametricism Research*.

Understanding such mechanisms of the cerebral apparatus allows interpreting the articulate creative path that is triggered each time one intervenes on a *topos* in order to transform it according to a determined framework of human aspirations.

Beginning from the primeval idea, it becomes necessary to define heuristic strategies toward the search for equilibrium between markedly different elements that are ascribable to the identity features of the place, to the fecundity of forms, to functional, cultural instances and to technological innovations.

It is a kind of journey without a definite route or pre-established destination and, perhaps, without any effective conclusion, which is undertaken through stimulating all the systems and mechanisms of our cerebral apparatus, also those of our unconscious, with implied and latent potential.

The inherent danger in this type of journey, each time new and different, is that it may trigger a certain inhibition of creative capacities, almost a kind of 'ideational apraxia', due to various causes, among which attitudes of passive adaptation to technological innovations, at times extreme, or a certain satisfaction in the unconditional repetition, often unjustified, of recognizably autographic forms, seem to prevail in contemporary production.

Fig. 2: Empirical logic and heuristic strategies. Zaha Hadid and Patrik Schumaker, *Parametric Urbanism*.

To safeguard fertile, dynamic and active creativity, it is therefore determining to use that part of the operating memory that may access and critically elaborate the sensitive, perceptive and emotive factors linked to the *topos* and previous experiences, to enrich the resources of the imaginary, abundant in signs at times merely functional, at others prevalently poetic or utopian [2], which are translated, after a logic-evolutive pathway into structured and coded project signs.

All the stages of design-concept thinking are characterized by alternating phases of releasing creative energy, of comparison and rational verification and of production and reception of impulses and stimuli in the sensorial parts of the brain. These are processes of design-concept acceleration, which beginning from the recognition of the actual configurative state of the site and existing structures, interpreted through specific orographic, territorial and cultural values, set off a continuous development of reasoning and possible prefiguring, congruent with the givens of the problem, with the expectations of the system of the asset, with the updated technological progress and with the contents of the apparatus of already experienced and thus acquired knowledge.

This apparatus of signs cannot but be proactive and strongly determining in defining the lines of force that must guide the entire procedure of an ideational thought that, with a deep sense of respect for the identity characteristics of the place, feels responsibility to produce designs of composite morphologies that are not only fitting to the geographic whole of the *topos*, but that can also positively affect the environmental quality of sustainable ecosystems.

With this responsibility, the morphological complexities of the project interventions represent a magical moment and a crucial workbench in which the process of manifesting the articulated systemic coherence of ideas is put to the test.

Ideas that, from the action of the first manifesting as impulse of elaborating sensitive and perceptive factors, to the fulfillment of a logical-evolutionary procedure that may clarify all the parameters of reference, remain closely connected to the concepts of freedom and complexity.

All this leads to a profound consideration on the choice of procedures that have a fundamental and not simply instrumental role, in the expression of the design-conception process in all its stages.

Suffice it to think, for instance, of the architectonic creations by Zaha Hadid who, with regard to the importance of the choice of suitable tools to shape the idea, states: *"From the start, I thought of architecture in a different form. I knew what I wanted to make and what I wanted to design, but could not make it in the conventional way, because with the traditional methods I didn't manage to represent it. The traditional tools of representation were of little aid. Thus, I began to search for a new way to design, in order to try to see things from a different point of view. Then, with time, those designs, those perspectives and those paintings have been transformed into my true instruments of representation"*. [3]

So design creation defined by strongly characterizing signs, or by apparent morphologic epidermic simplicity, combined with the complexity of inner lines of force, compel serious reflection on the innovative methodologies of representation of the product of architecture at the service of the primeval idea.

2. The sign of the place and its mathematical rationalization (R. Valenti)

Care for the environment, in a broad and articulate conception, comprises all those aspects of life that lead towards respecting and safeguarding nature, seen in its fullest meaning, in which it is possible to include the human component through its combining into communities.

The cognitive approach, preceding the project and its representation, is based on models that tend to simplify the complexity of the interacting components that, in their arrangement in system, constitute the problem to tackle and resolve. These initial considerations mean that there is a consequential effect between architecture, place and thought; namely that every architectonic choice, that takes the complete and complex panorama of a site into serious consideration, must, given the peculiarity of the task entrusted, start off from intense thought and interconnect, unavoidably, with the problematics connected with the site's sustainable development.

Since it is known that a place conditions and influences the formation of man, and since man with his ideas makes the project evolve, which in turn conditions the place, it follows that the preliminary reports and researches that consider the site a complexity to be interpreted and used, are grounded in this continuous cycle.

From the viewpoint of composition, the approach should tend towards a form of union and synthesis of the contemporary with tradition, oriented towards research in which innovation is combined with the specificities of the tangible and intangible signs found in the situation in which the intervention is being made. Rational thought, of functional and constructive logic, is nurtured and supported by the intuition of the overall sense of the environment. Overall, because a single idea may give resolute answers in different fields, from the economic to technological, to the social and environmental.

Indeed, regarding stabilized urban contexts, the social structure, in a given temporal and geographic frame, expresses, in the context of specific productive and economic conditions of the building process, the requirements and the ways of life of a determined group.

In this context, with reference to design and project creation, it is important to ask what the spatial and material limit is in which the process of growth and living world can coexist without coming into conflict.

It is a widely shared concept that architecture reflects and expresses civil and social life in which it operates, in continuous evolution and heavily influenced by the digital revolution. This latter has produced determining effects on the aspects of aggregation of daily life, among which one that is closely linked to design, namely the dissolution of the concept of space, in its strictly physical sense, which also entails a model of individualistic society, tending towards the globalization of expectations and desires.

The virtual dimension, wherein different cultures find a common denominator, on the other hand, implies the risk of a composite approach that renders architecture a separate issue from the physical space with which it interacts, with the consequent process of developing an *a-topos* that translates built realities into unknown and non-characterizing elements, dissolving, from a social point of view, that fiduciary relationship between the inhabitants of a place that in the societies preceding us and in the present small communities proves to be a substantial component of human life.

Fig. 4: ODBC – Odile Decq, Benoît Cornette, *Museum of Liaunig Collection*, Neuhus, Austria, 2004.

“The loss of place, asserts Christian Norberg-Schulz, proceeds at an equal pace with the loss of the basic language, of building customs and styles. Having impact above all is the loss of the basic language that, independently of the local language, renders an architecture as close to life as possible. [...] Since the formal language is based on qualitative knowledge, the prevalence of the measurable cancels it out” [4]

It therefore follows that a qualitatively appropriate understanding of the place is the binding foundation for the realization of architectures in concord with aesthetic, existential, social and also symbolic values; the design of the *topos* with its continuous transformations, in turn, must allow expressing the senses and meanings, as well as the essence of city and social living, with the store of knowledge and traditions, acquired and passed on.

The fascination exercised by the possibilities offered by progress in the scientific-mathematical field, spilling over into technique, contributes to giving form to an expressivity that makes the curved line evolved and fluid, apparently free, the emblem of the possibilities of contemporaneity.

Graphic elaboration, through digital manipulation with the continuous transformation of flow lines, besides achieving a captivating aesthetics of images, transfers and explicates content and meanings linked to the essence of places, to their history, to their traditions. Topology is the geometric science that allows managing the soft forms of contemporary expression with rigorous algorithms; it *“is the discipline of the relationships that occur in the place and the space surrounding the place and does not recognise metrics”*. [5]

The digital, with all the tools deriving from it, also offers the opportunity to translate what we thought exclusively conceptual in plastic models; three-dimensional printing, multi-axis milling machines, are instruments that, thanks to appropriate software, are able to give tactility to any form.

Consequently the representation, having expanded its expressive capacity, from the traditional to digital, whose software, founded on mathematical algorithms, enable an articulated dialog between thought, hand and project design, has acquired a wealth of elaborative possibilities that are close to natural processes.

Non-Euclidean subtended geometries, in this way, explicate complex structural forms, above all in the contents, and therefore their potential is still to be researched in configurative-qualitative aspects rather than in quantitative ones.

The ensemble of all these aspects, acting together on the random order of the process of planning the future and with which we are confronted in the moment of cognitive exploration and graphic elaboration, are determining in devising the process of developing the idea. They are precisely those which, identifying the signs of the specificity of a place, allow, through the project configuration, to maintain their complex and chaotic identity.

This approach to the problem, allowing architectonic form to emerge from the understanding and reflection on the surrounding environment, in turn, may take the aspects linked to building techniques, to materials usage and the morpho-typological features of the basic residential building of a determined context into serious consideration. The relationships that, in this composition pathway, are established between technological specificity and architectonic thought, tend towards experimentation that transforms intuition into innovation. The environment system breaks in irrepressibly, no longer in defining sinuous forms, as in nature, or conceptual, in relationship to the expectations of the social-economic system, but in the careful and respectful attitude of a heritage that may not easily be renewed.

Fig. 5: Zaha Hadid, *Competition for museum of Nuragic and Contemporary*, Cagliari, 2006.

3. Sustainable morphology as integral to the signs of iterative and matrix phenomenal realities (G. Taibi)

Very often it happens to have to take account of the consistency of widespread phenomenal realities, the fruit of the creative process of man that is manifested in a simple and spontaneous way.

Such are cases ascribable to the translation in architectonic terms of required apparatus, crudely expressed by those describing in practical terms that which represents necessary needs.

The mind engages in this fertile activity, carrying out a system of appropriateness between necessity and areas, planimetric and volumetric, according to the space available.

In all this, the human mind unconsciously also takes account of external factors, such as accessibility from the outside and the relationship of visual communication with the surrounding environment, which unequivocally tend to affect the articulation of his habitat.

We thus witness an expressive freedom that is, with certainty, detached from the competence of operators in that field, experts in the morphologic composition of making architecture.

In reality – it being understood that innovative processes and transformations that determine progress in the various fields of knowledge, art and technique are surely the outcome of those constructive qualities of the imagination, of fantasy - the product of creativity must be interfaced with the reality of the reference context.

Fig. 7: The site suggests. Emilio Ambasz, *Schlumberger Research Laboratories*, Austin, USA, 1982.

Everything must be brought into play in a very broad and shared concept, namely with appropriateness to the typology of the *topos*.

In practice, one faces a situation attributed to the systemic entirety of the complexity that plays a certain and determining role in the issue of sustainability in the morphologic order of architecture; sustainability that, generally, concerns a subject, whose interpretation is by vocation very broad and surely very close to conservation and the prospects of compatible development of the territory.

“It must in any case be recognized that at every historical moment, human activity, notably that of building, has set out to satisfy present requirements, implanted in some way in the groove of the former ones, but only where it could acknowledge their permanent validity, and projected towards the future, but only where it might augur a real expectation of advantage.” [7]

We must fundamentally reflect on the conditions with respect to which the human being, in expressing himself by producing morphologies adapted to the needed apparatus of the individual and grafted onto the

features of his family structure, are manifested in intuitive and instinctive forms of spontaneous architectures, but marked by testimony and a sentimental memory of the past.

We may, for a moment, consider that the intervention of man, in light of the concept expressed by De Rubertis, instills the canons with an intrinsic natural quality, so much so as to be considered formidable and certainly channelled among the interventions of a strong nature, of continuity with the past and with a powerful chromatic, pictorial and aggregating content.

And so these considerations, ironically, allow a reflection, namely that those individual and successively concerted interventions, may deserve reference to a general fabric and to have some value of note if seen in a context in which appraisal, comparison and competition must or may be regarded as a stimulus and spur to achieve results that have features of a certain quality in the panorama of artistic production.

But these spontaneous, sincere and impulsive formulations, reassessed in the light of opportune stylistic interpretations, face and are confronted with the distinguished interventions by those who, operating in the field with profundity of intention, bring into play a composure of forms studied in accord with the vigorous and forceful lines of the *topos*.

They are interventions that leave a mark, with decisive and significant character, upon the territory, sanctioning rigorous relationships with the site, in which one acts, with determination, in full accordance with the lines dictated by the morphologic configurations of the places.

In this sense, the perfect synchronous behaviour between the distinct features of particular interest suggested by places and acting according to the dictates of a meticulous rigor that envisages cultural preparation and sensitivity of those operating in the field, is successful and of certain efficacy in the outcomes of the interventions on the territory and in the increasingly dynamic, singular and articulated morphology of the projected compositional whole.

They are interventions that, precisely in being fully integrated in the environment, manifest morphological logic, sometimes sinuous, sometimes fragmented and subdivided, which in their evolutionary development, imply a coherent set of iterative and matrix processes.

Fig. 8: Zaha Hadid, *Dividing Curvature* is a method that creates curvature sensitive mesh.

They are interventions that express the intention of being liberated from the rigidity of Euclidean geometric schemes in order to arrive at decidedly more evolved new systems.

They are interventions that in a structural *unicum* of form, fuse art with nature, evoking “sharp, incisive and memorable images”, in a word “vivid”; an “inner need should characterize every image, as form and as meaning (...) as a wealth of possible meanings”. [8]

They are interventions in which the choices and treatment of materials, the relationships between solids and voids, the transparencies and the epidermic folding of the skin of the building, in relationship to the definitions of volumetric complexity of the architectonic organism, are determining.

It would be fantastic today to be able to reason in terms of transformation and flexibility in instantaneous time of the material and therefore of the morphological configuration of our volumetric layout.

The intelligent man-structure relationship, in which the space is deformed and adapts in real time in rapport to the needs of man, may certainly be a stimulating search, but in the utopian current state of things, it would seem at best to be able to combine with the dynamic and virtual qualities of an electronic game and certainly not with the problematics of real space.

In truth, we are witnessing today - and we are in a condition to be able to supply ample documentation on these lines - the propulsion and wealth of design-concept thinking, strongly dynamic, in which a robustly expressive freedom moves instinctively in interpreting the place, nature, environment and landscape.

Cities, without setting any brake on progress and development of our civilization, must emerge with determined intensity and succeed in the intention to allow favourable opportunities to the true concept of innovation in the processes of versatile creative fertility.

In this sense, we must apply local understanding to the developments of those territorial models and those architectonic morphologies that may give vitality and renew the productive life and processes of communication, on which the carrying out of our activities depends.

One possible response may be found in the composite expressions of form, generated by iterated and matrix systems, the indisputable locus of complexity theory.

Certainly, it would not be utopian to think of programming the growth and transformation of the city as in a morphogenetic systemic unity, which is self-regulating and that moves through procedures of calculation consisting of genetic algorithms that entail generative processes and selective criteria.

And so the domineering character of the production of doing architecture emerges.

We are in the presence of strong, well-defined signs and concepts in which sinuosity and undulation, fragmentary forms and broken lines define the lines of force of morphologic complexity.

In all this, there is also the concept and closeness to digital liquidity and fluidity of the designed forms that are inevitably linked to the stylistic trend of parametricism that, albeit moving in the direction of the non-rigidity of forms, in the non-serial repetition of elements, in the search of complexity as varied order, seems however to have failed to relate to the physical and ergonomic nature of the human being.

"Whereas all architecture of the last 2500 years was constituted from the arrangement of a small number of ideal geometric figures – cubic volumes, cylinders, hemispheres, and pyramids – Parametricism rejects these figures in favour of splines, blobs and NURBS surfaces. All the elements of architecture become parametrically malleable. (...) Innovation in architecture proceeds via the progression of styles (...) The style consists of methodological rules: some tells us what paths of research to avoid (negative heuristics), and others what paths to pursue (positive heuristics). The negative heuristics formulates structures that prevent the relapse into old patterns that are not fully consistent with the style, and the positive heuristics offers guiding principles and preferred techniques that allow the work to fast-forward in one direction". [9]

In the hope we may arrive at the theorization of the variability in real time of the order of the material-spatial configuration without further delay, bringing into play the automatic malleability of the constituent material, we are witnessing today, with greater determination, increasingly evolutive processes, in which composing in terms of architecture moves through systemic elaborations of complexity. It is the outcome of iterative procedures, wherein the fusion between the shapes of architectonic work is achieved through different modes of spatial interconnection, blurring, opportunely and softly, the borders between the forms of the versatile unity of the design-concept imagination.

Recognizing Cultural Heritage for Social Sustainability: A Spirit of Place Perspective

Juliana FORERO, Liangping HONG¹

⁽¹⁾ School of Architecture and Urban Planning, Huazhong University of Science and Technology, Wuhan, China

Abstract

This article discusses how through the acknowledgement of the spirit of the place for cultural heritage preservation, within the social sustainability context, it is possible to achieve sustainable development processes. After a brief review of these theories, the analysis of the creation of the urban park Mirador de los Nevados for the renewal of the downtown of the district of Suba in Bogotá - Colombia, give some ideas on how the link between social sustainability and cultural heritage preservation, can bring up a set of processes and practices for the enhancement of sustainable cultural and urban heritage preservation, without leaving aside the environmental and economic elements.

Keywords: cultural heritage, spirit of place, social sustainability, sustainable development

1. Introduction

Theories for Sustainable development principal dimensions –economic, environmental and socio-cultural- have not been equally developed and thus their relationship remains unclear. Academic and political approximations have generally been limited to economic and environmental sustainability, while literature about social sustainability is still inchoate. Indeed, social sustainability is still an under-theorized and oversimplified concept. Nonetheless, in the recent years, social sustainability has been slowly recognized as a fundamental component of sustainable development. Consequently, it has started to play an increasing role in urban planning and to be included in the governments' agenda (9) (23).

Urban cultural heritage is an essential element of city sustainable development. Nevertheless, research concerning the relationship between sustainable development and urban cultural heritage plays almost no role in social sustainability debates (34). Most studies ignore the social function of the cultural heritage and focus on two main fields: sustainable tourism and environmental degradation affects on material heritage; other studies list monuments, buildings and conservation areas, implying that the worthiness of cultural heritage only relates to the tangible objects (33).

To find new ways to interpret the relationship between cultural heritage and sustainable development, the debates regarding cultural heritage should be framed into the social sustainability studies. From this perspective the importance of the social function of cultural heritage would be recognized not only in the theory but also in the practice, while at the same time it would be a tool for the social sustainability development. The Spirit of Place theory, which embraces the essential categories for heritage studies - identity, memory and territory- and its sustainability, offer a model to integrate cultural heritage into sustainable development paradigm.

Under Spirit of Place theory for cultural heritage preservation, material and immaterial components cannot be divided, as well as the cultural, social, economic and environmental elements are required to be understood from an integral perspective. This condition is considered essential for the preservation of the communities' identity that has been protected and passed along from generation to generation (18) (30).

In addition, it is important to contextualize cultural heritage preservation under the sustainable development and urban planning conservation and preservation fields, in which the preservation and conservation of the historical and cultural places concerns not just to the importance of the object (the built heritage), but the protection of the social function of the heritage and its cultural representation in the space (25).

An analysis of the creation of the urban park Mirador de los Nevados, as part of the renewal of downtown Suba District in Bogotá, Colombia, give some suggestions on how the link between social sustainability and cultural heritage preservation -under the umbrella of sustainable development-, can further suggest a set of practices for the enhancement of sustainable cultural and urban heritage preservation without ignoring environmental and economic elements.

The case study presented in this document is not about an urban renewal project executed through the restoration of historical buildings or the implementation of sustainable tourism processes. This is an example of how governmental policies for social sustainability were implemented congruously with the cultural and social needs of a specific community, through the recognition of the cultural heritage preservation and its social function. This approach was foundational in developing the Mirador de los Nevados Park and explains why it has become a strong example of a sustainable cultural heritage preservation project. This is an urban renewal intervention project out of which the theory of the Spirit of Place was applied in pursuit of the rescue of the cultural heritage for the sustainable development the city of Bogota is looking for.

This paper analyzes how through the acknowledgement and use of Spirit of Place theory for cultural heritage preservation, within a social sustainability context, it is possible to achieve a sustainable development process. In this regard, cultural heritage is protected because of its cultural significance and social function in a specific territory and for a specific community. The strengthening of the local identity, linked to the past "not just in the continuity of the built heritage and urban spaces but also in the living culture that created, and is still shaping, the district townscape, or genius loci, that characterizes the heritage places" (25 p. 468), has no other consequence than the construction of the sustainable development processes based on cultural heritage

2. Spirit of place, sustainable development and social sustainability

Heritage is "the indivisible and valued creation that comes from people, culture and place together. It is tangible and intangible, not one or the other" (8 p.2). Heritage refers to the set of assets inherited from the past and directly related with the identity and memory of a specific culture in a specific territory (29). Problematically, perspectives on heritage have historically been divided into the material and the immaterial, giving rise to confusions about the meaning of heritage and its social function (8). The social function of the cultural heritage concerns social cohesion, integration and education, as well as the social and cultural distinction processes in multicultural societies (4). Presently, besides the preservation and restoration of the cultural heritage, people in charge of cultural heritage management must give attention to the social function of the heritage (29). Hence, the Spirit of Place perspective has emerged, without dividing or classifying the heritage and involving the community into its practices. This perspective has evolved into a tool for cultural heritage managers to promote social sustainability.

2.1. The Spirit of Place

The importance of the Spirit of Place perspective lies in its functionality. The recognition of the material and immaterial components as essential elements to preserve the communities' identity is driven by identifying the Spirit of Place for a specific cultural heritage preservation process.

Place and spirit are constituted by three elements connatural to the human being dimension: identity, territory and memory. Identity is the set of features of a person or a community that defines what we are and what we are not. Territory is the recognition of the place where we are born and inhabit. Memory is the way we

remember our past. The relationship of these three categories takes place in the construction of the community, which is considering the essential environment for interrelation of every human being.

Contemporary scholars argue conceptions of Place are premised on memory, identity and the relation of people to their territory. Thus, Place can be understood as the consequence of the multiple discourses, subjectivities, interactions and power relations in specific time and space (26). It is also defined as a singular fact determined by its space and time, by the topographic dimension, by its form and by its memory (10). Place is where social relationships occur, where everyday life is unwrapped, where the people celebrate, make rituals and other cultural and social constructions necessary for their life (7).

The notion of “spirit” corresponds to the immaterial elements of a person’s relation to Place, composed by the “social and spiritual practices, costumes, traditional knowledge and other intangible forms and expressions” (19). Spirit also encompasses the relationship between tangible and intangible social and cultural mechanisms.

“The Spirit of Place is ultimately the intensity of wholeness one experiences in the place” (6). This wholeness is related to unique and distinctive aspects of a place and its habitability, but only because of the soul of the human being that inhabit each place (5). It involves “aesthetic, historical, social or spiritual value of cultural significance” (30 p.2). Spirit of Place is the language that becomes material but dynamic, tangible but ephemeral, is the expression of the memory, the identity and the cultural heritage.

2.2. Sustainable Development and Social Sustainability

Sustainable development and heritage planning face a constant struggle between preserving cultural heritage and achieving economic growth and modernization. Currently, approaches for sustainable urban planning are focused on creating liveable built environments, disregarding a holistic perspective for community developments and specifically culture. This absence of social and cultural perspectives is evident in heritage planning research where the physical forms are the main focus (25). For the viability of sustainable urban and cultural heritage planning it is necessary to emphasize the interaction between citizens, physical environment, social organization and public policies (13).

Social sustainability “concerns how individuals, communities and societies live with each other and set out to achieve the objectives of the development models that they have chosen for themselves, also taking into account the physical boundaries of their places and planet earth as a whole” (9 p. 24). It involves specific cultural or social relationships, social structures, customs and values, which represent the social constraints on development. In this context, social sustainability combines the traditional social policies (equity, health, poverty reduction, livelihood, etc.) with emerging concerns about participation, social capital, needs, economy, environment and “more recently, with the notions of happiness, well-being and quality of life” (9 p. 24). These last issues, more intangible and less measurable involve concepts such as identity, social networks and most importantly Spirit of Place. Furthermore, these issues have become more and more important within government and policy maker debates (9) (23).

Analyzing sustainability requires addressing four principles: equity, inclusion, adaptability and security. Equity refers to the opportunities of access to sufficient resources to participate in community; inclusion relates to an individual’s opportunities to participate in community processes; adaptability refers to the resiliency of communities to respond to change; security includes both the communities’ economic security and confidence that they live in environmentally safe and supportive places. These principles are guided by seven dimensions of action: living, working, playing, engaging, learning, moving and importantly, Spirit of Place. Compared with traditional methodologies and perspectives for measuring welfare, the interaction between those principles and dimensions bring alternative social sustainability parameters of measures, where “soft themes” such as happiness and Spirit of Place, among others, can be also qualified (9).

Cultural heritage can contribute to the well-being and quality of life of communities, while also can mitigate the impacts of cultural globalization, becoming an incentive for sustainable economic and environmental development (15). In this light, “the loss of a sense of place in communities became a factor of vital concern in the context of cultural globalization and the main aspect striving for sustainable communities and sustainable historic environment” (15 p. 75). “The notion of sustainable includes understanding of need, in the true sense of necessity (...) [that] requires that needs be met within our social, economic and

environmental capacity” (16). In this light, it is reasonable to understand preservation as the action that allowed the manifestation of the spirit, as established by the Foz Do Iguaçu declaration (2008).

3. Mirador de los Nevados Park

Fig. 1

Fig. 2

Mirador de los Nevados Park is a metropolitan urban ecological park located a few blocks away from the downtown of Suba District in Bogotá and belongs to the Muisca Indigenous Reservation Area. The Park was created in 2002 as an attempt to give recognition to the Muisca Indigenous culture and its efforts to survive in the face of colonization and urbanization in Bogotá during the last century. It was built in a place that for more than fifty years served as a quarry and now is an environmental and ecological protected area. The park's name literally means “Snow-capped Mountains Watch point”, due to the fact the place is the only spot in the city from where it is possible to appreciate three of the most important snow-capped mountains of the Colombian central Andes ridge: their names are Tolima, Ruiz and Santa Isabel.

The site is one of the cultural and natural heritage places of the city and its architectural design is based on the Muisca Indigenous cosmology. Because of its historical, cultural, environmental and scenic values, the Mirador de los Nevados is an icon of the public space of the city. Furthermore, because of this minority's cultural beliefs regarding nature's protection, this park also became a platform for environmental conservation and education of the citizens. The development of non-formal environmental education strategies through the implementation of the program “Environmental Classrooms”, aims to empower the citizens and make them able to intervene and promote social actions on behalf of the improvement of their life quality and the environmental conditions of their territory.

Is important to understand the context within which the park Mirador de los Nevados was created. This site has a direct relation with the first inhabitants of the city in the district of Suba and their memory of the region. The historical and the socio-cultural dynamics that infuse the park are expressions of its Spirit of Place. The advent of a broad cultural heritage preservation ideal was the key to make the park part of the city's sustainable development process.

3.1. The context of the Park: Suba District history, Muisca community and their cosmology

The district of Suba is located at the northwest border of the city. It dates back to pre-Hispanic times when the great Muisca family of tribes inhabited this place. These groups subsisted through an agricultural-based economy, in which a commercial bartering system helped them exchange their products with other communities within the region. Their territory had a rich natural environment covered by forests, rivers and lakes. In 1537, during the Spanish colonial period, the economic and political structure of the native population was dissolved and their lands were expropriated. Centuries later, in 1954, Suba became a district of the city of Bogotá and six years later, due to its location, one of the engines of city's development. During the 1980s, Bogotá suffered a strong influx of immigrants and people from all over the country came over to Suba looking for better opportunities. This created a great cultural and ethnic diversity, but also the exacerbated complex social, cultural, economic and political tensions. Additionally, this area has the largest

State's social offer (health, education, welfare), yet there are high levels of inequity and inequality (1). The district's downtown is the historical location of ancient urban Suba, where the architectural heritage, history and identity remain visible. For Bogotá's Territory Management Plan, this place is considered an area of cultural interest and thus, its surroundings receive special legal preservation (20).

Suba is one of the most densely populated areas of the city. The ethnic population accounts for 4,5% of the total population of the district, out of which 0,75% are indigenous. There are two principal indigenous groups: Kichwa and the larger called Muisca. The community of Muisca is divided into two groups: Cabildo Indígena and the "Muisca Nation". Although only the first one has been officially recognized by the government, projects for cultural minorities in the area of Suba often include both of them (2).

For this indigenous community, Suba symbolizes their home: a place full of green spaces, where friends and families meet. This is the place they understand; here they know where are the stores, the parks, the spots where they can find peace: the park Mirador de los Nevados, the Planada, the central square, etc. It is the place where they were born and live; there, they have the feeling of being someone living somewhere (22).

The Muisca, in pursuit of being acknowledged as an indigenous population, celebrate meetings, forums, cultural activities, and other forms of demonstrations, in which they express their own identity, their projects and struggles. They inhabit the city while including the nature according to their cosmology and living notions. For them, mountains, lakes and wetlands are some of the most important elements of the relationship between earth and human beings (22). In the park, the contributing factor for all of these expressions to be possible is that the Muisca spirit is printed in the space. There the social function of the cultural heritage contributes to the renovation and reproduction of the communities (14).

An important characteristic of social sustainability is that instead of being understood as a static process, it is interpreted as a dynamic socio-historical process (23). The park is the expression of this understanding, where the social sustainability is promoted on the bases of a place and its communities' continuous historical and social processes.

At the same time, the community and neighborhood are the heart of the analysis. This is, the importance of community participation resides in the space given to its members to express their needs and aspirations while acknowledging their conception of the place they live (9). The participation processes that take place in the park are part of the social sustainability framework, in which it is possible for the Muisca people to maintain a contemporary urban, but yet indigenous, identity and memory.

4. The spirit of place, social sustainability and the park

Under the social sustainability approach, the governmental policies have to be articulated with traditional and more recent social policies involving the economic and environmental sustainability, but also the community participation and intangible elements that enrich the soul of the communities (9)(23).

As part of the national constitutional laws, the Colombian Government is bound to recognize cultural minorities. The government must promote spaces for the minorities to practice and experience their own cultural, political, environmental and economic path. The creation of the park and its designation as a natural and cultural heritage site for the city are part of the national efforts to meet this requirement (14). At the same time, policies for urban planning have been developed by national and local governments under the rubric of "sustainable cities": where cities should integrate environmental protection, economic development and individual welfare and social development, without depleting the natural resources for future generations. The policies for land use, occupation and expansion aim to prevent the expansion of the city into rural or protected areas. Sustainable conservation, restoration and natural resources use will support social welfare and economic development (24).

Although within this governmental policies framework it seems that once again the environmental and economic issues have prevailed over the social ones, as a matter of fact, the social sustainability principle has played a leading role in the instauration of the Mirador de los Nevados Park. Since conceiving of the park, the community of Muisca was fully involved. The planners, designers and promoters of the project, have consistently worked with community leaders to decide how to protect of the Muisca's cultural heritage

and restore an environmentally degraded area. Thus, the Muisca's indigenous beliefs about nature guided the "expert knowledge" of the planners for the design and construction of the park. At the same time, the main elements of the design and composition of the space, such as the trees and fauna, were also determined by the Muisca cosmology. The park's environmental educational programs were also developed by scientists jointly with indigenous expertise. Since Suba has been the home of the Muisca, during the park's creation and implementation, all the aspect related with the recovery, renewal and promotion of the environmental elements of this area were imbibed with cultural principles of this minority. Thus, the environmental protection was framed in the memory and identity of its indigenous inhabitants.

The park follows Garnham (1985) proposals to link people and space, including elements as diverse as architectural style, natural settings, memory, metaphor, image, spatial relations, cultural, history and societal values, public environments and daily and seasonal activities (21); these are also social sustainability elements. Further, the park is analyzed as a materialization of the social sustainability and the Spirit of Place relationship.

4.1. Materializing social sustainability and Spirit of Place for cultural preservation relationship

Urban renewal projects and the way they manage to recreate the space are fundamental tools for the materialization of the Spirit of Place and social sustainability relationship. This relation have to be printed in the urban space for it to be recognized and used by the people, for it to make the cultural heritage an essential foundation of sustainable development processes. Mirador de los Nevados park is the place where the tangible and intangible Muisca cultural representations interact with social sustainability elements that Colantonio (2011) has called "soft elements" (happiness, well-being and importantly Spirit of Place).

The design of the park is one of the expressions of how, the exaltation of the esthetic, social and spiritual value of Muisca cultural significance, make the park a place for the improvement of the quality of life of the Muisca and Suba inhabitant. The park and each of its sections inside are places that correspond to the understanding of the Place as a specific space characterized by its singular identity (18). It has as a consequence the representation of the Spirit of Place as the sense wholeness where the parks visitants will not only feel in a natural environment, but also in a place where they can feel connected to what they are. In this context, the seven dimension of the social sustainability become active thanks to the Spirit of Place for cultural heritage preservation materialized in the park Mirador de los Nevados,

Its six circle-shaped hectares, 3 obelisks, 7 rounded squares and several natural trails called "astrologic paths", cross the park representing the cosmic space as the Muisca understood it. The obelisks are placed in the highest parts of the park, representing the sun's equinox and winter and summer solstices. They also symbolize the way the indigenous understood the relationship between the Earth and sun. From the obelisks it is possible to see the districts of Suba and Engativa and the town of Cota. The squares names honor Muisca culture: Clock, Astral, Sun (Sué), Bochica, Chiminigagua, Bachue, Moxa Squares. They are further classified according to specific cosmological functions: 1. Central Squares where the principal attraction is the water mirror which emphasizes the ancient riverbed that disappeared hundreds of years ago; 2. The Observatory Squares the aforementioned snow-capped mountains can be viewed, symbolizing peace and the greatness found in the Mother Earth by the Muisca; 3. The Astrologic Squares embodying the astral map used in ancient times by the indigenous; 4. The Entrance Square surrounded by trees and plants, is a welcoming to the "Muisca Temple of Nature" (11)(3).

Fig. 3

Fig. 4

Besides, the achievements of this urban renewal project are not only represented in the landscape and design issues. It also contributes to the social tensions and problematic of the area. Under social sustainability approaches, urban renewal is defined as an integrated vision, addressing urban problems by improving social, environmental, physical and economic conditions of the area (9). Mirador de los Nevados, as an urban renewal project, was premised on social sustainability as an integral part of urban regeneration. This project took into consideration the social tension and cultural exclusion experienced by the community of Muisca and attempted to contribute to this situation's solution through the improvement of the environment and landscapes in the district, based on the spirit of the Suba community. Up to 2010, the park has served as a space for social, cultural and educational participatory processes for more than 240.000 people, giving them the opportunity to explore other alternatives for working on social problematic they are having in Suba and so in their personal live processes. At the same time, through the promotion of the non-traditional pedagogic environmental protection programs, the people interested in that subject incremented 40% in the area (2).

4.2. Spirit of Place for cultural heritage and social sustainability: Memory, identity and territory

According to the Spirit of Place theory for cultural heritage preservation, the place is understood from to the relationship between the human being and the space natural or man-made settings, integrating the memory and the identity of a particular community in a specific place (19)(31). This is also linked to the recognition of the social function of the cultural heritage, which connects the memory, the identity and the heritage (4).

In the park Mirador de los nevados, the social function of the cultural heritage corresponds to a citizen construction where heritage is not an expression of what is beautiful to show, but the memory saved as a reference of urban manners (32). Here the cultural heritage is appropriated and represented by a contemporary community, which determinate the sustainability of the project. From this point of view, people's well-being is based on the recognition of their memory, cultural needs and cultural particularities, thus they will protect the place as a non renewal material (34). Suba was the meeting point for the ritual meetings of the indigenous groups of the region. It was the place where they tried to conserve the Muisca lineage, by performing rituals for the moon and the water (1). It is where they have chosen to live and that is why these urban indigenous residents will continue taking care of their territory and their collective memory. This place embraces the social sustainability principles of equity, inclusion, adaptability and security.

Collective memory concerns a social group's conceptions, cultural transmissions and use of the past. It is use to reconstruct the image of the past according to the time and social discourses (14). When the sustainable development improvements are based on collective memory representations, the cultural heritage preservation will be done from a qualitative rather than a quantitative outlook, thus it is possible the "understanding of humanity's place on the planet" (17 p.40). Muisca community has found their sacred mountains, lakes and wetlands reduced because of urban expansion (22). The Park constitutes a sustainable alternative to the conservation of the nature required by this minority.

For the Muisca people their identity is linked to their territory. They have adapted and transformed their way of living, but not the way to understand their Muisca heritage. They live as any other citizen does: they study, work and take part of the economy. But, at the same time, within their daily life they also uphold their cultural traditions, games and rituals while in contact with nature (27). The Park has become a place where the social aspect of their cultural heritage is experienced. It is a place for re-creating their cultural tradition through the development of cultural and political activities according to their indigenous beliefs. Mirador de los Nevados is the scene for activities like the Turmequé game, Andean dances, traditional dances, concerts of traditional music, bartering, indigenous sports, mingas, indigenous week celebration and "environmental classrooms", among others. Here, cultural heritage is part of the definition of social sustainability, which is related to the relationship between individual actions and the created environment, individual life-chances and institutional structures, and the creation of social cohesion and participation and justice (23).

Further, Canclini established that the modern city is not only a place to live and work; it is also a place where cultural heritage expressions become a part of daily life. The park is a heritage site integrated into the city's public space framework. The public spaces make the cities; it is there, in the open space, in the streets, squares, parks and edifications, where the citizens experience being social individuals, developing their cultural identity and the strategies for public participation (28). These places constitute the physical support to satisfy the urban collective necessities that go beyond the individual interests. On the local scale, places

like the Park are fundamental for the construction of the identity and sociability. That is, therefore, a sustainable contribution to the areas of the city with social problems (12).

The sustainable development processes for cultural heritage preservation requires an understanding of communities' multi-variants (16), where the territory embodies the heterogeneity and complexity of urban live, which in turn requires multicultural recognition (28). A territory that embraces the historical landscape of a minority's culture, its aural and its visual memory, is a landscape that can be seen, smell, heard, full of colors, full of remembrance. Then the functions of the urban space are also cultural heritage (4) and its sustainability is understood as a socio-historical process (9).

If the cultural heritage is taken as a component of the sustainable development through the social sustainability approach, it would be a huge step to go beyond the traditional cultural heritage preservation approaches. At the same time, it would let the heritage to be stand into the socio-cultural components of the sustainable development in a comprehensive way.

5. Conclusion

The Spirit of Place theory for cultural heritage preservation converges with social sustainability by linking the people, its natural and created environments and their "chances of life" in the space. So, when it comes to cultural heritage preservation, both theories lean on the protection of the existent relationship between humanity and its surrounding nature and space, rather than on the material elements and the physical objects resulting from this connection. This means the traditional perspective for cultural heritage preservation is inverted: before it was first the recognition of the object (material features) to then recognize the subject (community). Now, framing the cultural heritage into the social sustainability approach for sustainable development, the subject (community) is recognized as the first component, thus the social function of the cultural heritage lies in the recognition of the subject to then heed the object.

The case of the park Mirador de los Nevados is an example of how an urban renewal project for cultural heritage preservation, rather than starting from the recovery of a physical object, it can began dealing with the socio-cultural representation of a specific community, and then make it tangible through the materialization of the Spirit of Place. Namely, the perspectives for cultural heritage preservation do not necessarily need to be based on the material heritage. Instead, this process must be done based on the cultural and social needs of the people living in the area that is going to be protected, preserving the Spirit of Place without splitting the tangible and intangible components of the heritage.

Social sustainability establishes that to make tangible the immeasurable Spirit of Place for cultural heritage preservation, it is necessary the inclusion of the community. The cultural heritage existence is not represented only by its materiality. The reason of the existence of cultural heritage lies on its constant revitalization through the daily usage given by the community. The inclusion of the community into the cultural heritage preservation process has to be focused on the social function of the cultural heritage which contributes to its renovation. Not considering the habitants, their experiences and values, lead to what Van Der Hammen (2009) calls "shell heritage", cultural heritage conservation processes fragile like an eggshell: if there are no people willing to live and preserve heritage in their everyday life, it would be very easily broken. Another important alternative to shift the traditional cultural heritage preservation to contemporary ones, where the heritage becomes an essential foundation for sustainable development, can be found in the social sustainability "soft themes" which are also totally linked to the perspective of Spirit of Place. Although there is a lack of methodologies to assess the intangible expression of the social sustainability, that does not mean these "soft themes" are not fundamental elements for the placement of the cultural heritage into the social sustainability approach. Well-being, happiness, memory and identity seem to be subjective and immeasurable, but when they are connected to cultural heritage processes, they become expressions of equity, inclusion, adaptability and security. The park has become a fundamental scene for equity and inclusion for the Musica and the Suba inhabitant to participate in community as cultural and social groups or as individuals. Also, this site is also a tool for the people's adaptability to social and urban changes, as well as offers a safe and supportive environment.

When the communities' identity is recognized and printed in the space, its infrastructure and in urban policies, those themes are notorious in the way the inhabitant uses and experiences the space, as well as it can be noticed how the social tensions are reduced. In the case of the park Mirador de los Nevados, it is

evident the impact the park had on the improvement of the quality of life of the community of Muisca and Suba. It not just brought public recognition to this minority in the city, but also through the implementation of environmental programs and cooperative associations. It is true the park itself cannot eradicate the social inequity in the district; however it offers a space for cultural and political participation where the power and control orders can be questioned, where the social and cultural empowerment is possible.

The social sustainability also concerns to the recognition of the particularities of a specific society in a specific place into the contemporary globalization processes. The Spirit of Place for cultural heritage preservation is a vehicle for the recognition of such particularities and the authenticity of a society. The Spirit of Place acknowledges the memory, identity and territory of a specific culture and its relation with the space. This guarantees the possibility of having sustainable cultural heritage preservation processes, where the modernization and the economic growth are promoted through the social and cultural needs of a community, promoting then social sustainable development. In the park Mirador de los Nevados, the implementation of non-traditional pedagogic tools for environmental education, as well as the recognition of the cultural heritage as an expression of an urban indigenous and urban minorities not only makes sustainable the park itself, but also brought a sustainable approaches for Suba district and the manage to this area social and environmental problematic.

When sustainable development is founded in conventional approaches from traditional social policies, considering that economical and environmental oriented sustainability policies are enough to reach social welfare and without including particular communities' conceptions of the space, neither its memory nor identity, it do not imply social sustainable process. The Park is an example of that. Social and Environmental sustainability of the park is nowadays a reality thanks to: 1. to the inclusion of cultural heritage, through the spirit of the place theory, into the social sustainability framework; 2.the coupling of this perspective with the national and local sustainability policies. In other words, cultural heritage and the recognition of its social function was the key of the success of social sustainability and rest of sustainable development processes that consequently derived after this urban renewal project at Mirador de los Nevados.

Through the approaches of social sustainability it is possible to promote development processes within which the principal goal is not the ultra-modernization of the space, but the development of solutions with cultural and identity contents to solve local urban problems for specific social and cultural urban space.

Abstract.

In the Basin of Mexico, where it is today Mexico City; in the fifteenth century, the most brilliant of the ancient Mexican kings, Nezahualcoyotl Acolmiztli transformed the natural landscape of his territory to fulfill its mandate as a ruler and record the progress and greatness of his culture and his people. The site is now a cultural landscape of great importance whose study is an enriching lesson in landscape architecture, sustainable development and environmental planning. The site, in addition to the unique beauty that holds, shows human thoughts and actions that produce the processes that lead to sustainability: after five hundred and sixty years 40% of that land is still cultivated and the site is heraldry of culture of ancient Mexico. The study here has led me to consider the prevalence of thinking about the action, therefore my research work focused on trying to establish how the architect configured his brain to think like and secondly to introduce new aesthetic categories in landscape architecture teaching.

Fig 1. The Lordship of Nezahualcoyotl seen from the eastern basin of Mexico.

Keywords: Think, configure, learn, awareness, teach

1. About the site and its current meaning.

The place we know today was the result of several circumstances and decisions: In the basin of Mexico during the years 1447 to 1453 AD, had an untimely frost followed by a prolonged draught that dried to two thousand square kilometers of lakes and disabled the crops leaving a natural catastrophic event that nearly wiped out the population of 300000 inhabitants.

Fig. 2. Location of basin of Mexico Basin of Mexico in 1447 Basin of Mexico today

At the time in the basin was dominated by three Lords (or kings) who ruled the manors of Tenochtitlan, Tezcoco and Azcapotzalco. They were joined in the Triple Alliance, the most powerful empire on the continent at that time. The lord of Tezcoco he was Nezahualcoyotl, Lord Totoquihuatzin reigned in Azcapotzalco and the great Moctezuma in Tenochtitlan. Given the emergency food lords emptied the royal granaries, their header cities were over populated and when famine struck Moctezuma decided to go to war against the people of South, following by Totoquihatzin to collect taxes. Nezahualcoyotl instead chose to locate water sources in the high mountains of eastern basin and channel water to his city by creating three irrigation systems to produce food. This decision was a radical change in the natural landscape of the city, region and in the life of the inhabitants of his dominion and whole basin.

Fig. 3. Tezcoco landscape The three irrigation systems of Tezcoco South system called Tezcoztinco system

This region consists of long ridges of piedmont, short valleys, and in that time, a long narrow strip of plain lake. The ancient lake was brackish due to the influence of saline soil. It is a semi-arid region of dry warm weather, twelve hours per day of sunlight with average temperature of 18° C., rainfall of 500 mm. annually during the summer and freezing winter. The soils are shallow, dominates the horizon B of basic mineral and vegetation that occurs along the altitudinal gradient includes riparian plants and *Halophites* in the plain,

grassland, xerophytic scrub and weeds in the foothills and forests of *Juniperus*, *Cupressus*, *Quercus*, *Pinus* and *Abies* in the mountains.

To channel water from the springs located at an altitude of 2600 meters to the plateau at 2200 meters channels were carved into the rocky surface of the mountains, following the contour lines, surrounding peaks and crossing the fords with embankments of which were built stone canals. The path of the channels, twelve miles on average, has a 2.8% of constant slope. Water velocity was regulated by increasing or decreasing the channel section and varying in depth to avoid turbulence. The main channel derived secondary and tertiary channels of distribution with a width ranging from 50 to 2.5 centimeters.

Fig. 4. The paths The spring zone Channel carved Mouth of the canal Domestic dam

Nezahualcoyotl awarded the construction of the channels through appropriate tax card, then entrusted its maintenance and management of water supply to the entire region as the Nahuatl agricultural calendar of 260 days per year.

Fig. 5. The longest embankment Embankment of Caño Quebrado Current production terrace

Simultaneously with the construction of canals were built hundreds of thousands of square miles of stone walls to contain about one hundred and fifty million cubic meters of fertile soil formed by silt dredged from the bottom of the dry creeks mixed with humus from the montane forests, these were provided in the 30000 hectares of productive terraces enabled.

This region produced amaranth and corn to feed the population of the basin by solving the famine, promoting the repopulation and subsequent glow of the whole basin due to biophysical symbiosis generated with the works of environmental adaptation and production management in time.

The underlying reason for the decision of Nezahualcoyotl was his intimate knowledge of its history as a nation, as a culture, as king his personal obligation and no doubt his knowledge of the geography of the state and its relation with their worldview: In the worldview of Mesoamerica was believed that two solar deities to be dismembered a monstrous being called Tlaticpac. A species of lizard fish whose back the earth's crust was created and whose belly aqueous created haven. Once created the earth, the deities place four cosmic

trees to prevent the two parts of Tlaticpac back to join. However these trees allowed the flow of the underworld and earth deities that were beyond earth and sky. In my opinion we are talking about the energy exchange in the trees flows through their vascular system, aspect that the ancient Mexicans were well aware and identified as the flow of energy which the plant life depends.

According with my interpretation the idea of the back of a lizard as the origin of the earth it is because throughout of Mesoamerica is full of mountain ranges that define their physiography. Also is this the reason why its inhabitants thought their deities inhabited hills archetypal. The idea that the sky comes from the aqueous belly of the monster derived from the fact that Mesoamerica region occupies a large subtropical fringe of the continent where rainfall is abundant, there are great jungles and mighty rivers, therefore, a high percentage of humidity.

It is relevant in a story like this to point out that the ancient knowledge this cultures had about the natural environment was deeply associated with the construction of their worldview. And in that construction saw themselves as custodians of the creation of the deities to ensure its perpetuation. I cannot elaborate more on this paper to explain the extraordinary manner in which their worldview influenced the lives of these people, but I can comment that the responsibility imposed on them by the traditions led them to study, conserve and were possible to reproduce the ways in which nature generates itself and is self.

In the case of Nezahualcoyotl say that when the situation resolved and recovered the prosperity of the state, built on the sacred hill of Tezcotzinco his magnificent royal palace whose conception is an outstanding display of talent from the king to transform the environment to living space with an specific end considering the worldview of his time, the biophysical characteristics of the site, human knowledge and aspirations of a ruler.

Fig. 6. The sacred hill of Tezcotzinco

The hill was considered sacred because Tezcotzinco was noted by Nezahualcoyotl great grandfather King Quinantzin, as the guardian mountain of the founding of the city of Tezcoco. The ancient Mexicans believed that the Ometeotl primeval god, the god dual (ome-two, teotl-god), live in the cave of a hill called archetypal Tamoanchan and from there blew the breath to life he deposited in the belly of pregnant women. It was a myth about the divine origin of life, why pointing to a hill as Tamoanchan of the founding of a city giving it a

status of divine origin which ensured the protection of god for their existence and development. With this background Nezahualcoyotl had to take stock of wisdom and intelligence to take the hill and physically dwell therein without offense to his people, it went like this:

Nezahualcoyotl was the seventh king of his line. The Acolhua people Kings. When his first ancestor, the King Xolotl, arriving in the region of Tezcoco around 1100 AD, he and his people still dressed in animal skins who were hunting and living in caves, but they knew pervert the course of streams and small rivers to irrigate the land they began cultivated to produce corn.

The king Quinantzin introduced the cultivated of cotton which began to manufacture their clothes, he built the first stone palace and organized the lordship as a perfect socioeconomic and cultural structure governed by an absolute monarchy responsible for the fate of his subjects. Turn preserving its land, values, customs and worldview. Nezahualcoyotl known himself as heir of this concept of a ruler, he knew the technical, scientific and cultural development of his people and the wisdom and power of their worldview. So when he saw himself before the environmental disaster, used the only resource he had, people who had gathered in Tezcoco, not to take them to die in the war but to build in the slopes of the mountains the most important productive landscape of the fifteenth century. Creating a great example of what is now environmental planning and sustainable development.

Fig. 7. Andesite rock

The Tezcotzinco (in center)

Productive terraces

At the time of Nezahualcoyotl built his palace at the hill of Tezcotzinco, Tlaloc Water God had become to be the most important and influential in the life of the inhabitants of the basin, of course as result of the drought from his vision had been decreed by the god. It was believed that god Tlaloc lived an archetypal hill called Tlalocan in which there were many bodies of water in all its manifestations: rain, rivers, lakes, waterfalls, underground streams, all forms that produce fresh water on the earth. They believed that for this reason the Tlalocan was full of jungles and forests inhabited by countless numbers of archetypal insects, birds, fish and mammals. The Tlalocan it was a paradise such that he only arrived the warriors killed in combat, mothers dying during the childbirth and misshapen people who was considered sacred too.

It is important to mention this background because Tlalocan became the legendary destination of the most valuable people in basin of Mexico. With this knowledge Nezahualcoyotl set out to recreate in the hill of Tezcotzinco the earthly image of Tlalocan, merged the two myths: Tamoanchan, the divine origin of Tezcoco and Tlalocan, fate of his people. This was the way the King could legitimately take the sacred hill.

To represent the Tlalocan in the hill of Tezcotzinco, Nezahualcoyotl made a master piece of what we now call landscape architecture:

Nezahualcoyotl knew the territories of today's southeast of Mexico and Central America because there came to his Kingdom and decided that the earthly image of Tlalocan it should resemble that of the land in which mostly rain, rivers, lakes, fish, wildlife and forests, so he built in the hill an analogy of that landscape.

To achieve its objective would have to modify the characteristics of a semi-arid area in warm dry climate of a place of warm humid climate, to transform a site of poor and shallow soil on a site of moist soil, fertile and deep, enter in an ecosystem of bushes and scrub vegetation needed to reproduce the characteristics of the jungle and finally introduce a suitable wildlife.

Then he first decided it was to occupy the southern slope of the hill that had an inclination sufficiently fit to be terraced. On the north slope of the hill there is a relict forests of *Quercus* adapted to the slope of 45° on average. The south side also has the best sunlight during the whole year and is sheltered from the wind by the same shape of the hill that creates a shadow of wind.

Fig. 8. Watersheds View from the west of the hill of Tezcotzinco Tezcotzinco map

On the hillside was terraced floors of 1.50 meters deep, were planted two tree species, *Schinus molle* and *Eysenhardtia polystachia*, to create an open forests with the following quality: the *Schinus* is a large ever green tree of very fine texture in foliage and *Eysenhardtia* it is a small deciduous tree also fine-textured, this combinations helped to create translucent shade during the summer and partial shade during the winter to take advantage of the sunlight.

Building the infrastructure of the main water channel, water was carried up the hill of Tezcotzinco making led to the eastern “noise” of the same. At that point it was built a collector and from there, a perimeter road carried water to three sides which built three stone structures, carved in rocks, called pools representing the way the people Acolhua ran from the arrival in the basin of Mexico to their settlement in Tezcoco.

Fig. 9. Slopes Stone canal The collector The perimeter road

Once the hill was equipped with water, small dams were built along the south side of the perimeter road these were stored in water and then drop it on the andesite rock, that way the water was sprayed and created enough moisture to modify the microclimate of the slope. At the same time were built waterfalls, fountains, ponds and canals filled with bodies of water to the hill.

When the slope south is obtained the right conditions the King ordered transplant all kinds of tropical plants at the site and enter the wildlife of the forests thus recreating a microcosm representing his idyllic worldview of Tlalocan.

2. Thinking about landscape architecture.

The above story is the vision of a planner and landscape architect on the work of a King and his people. For many years I taught this example of landscape architecture to my students and introduce in my teaching some aesthetic categories arising from this research such as: a) Compositional conceptual scheme and subordination of elements into the overall scheme. b) Cosmogonic development of compositional discourse. c) Three-dimensional space. d) Movement as a dimension on space. e) Physical and environmental manipulation of space. f) Integration of science and art in the design. g) Polyvalent handing of vegetation. h) Total production of a landscape model represented by global composition patterns. i) Controlled geometric landscape distinctive. j) Naturalism and livability. k) Erotic sensuality and design.

However in recent years I have seen growth in the work of landscape architecture a tendency towards the reproduction of iconographic “successful” models, this worries me a lot and led me to wonder the question of why such a situation occurs both at universities and professional work and I think that it is because we have lost sight of architecture students when they go to college what they should learn in a conscious manner is to configure their brain to learn to think like an architect and it is possible that professors we have been more concerned with teaching a design technique that enable them to produce, or unfortunately play architectural aesthetic models that will undoubtedly come from creative minds but not necessarily from the knowledge, culture, worldview, expectation and needs of the people and possibilities of treating or processing the environment to solve the problems of subsistence, habitation and development of the people.

This concern has come to me when I realized that the work I have been studying, describing, characterizing and explaining as example of environmental planning, sustainable development and landscape architecture, and it is, is not the work of a planner or landscape architect but a wise man who knew how to think, like

anyone in his time, how to transform the land to create a better place to live. So while his work we should be studied his thought and learn from him. Also I think our first responsibility as professor is to teach the students to think and for that they must learn to set up their brain that, even before entering college is simply of a student in the brain of an architect. I must say I consider the human brain as a tool that is configured to think a certain way.

How to accomplish this in case of our interest? Still do not know absolutely and it is a long way to investigate but I have traveled some ways in which we could begin to move. There also explain briefly the proceeding of the King Nezhucoyotl if we can find relations.

The first way I raise relates to creativity. It seems crucial to make clear that creativity is believed to be an essential condition in the practice of architecture is not from a single, small gift in the world. According to experts, there are three types of creativity: biological, cultural and specific.

Biological creativity is innate in all living things. Enables an organism to survive and is expressed in the homeostatic organization of the individual described by American physiologist Walter Bradford Cannon in 1932.

Homeostasis is the ability of a multicellular organism to self-generate and regulate themselves in a self-balancing internally and externally. In the case of human beings implies that such a balance in their biological and psychological organization there is a kind of skill inherent existence that allows life in any being. In the biological aspects homeostasis implies internal adjustments necessary to stabilize your body substances to the constant changes produced endogenously (by the body) and exogenous (external factors) during development. And in the psychological aspects it means to adopt the most adequate behavior to meet their needs in relation to the specific circumstances that arise in their environment. It is this ability to achieve an inner balance that allows the survival of a human being what we call biological creativity and it exists in every one of us.

With regard to cultural creativity will say, in principle, I assume the primary notion of culture (there are many notions) as the lifestyle of an individual or group of individuals. Therefore, from these sense, every human being has necessarily a culture. It means all of us we have a way to interact with our physical and social environment learned of our ancestors, our elders and our contemporaries that allows us to belong, be expressed and stay in our group or society. I call this cultural creativity. Whether if it is an independent social group or away from the overall process of civilization for some reason, or most cosmopolitan society "developed", culture or way of life that share occurs in each of their individual a perception of reality tempered by an informed perspective and/or formed from environmental wisdom and knowledge accumulated by the company, that leads him to make decisions about environmental and social survival, according to their capacity for analysis and learning of that knowledge sharing with the others. This call in the individual, become aware of their cultural creativity.

So that every human group, and every individual belongs to one is developing what we normally call their worldview, their customs, beliefs or philosophy. Stages represented by its experience of the world and humans, it is transmitted to each individual in the group so circumstantial and that enables you to practice life, that is instructed in the use of knowledge and cultural creativity.

This cultural creativity, then lies in the correlative building society and make their own individual person as such, from birth to death, accompanies from throughout his life and can change, evolve, transform and enrich themselves according to the interests, decisions and efforts of each individual. The level of awareness that the person has of the existence and use of cultural creativity that owns it is the sole responsibility.

This brings us to the specific creativity. In this regard recall that, as we know from ancient times all human activity preceded by the primal fact of having carried out a specific action to solve a basic need. In such a way that to the extent that humans have been able to recognize and codify the actions, increasingly complex we have taken from the "stone age" to "cyber age" professions that we have invented exercise of "a certain way" to solve "certain problems" specific in nature. Such is the case of landscape architecture, like so many others that are studied in universities.

What happens in the universe of professions is that humanity has built itself as "thinking being" reflecting and theorizing about the techniques and methods that practiced initially by trial and error, then by complex method prospecting problems, prior definition of procedures and use of technology to meet their needs and aspirations. Such reflection and theorizing over time of human practices has enabled the knowledge produce by mankind can be compiled, explained and taught to those who want to learn to exercise some of these practices in a specific way.

Thus, at some point in human history have been created and developed the professions that make up the specific content knowledge to be acquired to exercise them. This has worked in universities. More over the activity carried out by professionals in reality it is building the world in which we interact and so is taking shape in society a relative culture on that specific activity. In the case say that humanity shares an

architectural and landscape culture with ancient roots and branches that cross today look towards a future that seems, for now, endless.

Oriol Bohigas says in his seminal book of 1978 “the creation of useful forms is inherent to human progress” we might add here that sustain critical and conscious reflection, and learning about the real usefulness of these forms, in other words in how real people use and appropriate qualities and meanings of these forms, architectural and landscape in this case, and the processes by which they were produced is what is really at the substance of what we call progress.

In this regard and in relation to landscape architecture, we know that the discipline required for the exercise, according to the specific problem to solve to integrate into their production process intellectual and physical knowledge by the science of the earth, environmental science, human science, environmental planning, urban planning, architecture and technologies. All of which is learned and implemented through a design methodology and a technique for producing architectural and landscape forms, to the extent that it exercises over and over again in each problem is solved produces a feedback set in landscape architect’s mind his own idea of the activity that occupies, how is it constructed as an individual and their relative importance to society.

So at this point I will say that it takes creativity to practice landscape architecture but it is a specific creativity that comes with the culture of Landscape Architecture. What first draws knowledge and awareness of what this profession “is”, after of the experience of “making it” in practice and at the end of the depth of which each individual is able to build their thinking about her.

I think it is a fundamental topic in the teaching of landscape architects to help student build their landscape architectural thinking objectively and away from the myths of spontaneous creativity or “enlightened”. He also says Oriol Bohigas, full of reason “there is no inventions from scratch”. Thus in this, landscape architecture and any activity that human beings spend their time. In the end it is all part of human works as Borges said, and as such is perfectly accessible to others as we are all biologically constituted as homeostatic living through our creativity. We all belong to a group of people which have acquired cultural creativity we exercise daily to “life process”. And we are all able to acquire specific creativity produced by those who do landscape architecture in the world today and those who think about teaching and studying at universities.

Another fundamental topic it is referred to the ways of learning. I think we should try to acknowledging the way our students and ourselves learn. Clearly not all learn the same way and has been studied that according to the way we learn is the way we understand and express ourselves. I said that the acquisition and development of creativity as the foundation has a specific learning activity, therefore and because the practice of landscape architecture is essentially an intellectual activity, it is important to introduce here a note about how it happen learning in our brains.

Will include a brief note here on this issue as there is a vast literature on the subject and invite teachers to delve into it. The experience of authors like David Kolb and Catalina Alonso has led them to consider that there are four different types of learning: active, reflective, theoretical and pragmatic. In their experience everyone has a profile “favorite” of learning. I would say our cultural creativity has been gained from the exercise of this profile is the one we received in our education or is at once the one that best suits our biological and psychological skills.

Learning profiles have three primary psychological elements that make up: an affective component, it is feeling. A cognitive component, it is to know. And a behavioral component, it is doing. These components configure or structure the particular way in which person builds their own learning process, by which also produces their own learning strategies. This process affects all activities of an individual because the integration of components and the profile shape their attitudes, skills, understanding and level of depth learning. Hence the important of know your profile and do an exercise in introspection to recognize how you learn and how you express yourself. From there you will have to purchase a particular understanding of landscape architecture as an activity and human experience, and from there, surely you have to exercise it as your own means of expression. I make a brief description of the profiles:

a) The active profile. Form this page you learn when there is a direct and obvious link between a problem and an opportunity to address. When using specific techniques to do something with practical advantages. When you experience and practice with tools for effective feedback or under reliable supervision. When you have an immediate opportunity to apply learning.

b) The profile reflective. From this profile is learned in situations when you can see, think, reflect about an activity. When you can think before you act and assimilate before commenting or participating. Where the individual can take distance from the events and listening to or watching before acting. Where you can exchange experience with other within a clear framework. Where you can reach conclusions or decisions without pressure or time requirements.

c) The theoretical profile. From this profile is learning when the person is offered a part of a system, model, concept or theory. When you have time to explore methodically the associations and relationships among ideas and/or events. When you have the opportunity to question and test the basic assumptions or logic behind something, through questions and answers or by checking the consistency of some event, for example. When you feel pressure to pass test intellectually challenging in your analysis or teaching people that requires complex answers. When you are in structured situations with a clear purpose. When you come in contact with text or conversations logical, well structured and informed. When you can analyze and then generalize the reasons for success or failure.

d) The profile pragmatic. From this page you learn when you face new experiences, problems or opportunities which can include anything other than what is already known. When there is interest, drama, crisis, to bring about changes for various chores. When a person is allowed to generate ideas without political constraints, structural or viability. When left alone facing a difficult task to consider, which means you face a challenge with inadequate resources and under difficult conditions. When "try" things is the most appropriate.

When you know the profile to learning to use it, you should know that there is a "cycle" of learning that goes through four stages: concrete experience, reflective observation, abstract conceptualization and active experimentation. We all learn by the profile of our abilities and stage from which we can face the knowledge. There is a possibility that an individual scroll through the four stages in the learning process to traverse or partially. In the case you need to clarify in your mind what is your own process.

Let's say something about stages:

1) The concrete experience is based on the personal involvement eminently emotional. The person who learns from this stage tends to favor the feelings and creative abilities on a systematic approach to problems and situations. Learning in this stage is characterized by learning from specific experience related to people and their feelings. I would add that this people learn by commonly called intuition or empathy.

2) Reflective observation characterizes people who discussed ideas from various viewpoints, are careful in their assessments, persevering and trials intended to express "objective". From here we analyze the thoughts and feelings to form opinions based on learning the meaning of things from different perspectives.

3) The abstract conceptualization is learning stage involving the use of logical and systematic approach to understanding the problems and situations. Excludes the feelings of the individual may have in relation of what is studied and is based on trust that the person has on systematic planning processes, development or theories and "formulas" to solve problems, and their intellectual or understanding. From my point of view, these people build on a particular practice, thinking, concepts or theories, which then will allow the transmission of knowledge of the practice.

4) The active experimentation stage is closing the "cycle" and its quality is that the person learns thoroughly "something" just until you run it and experience how this "something" actually works. In this phase learning is obtained by evaluating the individual makes about things made by their results. The person who reaches this stage have the ability, first, to make things, then to risk them and through that influence people and in different situations through specific actions.

One more aspect I would like to mention with this intention of helping students to configure their brain of architect is the subject of the invention. Given that the landscape architect is a developer of spatial forms is expected of him who owns a limitless capacity for invention. I agree with this expectation, I think every architect "mature" which has acquired a vast architectural culture and learned to use a technique of projecting structured in a conscious process of creation has an unlimited capacity for invention, of course he will be compelled to exercise only when confronted by his own interest or for the needs and aspirations of the "other" to a specific problem of habitable space. Now I will clarify what I mean by invention and try to bring a new perspective, aided by some other authors.

According to José Ortega y Gasset dwelling is unprecedented by humans. I understand that for him human beings we are ontologically (thinking about physical existence) a limited life to the possibilities of pragmatic field. I would say a pragmatic field is in my opinion the living space that human being produced or constructed as a result of its action on the physical reality of the world. This means that humans are not found in nature as such ideal conditions just for "live" as most of the animals which find their habitat in the region of the world they occupy. Human beings actually occupy all world regions to build their "habitat" with technological resources cities are the typical example of this. Therefore what supports the development of human life is the ability of humanity itself has taken to transform and adapt the natural conditions of the land to its desire to inhabit specific ways. We call this environment. From this perspective I fully share the life of human beings is a multiple articulation of pragmatic fields and priority of building comes from the deepest desires that people have to live a certain way and not another or any randomly.

Another thinker, Martin Heidegger, he refers to architecture as poetry of the use of space. He said this is made by modeling the spatiality of something when it is ready for use. So I think that in landscape architecture exist not only the human need to carry out life in living space and all the experience that humans have accumulated after centuries to shape the land to inhabit, as well as specific knowledge in that field landscape architects have produced. There are also the qualities of the space will be transformed, these are of various kinds: natural, environmental, cultural, historical, urban, architectural, and cannot be ignored when thinking about its transformation, on the contrary it is these unique qualities of each space indicates that it is "ready for use" and exhibited in its materiality. This specific materiality of each space guides us on the use of technology, media and processes to coordinate the various pragmatic fields through modeling and transformation of that materiality. Throughout, as Heidegger would say, of the poetic experience of the individual on the area, throughout the poetic invention of the landscape architect. So I would say in the process of formal invention of the landscape architect his responsible is manifested in the time he sees an opportunity to transform the world, and his limits at the time he is holding his purposes to the achievement inescapable habitability.

According to Arthur Koestler in our perceptions of the world there is a phenomenon of inconsistency from the biological and cultural perceptual called bisociation, this explains why at times, to a specific space that we intend to "use", "feel" like something is wrong, something is missing or something on the materiality of that space is not right therefore requires an intervention. This is where the landscape architect finds the opportunity. However, the need to transform the space is not a necessity without purpose or direction. I said about human aspiration is to enable the physical space to inhabit. To meet this "purpose" and resolve the bisociation required, then a new construction. How landscape architect thinks the transformation of space expose his talents and limits as a creator. So following Koestler and summing up the above, I would say that creativity and invention are the result of maturation of the landscape architect in three stages: Biological maturation, it is expressed by the architect in his ability to adapt himself to his working environment, always changing where he acts circumstantially. Cultural maturation, it is the result of care and lifelong learning work by various means the architect carried out in relation to the world and his work. It is expressed in the evolution of his understanding and building of his idea and practice of landscape architecture. Personal maturity, this allows the architect to visualize his activity as a continuous process of synthesis and change that produces adaptations and transformations that humanity needs to make the planet habitable. That is, the maturation process of the architect gives to him access to knowledge and wisdom. This qualities manifest at the time to "catch" an architect, his ability to transcend its biological and cultural boundaries to become formally an inventor.

Finally I want to point another issue nodal in the formation of architecture students, is the practice of the review and critique of the concept of landscape architecture. I see repeatedly landscape architecture is taught and learned from a perspective focused on to worship and play a kind of "archetypal idea" of landscape architecture whose influence "inspires" a series of "prototypes", or what I call "iconography of architectural aesthetics", also widely evidence in the architecture of buildings which seems caused by a "mastermind" that "illuminates" the most famous architects and "dictates" them the forms should be created, the forms that everyone "should" follow. I think through this procedure has been emptied of meaning the landscape architecture. Far from what one might believe, this unthinking repetition of an aesthetic model or "style", as doing in present It is not consolidated it in the collective imagination and lasts, but it sells out quickly makes it "kitsch" and banality, disposable, fashionable, whose final destination is to be replaced by the "following".

So, in my experience, I have said there are many schools more focused on the architectural object than in the individual being that is forming as an architect. Then I invite you don't try to find the landscape architecture model but better build landscape architect's mind which it is the substance that produced landscape architecture in the world.

Abstract

In the north and in the south, in small and large realities, entire portions of land quickly recombine themselves rewriting new landscapes that are no longer rural and not yet urban: **rur-ban**. These are new territorial typologies, in which residual gardens, at times fenced and guarded, edge towards built-up areas, and remnants of the agrarian landscape between the new infrastructure systems design a new landscape characterised by the accumulation of waiting areas. The management of this spatial organization is particularly complex. One issue that arises concerns the pre-existing structures and the attitude to adopt with regard to their conservation, substitution, reuse, abandonment. The agricultural landscape of this sprawls area has many inconsistencies and it is difficult to interpret. Layers of activity and different temporality overlap and flank themselves by creating a Hybrid landscapes in which live together more or less visible traces of an agricultural past still recent and elements of new forms of expansion. These are spaces/depot in the complex system of values, knowledge and social relations that have characterized the agrarian world and its history [1] and for this reason they are a vehicle to promote and strengthen local identity. Imaginary landscapes that as designers our task is to interpret and reconstruct to trigger a process of appropriation of land by those who live in and to give dignity and identity back to areas that have lost it.

Parole chiave: Peri-urban landscape, sustainability, landscape heritage, agri-urban landscape, landscape value

1. Introduction

From North to South, in small and large realities, entire sections of land quickly recombine themselves hence rewriting new landscapes which are no longer rural but not yet urban: **rur-ban**. Margin territories where land uses and transformations, the result of unresolved conflicts between different interests, continue to create a varied landscape, but sometimes chaotic, confused, where open spaces still resist with historical connotations linked to the traditional agricultural activities in the face of advancing settlements that meet the needs of the greatest exploitation of the land. Often considered marginal parts of the territory, these peri-urban areas are spaces /depots for the complex system of values, knowledge and social relations that are characteristic of the agricultural world and its history [2] and also enclaves of naturalness and the presence of environmental ecology. These spaces, frayed and contaminated by urban living, represent chances for cities. It's here that the future will measure the ability of cities to compete on a new proposal of sustainability, for which the economical use of resources does not exclude the possibility of reproducing such resources, a project of urban and agri-urban and that, in addition to proposing cultivated fields,, clean energy parks, it also suggests blocks of city life. [3]

Planning strategies are therefore needed which are capable of managing the transformations focusing attention on the identity, economic and social values of the peri-urban spaces and the relationships between urban and rural areas which provide the quality of our landscape. Because quality is a territorial capital that is impossible to relocate, but which can instead be easily trivialized and stripped of its cultural and natural values.

2. Landscape and quality of living spaces

The awareness of the value and the importance of the quality of living spaces for the welfare of the population is a recent revelation. The landscape, for many decades, has been wasted or overlooked. So today we find ourselves having to deal with realities in which the processes of urbanization have led to anonymous territories and urban realities which are anything but sustainable, without paying any attention to environmental quality and the balance between the various components of the territory. In particular, when we focus on the coast, it is evident that the relentless pressure of mass tourism has transformed the coastal landscapes, resulting in phenomena of impoverishment and environmental degradation (pollution, coastal erosion etc.), the development of settlement models which are inconsistent with the existing characteristics, problems of accessibility and the utilization of substantial parts of the city, etc. ...

In Sicily, in the last 30 years, the Ionian coast of Messina has undergone profound changes in its urban structure and settlement induced and reinforced in part by the construction of new infrastructure parallel to the coast Fig. 1. New linear urban configurations have been developed which extended for miles, with a comb-like structure along the axis of the coastal settlements Fig. 2. Linear cities that have supplanted the structure of this region, known already known since the nineteenth century as "the land of evergreen gardens" due to the abundant lemon orchards whose presence influenced the economy, the habits, the social composition, the culture, the rituals, and the traditions of this place Fig. 3. Urban bodies that have cancelled the formal relationships identity, the history and the social economic system of the traditional style agriculture of this coastal area.

The pressure for building, the social and cultural changes and the globalization of the markets have dimensionally reduced the agricultural area, now almost in a state of neglect and not sufficiently supported by development policies and protection. Rural areas, which are now almost completely unproductive, which up to 50 years ago formed a landscape of citrus fruit, fruit trees, and olive groves.

"... An evergreen landscape, based on an intensive irrigated agriculture, among the most prestigious and productive in Sicily, and supported by human communities devoted to the primary activity which marked the economy of the two sides of Peloritani mountain chain and which was at its best and of its highest geographical importance on the Ionian coast between Messina and the mouth of the Alcantara." [4]

An environmental / landscape heritage of which only fragmented pieces remain.

Today the big manufacturers and merchants of citrus fruits have almost entirely disappeared along with the sorting and packaging factories, and seasonal employment, particularly of women, which up to the 1960's constituted the backbone of the economy, no longer exists. Niches of cultivation and highly specialized crops that are seeking a commercial space in the global market still survive, by focusing on the quality and uniqueness of production, such as the *Interdonato lemon*, perhaps one of the few *cultivars* of the Ionian coast of Messina, together with the *verdello*, to survive the farming crisis." [5]

All this has led to the creation of landscapes in which the progressive changes in the economy and society in urban areas have ended up distorting the social identity of the community to the point that it can no longer be identified by the aspects of the places for which it was representative for a very long time.[6] Along this coastal strip it is, however, still possible to find, in the interface between the urban and the rural areas, episodes of naturalness and identity that are important resources for re-creating this landscape which has been ruined by the logic of, all built-up. And the landscape can represent the starting point and the "value" on which to base any future projects for this community.

3. The suburban landscape of the Ionian coast of Messina

The suburban landscape of the Ionian coast of Messina represents an important area of transition between hillside and coastal ecosystems Fig. 4. An area heavily affected by several streams which over time have become receptacles and repositories for urban waste, and often the illegal home to craftsmen activities, small shipyards, weekly markets and seasonal fairs, car parks and camping areas, car washes, etc.. A landscape in which natural elements and the permanence of the traditional agricultural landscape

are still present, as well as historical and architectural features, both military and religious. It is considered as an external "green belt", a crown that in reality has different gradients of impairment and fragmentation in relation to the different areas Fig. 5. Circumscribed and partly cut off by the infrastructure system of the motorway, the railway line, pipelines and aqueducts, which open up to the rural area at the beds of streams where they appear to be a system of ecological networks connecting the sea to the mountains Fig. 6.

Its main problems are:

- Strong development pressures,
- Perceptual and functional degradation
- Residual nature of farming,
- Fragmentation of the agricultural areas caused by the presence of incongruous activities or infrastructure,
- Very high Hydraulic Risk with tendency of flooding,
- Presence of neglected natural features,
- Fragmentation of ecological corridors.

These areas on the border of the city, no longer countryside, but not yet city, form a landscape which is still defining itself whose main characteristic is that of uncertainty, instability [7]. Despite being subjected to high anthropogenic pressure they have essential functions of environmental compensation and protection which are essential to regaining an eco systemic equilibrium as a potential for education, recreation, cultural and historical identity. While not considered particularly valuable in themselves, since they are not economically productive, they have now become an important strategic value for their position in the middle of the in between, places on hold, suspended between urban, suburban and rural. They are represented in various urban plans as a blank space, to which a role has not been allocated and/or recognized except for that of future expansion, an empty space, the suburban area fringe between built up areas and open space, cut and crossed by both natural and anthropogenic infrastructure (streams, motorways, railway lines, waterways, etc...) is a place of opportunity for this linear city under construction Fig. 7. It is seen as the only large open space of the city, a reserve of greenery and naturalness, producing material goods which can be sold along the short-circuit chain of the local market, an infrastructure of regions with varying population densities [8]. A biological, landscape and historical heritage, which although strongly depleted and disjointed, does not deserve to be deleted, but which is waiting to be rediscovered and appreciated, as it is an integral part of the past and culture of this area and which could be considered the testing laboratory for a less destructive, more balanced and conscientious relationship between the demands of human activity and those of the territory, giving a specific function back to these areas within the lifestyle of this linear city Fig. 8. But to become a real possibility it is necessary on the one hand to change the agricultural policy of the area through an innovative cultural and economic project that can succeed in attracting a young workforce, and on the other hand to create a development project that takes into account all the characteristics of the area and that uses its natural resources in a prudent and thrifty manner.

4. Strategies for the enhancement of the surrounding areas

The fringe areas are characterized by excessive fragmentation and privatization which make the definition process difficult for politicians to formulate policies to integrate their protection and preservation through the dynamic and active management as required by the CEP (European Landscape Convention). These characteristics have in part led to a stagnation in planning which in turn has corresponded to an accelerated housing boom that has transformed these areas into the urban spaces they now are.

Landscape knowledge, more inclusive than the urban one could be an alternative in the management of these territories. It's flexible, relational, participatory, knowledge. It creates a mediation between the needs of identity and naturalness of places and the needs of the people and those of production and economic activities without neglecting the aesthetic aspects that are the subject of perception and appreciation of local communities. [9]

The peculiarities of the landscape are crucial to identifying intervention strategies and guidelines for the surrounding areas by promoting awareness and knowledge, protection, management, innovation, experimentation strategies.

These areas which are not occupied by urban functions offer a potential which should not be underestimated as regards land protection, reformation of ecological relationships, the construction of green spaces, the creation of new decentralized polycentricity which goes beyond the state of being periphery. [10]

The construction of a green infrastructure network, which reorganizes all of the green, peri-urban, agricultural, fallow, and structured green areas ..., through the activation process of recovery, requalification and regeneration which would allow a greater availability of peri-urban open spaces to be achieved including them as part of a network and hinge system between urban, suburban and rural areas.

4.2 The agricultural value of the surrounding areas

In recent decades the need for recognition of the agricultural value of the territory as well as its historical and cultural value has emerged, a sign of willingness to proceed with building the defence of their territorial identity. The measures undertaken by the Department for Agriculture and Forestry of Sicily, under the Rural Development Programme (PSR 2007-2013) [11], the n° 322 "Village renewal and rural development" or the n° 323 "Carrying out the restoration of the cultural elements of traditional agricultural landscapes", are evidence of a change in the way of looking at the rural world. I quote from the objectives of the measure "recovery of the rural heritage in its various constituent elements to improve the quality of life in rural areas and the attractiveness of the latter for the local population, visitors, tourists and entrepreneurs." But preserving the individual elements of the rural heritage cannot be considered sufficient. It 's necessary to insert them into a network to create a system to ensure continuity over time of the individual actions. Structuring a system that is able to give value to the elements as part of a common history. Designing a strategy to approach the area as a whole and not only through its individual components. It will be necessary to take action in the recognition of the relationships and the elements, which will enable a compatible recovery and reuse of such elements. On the other hand, these measures are targeted at rural areas and not the peri-urban agricultural areas, areas in which agriculture is currently conditioned by the urban environment that develops around it and tends to spread, threatening the same agricultural activities that need to be retrieved and promoted through a process of social involvement, in the knowledge that the earth is a common asset and the exigency not to further consume the land which is a non renewable resource. The peri-urban agricultural areas are "still poorly protected from the political sector, despite the virtuous synergies that some experiences between the edge of town and the countryside can generate, for example in terms of short chain eco-system services...." With regards to this, it is reminiscent of the projects, of direct sales, managed individually within a company or collectively through farmers' markets, or "vegetable plot" projects in which the individual cultivates produce on their own, or even urban agricultural parks, or rather park models intertwine the preservation and protection of the territory together with the defence of the economic function of agriculture and jointly respond to the increasingly urgent demands of the urban community in terms of open space, which are accessible and rich in cultural values and new forms of consumption. In Italy some reference experiences (with different levels of implementation) are the South Milan Agricultural Park, the Agricultural Park of Asti, the Agricultural Park of the plains in Tuscany. [12]

4.2 Landscape design as a development strategy

The logic of the system of green green-belts, agricultural parks, greenways, green wedges, could be a way forward if the territories of transition are considered as an opportunity for development of the whole community and not as a limitation of the unlimited urban expansion. So these areas are considered an asset in environmental, ecological, cultural and identity terms, in the principal scenic areas of the territory. It becomes necessary then that the peri-urban agricultural areas are "recognized on a social, political and administrative level and that they are protected by actions and specific laws aimed at this type of agriculture", as outlined in the Charter for the peri-urban agriculture, developed in 2006 by the Italian Farmers Confederation (CIA). But right now this is exactly what is missing. Planning instruments of Sicily are too old to be able to manage the changes that the social and economic reality of our territories have experienced in recent years. The management of the land is delegated to the Prg which continues to demonstrate how ineffective its tools are in the management of change, far from the changing nature of the reality and too abstract and not very attentive to the multiple indications that come from daily life experiences. The territories speak through the signs that daily human activity produces constantly making and remaking the face of our living environments Fig. 9,10,11. And knowing how to listen and recognize the latent characteristics of a place often becomes the basis for proactive and targeted planning. A plan that is capable of focusing on the material and non-material aspects of this territory that "no longer considers the landscape as an added value compared to the processes of transformation and development But rather an inherent value in those processes that should be assessed and disclosed appropriately. " [13] A value that has also been reiterated by the Pac - Community Agricultural Politics - which identified the conservation and enhancement of the landscape as one of the main objectives to be

achieved. There is still no project of the rural territory aimed at harmonizing the economical, social and environmental aspects that produces the agricultural landscape within an overall strategy that can be integrated with land use planning [14]. And above all there is a need to structure processes and policies regarding the commissioning value of the peri-urban and agriculture land through collaboration between government bodies, farmers and residents.

The European Landscape Convention, emphasizing the need for governments to become involved in the whole territory, of all landscapes, not just those of particular interest, defining the actions as being able to ensure the management of the landscape in order to guide and harmonize changes which are brought about by the processes of social, economic and environmental development. It provides dynamic management of the territories that should seek to improve the quality of the landscape according to the aspirations of the populations, through measures to enhance, restore or create landscapes. It also points out that the planning of landscapes concerns the formal process of study, design and construction by which new landscapes are created to meet the aspirations of the people concerned.

The Charter for the peri-urban agriculture, which partly reflects the principles set forth in the opinion of the EESC - European Economic and Social Council, which is another useful reference tool in regulatory matters. In fact it outlines the principles of conduct to which the public administration should aspire in order to define the planning and management criteria of the peri-urban areas aimed at protecting, upgrading and enhancing those particular areas, considering both the landscape and cultural characteristics and the agricultural-productive values, and the potential economical and social issues related to the concept of the multi-functionality of agriculture.

5. Conclusions

It is only in recent years that we have gained the knowledge that peri-urban open spaces are important to citizens who are increasingly searching for "landscapes" of open spaces and places where agriculture plays a renewed role in the production of goods and food near to the inhabitants, but also educational and multi-functional in a balanced relationship between development and sustainability.

With the entry into force of the CEP, the landscape was regarded as a tool to solve the problems of contemporary planners. The landscape has been laden with the mixed expectations of contemporary society and its development. Different definitions have been associated with the landscape in an attempt to catalogue a complex object which due to its polysemic character defies a single definition. In its preamble, the CEP emphasizes how the landscape is a cultural acquisition related to the perception of the people and as a result it is bound to their *uses and customs* and is closely dependent on the manner in which a population develops, lives and perceives their own territory. The landscape, then, as a palimpsest, like the continual writing and rewriting of a text that is the story of a society that by living in a space creates its own living area. Assuming this definition, there is a need to fix the meaning of landscape design. The landscape project cannot be an act of beautification and rectification of problems from the past. It's an act of planning the development of an area which manages to bring together the physical, economic, cultural, aesthetic, quality and social components. A project, that is not based on a finished pre-figured drawing, but a flexible development process that incorporates multiplicity and mutability [15]. A project that is based on knowledge and the rediscovery of values in order to build sustainable processes of re-designation of territories and the restoration of identity and dignity to the landscape. Which sees communities as protagonists in the transformation process and hence active partners in the planning strategy [16]. Only if the residents feel a part of where they live better will they be able to feel involved in the active plans and proposals to enhance and / or redevelop the suburban landscape with acts of shared protection.

Drawings, signs and codes in landscape representation

Stefano CHIARENZA

Dipartimento di Progettazione Urbana, Facoltà di Ingegneria, Università degli Studi di Napoli "Federico II",
Napoli, Italia

E-mail: stefano.chiarenza@unina.it

Abstract

The landscape representation is a complex process based on the acquisition of a whole range of aspects of perceptible reality and their transposition by significant graphic signs. This process can be considered as a graphic system of transcription, logically ordered that, by means and methods diversified, becomes a form of communication essentially visual and universally recognizable.

The impossibility to always use accurate mathematical projections as well as the need to express circumstances and peculiar properties of natural or anthropogenic elements - in fact independent of the projections - raises the problem of appeal to a class of conventional signs. In this domain of the sign, functions, syntax, meaning and practice are delegated almost completely to the designer who has to face a challenge epistemological and interpretative.

The management of complexity through the use of new media makes it possible today the renewed design of perceptive-spatial codes, able to make tangible the knowledge of the territory through signs that although a graphics reduction refer to broader meanings. As to say *less is more*. In light of these considerations, the paper tries to establish itself as a moment of reflection and synthesis of research activity still under development, aimed at testing visual-graphic signs and forms that explain a communicative function straddling the traditional themes of mapping and the innovative approach offered by the graphic-design.

Parole chiave: mapping, cartography, infographics, graphic design, graphic methods

1. Landscape representation as a complex process

Landscape representation is, historically, a complex process that involves a set of different problems. Indeed the creation of a map, at any scale it is produced, on one hand should overcome the inability to accurately represent the variety of natural or anthropic characteristics that constitute and characterize the topography of land; on the other, to solve cultural problems involving the proper interpretation of information. In other words, in reading a map it should be possible not only put the represented phenomena in proper spatial relationship, but also understand the role they play in events and human actions (socials, political and economic).

In the definition process of a map, that represent the graphic transposition of the land, then comes into play a complex chain of choices that moves from a real data selection - choosing only those true and reliable - to the definition of graphic choices, which must combine methodological rigor and readability, taking into account also semiological aspects.

In conclusion, the landscape representation is not referable to a mere instrumental realization but rather to an intricate path ideation, graphic design and processing control.

The performance of informative functions of the territorial map, at any scale and with any techniques it is made, being the visual translation of the knowledge synthesis from various disciplines (geography, geology, botany, architecture, etc..) binds so inextricably to a series of cultural aspects that govern the choices made and that involve multiple areas of science, also art and design.

Through such a cultural representation, the landscape takes shape and becomes perceptible and storable, allowing a thorough knowledge of all its tangible and intangible values: cities, countries, roads, monuments, hydrography, orography, etc., as well as flows of invisible relationships, human and social dynamics, and intangible phenomena. A complex reality, then, that is translated through a graphical organized in mental images, showing what no eye can see. The landscape representation, through an inevitable abstraction process, puts in front the magic of the concept and the charm of reality in a representative image in which being and appearance, the real and the reality concept become specular. Seen in this, the map "is transparent because it is a signified without a signifier. It vanishes in the visual and intellectual operation that unfolds its content. The map spreads out the entire world before the eyes of those who know how to read it. The eye does not see; it constructs, it imagines space. The map is not an object but a function. Like a microscope, a telescope, or a scanner, it is a technical prosthesis that extends and redefines the field of sensorial perception, or, rather, a place where ocular vision and the "mind's eye" coincide. As a mediation, an interface, it remains hidden" [1].

The act of interpretation in the cartographic representation is fundamental both in the definition phase which in the reading. To draw a map it is necessary to know the mental mechanisms of perception and interpretation that govern the response of the image in the mind of the reader. Instead, in decoding the map comes into play the individual culture: the territorial and spatial reading becomes a subjective interpretation of the viewer, albeit streamlined and oriented. In the modernly understood process of construction of the landscape's representation is therefore necessary to relate tightly two different forms of logic: that of the designer, based on scientific rigor and objectivity, and that of the spectator and his freedom to roam freely with his eyes and his thought. This means, as poignantly writes Jacob, to reconcile two ways of looking at the map, two points of view: one that considers its power of seduction "its status as an image, its oneiric and mythic implications, the reverie it suggests to the gaze whenever the viewer's eyes slip freely over its surface. This type of representation would seem to constitute a privileged space of projection for the viewer's desires, aspirations, and effective and cultural memories. The other thread follows the map as a rational construction an intellectual construction ruled by geometry, symmetry and the requirements of geographical knowledge: the map is an intellegible model, a device to be read, interpreted, and questioned as much as it is to be viewed" [1].

It then breaks the constrictive and exclusive bond between reality and representation, seen as a bijective correspondences of objective data. In mapping there is not mimesis. However the map has the power to reveal reality through a graphic log of correlations between two spaces - the real and the map space - apparently simple. It is in fact not only to represent measurable and mathematically defined spaces, but also intangible, real or desired. The mapping process is "creative, sometimes anxious, moments in coming of knowledge of the world, and the map is both spatial embodiment of knowledge and a stimulus to further cognitive engagements [2]. So, the map is a model of the real world made with a language that expresses the outlook of a social group and its interpreters. No representation can then be considered neutral, but rather focused on the choices that the coders make in the selection of various aspects related to the specific work aims, explicitly taking into account the perspective of the viewer. A representation that must be functional to the needs of users, now pointing to specific pathways, now going beyond other aspects or details.

Fig. 1: Mapping of fire risk areas in the region Emilia Romagna. Highlighted in red, the potential fire hazard on the basis of territorial and phytoclimatic characteristics. Graphic from the Regional plan of forecasting, prevention and active struggle against forest fires.

It is also impossible to distinguish the expression of spatial knowledge from its representation, and of course the recovery of this knowledge in unique ways.

If the metric properties are the basic mathematical character of a map, they represent only a small part of this, the visible expression of a more complex and dynamic set of relationships. In other words, the representation of the true size and shape of the world becomes the only objective data of a map that uses a set of abstractions - frames, letters, signs, scales, indexes, codifications etc. These forms, with their inevitable inconsistency, transmute the mental image into a spatial imagination far from objective.

In this sense, the process of research and identification by those who read the map goes far beyond the simple correspondence between symbols and key to symbols, coming rather true the recognition of model distinctive features, related to forms, spatial arrangements and mental associations.

2. From drawings to conventional codes and symbols

In the mapping process, it is therefore particularly important a semiological approach. In the chain from the empirical vision of the world to the mental schematization, abstraction plays a crucial role.

Places, paths, routes, distances, orientations, along with descriptive data, make the map a real database of relationships, that are simultaneously offered to read.

Among the consistent features of mapping are scale, framing, selection and coding. And metric scale is one of the fundamental aspects. Enlarging or reducing the space occupied by phenomena, alters a set of relations of meaning between them, their significance, underlining or making them even invisible. As noted Consgrove "scale selection and manipulation is thus a powerfully imaginative and generative act which at once records and sets in train chains of meaning and association in an active process of knowing" [2].

Framing and scaling are part of the map's mathematical projection that translates the three-dimensional real space onto the two-dimensional surface of the drawing.

And the abstract lines of the projection grid, visible or invisible, represents the first semiotic link between sign and signified, or between map and territory. Selection and encoding occupy this abstract space. The close connection existing between the metric scale of the map and the objects represented makes it impossible, in many cases, the use of exact projections, as well as, on the other hand, it is difficult to express graphically the peculiar properties that are independent of projections. It is therefore impossible to achieve a complete representation of phenomena (natural or artificial) without resorting to a set of conventional signs, even if it were possible their projection in true form and size. Even more evident when in a large scale, the gathering of information in small spaces would make the map - processed according to traditional projection methods - completely unreadable.

Fig. 2-3: The *Fool's Head Map*: a Fossil of the Financial Bubbles of 1720 (Amsterdam 1720) - Topical satire. It is not based on existing political or natural borders. The signifier and the signified are identical.

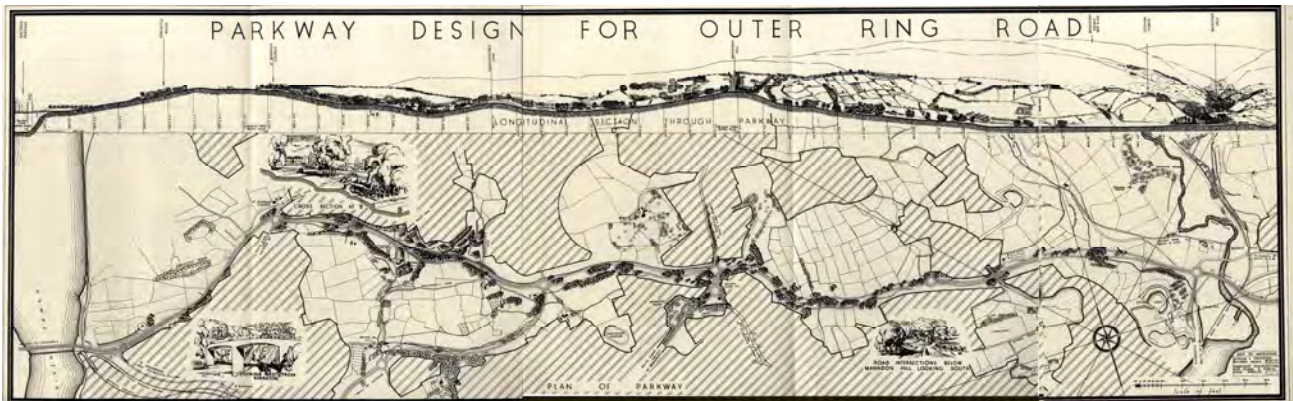

Fig. 4: Traditional plan and section of the parkway design for outer ring road – City of Plymouth 1943

The attempt to replace the multitude of words or drawings with representative signs that would be needed to explain exhaustively the character and qualities of the territory is already clear in the ancient and historical cartographic representations.

However, these are graphic reductions, sometimes in perspective, whose arbitrariness, directed to clarify specific conditions of the represented territories, was far from defining conventional signs. The necessity and undeniable convenience that such signs have proposed in the representation has determined their increasing use over time leading to further refinement and study of a wider symbology. A graphic reduction through signs that in the centuries has become a language, a real writing, easy, convenient and above all well-founded. An essential aid, but a real complement to the drawing, incomparably more appropriate to translate the intrinsic properties of objects, or of contexts represented, into mental images.

This language, although based on the reduction, however, is able to offer a set of information that sometimes the direct knowledge even can not give, and its semantics shareability defines the character of conventional code. The conventional signs, coded on an abstract and geometric basis, combined with evocative and symbolic signs, define together the interpretative key of the mapping and have gone through various ways throughout the history of representation.

The achievement of these results, in terms of communication, however is related to the depth of the relationship, in a rational level of visual perception, not only between the sign and the reality, but also among the signs themselves. Although the semantic language has always been historically and culturally determined, currently it is related to more rational signification's systems, is purged of cultural and ideological (political, religious, etc.) references, is studied and connected in order to achieve effects of readability and meaning's attribution that, while appealing to the emotional perception's sphere, with the expressive power that derives from it, leads to more appropriate understanding of the message, with a large ratio between the code and the message.

Fig. 5-6: Lay-out showing the growth of New York City from the beginning of the 19th to the beginning of the 20th century. Two examples of map produced by the Isotype Institute in 1944. (Images from the site www.fulltable.com)

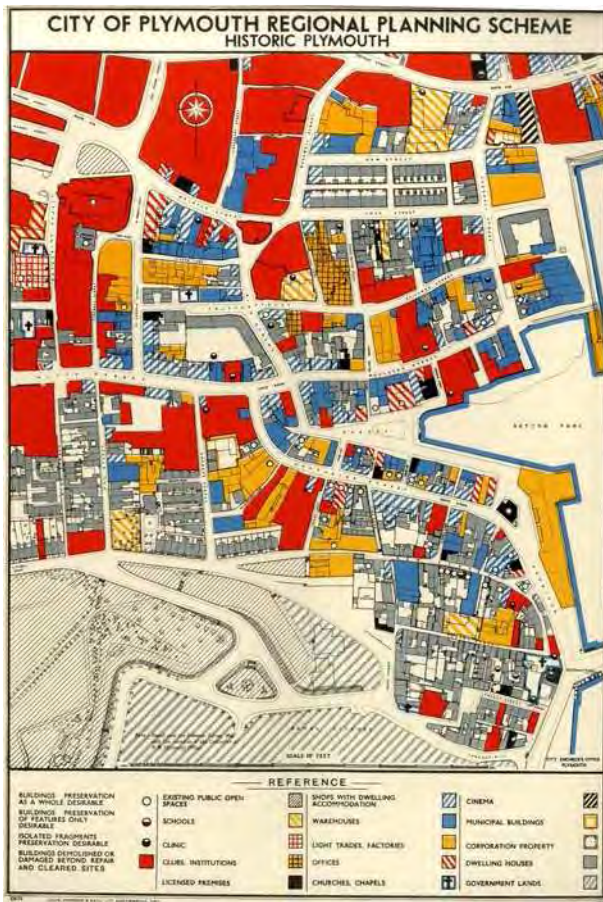

Fig. 7-8: City of Plymouth. Historic center. Regional planning scheme 1943. On the right: proposed central layout. Shewing properties existing 1943

The experience of reality is so transformed through a semiotics which links the space represented to a possible image of the real one. And the translation possibility through signs and symbols represented on the drawn map's space are surely limitless, only bound by the effectiveness in terms of readability and comprehension. The map thus becomes not a simple graph, to be read diachronically and sequentially, but a visual document, which has precisely the character of the synchronic vision.

The cultural assumptions, including on the basis of a more efficient coding, however, appear crucial to the proper interpretation and map reading. However, today the graphic transposition of phenomena pursues the objective of allowing a reading that, even if subjective, cannot be considered arbitrary. In this regard, the expressive codes must take into account the laws of perception, ensuring that the signs have either the connection with the meanings, or a correct expressiveness towards users, them ensuring, through conceptual logic operations, to comprehend the represented space. Compared to the painted or photographic representations, which immediately lead back to what is depicted, the map, with its own signs system, is an elaboration that, to support utility and meaning, must necessarily be abstract. And this is the strength. The cards are "mental constructs, ideas that produce and make it possible the change."

3. New ways in representing the space of territory. A research perspective: graphic design and digital media in cartography.

The importance of cartographic language as a set of signs that can direct visual interpretation of reality to the point of redefining the system of relations between the elements that compose it, assume today even more weight. By the development of new media and infographic representation's technologies it is necessary not only to rethink the role of the observer-user (often specialized), but, at the same time, the role of the cartographer as interpreter of an increasingly globalized culture.

Fig. 9-10: On the left hand: the 1972 MTA New York City subway map designed by Massimo Vignelli. On the right: The 2007 kickMap of New York City subway by Eddie Jabbour

Without disregarding science and scientific method, in fact, innovative representation's processes of the territory are emerging. The mutation of the relationship between design and knowledge related to the use of new media, opens the possibility of combining the use of different resources from different domains, such as sounds, animated graphics, and images. The role of design - expanded to information design - is significant in its ability to reduce the cognitive complexity. And this not only in the production of knowledge, but also in the processes of diffusion and assimilation of the same [5].

The representation's process of the territory, intended as wide communication system, requires a theoretical and experimental work in which those involved are both designers and users.

The transposition of a large set of data into information is - as widely noted - one of the implicit aims of representation. The internalization, interpretation and use of such information by the user, transform it, instead, into knowledge.

It is then fundamental the way in which this information is presented. In this sense, the research's field related to the way of representation of the territory must extend to computer-based interactive visualizations. These can, in fact, convey a more complete understanding of a set of processes generally invisible. In particular, the graphic design based on the interactive presentation of information on digital media appears as a new frontier in cartographic representation. Interaction as "a manner of presenting information to a community of users in a non-linear way, i.e. as hypertext or information in form of branched structures composed of semantic nodes with choices for the user to move through this net of nodes" would enable new methods of presentation and understanding of the territory.

Perception studies in cartography, linked to sensorial stimuli, were applied, so far, mostly on print-based, using static resources (typography, illustrations, etc.). Their application in the domain of interaction design through new media would lead to an innovative design approach, which could be called "global". In this process, graphic design fits in a propitious way, because an effective communication depends on the use of resources intrinsically linked with the aesthetic.

A function that has been defined by Gui Bonsiepe as audiovisualistics or visual rhetoric [5] able to keep and maintain a high level of attention and curiosity of the users, contributing, through the clarity of communication, to the reduction of cognitive complexity.

Fig. 15: *Visualizing airfare*. In this caGIS map design, Daniel P. Huffman collected fares for all 100+ direct international flights on British Airways out of Heathrow airport in London, interpolated a global surface, and threaded isolines.

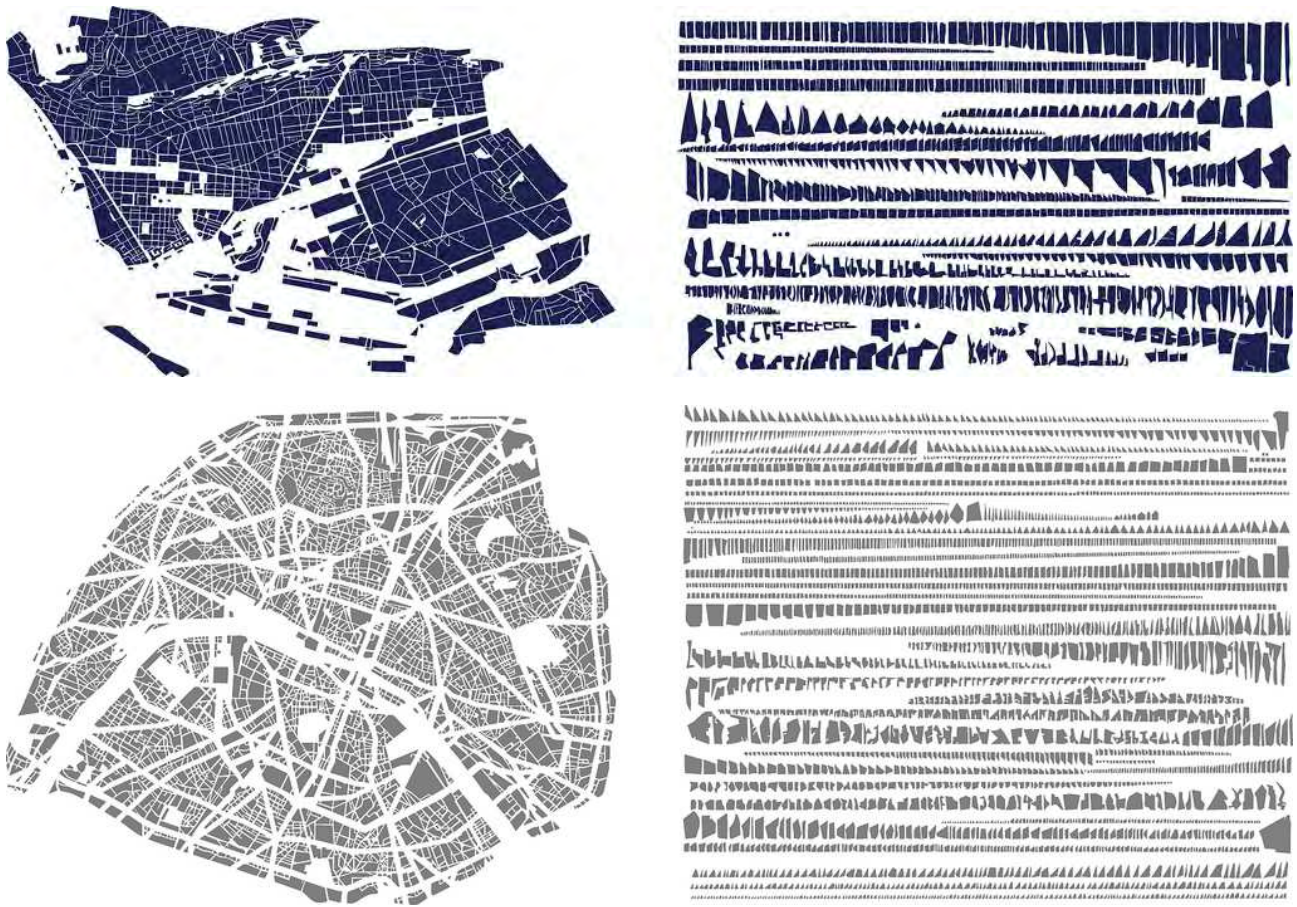

Fig. 16-17: *Anagrammes graphiques de plans de villes*. The city map is deconstructed, then reassembled in a taxonomical tableaux. From the top: La Harve and Paris cityscapes. Images produced by the French artist Armelle Caron.

An epistemological and interpretative challenge that graphic design faces by means of a cognitive mapping, structuring a set of information in form of text, sketches, videos, voice recordings, photos, illustrations, diagrams and animations using an interface that can be perceived, well understood and implemented by the end user. Obviously managing this complexity is a design problem. In the last two decades many researchers have turned their attention to the problems of visualization (however an old and familiar problem to cartographers). New research is also based on the animation, in the process of map design (eg. Di Biase, etc.) [10], and many related issues also involve latest research in GIS.

However it should be emphasized that that the characteristics related to the graphic design are largely disregarded in the cartographic approach and the projectual designer's experience is often considered insignificant, if not rejected, only giving preference to engineering aspects. By contrast, an integration of knowledge and experience, which takes into account the enormous aesthetic values implicit in the mapping process, would lead to a strengthening of cartographic product. An intellectual migration from the scientific to the artistic domain and vice versa, of considerable extent.

The aesthetic representation side, in fact, greatly influences the way in which this is able to be perceived, strongly influencing the readability. The researches by Bertin and Ostrowsky [9] represent, in this sense, pioneering examples of studies focusing on the profound relationship between graphic and mapping, the first in semiological sense, the second in the artistic connotations.

Established this relationship it is clear that the use of new media, by now become settled habit in graphic design, plays a crucial and innovative role in the representation of territory. The use of GIS programs, paradoxically, pulls away from more specific research applications, consolidating wrong aesthetic habits.

Certainly, a correct representation requires a scientifically rigorous design, but in mapping process it is necessary the balance of science, art and technology.

In light of these considerations, the present paper - without claiming to be exhaustive with respect to the issues addressed - then tries to establish itself as a moment of reflection and synthesis of research activity still under development, aimed at testing visual-graphic signs and forms that explain a communicative function straddling the traditional themes of mapping and the innovative approach offered by the graphic-design.

E-mail: apascual@arquitectura.cujae.edu.cu
jorgep@arquitectura.cujae.edu.cu

Abstract

Currently the presence of Open Spaces of Public Use (OSPU) becomes more and more diverse and gets higher relevance. The elevation of the qualification of the OSPU contributes to promote well designed, comfortable inhabitable areas and of high environmental value, contributing in great measure to the development of sustainable cities. The present article proposes a methodology for the classification of the Open Spaces of Public Use on the base of an integral approach. It conceives: the morph-typological, functional, socio- psychological and ecosystem based (urban ecosystem) dimensions. The starting point is placed in the established relationship between man and his environment which are defined by the interacting physical, psychological and socio-cultural elements. Additionally a theoretical model for the classification of these urban spaces is structured. The setting in practice of this methodology would allow the planner having the necessary analysis tools in order to determine the vocation of each OSPU. The paper presents the methodological focus of the present investigation which develops the proposal of a spatial model of relationships. It also reveals the interrelations between them. As a result, an optimal association of the elements is achieved. It integrates man's relationship with its environment in the analyzed spaces.

Keywords: Open spaces, typology, spatial model of relationships, man's relationship with the environment.

1. Introduction

The importance of cities has increased significantly over centuries. The spatial dimension of population growth during the recent decades has contributed to today is seen as critical for the future of the 7 000 million already registers the humanity on Earth. According to (Abounaga, 2011), is considered that 70% of the population lives currently in urban areas. This situation, influenced among others, by the migration process to urban centers, entails significant changes in relation to energy, water, food and materials consumption. They are also associated with increased levels of pollution arising the electricity generation, the creation of urban waste and transport emissions and other processes associate to urban complexity. They constitute additional causes of ecological and social tension important. For these reasons, cities are among the sectors of greatest influence.

The predominant trends of metropolitan expansion introduced contrary to the sustainability guidelines in the form and composition of the city. The presence of "megacities" is an example of this.

At the same time, the city starts to get distorted traditional compact compared to the pressures of urbanization. The "diffuse city", with an opposite structure to the previous, consumes potential areas for cultivation, generates an increase of distance and infrastructure and rises the demand of transport and energy. As a result, the urbanized area extends and modifies the surrounding natural areas and their life cycles, coupled with a deterioration of social cohesion.

The city as a collective is the place par excellence of exchange and encounter of its citizens and visitors, particularly in public spaces, which began to materialize and modified from the beginning in the socialization of men and progressive specialization of labor along the story. No one could speak without considering the city itself in its entire dimension because the public space is inherent to the conception of the city.

Fig. 1. Open Spaces of Public Use. Corner of Obispo and Aguiar Street, Havana, Cuba, 2012. Source: Authors.

Moreover, the public space is of secondary importance in the international public agenda. However, each day increases the demands of the inhabitants for incorporation into the city where they live, of outdoor spaces that allow for interaction between them. The city is committed by an upgrading of public spaces to solve the needs of raising the quality of life for its inhabitants. Following the established development patterns, contemporary societies are facing severe social and ecological crisis.

Therefore, the problem of habitat enhancement is one of the main challenges facing by the city. In that effort, clear understanding of the potential and limitations of the territory, especially against the subject of the various types of open space of public use, is one of the key challenges.

2. Materials and methods

The paper shows the results of an extensive literature review. It is part of a larger research that approaches the issue of open space planning and contemporary urban design.

The analysis draws attention to the activity of planning and urban design, linking it to the dimensions, variables and indicators considered. We designed a tool that facilitates the interpretation of open space systems as a promoter element of sustainability. The proposed theoretical model summarizes this vision of integration.

In the first stage we analyzed a set of definitions relating to urban open space and existing methods for its classification. The selected elements were structured systemically, for which multiple dimensions were registered by the authors. This theoretical and methodological base is transferred to the synthesis process, from the elaboration of a matrix that interrelates the issues identified. The matrix study correlates the elements of the proposed methodology for classification of Open Space of Public Use. The methodological approach points to the proposal of a Spatial Relationship Model, which integrates a set of dimensions, variables and indicators. Also has been possible to graphically illustrate the different aspects selected for analysis, and the interrelationship between them.

3. Results and discussion

Public space is a place of connection and identification. In addition to physical features, public space set the field for the deployment of imagination and creativity. The quality of public space can be mainly evaluated by the intensity and quality of social relations that facilitates its ability to receive and mix different groups and behaviors, and their ability to stimulate the symbolic identification, expression and cultural integration.

In the area of definitions, modern public space coming from the formal separation (legal) between urban private property and public property. However, the dynamics of the city and its inhabitant's behavior create public spaces that are not legally, or were not designated as such.

It is possible to develop different activities in open spaces that can be carried out in different types of buildings. Therefore, in this investigation the open space is handled as an property type, which basic physical characteristics, that distinguish it from other existing buildings in the city, are essentially it has no walls or ceiling.

Although the authors differ in the use of terminology, they agree that the open spaces contribute positively to urban areas. In addition, these types of spaces contribute significantly to three areas of urban sustainability, from social, environmental and economical point of view.

In this investigation the Open Space for Public Use (OSPU) is defined for all open space is intended for public use, accessible to all citizens and its legal conditions are considered public property.

3.1 Methodology for the classification of OSPU

Identification of the morphotypological dimension

The urban development process currently manages the buildings as isolated objectives in the landscape. Generally, the decision making process related to urban growth, is made from land use plans in two dimensions, without considering the three dimensional relationships that exist between buildings and open spaces, neither a real knowledge about the behavior of people in these spaces. The grouping of urban open space into different categories has been occasionally addressed as a planning tool. Generally these groups have been managed on a typology or hierarchy of these spaces.

The best known of definitions related to the use of urban open space was developed about thirty years ago by (Newman, 1972). At that time, different categories for open space were listed: public, semipublic, semiprivate and private sectors.

Moreover, a study has been presented that address the visual and spatial aspects of urban environments, which are determined by the components: route, site and location. The route corresponds to the street and

can be considered as a space oriented to the movement. However, portal refers to the thresholds and transitions between spaces and between public and private areas (White, 1999).

There have been identified six elements related to the visual component of the urban environment in general. Therefore defined: locate, focus, scale, proportion, rhythm, and materials. (Cantacuzino, 2000).

In this regard, recent studies conducted by Spacesyntax Laboratory, relate the behavior of individuals and the use of space to the spatial properties of space, given by their morphological characteristics and visibility. This approach suggests that the best locations for stationary use unscheduled, are independent of the attractions or facilities of the space, however, could be associated with the visual properties of the person experiencing this stationary. It is argued that the configuration of space, particularly its effect on visual permeability, it is important for the generation of movement.

Other research on open spaces defined a hierarchy given by the size or the area it occupies. This includes small local park, local park, district park, metropolitan park, regional park and linear open space (Llewelyn-Davies Planning, 1992).

Some authors have argued that a hierarchical approach to the provision of urban open space fails to recognize the potential of smaller open spaces ensure to the experiences of different users and people who want to use the open spaces near their homes.

In physical terms, open spaces for public use are key components of functionality and ways of life in town. This shows the roll that carry out these spaces in the urbanization and in the quality of social life.

The network of public spaces is the component of urban space that allows the connection of one point to another in the city, spontaneous communication between citizens and the perception of the urban. The city as a collective is manifested primarily through its network of public spaces. The concept of open space should be conceived as a system.

Incorporating the spatial concept of Continuous Landscape, combined with the theoretical concept Productive Urban Landscape sustainable (Viljoen, 2005) proposed a new perception of urban scale landscapes, offering the city a wide range of lifestyle benefits of the population. These advantages will be marked in environmental, sociological and economic.

Referring to the open spaces in this research approaches the network of public spaces and others, which increase its public character through its incorporation into a coherent landscape strategy. It essentially depends on the level of access that these are granted.

Although sources differ on the use of terminologies, the authors presented propose a classification of open space from morphotypological concepts. It follows that the proposal is based on the classification of a first morphotypological dimension for the study of open space for public use.

Identification of the functional dimension

From a historical perspective, the space in cities has complimented three vital functions over time: a meeting place, market, and connection space. As a meeting place where the city was the scene going on exchange of social information of all kinds. As a market, the open spaces of the city were the territory where they carried out the exchange of goods and services. Finally the streets of the city supplied access and connections between all city functions (Gehl, 2001).

One of the most important concepts for the achieving of accessible spaces is the mobility. It involves the systematic application of the accessibility principles to those areas of the external environment enabling the development, use and enjoyment of it. In this century develops a more comprehensive concept of accessibility to the physical environment, which takes into account the removal of physical barriers, and also the psychological and social barriers (Cazanave, 2007). Studies show the public or private character of a space according to their degree of accessibility. In this case it doesn't refers to accessibility in relation to disability, but the qualities that have the space to invite or not the individual's participation (Hertzberger, 2005). Figure 2

More recent studies conducted by (Llewelyn-Davies, 1992), suggest that the open spaces have seven functions: recreational, structural, comfort, environmental, social, cultural and educational.

It is important to point out that the multifunctionality of open space is its ability of functional transformation. A greater concentration and diversity of activities in an open space generates a greater radiate of influence. Therefore its position within the open space system becomes hierarchically more important because a multipurpose trip is always more attractive to the user.

The open space is related to other land uses from its functional interaction with the rest of the property, which is a determining factor in their locational logic (Ayala, 2007). It can take two forms. The first one is when the open space has a specific purpose, for example, its function isn't directly related to land uses that surround it. The other case occurs when the open space is part of the functional relations of surrounding

land uses, then could be affirmed that open space is an extension of architectural space because its function is to vestibular others land uses.

The Continuous Productive Urban Landscapes (CProUL) assume open spaces used for urban agriculture as the main element, and they influence in a direct way on the development of the food system of the city. Thus, they increase the productivity of these not only in the economic order, but that they become multifunctional spaces, providing areas for recreational activities, with the ability to function as urban green spaces, access routes, and others variants.

These examples sustain that the authors make the classification of open space from the functionality, which corresponds to the functional dimension of our proposal for the classification of open space for public use.

Identification of the socio-psychological dimension

The city is the society registered on the land [...]. (Lefebvre, 1968)

Since early 1960, many researches have been conducted that have focused their study in the field of environmental perception, and specifically in the perception of people in the urban environment. Early studies took into account the environmental image. These results reinstated the elements related to the experience of sense of place and lived, as experiences associated with the urban environment. Also explores how people perceive the environments and experience the places. Coupled with the concept of sense of place emerges in parallel the phenomenon of no place and other concepts such as invented or reinvented place, authenticity and values of the spaces.

The boundary between public and semi-public space is often difficult to determine, as a result of privatization, globalization and development of communications. It is important to pay attention to accessibility within the urban area. Also it is recommended for urban designers focus studies towards the concept of public life, which indicates an enhancement in the activities related to the sociocultural aspect of public life. The concept of social space (spaces that support social interaction and public life) have been identified, without consider if the public space or private space are actually publicly accessible. While planners have linked public spaces with public life, traditionally increasingly public life is related to private places (cafes, books stores, etc.) (Banerjee, 2001).

Fig. 3. Symbolic space that builds identity under the forms of ownership and roll. Mercaderes Street, Havana, Cuba, 2011. Source: Authors.

More recent studies show that this field has been supplemented by work on the symbolism and meaning in the built environment. Figure 3

(Lynch, 1991) first reflected on the legibility, where he studied on the base of direction and movement (mobility) of people within the city. Later he placed special emphasis on the issue of the mental image of the city. He proposed the concept of imagineability and the five physical elements that make up the city were identified: (path, edge, region, node and landmark).

(Choay, 1965) stated that "... from a social point of view, [...] is the quality of public space, its charm, accessibility, what counts, more than its gross dimensions."

On the other hand, (Gehl, 1996) advocates a typology for the classification of urban open space that organizes the activities carried out in public in three categories: required, optional, and social. It proposes a typology that takes into account the user as a fundamental element. The analysis focuses on the aspect of accessibility to these open spaces from housing. It's determined by three sets of open spaces: residential, neighborhood and civic. The clustering in this type takes into account the physical distance which are the spaces from the housing. The second factor relates to the people with whom one might interact in these spaces, whether in order to spend time, meet or just observe. About the transition between these three groups of urban open space (for residential, neighborhood and civic urban open space) there is an increased likelihood that users will know every time a smaller percentage of other users. The experiences of these three groups of urban open spaces offer three levels of society: familiarity, sociability and anonymity. This classification pays attention to the study of a typology of urban open spaces from the user point of view.

People are important elements within the urban landscape, the roll they play as users of the city contributes greatly to the visual interest of urban spaces. That is why the movement and population diversity is an important part of the texture of the open spaces. It's provided by the colors, sounds, smells, feelings, perception of space, the use and the appropriation.

Moreover, the public space should regain its rightful place within the structure of the city. In order to achieve this goal, (Carrión, 2007) proposed a classification taking into account the constraints that define these spaces: symbolic, symbiotic exchange and citizenship.

The importance of public spaces as a natural social control has been addressed by different planners as Oscar Newman and Bill Hillier. The first states that the social control of public space (defensible space) is essential to solve the problem of vulnerability of residential space, families and of the person.

A key issue to consider open space of public use at the scale of the city is the inclusion. A key strategy to ensure the use of these spaces by all is the heterogeneity, including the presence of different functions and users. This ensures safety.

Although most authors have considered important to the work from the dimensional point of view, urban design has four dimensions, where the time factor is the fourth dimension (Carmona & Tiesdell, 2007). This important aspect is linked to almost all aspects of urban design. Among them are the manner in which the environment is perceived, the manner in which the spaces incorporated meanings, how the new spaces are adapted to the urban context, and how robust are considered, the form in which case the transformation of the spaces over time, and duration in time that the design process might take, are aspects to consider.

As a result of this observation, we can say that many authors point to the study of urban open spaces from the viewpoint of social and psychological. In this sense, this research defines the sociopsychological dimension to the study of open space for public use.

Identification of the urban ecosystem dimension

According to (Rogers, 1999) to transfer the sustainable development paradigm to the problems of the city, which is understood as a particular ecosystem (urban ecosystem), we adopt the category of urban sustainability. The adoption of such category involves understanding the city as a complex system where multiple processes interact with their respective flows of energy and materials, giving it a metabolic character.

Moreover, the microclimate, the morphology and urban open space are interrelated. This correlation is of increasing importance because the levels of population growth, coupled with the processes of migration to urban centers leads to significant changes in relation to energy use, air pollution occurs in urban areas and therefore the effects of urban heat island tend to increase. Another determining factor in the current problem is the growing concern of contemporary societies prevalent product of environmental degradation and unsustainable development patterns that have been established.

As the city becomes more complex, for example when increasing the likelihood of contact between different carriers of information, internal organization increases and decreases the energy required for operation. Thus, the efficiency of the urban system significantly improves time to maintain or increase its structure requires less energy input. This situation is favored savings from complex models and compact city.

However, regardless of land use is an essential principle for urban sustainability, the best urban models from a holistic approach, not just those based in more compact patterns, because in such conditions, the ventilation and lighting interior is naturally difficult to solve. Urban models with land use coefficient between 0.25 and 0.6, using tall buildings mean (average between 2.40 and 4.10 floors) allow densities between 270 and 470 people per hectare and at the same time, promotes appropriate environmental conditions inside buildings (Gonzalez, 2011)

Without doubt, the most important concern is related to the indicator or green open space per capita today and tomorrow. In all cases it is estimated that their proper proportion contributes to solving the existing problems between urbanization and nature. This indicator provides the following benefits: involved in the rescue of aesthetics, landscaping, sanitation, hygiene and physical and psychic well-being of the inhabitants. Their determination is closely related to appropriate densities for each urban area, taking into account that the density should be directly proportional to the open space. Its calculation varies depending on the scope adopted in relation to the concept of open space and the elements that compose it. International standards provide a range of 8 to 12.5 square meters of green area per capita at least. Some authors consider that, at least 20% of the urban area should be green. However, even in the absence of an applicable standard for calculating the minimum urban green area on the basis of ecophysiological concepts, so some sources propose to take as a criterion psychosocial and cultural surveys in relation to green spaces for public use.

Are invaluable benefits of vegetation. The vegetation cover in urban areas ensures the regulation of its microclimates, noise and atmospheric pollution, air velocity, humidity and solar radiation. In this context, green infrastructure, which open spaces are a vital element to be their key container can be a way to mitigate these impacts through the local water catch basins to groundwater, the use of innovative technologies to limit runoff, among other precepts of ecological design.

Similarly, the positive effects are seen in the immediate context, depending on the morphological and physical and environmental conditions. Furthermore, according (Gonzalez, 2011) evapotranspiration capacity of the vegetation has, moreover, an effect on the conditions inside the buildings. Therefore, the microclimate control depends on the global and systemic vision of open space of public use.

In the man environment, sensory processes play a role. The effects and manifestations of physical environmental factors and their interactions are received through the senses as stimuli, producing sensations that are classified and interpreted according to individual characteristics of people. These perceptual judgments are assessments that are expressed as feelings of comfort or discomfort. Define the parameters involved in the evaluation of environmental comfort conditions, including comfort from the standpoint of visual, thermal, auditory, physical and social. It's complex due to the multiplicity of factors interact, which feed the sensations perceived by humans. Among the variables are: to glare and light levels involved in the light environment. Furthermore, the insolation, air temperature and heating, the wind speed and direction affect the thermal environment. Influence the sound stage, vehicular and pedestrian volume, source-receiver distance, font type, noise level and type of pavement, while intervening in the environment geobiological air quality. Finally, mediate the physical behavior and social networks and mobility techniques, both pedestrian and vehicular (de la Peña, 2011).

It can be argued that the extreme environmental conditions affecting the welfare of the citizen. From this study warns that if these conditions are unfavorable, the capacities of people tend to diminish. Otherwise, if these are favorable, its capabilities will be developed.

The research findings show the close relationship between the perception of the natural environment and human health. It shows that people perceive green spaces in terms of specific dimensions, where some are considered more relevant with respect to the rehabilitation of people in a situation of stress. According to (Grahn & Stigsdotter, 2009), identified eight dimensions results in relation to sensory perception. In general order of preference set: serene, followed by space, natural, rich in species, shelter, culture, and social prospect. Shelter and natural dimensions have been related more to the stress. From a planning perspective, the results show that green spaces can be considered as contributing to the welfare of mental health.

This analysis helps to perceive the human as a being reactive to physical environmental factors, primarily in open spaces for public use. For this reason it is important underlying the Urban Ecosystem dimension to the study of open space of public use.

From the analysis of the published definitions regarding open space and existing methodologies for their classification can be stated that the types studied did not take into account a holistic approach to the study of OSPU. This provision suggests that a large proportion of the types studied were defined from the position of the planner. However, this research supports the view that the quality of urban life is related to the human dimension that takes the city for its own people.

As a result, are defined for the study of the Open Space Public Use, morphotypological, functional, sociopsychological and urban ecosystem dimensions, the variables and associated indicators, and the interrelationship between them.

3.2 Identification of dimensions, variables and indicators

Defining the spatial pattern of relationships

To survive, man must live in balance physical, mental and social environment (de la Peña & Díaz, 2010). Provided as a whole environment of physical and natural factors, aesthetic, cultural, social, legal and economic interacting with the individual and the community in which they live.

The man environment relationship is manifested in three areas: physical, psychological and sociocultural (Collective of authors, 1991). The first, as a place to live, consume resources and eliminate waste, psychological, and relationship established through the senses and allows the man to be aware of its existence and its meaning, while the sociocultural acts in shaping individual identity and social group. From the exposed foundation, we propose a Spatial Model of Relationships integrating a system of dimensions, variables and indicators, which has been identified graphically, the different aspects selected for analysis, and the interrelationship between them. (Fig. 4)

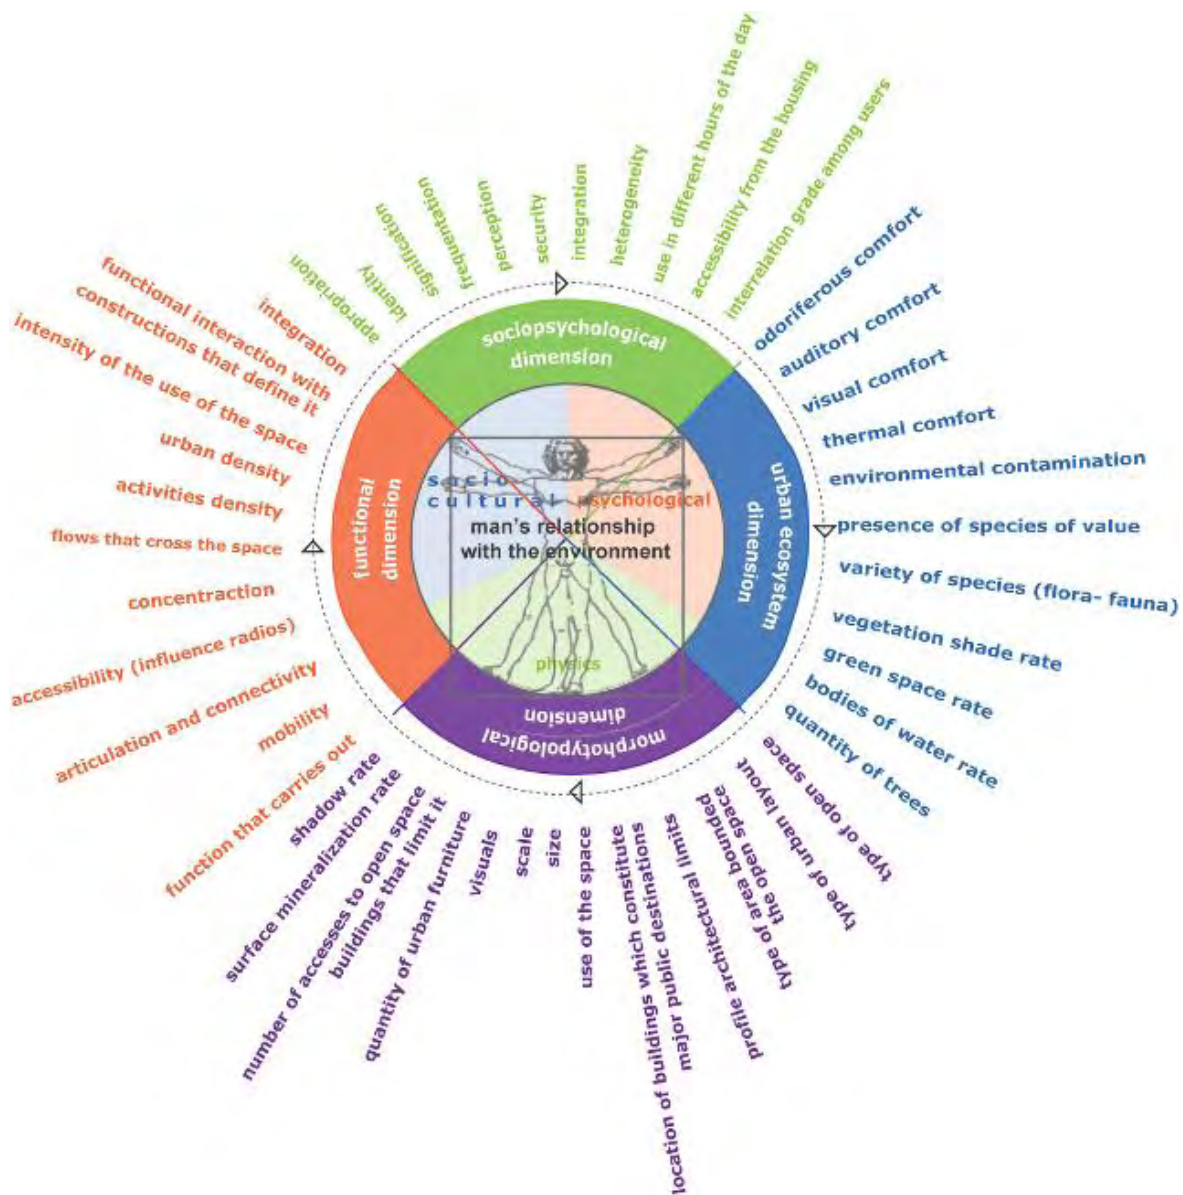

Fig. 4. Spatial Model of Relationships. Source: Authors.

4. Conclusions

Raising the qualifications of OSPU helps to promote well-designed living areas, comfortable and high environmental value, contributing greatly to the development of sustainable cities. The proposals presented in this paper are an analytical tool to better understand the classification of open space for public use in urban areas.

The model developed to graph the relationships established between the different dimensions, variables and indicators proposed in this classification. It contains a particularly attractive conceptual, visual and didactic. Especially emphasizes the systemic links between the issues discussed. It achieves an optimal association of the elements of man's relationship with their environment in these spaces.

In view of the continuity of research, the proposed methodology for the classification of OSPU will be applied to a case study. Its implementation will implement and evaluate the analytical tools necessary to determine the vocation of each open space of public use. On this basis we can analyze the contribution of this methodology for the planner to achieve greater assertiveness in decision making from the standpoint of planning and urban design.

An example of integrated management of an heritage site : Bibracte – Mont Beuvray (Burgundy, France)

Vincent GUICHARD¹

⁽¹⁾ General Director, BIBRACTE – Centre archéologique européen, F-58370 Glux-en-Glenne (France)
vg@bibracte.fr

Abstract

Bibracte is the name of the former capital of the Aedui, the powerful Gaulish people who occupied a vast area between the Saone and the Allier rivers during 2nd and 1st c. BC. Abandoned shortly after the Roman conquest, the site of Bibracte was rediscovered and intensively excavated during the second half of the 19th century. It thus became one of the key Celtic archaeological sites. Bibracte is also an emblematic place in French national history, as several major episodes of the Gallic Wars took place there. Bibracte has been the subject of an ambitious international research programme since 1985. The programme was lucky to benefit from the new dynamic in archaeology in France over the past twenty-five years, as well as the interest shown by François Mitterrand, a major public figure, in this historical site set in a stunning natural environment. Today, Bibracte is an original research and cultural setting, with high quality facilities established as part of the state's large-scale public works policy. Bibracte manages a European archaeological centre, hosting researchers and students from a dozen or so European countries. The centre is also a cultural venue and receives large numbers of visitors. This article aims to introduce the centre, which is unique in the sheer scope of its research, cultural and economic missions.

Keywords: archaeological heritage, cultural landscape, integrated management

Introduction

The concept of integrated management emerged at the same time as the idea of sustainable development, with the two concepts being considered mutually dependent. For obvious reasons, they have both been applied predominantly to environmental issues, with a symbolic milestone being reached at the 1992 Rio Summit. Since this time, these concepts have increasingly informed environmental policy and law, as is the case with [1], for example. Applying these ideas to cultural heritage would seem to be both obvious and necessary. Explicit mention of integrated management in normative documents relating to cultural heritage remains extremely rare, however. The founding documents of UNESCO concerning cultural heritage, for example, mainly drawn up before the 1980s, have not yet been updated to include this concept, and in French law, only landscapes (seen as cultural objects par excellence) are subject to integrated management under environmental regulations which will, from now on, be combined with town planning legislation.

Twenty years on from the Rio Summit, integrated heritage management is mentioned only rarely and inconsistently in the management plans of some of the sites on the world heritage lists, for example (c.f. some case studies in [2]), or in non-normative documents issued by international consultation bodies (such as the European Council in particular). This organisation has, in fact, been integrating the concept into the heritage arena since the 1970s and makes constant reference to it (c.f. The Faro Conventions [3]), advocating a systemic, integrated management based approach to heritage sites [4].

On a much more practical level, integrated management is rarely mentioned when management plans for heritage sites are being drawn up. The fact that the concept is not specifically referred to does not, however, mean that these policies do not advocate integrated management in practice; it is, for example, the underlying principle behind the French *Grands Sites* policy [5]. From a practical and operational point of view

this allows us to define as integrated management a formalised and planned management style which has as its primary objective the long-term preservation of a site's authenticity, based in particular on the knowledge and involvement of local communities on all levels.

The particular political context of the time meant that the management structure implemented at the Bibracte heritage site in the mid-1980s corresponds very precisely, in our opinion, with integrated management criteria, even though the concept is not specifically mentioned in the founding documents of the organisation's management. We hope that this report of our experience will contribute to raising awareness among heritage site managers of the potential of this concept, which guarantees a site's long term sustainability, while safeguarding the interests of community stake-holders.

Bibracte's triple identity: a site, a research centre and a museum

Bibracte is unique in that it brings together three complementary elements: a natural and historic site, a research centre, and an archaeological museum, which are all managed by one public body [6, 7].

Located in the heart of Burgundy, on Mont-Beuvray in the Morvan mountains, Bibracte was founded at the end of the second century B.C. by the Aedui, a Gallic tribe who had their capital here for a century. With its 12km of fortifications and buildings spread over 200 hectares, Bibracte is one of the best preserved and most characteristic of the late Iron Age fortified towns or oppida. It is also a site of historical significance, where Julius Caesar settled after his victory at Alesia to finalise his work on his Commentaries on the Gallic War.

Mont-Beuvray is a remarkable natural site, rich in beech forests and panoramic viewpoints which open onto protected landscapes (fig. 1, 2, 3). Since 2008, Bibracte / Mont-Beuvray has been listed as both an historical monument and a Grand Site de France. This title is awarded by the Minister of Ecology to organisations managing major natural sites in an exemplary way. Above all, the site as a whole is suffused with a site-specific atmosphere, experienced by all who visit.

Bibracte is a reference site for archaeological research on the Iron Age, benefitting from an ambitious research programme involving several European universities. Thanks to these archaeologists, the town of Bibracte, abandoned two thousand years ago and all but forgotten, is finding new life. Bibracte functions both as a place of fieldwork for researchers and students from a dozen or so countries, and as an archaeological park which is constantly evolving, allowing us to discover an unknown chapter of our history (fig. 4, 5). Bibracte also endeavours to operate as an experimental site for archaeological work, both in terms of museography and research methodology. Welcoming artists to the site is the result of a desire to explore new forms of cultural programming.

As the main introduction to the site, the Bibracte museum exhibits the results of the archaeological research which takes place here, and puts this work into perspective (fig. 6). Its aim is to demonstrate, using the example of Bibracte, that the inhabitants of 'middle' or 'temperate' Europe reached a major developmental milestone just over 20 centuries ago, by inventing an urban model unique to this area. The museum was built by Pierre-Louis Faloci in 1995. The materials used (stone, steel, glass and concrete) were chosen to embody the stages of human progress. The repeated motif of the square, visible in the building's fabric, evokes the criss-cross pattern of excavated landscapes. The deliberate choice of strong and simple geometric shapes, cinematically framing the landscape, definitively places the architecture in the modern era.

The site and its audiences

As a result of its triple nature, Bibracte is host to a very diverse set of visitors. First, we receive researchers, students and heritage professionals participating in scientific programmes at the European Archaeology Centre. These visitors are recruited on a Europe-wide scale, principally through partnership agreements with scientific organisations such as university institutions, public laboratories or museums which participate in the Mont-Beuvray research programme (fig. 7). They include several hundred individuals and complete around 8,000 working days at Bibracte per year.

The museum, meanwhile, welcomes over 44,000 visitors per year [8]. School trips account for a significant proportion of this number, with 8,000 children and teenagers spending at least one day at Bibracte. The remainder is made up mainly of family visitors, of whom 40% come from the local area, 30% from other regions of France, and the rest from other countries, primarily the Netherlands and Belgium. Among our visitors, those attracted to the Morvan area by its landscape are as well represented as those who come because of a love of heritage and history. In this regard, the breakdown of visitor numbers at Bibracte is somewhat different from that of museums in urban settings. We have demanding visitors who appreciate the quality of our environment as well as its archaeological content, and who are open to new initiatives.

The particular breakdown of our visitors can be explained by Bibracte's geographical location, and our location also means that we have to bear in mind a particular set of social obligations. Bibracte is located in a poor, mountainous area which has suffered from massive depopulation since the mid-nineteenth century as

a result of the combined effects of emigration and the carnage of the First World War. A region of landscapes clearly scarred by agricultural decline, where austere pine plantations have replaced the old pasture system, Morvan could be tempted to become more inward-looking. The Morvan identity, based on traditional music, language and customs has been reinforced over the last few decades. Paradoxically, newcomers from outside the region, including some from Nordic countries, who have settled in the region in large numbers since the 1990s have contributed a lot to this. Within this context, Bibracte exists in the role of a cultural centre for a local population with very few other cultural opportunities, which is why the museum's programme is not restricted to archaeological exhibitions (fig. 8). A concerted effort is made to produce alternative events related to artistic creation or contemporary issues, to welcome artists in residence, run multi-disciplinary festivals and arrange sessions with scientists, etc. This cultural openness also helps to demonstrate that archaeology is not a passive approach which can be counted on purely to feed into a traditional view of the land, but is rather an approach which can be used as a resource in support of current issues.

An organisation in charge of the integrated management of the site

Bibracte's recent history helps to explain the uniqueness of the organisation charged with the running of the site. In 1981, just after his election as President, François Mitterrand initiated the launch of an archaeological research programme at this highly symbolic site of a short-lived Gallic union in 52 B.C., where Julius Caesar wrote the first history of the land which would eventually become France. There was another argument in Bibracte's favour; the site is located in the constituency which, 35 years previously, had returned Mr. Mitterrand to parliament.

These exceptional circumstances explain why Bibracte received particular attention from the national authorities and why such a unique management structure was implemented here. The resumption of excavations in 1984 came about as a result of the involvement of various European countries such as Hungary and Czechoslovakia which had until then been isolated behind the Iron Curtain. At the same time, this new activity at the site was attracting an influx of visitors which needed to be managed. The site was eventually included on the list of *Grands Travaux de l'Etat* in 1989. A management structure in the form of a semi-public company having private legal status (*société d'économie mixte*) was put in place, bringing together state and local organisations to implement a significant programme of investments consisting of arranging the financial management of the site by setting up a public property of 950 hectares, and creating the facilities which were inaugurated by François Mitterrand in 1995.

The *société d'économie mixte* was replaced in 2007 by an *établissement public de coopération culturelle* (EPCC). This new type of public organisation was established by legislation passed in 2001 to allow significant cultural facilities such as museums and show venues to be run as partnerships. Under this system, the facility itself is managed by an independent organisation, with policy and financing arranged by a governing board which includes representatives from the founding bodies. This type of management structure has two principal advantages in combining the policies and resources of all the different bodies involved, and in creating a management structure where roles and responsibilities are clearly distributed between the elected representatives (who define overall strategy and direction) and the director (who has responsibility for the operational running of the organisation). In Bibracte's case, the establishment of the EPCC only reinforced the existing management structure which had been in place under the *société d'économie mixte* system.

Today, "Bibracte" is the name of a public body which simultaneously coordinates and manages:

- the Bibracte archaeological site,
- the European Archaeological Centre, and
- the Museum of Celtic Civilisation.

The main members of the organisation are: the French state, the Burgundy Regional Council, the General Councils of the Nièvre and Saône-et-Loire départements and the Morvan Regional National Park.

Bibracte directs all operations, including conservation and study of the site, as well as development and visitor management. This structure allows us to avoid the problems often encountered when a large number of institutional bodies are involved at the various stages of this process. Often, there are ministries in charge of ecology and culture involved in the legislation concerning protected sites, other ministries in charge of research and higher education involved in the management of researchers and students, yet more ministries in charge of culture, education and tourism who are involved in the management of public access, not to mention the different levels of local administration in a country where tens of thousands of public authorities share management of national policy.

In order to deal with the many roles fulfilled by the organisation here, the thirty-strong Bibracte team covers a very wide skill-base.

The Director General, an archaeologist by training, is responsible for research, training and cultural development. In addition to general administrative tasks, his three main roles are to coordinate the research programme, to plan cultural events such as exhibitions, and to develop collaborative partnerships. He has two assistants, one in charge of the operational management of the research programme, and one dealing with the cultural programme and communication. His team also includes a collection manager, a restorer, a librarian researcher, a photographer, a topographer, an education team comprising two permanent members of staff and 15 or so temporary/seasonal guides, as well as two administration assistants.

Logistics and landscape management is covered by 5 maintenance technicians, 2 purchasing and public marketing officers, 4 front of house staff, one person overseeing tourism advertising, one commercial assistant and one administration assistant. The logistics director also has the support of around 15 members of staff from sub-contracted companies who, between them, provide 10,000 nights' accommodation and 30,000 meals per year, site maintenance and forestry services, with around 5000 m³ of wood sold annually. The staff is completed by a 3-person administration team.

The Director General is supported by 3 advisory committees.

- The scientific council comprises eight international experts who help to set scientific and cultural policy and ensure that this evolves as required.
- The site management committee takes decisions regarding site management and development and includes representatives from the relevant administrative bodies, such as the Ministries of Culture and Ecology.
- The site operating committee brings together all the local public operating groups which partner Bibracte in the area of tourism.

A sustainable management plan

The development plan drawn up for the site is the result of a process of trial and error [9]. The in-situ evocation of Gallic towns is always a challenge. Remains are never imposing and are extremely fragile, particularly in the (very common) case of the elusive remains of wooden constructions. In addition, the Bibracte site is spread over a large area covered by a very dense forest. The best time to see the town's remains, therefore, is when archaeologists are working in the field in the summer. This is why we have always favoured guided trips of excavations on the 'industrial tourism' model, demonstrating archaeologists' working techniques as well as the results of their work.

Following the restoration and development of various remains carried out in the 1990s, in particular that of the Porte du Rebut, one of the principal entrances to the town, it was quickly understood that these piecemeal interventions would not be enough to demonstrate the scale of the ancient town, or to communicate the characteristics of its layout. Consequently, a pilot research study was carried out, with the assistance of a landscape architect, with a report issued in 2006 under the somewhat provocative title *La Mise en valeur des sites archéologiques invisibles* [10] (Developing Invisible Archaeological Sites).

The study starts from the principle that, as the few visible historical architectural remains are spread over such a wide area, the 'natural environment' needs as much attention as the archaeological remains, with the forest, a significant feature of the landscape, being responsible for the 'magical atmosphere' of the site. There is a focus on the motif, or 'features', which should be the key detail of the context (the 'templum'), with the whole constituting a 'place'. There is, therefore, an emphasis on the following elements:

- The 'legibility' of the relief plans (the geographical scope);
- The clarity of the significant areas of archaeological interest. Each set of remains (motif) should be comprehensible without aids, should absolutely illustrate the precedence of the remains in relation to the elements which make up the modern landscape, and in relation to the development.
- The attractiveness of the 'spaces'. Each set of remains should be placed in a visually attractive setting.

These guidelines led to the establishment of a long-term forestry development project with the aim of opening up the topography of the town and creating a set of development scenarios (fig. 9). These development plans were all integrated into the programme, regardless of their size, from minor landscaping projects to excavations, consolidation of remains to the installation of more large-scale protective measures (fig. 10).

Summary

While Bibracte came about as a project conceived at the highest state levels, it is useful to remember that the current organisation and facilities are the result of largely empirical development, and of a history which has not been without its debates between the state, local politicians and archaeologists. The latter have often seen their plans restricted by the ambitions of politicians to the point where, at times, it could have felt as if the management of the site was slipping from their control. We should remember that the archaeologists who carried out the first excavations here in the mid-1980s could never have imagined the eventual scope of the organisation. Bibracte has benefited from a happy set of circumstances, and the excellent intuition of particular individuals. The research programme was lucky in that it was forced to internationalise (due to a lack of French specialists in the field) just at a time when the European project was on the lookout for symbolic initiatives. The management structure which was meant to be a short-term solution while building work was completed proved to be sufficiently robust and efficient to be sustained for 15 years.

This atypical journey has created a unique facility, which is paradoxical in that it combines elements which are usually, if not opposed, then certainly dealt with separately. These include:

- The local and the international - A strong link to the Morvan heritage site and operations based on resolutely European scientific research networks.
- The cultural and the rural - Bibracte is the only example of a cultural facility conceived at the national level and established in such a rural setting, with fewer than 50,000 residents within a 50km radius.
- Cultural heritage and the environment - Bibracte / Mont-Beuvray attracts as much attention for its environment, with its ancient forest, in a protected hedged-farmland setting, as for the archaeological remains of the largest Gallic settlement of Caesar's time.
- The scientific and the economic - Bibracte is a complex organisation which combines the conservation, study and development of a site with cultural and educational aspects and whose research activities contribute to the constant revitalisation of the tourist experience.
- Local and national politics - The state and the Ministry of Culture are, without question, the most significant of Bibracte's public partners, but local organisations such as the regional, departmental and regional national park bodies are also closely involved in its management.

We can view Bibracte as a sort of laboratory, where we experiment on ways in which to deal simultaneously with archaeological research, heritage management, international cooperation, and reinvigorating a rural area, using an integrated management structure linked to a symbolic heritage site. The experiences of the past 25 years at Mont-Beuvray, including successes as well as difficulties, have produced a valuable knowledge base which, in our opinion, bears witness to the value of this management structure, considering conservation needs, the knowledge of experts in the field, and the ownership needs of the local community.

Mythical landscapes: The Garden of the Villa “Ariadne” at Knossos.

Zanon Flavio, architect, Ph.D.
Ministry of Culture and Tourism, Heráklion, Greece
skoutzan@otenet.gr

Abstract

In this essay is presented the construction of the residence and garden of the man who revealed the Minoan civilization to the world. A discovery, done by Sir Arthur Evans, which was undoubtedly a multifaceted cultural occurrence; a total of events touching upon archaeology as well as architecture. The house, once likened to “an English bungalow from British India transported to Crete”, has been analyzed in full interrelation with its particular Victorian-Edwardian garden, being one of the few examples old Mediterranean gardens in Greece.

The building’s construction has been presented through the architect’s diaries and drawings, comparing the endeavor against the hermeneutic definitions of his German colleague H. Muthesius, on what constitutes a British home. At the same time the most important trees and plantations of its garden have been catalogued and examined in the light of the exotic, pictorial and mythic influences emanating from the discovery of Knossos; as suggested by the house’s name ‘Villa Ariadne’.

Subsequently there is a short reference to the actions taken recently towards establishing the Villa Ariadne’s garden, as a listed monument; a process that for long time has been neglected in Greece but recently has found the way to confirm itself.

Keywords: Greece, Historical gardens, Myth, Paintings.

1. Sir Arthur Evans and Knossos

The Villa Ariadne and its garden were constructed from 1906 to 1907, adjacent to the Minoan antiquities of Knossos. The general planning was carried out in accordance with the wishes and suggestions of Sir Arthur Evans; the area’s principal archaeologist. The building’s implementation as well as the technical drawings (Fig. 1) was made by the English architect Christian Doll. There are also architectural drawings detailing the irrigation system with its water reservoirs, but there are none to indicate the precise location of the trees, shrubs and paths. This fact allows for interpreting this design shortfall as the result of an accepted and established perception of landscape design, where different depiction techniques in descriptive geometry prevail.

Reference is made here to perspective drawings or pictorial representations as primary tools for garden/landscape design, as established from the picturesque era. Thus in designing gardens the

architectural plan was deemed not as suitable as the perspective representations which often manifested as paintings.

Yet in the case of the villa there was in addition on behalf of the owner – possibly in the sweep of a naturalistic attitude similar to that of William Robinson – an approach of a more personal nature. Evans' recorded experiences with regard to the flowers of Crete prove exactly what could be characterized as a late-romantic inclination with almost ecological overtones towards nature. [1] Such tendencies have apparent affinities with the studies of Gertrude Jekyll. Well known are her often geometric flower beds where by employing free movement and color combinations, placed plenty of plants and flowers, in an attempt to embrace as many species as could be encountered within a natural setting. [2] Approaches similar to either Robinson or Jekyll, without the help of architectural drawings were employed under the instruction of Evans, consciously or not, in realizing the general concept of the villa "Ariadne" (Fig. 2). The above can be claimed with enough conviction, taking into account his purposeful personality evident in other matters where he could have simply put his trust in expert professionals. Besides, there are several testimonials about his difference towards the decisions of his engineers. [3]

This particular element of Evans's personality corresponds to the interpretations of the German architect Hermann Muthesius. At approximately during the same period as the villa's construction by Doll and Evans, Muthesius argued that each Englishman constructs his house for himself. As a general rule no elements of grandeur are added. Moreover, the last goal of the construction process is to render the house and its garden as a whole. All three characteristics correspond exactly to the conception and construction of the villa "Ariadne". The fact that the villa, beyond Doll's professional involvement throughout, was the product of the owner is evident by the alteration, for example, – the architect called it a *distortion* – he demanded in the kitchen floor. For this reason the greater weight in the conception and selection of the trees could justifiably, according to Muthesius, fall upon Evans himself. The whole endeavor for the British villa confirms the views of the German architect; especially the notion that the British owner does not wish to break from a morphological rule in fear of eccentricity. The only decorative elements could manifest only in a renaissance fashion, often seen on columns and their upper moldings. Doll, true to this tradition, would become involved in Cretan themes: for the upper moldings of the villa "Ariadne" he would measure the moldings on the walls of Candia, attributed to Michele Sanmichelli, and work them into his own design. [4]

2. The garden of the villa 'Ariadne'

At this point we revisit Evans' intervention in the Garden. In fact the first noted intervention by the categorical owner with regard to the garden's design is his alterations concerning the circular flower-bed by the entrance and the road/path for accessing the garden. Subsequently prior to his departure for Rome, Evans would pass on instructions to the architect regarding the kinds of plants that were to be ordered from Athens. These would become, besides the strict observations of his client, another source of unease in the life of the overseeing architect in Crete. The plants arrived on the island in March 1907 by sea after a difficult journey that caused him even greater unease. [5]

The basic species of great trees that were planted soon after, belong to the genera of *Cupressus*, *Pinus*, *Phoinix*. The *Cupressus sempervirens horizontalis*, *C. verticalis* and the *Pinus brutia* pines essentially functioned as windbreakers on the northwestern and eastern border respectively. Singular exception among the latter species are three impressive examples of *Pinus canariensis* planted in the planting-beds of the main entrance.

In the same planting-beds lie most of the garden's tree 'protagonists': the palm-trees. This family is represented by the species *canariensis*, *thoeofrasti* and *dactylifera* along with the impressive *Washingtonia filifera* (Fig. 3).

Fig. 3: View from South - East of main façade of Villa "Ariadne", 2004.

Most of them have been planted in the largest ellipsoid planting-bed, delineated by a hedge of *Pittosporum tobira*, where opposite the main entrance Evans placed a statue of the roman emperor Hadrian. These hedges' role in the original design was just this: to accentuate the plant-beds' outline. This morphological decision, confirms the aforementioned tendency to design in the manner of W. Robinson or G. Jekyll; that is, determining points in the garden where within the confines of geometrical planting-beds seasonal and non-seasonal plants alternate. Unfortunately the singular reference to be found concerning their species lies with D. Powell. [6] Her account though is general and descriptive of a state of the garden during a much later time than when it was closely overseen by the famous archaeologist. When the film critic, was describing the planting-beds, the garden had already begun to show the signs of poor maintenance. The most sensitive plants (herbaceous plants and bulbs) in Evans' time, which may have been either anemone or tulips, admired by him during journeying in the Cretan countryside, have not survived. [1] The sole plant, again with ideal references to G. Jekyll's favorite plants that impressively survives without watering during the summer months is the species *Vinca major* that blooms in early spring.

In conclusion this Victorian garden's essential character is mediterranean: a place with shaded pathways made of cobblestones, instead of the large areas of grass typical of English gardens. Even the *pittosporum* hedges, purposed to encircle the planting-beds and which grew into large shrubs once free from the limitations of pruning, today offer valuable shade to the rare visitors. For this reason the areas for rest and outdoor gatherings were the villa's western and eastern verandas. In the first of the two there is indeed one of two grandiose examples of *Bougainvillea*, providing protection from the sun. The other climbing plant has completely covered half of the so called 'pool' area.

Again, from the testimonials of D. Powell we can find references to some other species of plants that she observed during her first stay at the villa, in 1935. At first she identified hibiscus (*Hibiscus* ssp.) and jasmin (*Jasminum officinalis*) on the eastern veranda. These species sadly are no more in the garden's present state. Also lost from the flowerbeds by the entrance, as shown in photographs from the Ashmolean Museum, an *Araucaria bildiwillii* and at least two *Yucca gloriosa*. Further along her book Powell makes note of pomegranate trees (*Punica granatum*) and *Plumbago*, present even today. Among the clusters of palm trees, in growth at the time, Powell observed rose bushes (*Rosa* ssp.) and *Lonicera caprifolium*, although there is no reference to the areas where irises (*Iris* ssp.) grow today. These were widely spread at the time due to the preference shown towards them by the Turks during their presence on the island. Despite the fact that, as evidenced by the correspondence between himself and his half-sister, Evans loved irises either wild or cultivated there is no testimonial on whether their planting was the archaeologist's choice. [1]

3. Mythical landscapes and painting

Undoubtedly, in the conception of this garden there was a strong element of naturalism as well as an innate exoticism with regard to the uncommon, for an Englishman, Mediterranean species that were chosen. Yet the mythical component in its creation was probably the basic theoretical and aesthetic foundation. In fact the first direct correlation in this hypothesis is the name of the mythical king Minos' daughter, given to the villa in the midst of the garden. As for the inspiration which informed the selection of the palms, pines and plants in general, one could suppose that it originated primarily, beyond mythology, from painting, literature and Evans' own travels.

Initially, there will be an isolated examination of the following pair of trees: palm trees and cypress trees. This pair has been, since the renaissance a codified image, a symbol of the flora of the East. For example, one can refer to the paintings "St. Mark's sermon in Alexandria" and "Venetian ambassadors in Damascus" by Giovanni and Gentile Bellini respectively (Fig. 4). These were representative of many eastern models – to be transmitted to the west – within a very wide group of paintings which stand out on account of their artistic excellence. In the first painting to the right of the church, which resonates possibly with that of the "Twelve Apostles" in Constantinople, one can see a palm tree. In the second painting – with reference to the vertical architectural elements of the minarets – appears another palm tree next to a cypress. In both Bellini paintings the species *Pinus* and *Cypressus*, which are characteristically correlated with the surrounding built space, represent the exotic flora.

It is the exact association with the names recalled to memory by the paintings, along with the corresponding far away travels: the names Alexandria and Damascus. The references from mythology and literature to these two species are innumerable. The focus here is painting because despite the non existent mythical and literary evidence in the case of the villa, it is our belief that Evans was a visual type. Thus the stressed point becomes clearer: garden design of the era in question was based on painting. A further supporting element to the present thesis is the archaeologist's love for his collection of paintings kept back in Britain. Such was a passion he was unwilling to be deprived of in Crete. In fact, his insistence to install railings for the display of canvases, in a house designated for archaeological research, confirms his devotion to paintings and by extension to art. [7]

Fig. 4: G. Bellini(attributed), Detail from “Venetian ambassador in Damascus in 1511”, Louvre, Paris.

Fig. 5: J. W. Turner, The golden bough, 1834. Clore Gallery, London.

Essentially the theme of palm trees and pines provides us the opportunity to confirm an interesting spiritual dichotomy in Evans’ personality. Reference is made here to the mutation of elements from the official, actual History into his own. This has been noted in reference to the historical archaeological area of the Minoan palace, with the example of the naming of the ‘Royal Villa’, which of course refers to the villa ‘Ariadne’, and consequently also confirms the rule. A similar identification has been made in the case of the two species of trees. There is a relevant description on Minoan planting in a passage within the first tome of Evans’ foundational book “The Palace of Minos” (1921), years after the initial plantation works at the villa (1907). The passage relates that near the “North Entrance” of the archaeological area, in Evans’ opinion, there were terraces on multiple levels like in Babylon. In consistency with the popular exotic-orientalist frame of reference, the terraces were planted in the manner of the fabled hanging gardens. The hypothetical trees which he envisioned were palms and cypress; the same species that he had planted at his villa. Evans considered the terraces by the North entrance to be planted according to the temperament of the Minoans which in fact coincided with his own. [8] A personal identification which in the case of the palm trees had an actual historical connection: the palm tree – possibly *theofrastii*- depicted in the fragments of the “Throne Room” fresco, one of the first important finds to be unearthed during the first excavation at Knossos, in April 1900.

The other large group of trees that figure prominently alongside the palm and cypress trees are the pines. Concerning the symbolic correlations which determined their selection, the particular Greek species planted mainly along the principal road leading to the main entrance to the villa as well as at the area of the “Taverna”, there will be relevant reference made. The hypothesis here is the potential design of a romantic garden in the world of French-English painting of the 19th century. In presenting such correlations it is important to stress that a defining factor in the unfolding of events, including archaeological ones, was the particular zeitgeist; regardless of whether such influences were perceived or not by the persons involved.

The *Pinus brutia* which were planted on the edge of the main road and in the space surrounding the “Taverna” are very similar, owing to their umbrella – like crown, to the species *Pinus pinea*. They are remembered from the time of Lorrain, in the landscape paintings with their well known silhouette invoking the “Mediterranean country where lemons bloom”. Such a symbolic at first, image later found response in English painting; specifically in the following paintings by Turner: “The golden bough”, “Landscape: woman with a tambourine” and “Child Harold’s pilgrimage”. A defining example for the use of these ‘key’ trees, charged by their symbolic significance or for their reference in literature, also relevant to the theme of travelers to whom Evans belonged, is the aforementioned quotation from Wilhelm Meister. In fact, since the renaissance lemon trees along with the other citrus fruit were trees that recalled to memory Arabia and the Indies from whence it originated. Following this list of trees in painting, from the shiny illustrated orange leaves of Botticelli, through the dark forests of the ‘reformers’, we arrive at the luminous pines of Turner (Fig. 5). These trees were used as symbols in the Renaissance; now they have acquired a new dynamic relationship with the landscape of Romanticism.

Fig. 6: The *Pinus brutia* trees leading to the main entrance to the villa.

If this image of the ‘Pines of Rome’ – or the Roman fields and by extension of the Mediterranean – was the debtor for the aforementioned linear planting along the main road, as sole evidence we have Evans’s journey to the ‘Eternal City’ just a day after he gave his instructions regarding the trees of the villa. It is appealing in some way to combine the prospect that images from the landscape and gardens of Rome may have contributed at a later time in informing the design of the road in question. With the method of induction, this design hypothesis would yield the following information: the linearly planted *Pinus brutia* (Fig.6), compared to the plantation of 1907, found their place in a later period than the other plants. Either way the correspondences with Rome in the garden would become more apparent and glorious in the instance of the Roman artifacts uncovered by the English archaeologist and arranged there. Instead of placing, for example the orientalist chinoiseries of the common large parks, here were the archaeological artifacts found in situ; because Evans’s references gained strength from the same exotic – as an English traveler and archaeologist – material of the area.

Rightly following the description of the archaeological fragments one couldn’t omit mentioning a more casual although equally decorative element for such a garden, such as the exotic bird cages. Indeed placed under the giant *Bougainvillea* to the north there are empty cages that possibly housed the first peacocks which today roam free and reproduce within the archaeological space south of the residence. Beyond the naturalistic meaning that peacocks exude, the value of their presence in the garden of “Ariadne” had once again connections with painting.

In general, from Roman times until the Renaissance, the peacock form would decorate reliefs and paintings. Originating from the Indian forests, its presence in works of art was justified due to its incredible beauty, but also due to the multiple levels of interpretation which the peacock made available to the artists. Reference has already been made to the Bellini Venetian family of painters in relation to the theme of palm and cypress trees. For many of Evans’s compatriots – such as Ruskin – Venice was a part of the East in the West. Therefore concerning the popularity of the peacock in paintings we have adopted the example of the “Barbarigo Altarpiece” by Bellini, as being the most germane to the British enthusiasm for the ‘Most Serene’; without forgetting later, and more contemporary with Evans, works featuring peacocks such as the “Grand Odalisque” by J. A. D. Ingres or the “The Visit of the Queen of Sheba to King Solomon” by E. Poynter.

4. Conclusions: Historical gardens in Greece.

In conclusion, in the overall case of the Knossos archaeological space – a life’s work for the traveller – archaeologist Evans, exemplary of the cultural and political class in which he belonged – the restorations, reconstructions, the designs for the villa and its garden, are elevated to a complete work; A work of archaeology, architecture, landscape and, with the appropriate differentiations, of Art. We have seen the determinative influence of painting upon the concepts of design for the garden of the villa ‘Ariadne’, as well as on the issues of restoring the Minoan antiquities or on Evans’s references in the archaeological content of the four volume “The Palace of Minos”. Most of these refer to the management of painting terminology; specifically to “rosso veneziano” or the art style of certain artists such as Tiepolo and Longhi, for example. [8]

Along with the naturalistic trend and pictorial attitude, in designing the Victorian-Edwardian garden of “Ariadne”, one detects another long-standing link: the selection of flora based on the prehistoric myths which clothed it; as in the instance of the palm and cypress trees, the hypotheses surrounding the discovery of the ‘Throne Room’ fresco, or the descriptions of hanging gardens.

At this point, regarding prehistory, we will make a final reference; this time to the book by the great anthropologist James Frazer: “The Golden Bough”. The book was published in 1915, a few years after the grand restoration – reconstruction of the “Grand Staircase” in Knossos. [9] The title of the book, which analyzes events or themes “shrouded in darkness and mist” such as the structure of Magic and rituals or sacrifices, refers to the myth recounting the descent of Aeneas into the realm of shadows while bearing a golden bough. In this example, in Turner’s painting, a symbolic merging of all the basic elements of this garden’s design takes place. The case of the ancient fresco featuring the palm tree, belonging to a room in which possibly initiation rituals took place, could be an object of study in Frazer’s “Golden Bough”. With the painting in question, the present paper’s account is amplified by the presence of *Pinus pinea* – *Pinus brutia* which frame the scene (Fig. 6).

With the aid of the short story by Virgil via Frazer, we could bring our hermeneutic analysis to completion, with the following metaphor: in the eyes of Evans his garden assumed the appearance of the *golden grove nemorensis*, though in Crete. The balanced placing in a pictorial spirit of the large trees, such as pine and palm trees, was linked to their mythical allusions not to the name of Diana but to that of Ariadne.

Considering all the involvement of literary mythology and painting in the design of this garden, the serious issue of its protection needs to be put forward. In Greece the presence of historical gardens is not quite substantiated. Firstly one observes their total absence from the landscape. In my almost fifteen-year stay in Greece, I have only come across five instances of gardens which truly fulfil the term ‘historical’. If we focus on the state of the “Royal Garden of Athens” – arguably the worthiest example of a Greek historical garden – the problem that stands in the way of all important gardens being listed as ‘historical’, according to the postulates of the Carta di Firenze, will become apparent.

The “Royal Garden of Athens” was built by the Queen of Greece Amalie in 1839. Until today only the architectural sections within its enclosure, have been listed as national monuments: small buildings, pergolas, paths etc. Yet, there hasn’t been a detailed survey of the trees and shrubs – the *green* elements – which are essentially an integral part of the garden’s architectural fabric. The same was true for the villa ‘Ariadne’ until 1994 when together with architects Nikolaos Skoutelis and Firuz Habibi Minnelli we surveyed all elements of the garden; from the building itself to the smallest shrubs. But until 2009 there was not a tried legal framework within which such precious material could be put to use. This changed with the submission of material for the declaration of a perennial *Crataegus* and a grand *Platanus*, as “monuments of Nature”; both in Crete. The first lives next to the important archaeological site in Zominthos, under mount Psiloretos, and the other in the village Krasi. Just that was the missing tool for articulating the notion of the historical garden. The trees in themselves are perceived as living monuments. In the case that they are part of a garden which is correlated with cultural material, the processes of protection takes place with the contribution of two ministries: The Ministry of Agricultural Development and the Ministry of Culture. The name for projects of such kind is Special Environmental Study.

THE CITY BORDERS: NEW OPPORTUNITIES FOR THE MEDITERRANEAN CITY

Raffaella DE MARTINO, Luigi FOGLIA

Dipartimento di Restauro e Costruzione dell'Architettura e dell'Ambiente, Facoltà di Architettura, Seconda Università degli studi di Napoli, Aversa (CE), Italia
raffadema@libero.it, luigi.foglia@gmail.com

Abstract

The model of a suburban growth, in its continuous and messy expansion, erodes the rural territories that characterize the Mediterranean area, creating processes of modernization, where the consolidated models of development are undermined by regressive phenomena. The condition of being a border area can produce many critical knots with a strong environmental impact on the territory. In order to promote a sustainable growth of the Mediterranean city, therefore, rethinking the city border, meant as a crucial interface among the complex relationships of interchange between the urban/rural system, play today a key role in restoring the levels of liveability in the "sensitive" zones. In these areas, interventions of environmental rehabilitation and design of common spaces represent functional tools to define innovative methods for the control of the territorial transformation and management, able to directly affect the changes of the environmental micro and macro-systems. Through aimed actions the constitution of an ecological peri-urban network is configured, which can allow the restoration of the ecosystems compromised by now, the constitution of new natural units and, above all, the progressive recreation of the connections among such units as essential condition to the preservation and improvement of the values of territorial biodiversity.

Keywords: border contexts, regenerative processes, ecology of the border.

1. Introduction

The model of a suburban growth, in its continuous and messy expansion, erodes the rural territories that characterize the Mediterranean area, creating processes of modernization, where the consolidated models of development are undermined by regressive phenomena. The condition of being a border area, evolving towards *rurban* hybrid sceneries, can produce many critical knots with a strong environmental impact on the territory, for which it is necessary to intervene through aimed actions, that act as regenerating factors of the original orders. In order to promote a sustainable growth of the Mediterranean city, therefore, rethinking the city border, meant as a crucial interface among the complex relationships of interchange between the urban/rural system, play today a key role in restoring the levels of liveability in the "sensitive" zones, that is in the contexts characterized by a high rate of construction and low values of environmental and social comfort. In these areas, interventions of environmental rehabilitation and design of common spaces represent functional tools to define innovative methods for the control of the territorial transformation and management, able to directly affect the changes of the environmental *micro* and *macro*-systems. Through aimed actions the constitution of an ecological peri-urban network is configured, which can allow the restoration of the ecosystems compromised by now, the constitution of new natural units and, above all, the progressive recreation of the connections among such units as essential condition to the preservation and improvement of the values of territorial biodiversity.

With this contribution a method of critical reading of the *border system* is proposed in order to support the integration of technological/planning solutions with strategic choices aimed at the maintenance of the

ecological and environmental qualities. Through the application of a synthetic model to a case study, an interpretation of urban regeneration is delineated that offers an alternative to the new models of development delocalized, aiming at the environmental rehabilitation of the existing area and strengthening the ecological peri-urban networks instead of the *ex novo* construction of the settling systems.

2. The nature of the border in the Mediterranean city

Speaking about urban development, it is evident how today it must be defined the strategic role that the city border design can assume in restoring the unstable balances established in the Mediterranean city: from "sensitive" zone of verifiable environmental and social degradation, to potential reservoir of areas with an unexpressed quality, able to welcome renewed urban and territorial evolutionary configurations.

In order to make such a semantic translation we need to define the new spatial and relationship dimensions that can be found in the interpretation of the urban border. From the definition by Kevin Lynch [7], according to whom the border is an element of linear interface between two separate units, the image of an urban limit can be configured endowed with a "thickened" spatiality, a deep fringe, also some tens of kilometers deep, where the housing dispersion is compared with the fragmentation of the agricultural ground and the creation and dismissal of productive activities. As a corollary, the phenomenon of the spatial expansion of such areas often comes to conform *rurban* evolutionary sceneries with a strong systematic hybridization, where the contiguity with the urban centre of reference is disregarded. The destiny of the fringe areas of the Mediterranean city must often face the carelessness of the places, the environmental and landscape degradation, as well as a progressive dereliction of the human-made places leaving on the territory a quantity of unused construction that is not proportionate to the housing density.

Nevertheless, latent potentialities to start regenerative processes are contained really in the character of vagueness of the border surrounding the Mediterranean city and it can be a real *buffer zone*.

Mentioning Gilles Clément [5], "*the limits - interfaces [...] constitute, in themselves, biological thicknesses [...] their wealth is often higher than that one of the environments that separate.*" Borders can be interpreted, therefore, as some spaces of potential evolution, some real places of centrality of a latent city. Similar areas can be configured in a complex system of permeable and "multisignal" environments, where traces of the original settlements intersect with what has remained of the rural organization of the territory, including areas of survival or regenerated spontaneous nature. Such elements, if interconnected according to a strict systematic logic, can constitute in their whole the occasion for the reconstruction of identity processes of the places and cohesion of the settled communities. At the same time, the role played by each of them of the qualitative-quantitative level of interaction with each element, can represent some effective references on which planning integrated strategies of environmental and ecological rehabilitation, aimed at recomposing an urban border landscape and its relative values of fruition.

2.1 A tool of reading

Rehabilitating the border areas of the Mediterranean city and letting them intervene in the urban and territorial regenerative processes means to define integrated strategic approaches, able to influence the economic, social and environmental aspects of a hybrid system of "border", recovering its complexities at the same time. Within such processes, the control of the environmental quality through *low-tech* interventions, aimed at the restoration of the values of comfort outdoor and fruition of the connective spaces – with full respect of the specific characters of the place –, assumes a decisive role today.

In order to make a proposal of methodological approach able to rationalize the interventions of environmental rehabilitation and conjugate them with actions aiming at preserving/increasing the ecosystematic complexity, the configuration of tools of analysis is necessary, able to decode the *typological invariants* of the border areas.

In the scheme below (fig.1) it is described our proposal for an open and implementable conceptual model, carried out on the base of the *urban transect* proposed by the New Urbanism in the Smart Code and of the *pattern language* conceived by Christopher Alexander [9]. Such a model – even though still with an experimental character – wants to make the first moment of study for a systematic development of an approach based on the shared knowledge of the territory. In such an approach the *pattern language* by Alexander, in the perspective to involve third operators too, is simplified and declined to the structure of the Mediterranean city border, to give an agile and fast tool of immediate reading.

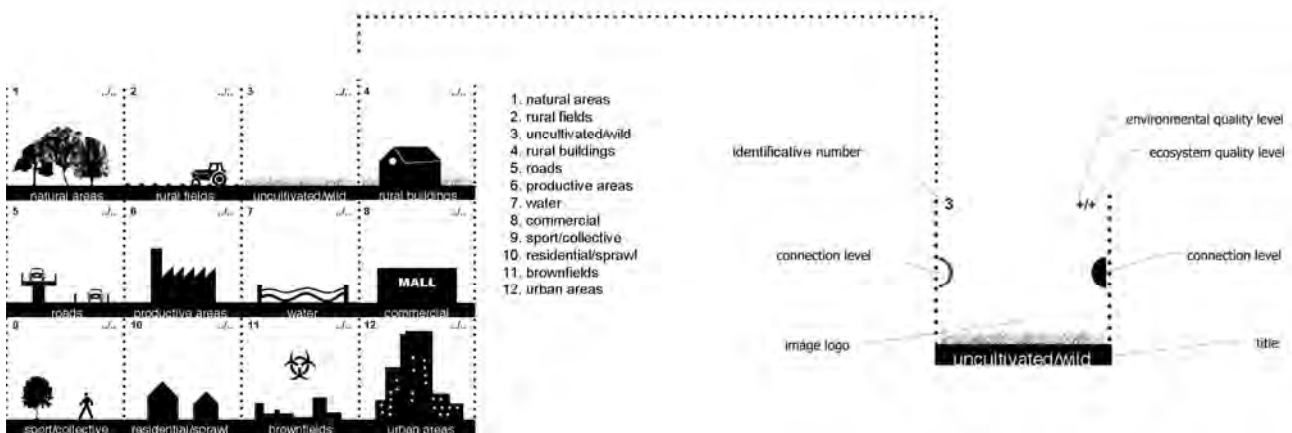

Fig. 1: Model of composition of the typological invariants of the border and structure of the patches.

The typological invariants individualized up to now are described in graphics in the "patches" to which both a synthetic dealing of the "problem", and a brief enunciation concerning the possible planning strategies to be undertaken (such indications are not mentioned in this paper) are referred. Each patch, besides the identifying number, the title and the image/logo, has got a value (expressed in qualitative scale with a gradient varying from -- to + +) that represents the level of environmental quality in relationship with the level of ecosystematic quality of the whole described section. Such a value makes reference to what was found in the whole area. In the border areas, that is in the ecotone areas (whose description is postponed to the following paragraph), the level of the connections/interactions is indicated – on the base of the values related to the environmental/ecosystematic quality of the area of study – in comparison with the adjacent patches. Such values are indicated by a dot set between the two units considered: when the dot is full it shows a good level of connection, when it is empty it shows either a scarce level of connection or a problematic systematic interaction. Through the free composition of the patches of the model to form either a monodimensional or a bidimensional pattern/grid (according to the complexity of the analysed system), the possibility to simulate the different systematic configurations of the border areas is offered, on whose base it can be elaborated an investigation, aiming at the individualization of criticality elements and their relative repercussions on the environmental and ecosystematic comfort quality. Considering the characters of connectivity and systematic hybridization of the Mediterranean city borders, the landscape can represent a new paradigm of reference, no more only formal, but of process: we can hope, therefore, that from the planning creation a new environmental scene can be made, able to integrate equally naturalness and artificial construction. The planning choices, localized on either "area " or "border" patches of the model, will desirably be able to orientate towards an ecological dimension, according to a design plot overlapping the preexisting natural networks, creating new "signs" characterized by a high biological and environmental complexity: a green space network able to assure a real integrated development of the urban/landscape interface.

2.2 The ecosystem border

The city represents a complex artificial ecosystem and equally to any other ecosystem, it is made up of ecotopes with different levels of naturalness: artificial (buildings, industries, infrastructures), semi-artificial (small gardens, trees, urban gardens), semi-natural (agroecosystems, urban forests, parks, etc.). The urban ecosystem degrades from the city centre towards the suburbs, changing into agroecosystems and natural ecosystems. From the ecological point of view the border, meant as a peripheral, unimportant, secondary, abandoned figuration, is not correct. The border spaces are rather places with a precise role established by the communities' reciprocity links with the environmental context. So the border condition is conceived as wealth, reciprocity and interchange among different and adjoining ecosystems, strongly interrelated among them and among which energetic and building material and construction streams are established.

The reading of the border, from the ecosystematic point of view, involves the recognition of the *structure* and *function* of the elements, it is made up of. The structure recognizes the spatial characteristics, therefore shape, dimension, number of the biotopes that compose the country *pattern*; while the function of the landscape defines the relationships (energy streams, building material transfers) that are established among

the elements of the analysed environmental system. A system able to be in a balance of structure and operation, and to react, therefore, to possible perturbations of natural and human origin, can be defined as *stable*. The possibility that an ecosystem has to develop a certain stability is strongly linked with its biodiversity, that is with the richness and homogeneity of species present in it. Moreover the reading of the border must consider the ecotone areas. The ecotone is a border or a transit area among different environments and it develops important ecosystematic and ecological functions, as a place characterized by a high biological difference. "These areas of configuration among different environments are structurally and functionally areas where energy, material, organisms streams are very high, because they are conjunctions among different ecological niches" [3]. The ecological approach to the border leads to individualize territorial realities characterized by energetic values, so that they can be considered as "reservoirs of naturalness" within the urban landscape (*core areas*). Such areas function as shelter and sustenance of the fauna, so favouring the safeguard, preservation and increase of the flora-fauna biodiversity. In order to make the biodiversity safeguard be effective, it is above all necessary that such territories are connected among them, according to a network logic. Within the peri-urban area, therefore, you must look for the possibility to carry out an ecological connection between the layers of rural territory, characterizing the urban border, and the green space present in the compact centre tissue. Such corridors will allow the animal species to move from an environment to the other, so avoiding confinements in closed biotopes.

3. An application: the case study of Marcianise

The analysed area for the methodological application, located in the fringe tissue in the south of Marcianise (CE), shows features of variegated complexity: situated in the transit area between the widespread suburbanization and the agricultural landscape of the *Ager Campanus*, it is surrounded by the area of industrial development, the infrastructural network and the area destined by the urban planning to welcome tertiary and sporting services, on which it has already been hypothesized the realization of a *green ring* acting as a limit and a filter for the urban expansion.

On the area (fig.2) there are permanences of remarkable historical-landscape interest that configure a complex system of permeable and multisignal environments. We want to analyse the environmental section A-B (proceeding from the south to the north) of the considered area, proposing a reading of the typological invariants of the border, made for a linear approach of the patches of study, according to a pattern of monodimensional structure. In the considered section, the values of the levels of environmental comfort (read on the base of the parameters of the *thermal comfort, visual comfort, acoustical comfort, fruition of the spaces, conditions of environmental hygiene, perceptive integration*), appear to degrade according to a gradient that has its maximum peak in the natural and agricultural areas and its minimum peak nearby the industrial area and the infrastructural system of connections *a raso* and superelevated connections.

Fig. 2: Border area of Marcianise: environmental section.

3.1. The reading of the border

The analysed territorial section has been schematized, according to the methodology previously exposed, in the monodimensional pattern (fig.3). The reading and interpretation of each patch need a double consideration: one of environmental and ecosystematic character, that is linked with the structural and functional characteristics of the ecotopes, the other related to the potential role that the single parties can have for the construction of a territorial ecological network. It's evident, besides, the necessity to analyse and appraise the conditions of the transit areas between two patches, the ecotone areas (represented in the model by dot lines), on which it can depend the highest or lowest environmental permeability of the analysed system and its consequent territorial fragmentation.

The reading of the section A→B from an ecological / ecosystematic point of view can be interpreted this way:

- The patch 10 represents an urban territorial part where the massive construction and the waterproofing of the grounds have brought to a strong ecosystematic impoverishment and the impossibility to "link" with the local ecological network;
- The patch 2 represents an agricultural ground characterized by horticultures in open air. The lots are mainly developed in length and the ecotone areas are often made up of either grapevines or poplars. Despite the bioenergetic value of the seeded areas is not very high, the presence of the rows guarantees higher stability to the area and above all it has an important function from the ecological point of view, as it constitutes a widespread connection composed by micro-corridors and small units of habitat;
- The patch 3 of the analysed territorial section represents an uncultivated area, where a grassy-shrubby spontaneous vegetation developed. In this case, both the stability of the environmental system and its ecological role can be notably improved through, both area and linear, small interventions, aiming at increasing the level of naturalness and establishing the ecological connections again;
- The following patch belongs to the typology 2 and has the same characteristics in qualitative and aggregating terms as the previous one. A difference is nevertheless verifiable in the ecotone areas 3/2 and 2/9 characterized by a higher level of naturalness in comparison with that 10/2 one;
- The patch 9 shows the presence of a sporting space: a velodrome. A sporting structure like that one present in the area, from an ecosystemic point of view, can represent, despite its high level of human-made, a natural nucleus. The role, that the ecological mosaic – made up of the green spaces of the sporting structure and rows of trees present in the parking area – can play, is that one of *stepping stone* in comparison with the territorial ecological network;
- The patch 1, natural areas, represents a changing area. It is a *green ring*, an area about 200 meters wide, made up of trees, hedges and cycle-pedestrian tracks that will surround the city for a length of 10 kilometres. Once the works of rehabilitation will be completed, this green ring will be configured as a real ecological corridor, able to connect the natural basins present in the city border to the network and favour the diffusion of vegetation and movement of the animals. So the viewpoint of the green ring won't be only that one of the preservation of the residual nature, but also and above all the restoration of new ecosystemic units able to have polyvalent effective functions for a model of development with a lower impact on both natural and human-made environment;
- The patch 5 highlights the presence of 3 linear infrastructures of communication: a superelevated state highway, the high-speed railway line, superelevated too, and finally a farm road at grade. The multiple infrastructural axes cause noteworthy impacts on the ecosystems (pollution, disturbance, destruction of habitat, etc.). The most devastating effect is the interruption of the environmental continuity and the consequent fragmentation of the natural habitats;
- The patch 2, even having the same characteristics of those ones found in the first part of the section, results strongly damaged in bioenergetic terms by the presence of the multiple infrastructural axes;
- The patch 6 shows the presence of an industrial area. Considering its environmental features, the area results very weak from an ecosystemic point of view and now it can't play any role for the construction of an ecological network.

Fig. 3: Modelling the environmental section A-B, referred to the case study of Marcianise

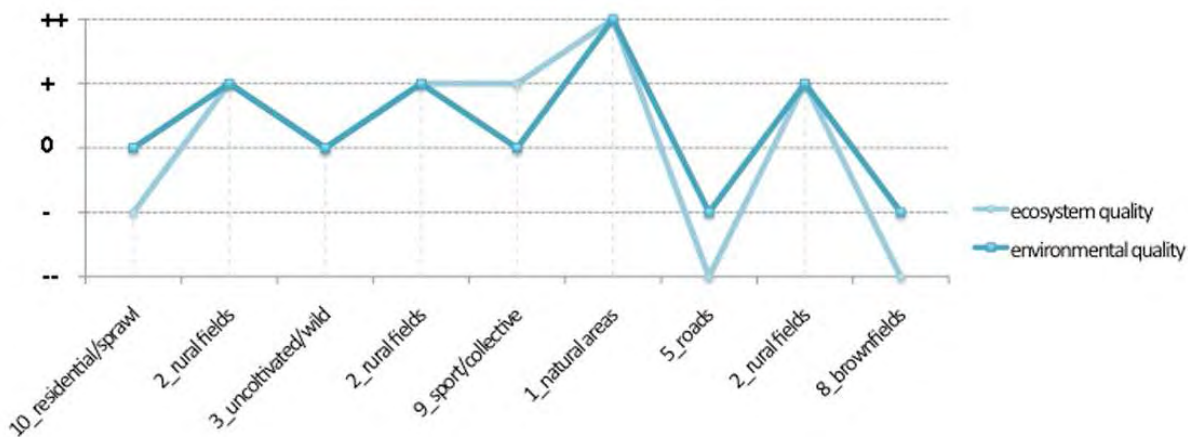

Fig. 4: Trend of the values found in the model applied to the study case.

4. Conclusions

In the processes of the border transformation and safeguard, meant as an incubator of the new evolutionary urban and territorial dynamics, the Technology of Architecture can be an interpreter and a promoter of integrated ways of intervention able to protect the delicate ecosystemic balances and establish best forms of relationship between the man and his own environment. The reading of the data related to the application of the model proposed on the case study of Marcianise shows (fig.4) how the quality of the connections / interactions related to the ecotone areas can meaningfully influence the levels of global environmental and ecosystemic quality of each patch. It can be hypotized, therefore, that the regenerative interventions located on the ecotone areas can produce improving effects verifiable in the whole described system.

From here the configuration of a complex and variegated picture emerges. It is necessary to reiterate the application on new cases study to link the tool with the legibility and usage, so that the model can fully interpret such a complexity, even keeping an agile and speedy character. For this end it is delineated the possibility to start spreading the data related to the mapping of the Mediterranean city border, stimulating a sharing of the third person who doesn't belong to the staff, through an information interchange shared on web platform and social network.

Notes

The paragraphs 1, 2.2, 3.1 and 4 are edited by Raffaella De Martino, the paragraphs 1, 2, 2.1, 3 and 4 are edited by Luigi Foglia.

Raffaella De Martino and Luigi Foglia are both Researchers in Technologies of Architecture and Environment (ICAR 12) and they lead activity of research within the environmental planning with the Research Department of Restoration and Architecture and Environment Construction of the Second University of Naples_SUN.

Abstract

Presently urban territories are significantly impacted by different kinds of pollutions. Such impact may damage the landscapes and cause negative impact to the man and to the environment. Among of the other pollutions, toxicity is one of the most dangerous. The kinds and sources of toxicity of urban territories are analyzed. The main of them are different waste components, as industrial as domestic. For example, lubricating cooling liquids may penetrate into soil and into ground water and cause significant damage to environment and to the man's health. That is why it is necessary to provide high quality environmental control of toxicity of urban territories. Methods of control are investigated. It is shown that the most convenient to use are biological monitoring methods. Results of environmental control of toxicity of urban territories using biological monitoring methods are described on the example of Samara region of Russia. As biological testing objects crawfishes *Daphnia magna* Straus and algae *Chlorella vulgaris* Beijer were used. Results of biological testing showed that some of often used waste components have high degree of toxicity. Methods and means of minimization of negative impact of toxicity of urban territories are considered. Approaches to toxicity reduction and to rehabilitation of contaminated sites are suggested.

Keywords: Urban territory, Environmental control, Monitoring

1. Introduction

Rapid increasing of world population causes significant growth of urban territories. Present urban territories may be characterized by higher population density and vast human features in comparison to areas surrounding it. Urban territories are including cities, towns or conurbations, as well as settlements such as villages and hamlets. Environmental pollution is a serious problem of urban territories. Impact of different kinds of pollutions may damage the landscapes and cause negative impact to the man and to the environment. In general all urban territories impacted by man may be defined as "Built Environment". The sources of environmental pollutions are differs depending on the kind of territory. Among of the other pollutions, toxicity is one of the most dangerous.

Toxicity is the degree to which a substance can damage a living or non-living organism. Toxicity can refer to the effect on a whole organism, such as an animal, bacterium, or plant, as well as the effect on a substructure of the organism, such as a cell (cytotoxicity) or an organ (organotoxicity), such as the liver (hepatotoxicity). Thus, toxicity is ability of some chemical or other substances to cause negative influence to organisms and to damage it.

Environmental control of toxicity of urban territories is efficient way for gaining the precise information about the degree and danger of toxicity as well as for it forecasting and further reduction.

This paper is devoted to environmental control of toxicity of urban territories by using of biological monitoring methods on the example of Samara region of Russia.

2. Analysis of Sources of Toxicity of Urban Territories and of Its Negative Influence

The sources of toxicity of urban territories generally may be subdivided to three main types: chemical, biological, and physical.

Chemical toxicants include inorganic substances (e.g. lead, mercury, asbestos, hydrofluoric acid, chlorine gas), organic compounds (lubricating cooling liquids, organic waste, methyl alcohol etc.) and poisons from living things.

Biological toxicants include bacteria and viruses that can induce disease in living organisms. In many cases biological toxicity can be difficult to measure because the "threshold dose" may be a single organism. Theoretically one virus, bacterium or worm can reproduce to cause a serious infection. However, in a host with an intact immune system the inherent toxicity of the organism is balanced by the host's ability to fight back; the effective toxicity is then a combination of both parts of the relationship. A similar situation is also present with other types of toxic agents.

Physical toxicants are substances like coal dust, asbestos fibers etc. Due to their physical nature, physical toxicants interfere with biological processes.

In general, the most significant sources of toxicity of urban territories are: transport (mainly automobile transport), industry, agriculture. But sometimes influence of domestic sources may be also rather significant.

The sources of toxicity may cause negative influence to the man's health and to environment. It is possible to subdivide negative influence of toxicants to the different scales: large-scale (global) pollution of environment caused by many different sources; regional (territorially restricted), local (e.g. town territory), and single sources influence.

The sequences of toxicants negative influence are widely differ depending on the kind of toxicants, the scale and the time of impact, the object of impact.

Negative influence of toxicity to the man's health may cause different illnesses. Toxicity of a substance can be affected by many different factors, such as the pathway of administration (whether the toxin is applied to the skin, ingested, inhaled, injected), the time of exposure (a brief encounter or long term), the number of exposures (a single dose or multiple doses over time), the physical form of the toxin (solid, liquid, gas), the genetic makeup of an individual, an individual's overall health, and many others. A substance which is a skin sensitizer causes an allergic response from a dermal application. Carcinogens induce cancer, or increase the likelihood of cancer occurring. Reproductively toxic substances cause adverse effects in either sexual function or fertility to either a parent or the offspring. Specific-target organ toxins damage only specific organs. Aspiration hazards are solids or liquids which can cause damage through inhalation.

Environmental impact of toxicants is tend to be focused on degradability, bioaccumulation and aquatic toxicity. E.g. penetrating of toxicants into ecosystem leads to it propagation in atmosphere, water, soil, food and for further pollution. Evaporation of toxicants may cause its penetration into large distances. Thus, a significant part of urban territory may be polluted.

3. Methods and Results of Environmental Control of Toxicity of Urban Territories on the Example of Samara Region

Environmental control of toxicity of urban territories is a complex procedure including estimation of sources of toxicity, determination of the most potentially dangerous zones of toxicity of urban territories, selecting of methods of estimation of toxicity, analysis of results of estimation of toxicity, conclusions about the degree of toxicity, and, finally, development and implementation of methods of reduction of negative impact of toxicants.

Toxicity can be measured by its effects on the certain target (e.g. organism, organ, tissue or cell). Because individuals typically have different levels of response to the same dose of a toxin, a population-level measure of toxicity is often used which relates the probabilities of an outcome for a given individual in a population [1, 2]. One of generally accepted target of such measure is the LD₅₀. When such data does not exist, estimates are made by comparison to known similar toxic things, or to similar exposures in similar organisms. Then, "safety factors" are added to account for uncertainties in data and evaluation processes. For example, if a dose of toxin is safe for a laboratory rat, one might assume that one tenth that dose would be safe for a human, allowing a safety factor of 10 to allow for interspecies differences between two mammals; if the data are from fish, one might use a factor of 100 to account for the greater difference between two chordate classes (fish and mammals). Similarly, an extra protection factor may be used for individuals believed to be more susceptible to toxic effects such as in pregnancy or with certain diseases. Or, a newly synthesized and previously unstudied chemical that is believed to be very similar in effect to another compound could be assigned an additional protection factor of 10 to account for possible differences in effects that are probably

much smaller. Obviously, this approach is very approximate; but such protection factors are deliberately very conservative, and the method has been found to be useful in a deep variety of applications.

Assessing all aspects of the toxicity of cancer-causing agents involves additional issues since it is not certain if there is a minimal effective dose for carcinogens, or whether the risk is just too small to see. In addition, it is possible that a single cell transformed into a cancer cell is all it takes to develop the full effect.

It is more difficult to determine the toxicity of chemical mixtures than a pure chemical, because each component displays its own toxicity, and components may interact to produce enhanced or diminished effects. Common mixtures include industrial waste, gasoline, cigarette smoke etc. Even more complex are situations with more than one type of toxic entity, such as the discharge from a malfunctioning sewage treatment plant, with both chemical and biological agents.

Biological monitoring is the kind of environmental monitoring allowing to estimate efficiently the degree of the toxicity of different sources. Presently many scientists have carried out research devoted to using biological indicators as test-objects. For example, it is well known that for estimation of quality of water it is using Woodiviss index. For estimation of degree of the toxicity of water medium green protococcus algae *Chlorella* (*Chlorella vulgaris* Beijer) and craw fishes *Daphnia magna* Straus are often used as test-objects.

Peculiarity of developed method in comparison with existing methods is complex consideration of the main toxicological values of toxicants (e.g. lubricating cooling liquids) on the basis of it point-rating ranging.

The following toxicological characteristics have been taken into consideration:

- irritating impact to eyes;
- skin-resorptive impact;
- sensitizing impact;
- toxic particles assignable under exploitation of lubricating cooling liquids (number of singled out toxicants and it class of danger);
- toxicity during inside-stomach injection.

In table 1 the scheme of points of distribution during estimation of degree of toxic impact of lubricating cooling liquids to the man and to environment is presented.

Table 1

Distribution of balls during estimation of degree of impact of toxicants to the man and to environment (on the example of lubricating cooling liquids)

| Name of indicator of estimation | Parameter of estimation | Points |
|--|--------------------------------|----------|
| Irritating impact to eyes | Do not cause of impact | 0 points |
| | Causes weak impact | 1 point |
| | Causes irritating impact | 2 points |
| Skin-resorptive impact | Do not cause of impact | 0 points |
| | Causes weak impact | 1 point |
| | Causes irritating impact | 2 points |
| Sensitizing impact | Do not cause of impact | 0 points |
| | Causes weak impact | 1 point |
| | Causes irritating impact | 2 points |
| Toxic substances assignable under exploitation of lubricating cooling liquids (for estimation the substance corresponding to the most high class of danger is selected) | I class of danger | 4 points |
| | II class of danger | 3 points |
| | III class of danger | 2 points |
| | IV class of danger | 1 point |
| Toxicity during inside–stomach injection (medium mortal dose (LD50) under injection to stomach) | LD50 ≤ 5000 mg/kg | 2 points |
| | LD50 > 5000 mg/kg | 1 point |
| | Toxic impact is not determined | 0 points |

Points gradation is distributed as follows: classes of toxicity of substances, singled out during exploitation of lubricating cooling liquids are estimated using 4-point scale, and toxic characteristic of impact to man – using 2-point scale.

Total rating point is determined by summing up of components of points of estimation. Total rating point has 5 gradations, illustrating the degree of negative influence of lubricating cooling liquids to the man and to environment. Scale of estimation of degree of impact of lubricating cooling liquids to the man and to environment by total rating points is presented in table 3. Additionally with the purpose of improvement of visualization the scale may be ranged by using of different colours.

Table 2

Scale of estimation of degree of impact of lubricating cooling liquids to the man and to environment by total rating points

| Total rating points | Degree of impact of toxicant | Suggesting for coding |
|---------------------|------------------------------|-----------------------|
| 10-12 points | Hyper impact | HI |
| 7-9 points | Strong impact | SI |
| 4-6 points | Moderate impact | MI |
| 1-3 points | Weak impact | WI |
| 0 points | Do not cause impact | NI |

Figure 1. Degree of impact of different kinds of lubricating cooling liquids to test-object *Chlorella vulgaris* Beijer

Experimental research were carried out in Russian State accredited R & D laboratory NIL-9 "Vibration, Acoustics, Ecology and Life Protection" of Togliatti State University according to the requirements of accredited methods of determination of acute toxicity of probes of surface fresh, ground, drinkable, sewage waters, water extractions from soil, sewage sediments and wastes in laboratory conditions by variation of optic density of test-culture green protococcus algae *Chlorella* (*Chlorella vulgaris* Beijer) according to methodic ПНД Ф 14.1:2:3:4:10-04 16:1:2:3:3.7-04 and by determination of mortality of craw fishes *Daphnia* (*Daphnia magna* Straus) according to methodic ПНД Ф Т 14.1:2:4.12-06, 16.1:2:3:3.9-06.

As experimental samples 1 dm³ probes of wastes of the most widely used marks of lubricating cooling liquids used in "AVTOVAZ" Enterprise were investigated: БЕЛС-1, Автокат Ф-78, Автокат Ф-40 etc.

For achieving of water extraction the mixture of water and of lubricating cooling liquids in proportions (1:27 and 1:243) was agitated during 1 hour and stored during 24 hours. Than resulting suspension have been centrifugated during 10 minutes under rotation number 5 000 rotations per minute and supernatant liquid have been used for biological testing.

Results of biological testing are presented in fig. 1 and 2. Toxicity of different marks of waste lubricating cooling liquids have been determined. It is shown that a number of the most widely used marks of lubricating cooling liquids have hyper toxicity and strong toxicity.

Figure 2. Degree of impact of different kinds of lubricating cooling liquids to test-object *Daphnia magna* Straus

By using of suggested method of point-rating ranging of lubricating cooling liquids results of complex estimation of toxic impact of different kinds of lubricating cooling liquids to the man and to environment have been achieved (table 3).

Table 3

Results of complex estimation of toxic impact of lubricating cooling liquids to the man and to environment on the basis of point-rating ranging

| Name of indicator of estimation | Kinds of lubricating cooling liquids | | | | | | |
|---|--------------------------------------|--------------|---------|-----------|----------------|------------|----------|
| | АВТОКАТ Ф-78 | АВТОКАТ Ф-40 | БЕЛС-1М | ТОСОЛ ОИЗ | ТОСОЛ ОИЗ «НК» | ТОСОЛ - АМ | ТОСОЛ ТС |
| Irritating impact to eyes | 2 | 1 | 2 | 1 | 2 | 2 | 2 |
| Skin-resorptive impact | 0 | 0 | 2 | 1 | 2 | 2 | 2 |
| Sensitizing impact | 0 | 0 | 0 | 2 | 2 | 2 | 2 |
| Toxic substances assignable under exploitation of lubricating cooling liquids | 3 | 2 | 2 | 2 | 2 | 2 | 2 |
| Toxicity during inside-stomach injection | 1 | 1 | 2 | 1 | 1 | 1 | 1 |
| Total points (summarized) | | | | | | | |

By using of suggested scale of point-rating ranging graphical visualization of degree of negative influence of different kinds of lubricating cooling liquids to the man and to environment have been developed (fig. 3).

Figure 3. Degree of ecological safety of different marks of lubricating cooling liquids determined on the basis of results of complex estimation of toxic impact of lubricating cooling liquids to the man and to environment

As the next object of toxicity investigation the territory of former industrial plant "Phosphorus" was selected. The problem is that when the plant was closed the toxic wastes on the territory of the plant were remained, at its presence causes significant potential negative impact to environment.

More than 30 probes of organic wastes of former industrial plant "Phosphorus" were analyzed. Results of analysis are showing that the most of wastes are hyper-toxic. For example, the results of biological testing of wastes in cisterns located in railways on the territory of former industrial plant "Phosphorus" are showing that waste probe causes hyper-toxic impact to test-object *Daphnia magna* Straus. The impact of waste was tested in range of concentrations 0,011%-1,0. Death rate of test-object was 100% during the several minutes. The same results were achieved for to test-object *Chlorella vulgaris* Beijer: hyper-toxic impact to test-object was observed even for maximal dilution proportion.

Thus, the most widely-distributed toxicants of urban territories may have hyper-toxicity and cause significant negative influence to man's health and to environment.

4. Methods and Means of Minimization of Negative Impact of Toxicity of Urban Territories

It was shown before, that some products (like organic waste, lubricating cooling liquids etc.) have high toxicity levels and may cause significant negative impact to urban territories population health and to environment. That is why it is necessary to develop efficient method and means of minimization of negative impact of toxicity.

Main methods of toxicity reduction in urban territories conditions are shown in figure 4 and including:

- using the materials without toxicity or with low toxicity;
- implementation of industrial technologies with reduced using or with total absence of toxic substances;
- utilization of toxic waste;

- arrangement of system of collection of toxicants in urban territories;
- cleaning of urban territories from toxic substances etc.

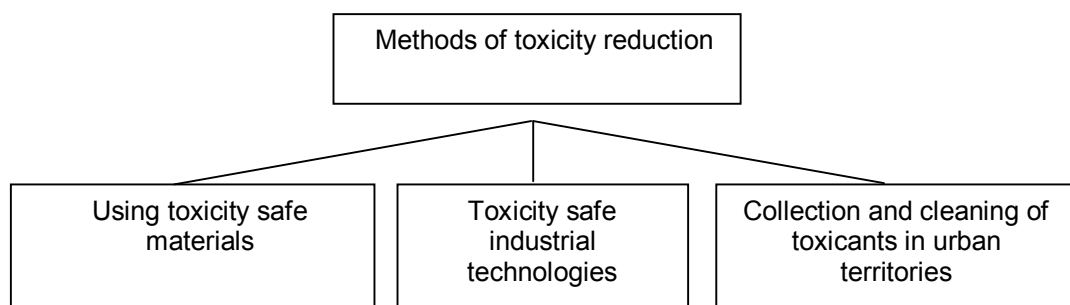

Figure 4. Main methods of toxicity reduction in urban territories

Detailed methods and means of minimization of negative impact of toxicity of urban territories are differs depending on the kind of toxicant. For example, for reduction of negative impact of lubricating cooling liquids it is reasonable to use ecologically safe technologies of treatment without using of lubricating cooling liquids (so called "dry treatment"). Such technologies are presently used in some advanced enterprises, e.g. in AVTOVAZ [3]. There are some well known methods of organic waste treatment (e.g. biological composting). One of the prospect methods is automated design and modeling of technological processes without application or forming of toxic substances.

Significant problem is rehabilitation of contaminated sites from toxicants. In urban territories conditions the most often case of toxicity contamination of soil is oil pollution. The complex methods of soil rehabilitation should be used: monitoring of degree of contamination, localization of polluted areas, collection of oil, soil treatment by different technologies: thermal treatment, physical-chemical treatment, biological treatment etc.

It should be noted that methods of toxicants control are very important not only for receiving the precise information about the degree and danger of toxicity for the health of inhabitant of urban territory and ecological safety, but also for toxicants forecasting and further reduction of it negative impact.

Thus, only complex using of different methods and means allows efficiently reduce toxicity in urban territories conditions.

5. Conclusions

Toxicity is one of the most dangerous sources of pollutions of urban territories. Analysis of kinds and sources of toxicity of urban territories shows that the main of them are different waste components, as industrial as domestic. For example, lubricating cooling liquids may penetrate into soil and into ground water and cause significant damage to environment and to the man's health.

Provision of high quality environmental control of toxicity of urban territories is very important not only for receiving the precise information about the degree and danger of toxicity for the health of inhabitant of urban territory and ecological safety, but also for toxicants forecasting and further reduction of it negative impact.

It is shown that for environmental control of toxicity of urban territories the most convenient to use are biological monitoring methods. It is described using of green protococcus algae *Chlorella* (*Chlorella vulgaris* Beijer) and craw fishes *Daphnia magna* Straus as test-objects for estimation of degree of the toxicity of urban territories toxicants.

New method in comparison with existing methods is complex consideration of the main toxicological values of lubricating cooling liquids on the basis of it point-rating ranging. The following toxicological characteristics have been taken into consideration: irritating impact to eyes; skin-resorptive impact; sensitizing impact; toxic particles assignable under exploitation of toxicants (number of singled out toxicants and it class of danger); toxicity during inside-stomach injection.

The scheme of points of distribution during estimation of degree of toxic impact of lubricating cooling liquids to the man and to environment is presented. Points gradation is distributes as follow: classes of toxicity of substances, singled out during exploitation of lubricating cooling liquids are estimated using 4-point scale, and toxic characteristic of impact to man – using 2-point scale.

Experimental research of wastes of the most widely used marks of lubricating cooling liquids used in "AVTOVAZ" Enterprise were carried out in Russian State accredited R & D laboratory NIL-9 "Vibration, Acoustics, Ecology and Life Protection" of Togliatti State University. Results of biological testing are showed that a number of the most widely used marks of lubricating cooling liquids have hyper toxicity and strong toxicity and thus may cause significant negative impact to urban territory inhabitants and environment. By using of suggested method of point-rating ranging of lubricating cooling liquids results of complex estimation of toxic impact of different kinds of lubricating cooling liquids to the man and to environment have been achieved. Degree of ecological safety of different marks of lubricating cooling liquids is determined. As the next object of toxicity investigation the territory of former industrial plant "Phosphorus" was selected. Results of analysis are showing that the most of wastes are hyper-toxic. Methods and means of minimization of negative impact of toxicity of urban territories have been described. Only complex using of different methods and means allows efficiently reduce toxicity in urban territories conditions.

Abstract

Environmental issues are becoming more and more important during the procedure of planning of cities. Noise impact may cause significant discomfort for inhabitants and health damage. That is why it is necessary taking into account noise factor during environmental planning of towns. Noise sources of urban territories are considered. It is shown that for the towns of Russia transport noise is the main source of acoustical pollution of the territory. The most serious problems and reasons of increased transport noise levels impact to the population of Russian cities are discussed. It is pointed out that in many Russian towns the living areas are situated close to transport highways and to industrial enterprises. Results of experimental noise investigations for the different towns of Samara Region of Russia shows that there are exist some zones of urban territories with increased noise levels. Peculiarities of cities environmental planning taking to account transport noise impact are considered on the example of Togliatti city of Russia. Approaches to environmental planning of existing and new districts of Togliatti city to provide the required sanitary norms of noise impact are suggested, including architect solutions, sanitary-protective zones provision, different kinds of noise barriers installation, restriction measures of high traffic movement near to the hospitals, schools etc.

Keywords: Environmental planning, noise, towns, sources

1. Introduction

Rapid growth of towns causes many ecological problems. Among of them are energy consumption growth, increasing of water, air and soil chemical pollutions, rapid growth of domestic and industrial wastes etc. All these and other factors are causing negative influence to the man's health and to environment, that is why during towns planning it is necessary to take into consideration ecological issues.

In total ecological state of towns of Russia is estimated by the complex of factors. Among of them are volume of negative emissions to atmosphere and to water reservoirs, soil pollutions by chemical substances, levels of physical factors, indexes of atmosphere pollutions etc. Taking to account ecological conditions, all towns of Russia are subdivided into 5 categories of ecological state: 1 - problem-free, 2 – satisfactory, 3 – moderate-intensive, 4 – intensive, 5 – critical. Approximately 100 towns of Russia are having 5th category. Almost all large towns of Russia are having intensive and critical ecological state.

Significant parameter is the presence of zones of ecological impact of towns which are differs depending on the concentration and kind of industry and geographical position. These zones are especially large in major industrial agglomerations with combined impact of industrial and transport pollutions: Moscow agglomeration with more that 200 km length, Saint-Petersburg agglomeration with more that 150 km length. Some industrial & transport regional centers of Russia are also have distinguished zones of ecological impact. E.g., large towns of Volga region are traditionally have significant zones. Samara region is one of the industrial centers of Russia having the zone length more than 100 km.

The problem of physical pollutions (acoustical pollution, infrasound, electromagnetic fields, ionization etc.) negative impact probably not so evident as water and air pollution. In a meantime, half of inhabitants of towns are presently affected by increased noise levels. And the town's noise level is trend to be increased. Noise level in large cities is growing every year approximately up to 0,5 dBA. Increased noise impact may cause significant discomfort for inhabitants and health damage. Damaging influence of intensive noise to the human's health is not restricted only by impact to ears. It is known, that noise is affecting to the human's central and vegetative nervous systems, influencing to the human's psychological condition etc. That is why it is necessary taking into account noise factor during environmental planning of towns. This paper is devoted to the questions of environmental planning of towns taking to account noise factor on the example of Samara Region of Russia.

2. Analysis of Main Noise Sources of Towns

Noise sources of urban territories may be subdivided into two main groups: separate noise sources and complex noise sources. As separate single vehicles, exhaust systems of ventilation, single mounts of industrial enterprises etc. may be considered. Complex sources are transport flows, industrial enterprises, stadiums etc.

As the main noise sources of urban territories the following sources may be pointed out:

- noise from separate automobiles, motorcycles;
- noise of automobile transport flows;
- noise of railway transport;
- noise of aviation;
- noise of trams;
- noise of open lines of subways;
- noise from industrial enterprises and transformer substations;
- noise from different kinds of building works;
- noise inside of residential settlements (waste-transportation machines, sport games etc.).

Sound levels or equivalent sound levels, dBA of the main noise sources in living area are shown in table 1.

Table 1

Sound levels or equivalent sound levels, dBA of the main noise sources in living area at the distance 7,5 m

| N | The kind of noise source | Sound levels or equivalent sound levels, dBA |
|----|---|--|
| 1 | Passenger trains | 80-87 |
| 2 | Freight trains | 85-95 |
| 3 | Sorting and cargo stations | 95-100 |
| 4 | Cars | 75-85 |
| 5 | Tracks | 83-95 |
| 6 | Buses | 82-92 |
| 7 | Automobile flows | 75-98 |
| 8 | Motorcycles | 81-100 |
| 9 | Open lines of subways | 80-93 |
| 10 | Transformer substations | 71-89 |
| 11 | Industrial enterprises | 70-98 |
| 12 | Noise inside of residential settlements | 70-85 |
| 13 | Trams | 75-90 |
| 14 | Aviation | 70-92 |

The degree of impact of different noise sources to inhabitants is depends on the number of factors: mutual dislocation of noise sources and living area, intensity and kind of moving transport flows etc. Generally, from the point of view of ecological impact, automobile transport is considered as the main noise source creating 60-80% of total acoustical pollution impacting to the town's population and giving up to 90% from all population complaints to negative noise influence. Transport noise level is increasing together with the cities growth. When the scale of city transport flows is bigger, acoustic discomfort zones are considerable increased. Transport number in towns is increasing with every month. Therefore the problem of transport

noise reduction in towns is so important.

Samara region is one of the leading industrial regions of Russia. The biggest towns of Samara region are Samara (the capital of region), Togliatti (automobile capital of Russia), Syzran and Zhigulyovsk.

As typical industrial towns Samara, Togliatti and Syzran have as a number of large industrial enterprises as considerable automobile transport park, making significant acoustic impact to abutting dwelling territory. Samara also has railway transport, trams and metro; Syzran - railway transport. The problem of noise impact in these towns is intensified by the fact that some industrial enterprises and highways are closely adjoining to cities dwelling areas. As result significant part of cities population is affected by increased noise level [1-3]. The peculiarity of Zhigulyovsk town is that it is situated near to the Zhigulyovsky reserve and Russian national park Samarskaya Luka. In a meantime Zhigulevsk has transport roads with intensive traffic and some industrial noise sources.

Thus, there are several main noise sources on the territory of Samara region. But the most important source of disturbing noise for the population of Samara region is automobile transport. Noise of moving automobile is induced by the noise from the engine and its systems, automobile aggregates, oscillating body, tires, noise of auxiliary equipment etc. Taking to account continuous growth of transport number of the region, the problem of transport noise impact to the inhabitants is coming more significant with every year.

Togliatti city of Russia has as a number of large industrial enterprises as considerable automobile transport park, making significant acoustic impact to abutting dwelling territory. The problem is intensified by the fact that some industrial enterprises and highways are closely adjoining to city's dwelling area. As result significant part of city's population is affected by increased noise level. It should be noted that such situation is typical not only for Togliatti, but also for many other towns of Russia and West Europe, especially for towns with ancient history.

Automobile transport is the main external noise source affecting to Togliatti city dwelling area. Specific city peculiarity is large automobile transport park, the most part of which consist of cars. This causes intensive transport flows at city's streets, which are generating significant noise impact. It should be noted that for Togliatti city comparatively homogeneous composition of transport flows is typical - railway city transport is absent, impact of aircraft noise is excluded.

But for other towns acoustical situation may differ. For example, in Hong Kong living areas are located near to airport and aviation noise here is very significant. In many towns impact of railway noise is also significant.

The other main source of town's acoustical discomfort is industry.

It is also should remember about some other noise sources in towns like sport and cultural objects, food industry etc.

3. Experimental Investigations of Noise Levels in Different Towns of Samara Region of Russia

In years of 2001-2011 collaborators of R&D laboratory "Vibration, Acoustics, Ecology and Life Protection" of Togliatti State University have investigated external noise sources levels on the territory of Samara region. Measurements were carried out by using of "Octava 101 AM" sound level meter and other equipment.

As a measuring parameters equivalent sound levels L_A and maximal sound levels L_{Amax} (dBA), octave and 1/3 octave spectra of sound pressure (dB) were used. Measurements have conducted in daytime in weekdays mainly in rush hours and during the lunch-time; and in night time (since 23.00 till 7.00). Method of noise measurement in noise "dangerous" points have been carried out according to Russian State Standard 23337-78*. Measured noise levels were evaluated according the requirements of Russian Sanitary Norms CH 2.2.4/2.1.8.562-96. Requirements of Russian Building Norms and Rules were also taken into consideration.

Results of measurements in every point have been presented as measurements registration forms, which including date, time and place of measurements carrying out, measuring points numbers and digital data of readings of noise levels in measured point, as well as in form of spectral presentation of sound pressure levels [1-3].

In Samara city noise levels were measured in some of the most important streets. The most significant exceeding values of sanitary norms requirements were obtained in Kuibyshev Street, Stara Zagora Street, Stavropolskaya Street and Moskovskoye Highway. An example of spectral presentation of sound pressure levels on the point of measurements Stara Zagora street, 255, Samara city is shown in figure 1.

In Zhigulevsk town the most significant noise levels were fixed near to the living houses situated near to railway station and highway Moscow-Chelyabisk. The scheme of points of noise measurement in Syzran city is shown in figure 2. The most significant noise levels in Syzran city were measured near to the Central Supermarket and railway station.

For Togliatti city comparatively homogeneous composition of transport flows is typical - rail city transport is absent, impact of aircraft noise is excluded. Transport and industrial enterprises are the main noise sources for Togliatti city. As object of study living territory of the Avtozavodsky, Central and Komsomolsky districts of Togliatti city was selected near to the streets with intensive transport movement and near to industrial zones. In total over 150 points have been investigated [1, 3].

As we may conclude from the results of measurements, the most significant excess of standard equivalent noise levels is observed for the following points. Komsomolsky district, night time: point K-07, Matrosova Str., 60, the value of exceeding of normative requirements of equivalent noise level is 8 dBA, maximal noise level - 6 dBA; point K-12, Yaroslavskaya Str., 11: the value of exceeding of normative requirements of equivalent noise level is 5 dBA, maximal level - 8 dBA; day time: point K-10, Chaykina Str., 67, the value of exceeding of normative requirements of maximal noise level is 9 dBA; point K-13, Yaroslavskaya Str., 61, the value of exceeding of normative requirements of maximal noise level is 9 dBA. Central district, night time: point C-18, Lenina Str., 98, the value of exceeding of normative requirements of equivalent noise level is 10 dBA, maximal noise level - 5 dBA; point C-23, Mira Str., 60, the value of exceeding of normative requirements of equivalent noise level is 12 dBA, maximal noise level - 12 dBA; day time: point C-6, Central district, Mira street (near to bus stop "House of Nature"), the value of exceeding of normative requirements of equivalent noise level is 6 dBA; point C-5, Central district, Banykina street, the value of exceeding of normative requirements of equivalent noise level is 7 dBA; point C-7, Central district, Komsomolskaya street, the value of exceeding of normative requirements of equivalent noise level is 6 dBA, point C-24, Mira Str., 114, the value of exceeding of normative requirements of equivalent noise level is 4 dBA, maximal noise level - 3 dBA. Avtozavodsky district, night time: point A-32, Dzerzhinskogo Str., the value of exceeding of normative requirements of equivalent noise level is 8 dBA, maximal noise level - 3 dBA; day time: point A-04, Topolinaya Str., 21, the value of exceeding of normative requirements of maximal noise level - 19 dBA.

Near to the Central and Komsomolsky districts of Togliatti city it is situated a number of industrial enterprises united to so called "North Industrial Unit". Noise estimation and monitoring of North Industrial Unit enterprises for further determination of sanitary zone have been also carried out. Here there are also some points of measurements with exceeding of normative requirements of equivalent noise level

Analysis of measurement results of external noise levels in living territory of Samara region shows, that there are noise dangerous zones of dwelling territory. The most serious problem of noise influence is for the dwelling territories of Samara region adjoining to transport highways. Values in a number of measured points are extremely close to maximally admitted normative requirements.

Thus, it is possible to speak about the existing of real problem of noise safety of Samara region provision. It is necessary to carry out further investigations of noise levels in all large cities of Samara region.

4. The Principles of Towns Planning in Russia Taking to Account Environmental Issues

In Russia every town must have 3 kinds of planning documentation: general plan of development (reconstruction); projects of planning and of building of total towns and of its separate parts; plan of land-economical gradation of town's territories.

General plans of development (reconstruction) of towns are having significant meaning for provision of the required state of environment in long-term prospect. General plans are developing for the period of 25-30 years. General plans of construction and reconstruction of Moscow, Saint-Petersburg, large regional centers are утверждается by Government of Russian Federation. Every 5 years general plans are précised according to variation of conditions of development of towns.

There are three main principles used during development of general plans of towns: zoning principle, ecological safety principle, rational territory organization principle.

Zoning principle means division of all the territory of town to four parts – industrial, living, culture-domestic and recreational. Requirements of ecological safety are admitting taking into consideration of norms of roads displacement, of living and administrative buildings, rest zones, fitting to the requirements of sanitary norms of maximal permissible concentrations and exhausts, for the displacement of sanitary-protective zones, waste disposal etc.

General plans of towns are the basis for development of projects of planning and building of town and of its separate parts. According to the requirements of Russian legislation planning and building of towns must foresee creation of the most favorable conditions for life, rest and health of population. The main task determining the order of complex improvement of towns is prevention and liquidation of harmful and dangerous influence of environmental factors to the living conditions of man.

Before to allow to make the construction of living houses or industrial objects it is necessary to receive positive conclusions of Russian State organizations of ecological and sanitary-epidemiological control and

oversight for organizations of all forms of propriety. It is one of the guaranties of provision of ecological safety of population.

Plans of land-economical gradation of cities are considering dislocation of communications for energy, water and heat supply, as well as waste management, rainwater escape etc. Plans are developing and realizing according to the sanitary norms and rules under control of sanitary-epidemiological organizations.

Some other kinds of town's planning are also significant. Among of them are complex plans of town's social-economical development; territorial complex schemes of town's environmental protection; different targeted scientific-technical programs.

Plans of social-economical development are intend for determination of the prospects of town for the nearest 5-10 years taking to account construction and reconstruction of enterprises, increasing of culture-domestic sphere, of residential building. Territorial complex schemes of environmental protection of towns are the main document which is forecasting for creation of plans of social-economical development of towns. The schemes are forming the informational-methodical and normative-technical basis of the plans. These schemes may be used for development of measures for prevention and liquidation of damage to environment from economic and social development of town, increasing of it territory.

5. Peculiarities of Acoustical Planning of Towns and of it Realization on the Example of Samara Region of Russia

During acoustical planning of towns it is necessary to take into consideration a number of architecture-planning solutions. Some of them are:

- rational acoustical solutions of plans of industrial areas and of general plans of objects;
- rational dislocation of technological equipment;
- rational displacement of working places in enterprises;
- creation of noise-protective zones etc.

The most noisy transport highway streets of towns may be considered as «transport corridors» with the main task of transportation of people and of loads. Transport highway streets are causing significant influence to the environment (not only noise but also air and soil chemical pollutions etc.) and should be isolated form the living areas. This requirement is necessary to take into consideration in architecture-planning decisions of building of living areas.

For provision of acoustical comfort it is reasonable to use first of all the solutions deciding not only noise-protective, but also architecture-planning questions. Earth mounds and artificial hills protecting the living area from transport noise should look as landscape elements and to have pictorial form.

During towns planning it is necessary to take into consideration correct zoning of territories surrounding the traffic interchanges which are traditionally the most noisy part of highways. In the zone near to transport highway it is not reasonable to dislocate living and social buildings of high этажности, because to protect it from negative noise impact it is necessary to erect noise barriers of high height.

Among of town planning solutions for noise reduction it should to point out the following measures:

- observing of the principle of zoning, giving the separation of noisy sources from urban territories;
- transferring of noisy enterprises beyond the bounds of living area;
- construction of special noise-protective living buildings.

Values of admissible gaps between single noise source and the object to be protected may vary in very wide range: from 8-10 up to 500-1000 meters. In zone of gaps auxiliary buildings and areas (garages, car parks, storehouses etc.) are dislocated. For many cases the gaps are should be considered as auxiliary measure.

Efficient town planning solution is using of noise-protective planting trees and shrubs. Approximate values of sound decay by using of several different kinds of planting trees and shrubs for single noise source are shown in table 2.

Results of measurements are shows that mean decay on the distance 10 meters of stripe of planting trees and shrubs is 1,5-2,0 dBA for trees and 2-4 dBA for rich trees and shrubs. But it is necessary to point out that for low frequencies sound decay by using of planting trees and shrubs is insignificant.

High efficiency measures of transport noise reduction are development and using of alternative transport as well as more intensive using of public transport.

As alternative to automobile transport using of bicycle transport may be suggested. In this case during the planning of town's territory it is necessary to foresee special bicycle roads, places for bicycles parking etc.

In many towns noise protective barriers are using for noise reduction. But the installation of noise barriers in towns may significantly change external look of town, that is why before to make the decision to install noise barrier (even the acoustical effect is good) it is necessary to have the detailed consultations with architects.

Reduction of noise of living territories of urbanized complexes up to admitted hygiene requirements in present conditions is sophisticated scientific-research problem, which may be decided only by complex measures.

Table 2

Reduction of sound pressure level and sound level by planting trees and shrubs, dB/m

| Kind of planting trees and shrubs | Frequency octave bands, Hz | | | | | Sound level, dBA |
|-----------------------------------|----------------------------|-----------|------------------|-----------|----------|------------------|
| | 250 | 500 | 1000 | 2000 | 4000 | |
| Pine forest | 0,1-0,11 | 0,1 | 0,1 - 0,15 | 0,16 | 0,14-0,2 | 0,15 |
| Furtree forest | 0,1-0,12 | 0,14-0,17 | 0,18 | 0,14-0,17 | 0,23-0,3 | 0,18 |
| Dense deciduous forest | 0,05 | 0,05-0,07 | 0,08-0,1 | 0,11-0,15 | 0,17-0,2 | 0,16 |
| Green dense trees and shrubs | 0,13-0,15 | 0,17-0,25 | 0,18-0,35 | 0,2-0,4 | 0,3-0,5 | 0,3 |

In whole all measures of noise reduction in the dwelling territories may be conditionally divided into several big groups:

1. Urban development and building-acoustic methods of noise control: rational acoustic planning of neighbourhood units, industrial enterprises and highways, erection of noise-protecting shields, noise-protecting planting trees and shrubs, increasing of sound-insulating qualities of buildings, development of noise-protecting screens constructions, foaming of the systems of settling groups on the basis of mass velocity passenger transport with definite functional zoning of the territory, removal of dwelling areas from intensive noise sources, using of compositional grouping of buildings etc.
2. Administrative-organizing measures of noise reduction: noise levels reduction due to decreasing of intensity and noise of transport flows; improvement of roads quality, using of road surface with lower noise; provision of rational velocity of movement; provision and even exclusion of automobile (especially lorry) transport traffic in central parts of town and in living area streets etc.
3. Legal acts, technical norms, prohibitions of noise generation in living zones etc.
4. Using of the technical means of acoustical radiation reduction.

Measures to reduce transport noise may be widely divided to two groups: reduction of transport noise levels in the source of its generation and on the ways of noise propagation.

Many scientists are supposing that the most efficient measure is transport noise reduction in the source of its generation. Design and exploitation of noiseless automobile constructions, especially in low frequency range, is one of the most efficient and economically reasonable ways of noise levels reduction in the living area. At city's level it is necessary to unite the efforts of scientists, designers of "AVTOVAZ" cars perspective constructions, specialists of transport department of administration. It is necessary to restrict responsibility for noisy automobiles using. While toxins of automobiles exhaust are strictly controlled by state automobile inspection, noise control of automobiles during exploitation is completely absent.

Some other measures of noise reduction should be used: rational organization of transport flows, prohibition of transport movement at some districts etc, as it pointed out above.

It is necessary to reduce intensity and noise of transport flows. It is required to exclude lorry transport traffic. Secondly, it is recommended to use noise-damping road surfaces. Such surfaces have been developed presently by many foreign companies. For example, there is road surface "Viaphone", having reduced granulation and insignificant thickness of layer (2-3 sm). Other type - porous draining road surfaces. For example, "Gerland Routes" company suggests road surface Epsibel. "Colas" company is using in "Golsoft" mixtures recycled rubber from the automobile tires in two layers, providing noise reduction 8 dBA.

One of the modern approaches to town's noise planning and abatement is using of software for noise propagation calculation and for noise forecasting [4].

Let us consider some solutions for town's noise planning and reduction on the example of Togliatti town.

Evaluating transport noise influence to the living territory along to Banykina street of Togliatti town, it should be taken into consideration, that along this street blocks of city hospital and two schools are situated. For these objects hygiene requirements are especially strict. Further experimental investigations are required here.

Along with using of administrative-organizing measures of noise reduction and using of noise-damping road surfaces in this case it is efficient to use acoustic screens. For described area it is preferable to use acoustic screens-walls with sound absorption (as a rule, this kind of screens is using sound-absorption material and metal constructions). Noise reduction effect of suggested screens is provided by varying of it height, length, distance between noise source and shield.

For noise reduction in other parts of living territory in Banykina street of Togliatti town it is possible to use acoustic screens of combined type, combining acoustic screens-walls with fill or hollow. Efficiency of such shields may be significantly high without additional expenditures, connected with increasing of hollow depth or fill height.

In order to achieve noise attenuation in all frequency range, it is necessary to use hybrid type shields, combining muffling properties of acoustic panels with sound absorption material and active noise mufflers. Construction of hybrid acoustic screen have been developed. Construction includes active sound emitters and at least two independent controllers with using of multi-channel adaptive signal for low-frequency sound attenuation. Construction is patenting. It is possible use to use tunnels for noise reduction in this zone.

Peculiarities of external noise affection to the living zones of Komsomolskaya street of Togliatti town that a number of many-store buildings of this street (for example, between Lenina and Pobeda streets) are situated butt-ends to noisy transport highway, what contribute to transport noise penetration into internal parts of houses.

In total, effective noise reduction in living areas may be achieved by provision of complex administrative-organizing, urban development and building-acoustic measures: acoustic screening, noise-protecting planting trees and shrubs, increasing of noise insulation of buildings windows etc.

6. Conclusions

Negative impact of acoustical pollution now is one of the most serious problem as for populations health as for town's environment. At least half of inhabitants of towns are presently affected by increased noise levels. And the town's noise level is trend to be increased. Thus, it is necessary taking into account noise factor during environmental planning of towns.

Analysis shows that for the towns of Russia transport noise is the main source of acoustical pollution of the territory. It is pointed out that in many Russian towns the living areas are situated close to transport highways and to industrial enterprises. As result a lot of population is impacted by significantly increased noise levels.

Results of experimental noise investigations for the different towns of Samara Region of Russia are described. Estimation of measured noise levels on the territory of Samara region comparing with sanitary norms requirements have been done. Results of estimation are shows that there are exist some zones of urban territories with increased noise levels. Values in a number of measured points in day time in the territory of Samara region are exceeding the norms or extremely close to maximally admitted normative requirements. Thus, it is possible to speak about the existing of real problem of noise safety of Samara region provision.

Peculiarities of cities environmental planning taking to account noise impact are considered on the example of samara region and of Togliatti city of Russia. Approaches to environmental planning of Togliatti city to provide the required sanitary norms of noise impact are suggested, including architect solutions, sanitary-protective zones provision, different kinds of noise barriers installation, restriction measures of high traffic movement near to the hospitals, schools etc.

In total, effective noise reduction in living areas may be achieved by provision of complex administrative-organizing, urban development and building-acoustic measures.

A net of small museums for policies of planning, safeguard and government of Mediterranean archeological landscape

Francesca FATTA, Domenico TOSTO, Andrea MANTI

Department of Architettura e Analisi della Città Mediterranea, Faculty of Architettura, University Mediterranea, Reggio Calabria, Italy

E-mail: ffatta@unirc.it, domenico.tosto@unirc.it, andrea.manti@unirc.it

Abstract

We propose an integrated plan of small museums (*antiquaria*), strongly deep-rooted in the reference archaeological areas, in the northern Mediterranean region of Tunisia, where there are numerous sites of great value, sometimes not very well-known, that show basic analogies and common tourist-cultural interests. We have been able to point out, and not only in Tunisia, that still today the most important classical museum systems draw on the nineteenth-century idea of Vivant Denon, that is the great museum holding, in a succession of numerous expository halls, different collections coming from several parts of the region, in order to exalt the great variety and the treasures of the national territory.

Today this system appears very damaging for the more distant sites that are actually deprived of their memories to advantage of the capital, to be actually deprived of local testimonies, also of great dimension, as well as of great value.

The structures considered more suitable to support a diffused cultural tourism are, on the contrary, small museum architectures situated inside the archaeological areas that privilege a more direct and immediate approach with the reference context. To this aspect of “ecomuseum”, we should add an important program of communication for the implementation of a virtual dimension of the museum itself, that can be supported both in the sphere of the *antiquarium*, in specific fields dedicated to the projections of the reconstruction examples, and for the communication of a “virtual museum” to visit on-line.

Today the aspect of the virtuality represents one of the most explicit forms through which a museum tries to promote itself and to renew the interest for the art works it preserves, in a more and more demanding and competitive tourist cultural context.

Parole chiave: Antiquaria, Virtual Museum, Virtuality Represents, Archeological Landscape.

1. Una rete di piccoli musei per i siti archeologici mediterranei. Il caso della Tunisia (Francesca Fatta)

L'argomento generale del Forum ci ha indotto a considerare il valore del paesaggio archeologico mediterraneo come un bene da canalizzare in nuovi ambiti di progettazione, tutela e governo.

Vi è una moltitudine di siti storici sparsi in area mediterranea, e specie in nord Africa, di cui solo pochi sono realmente conosciuti e fruiti da un consistente pubblico. Questi luoghi, spesso testimoni da una importante storia urbana e ricchi di grandi presenze archeologiche, sono fuori dai circuiti di comunicazione più ricorrenti, appannaggio solo di pochi studiosi e privi delle più elementari attrezzature per accoglienza.

A questo proposito si è pensato ad un progetto integrato di piccoli musei (*antiquaria*) strettamente connessi alle aree archeologiche di riferimento, dislocati nella regione nord mediterranea della Tunisia, ove sono presenti numerosi siti di grande pregio, talvolta poco noti, che presentano analogie di fondazione e comuni interessi turistico-culturali.

Si è potuto rilevare, e non solo in Tunisia, che ancora oggi i più importanti sistemi museali di tipo classico riprendono l'idea ottocentesca di Vivant Denon, ovvero del grande museo capace di ospitare, in un

susseguirsi di numerose sale espositive, collezioni differenti provenienti da più parti della regione, per esaltare la grande varietà e la ricchezza del territorio nazionale.

Questo sistema appare oggi molto penalizzante per i siti più distanti che vengono, di fatto, spogliati delle loro memorie a vantaggio della capitale, per restare privi delle testimonianze locali, anche di grandi dimensioni, oltre che di grande pregio.

Le strutture che si ritengono più adatte a supportare un turismo culturale diffuso sono, al contrario, piccole architetture museali situate all'interno delle zone archeologiche che privilegiano un approccio più diretto e immediato con l'ambiente di riferimento.

Architetture di dimensioni contenute e ben inserite nel contesto paesaggistico, relazionate all'interno di una rete di altrettante strutture, e coordinate da azioni e sistemi di comunicazione integrati.

Uno dei casi studio che si è analizzato è il sito di Dougga (o Thugga) per il quale si è considerata una rete di comunicazione virtuale con i maggiori siti dell'antica Numidia, al confine con l'Algeria: Bulla Regia, Chemtou (l'antica Simitthus), Thurburbo Majus, Utica, oltre alla più nota Cartagine.

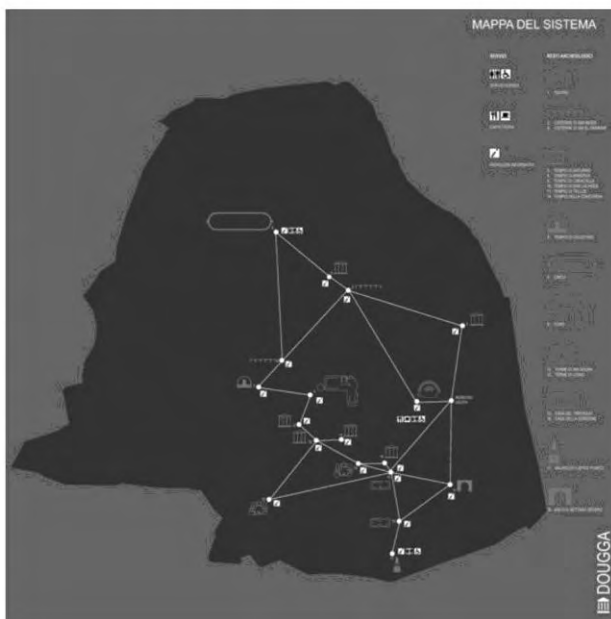

Fig. 1-2-3: Progetto per un parco archeologico a Dougga.

L'antica Thugga conserva numerosi resti di monumenti punici, numidi e romani, che ne fanno uno dei più importanti siti archeologici della Tunisia. Per l'eccezionale stato di conservazione di alcuni suoi monumenti, che rivelano la tipica struttura delle cittadine romane del Nordafrica, il sito è annoverato nella lista dei Patrimoni Mondiali dell'Umanità dell'UNESCO, ma questo non è stato sufficiente per creare infrastrutture e servizi d'accoglienza di cui il sito è totalmente privo.

Dal capitolium, al teatro, alle terme, alle domus, al mercato, Thugga può considerarsi un paradigma della colonia romana in Africa, per la sua organizzazione urbana e per le testimonianze ancora leggibili per molte sue parti.

Per poter apprezzare alcuni tra i mosaici più raffinati, come quello della casa di Ulisse, il visitatore però deve recarsi al Museo del Bardo a Tunisi, così come per molti altri reperti di grande interesse che sarebbero più comprensibili e apprezzabili se esposti nei pressi dello stesso sito di provenienza.

La stessa sensazione di privazione del bene archeologico da visitare in sito, si prova a Bulla Regia, Utica, Thuburbo Majus, Thysdrus e perfino presso la stessa Cartagine che comunque ha un proprio museo.

Per questo si è pensato ad un progetto che preveda non soltanto un parco archeologico per la fruizione del sito, tagliato *ad hoc* per visite brevi, di media o di lunga permanenza, organizzato con aree di sosta, punti d'informazione, zone panoramiche e un *antiquarium* che possa informare, comunicare e intrattenere i visitatori e gli studiosi che si recano a Dougga.

A questo aspetto di "museo diffuso", dovrebbe aggiungersi un importante programma di comunicazione per l'implementazione di una dimensione virtuale del museo stesso, che può sostenersi sia nell'ambito dell'*antiquarium*, in specifici settori dedicati alle proiezioni dei saggi di ricostruzione, sia per la comunicazione di un "museo virtuale" visitabile sulla rete da chiunque sia interessato.

L'aspetto della virtualità risulta oggi una delle forme più esplicite con cui un museo cerca di promuoversi e rinnovare l'interesse per le opere d'arte poste al suo interno, in un contesto turistico culturale sempre più esigente e competitivo.

Fig. 4: Dougga: Il paesaggio ricostruito della antica Thugga e il paesaggio archeologico a confronto.

2. Le tecnologie a supporto di un turismo culturale nel Maghreb

(Domenico Tosto)

La proposta di realizzare una rete di strutture museali, connesse tra loro, nelle zone archeologiche presenti in Tunisia nasce dall'idea di creare un sistema a supporto di un turismo culturale che trova sempre maggiore diffusione nell'area del Maghreb. Architetture piccole e ben inserite nel contesto paesaggistico, relazionate all'interno di una rete di altrettante strutture, e coordinate da azioni e sistemi di comunicazione integrati.

Il sistema si basa sull'apprendimento collettivo tramite il quale ogni museo è in grado di fornire informazioni, creare nuove attività e servizi e di adattarsi nel tempo, rafforzando sempre di più la sua posizione di paradigma culturale. Infatti il museo oltre a proporre l'idea di luogo in cui si conserva e preserva l'oggetto, punto di riferimento della raccolta di tutte le informazioni che riguardano la crescita e sviluppo della società, oggi deve confrontarsi con l'evoluzione di quella società di cui lui stesso ne preserva la memoria.

Una evoluzione culturale che trova nell'avvento delle nuove tecnologie, un valore aggiunto e un nuovo linguaggio di comunicazione diretto e globale.

L'interazione tra i beni culturali e le nuove tecnologie potrà creare numerose opportunità a livello conservativo, comunicativo e di sviluppo economico per quello che riguarda il ricchissimo patrimonio storico artistico presente in Tunisia e in tutto il Maghreb.

Fig. 5: Museo Virtuale di Ercolano

Fig. 7: The Virtual Museum of Iraq

Fig. 8: Museo Virtuale del Louvre

Il concetto di Virtual Heritage (VH) segna un cambiamento profondo, una vera e propria transizione tra paradigmi diversi; una trasformazione in cui le tecnologie della comunicazione e i processi di virtualizzazione dell'esperienza assumono un ruolo di primo piano.

Con il termine VH intendiamo l'ambito di applicazione per soluzioni tecnologiche e progetti di comunicazione del patrimonio culturale.

L'utilizzo delle tecnologie applicate al patrimonio architettonico e culturale crea un nuovo sistema di comunicazione che rende diverso, dinamico, il rapporto tra la conservazione e la fruizione del bene, che prima poteva essere considerato unico e unilaterale.

L'utilizzo delle ricostruzioni virtuali ha lo scopo di promuovere una nuova alfabetizzazione culturale che trova nelle tecnologie multimediali uno strumento di trasmissione e trasformazione dei dati in sapere digitale.

La realizzazione di strutture museali virtuali dà la possibilità a qualunque sito di diventare esso stesso strumento di promozione e comunicazione di se stesso e del territorio. La simulazione di un paesaggio che ormai non esiste più, proietta il visitatore in un ipotetico viaggio nel tempo che propone una nuova dimensione percettiva, esperienziale e cognitiva simile a quella che l'uomo ha nella realtà.

Inoltre l'utilizzo della realtà virtuale permette di fornire tutta quella parte di informazione che un museo non può offrire, al di là della presentazione degli oggetti che possiede che, il più delle volte diventa essenziale per la comprensione degli stessi, attraverso questa tecnologia l'utente si trova immerso all'interno di uno spazio che non esiste più ma dentro il quale può muoversi e cercare le informazioni richieste.

La Realtà Virtuale, superata l'iniziale obiezione per quello che può essere considerato come un ossimoro, è una tecnologia che applicata al patrimonio storico-culturale offre molteplici opportunità:

- catalogazione di oggetti tridimensionali,
- allestimento di musei e mostre virtuali,
- documentazione di interventi di restauro,
- ricostruzione di siti archeologici e di ambienti complessi di interesse storico-culturale.

Le scene tridimensionali ricostruite tramite l'utilizzo di software e grazie all'uso di immagini digitali ad alta risoluzione, oggetti tridimensionali ed effetti sonori, al giorno d'oggi possono raggiungere un elevato grado di realismo.

Elemento su cui si basa l'applicazione della Realtà Virtuale è il concetto di interattività, attraverso il quale viene consentito all'utente di muoversi in un ambiente ricostruito, cambiare visuale e compiere delle azioni come se questo fosse realmente presente nella scena.

Pertanto, in una stessa applicazione è possibile creare diversi "percorsi" predefiniti, ognuno dei quali con contenuti e informazioni multimediali diversi e appropriati al contesto di fruizione ed alle diverse possibili tipologie di utenti.

Le possibilità di strutturare ed organizzare le informazioni in modo appropriato, rende la Realtà Virtuale un potente e flessibile strumento di comunicazione e di diffusione del sapere digitale.

Fig. 9: Villa Livia: rapporto tra immagine reale e immagine virtuale (*Virtual reconstruction in the via Flaminia and Villa di Livia project*- di Eva Pietroni. Il Scuola Italiana di Archeologia Virtuale - Monselice (Padova)).

La realtà virtuale (VR) è un medium in cui i sensi umani sono circondati da (o immersi in) stimoli, parzialmente o interamente generati o rappresentati da mezzi artificiali, e in cui tutte le immagini vengono visualizzate secondo il punto di vista di un singolo osservatore, anche se in movimento.

L'utilizzo della realtà virtuale permette di simulare e processare in tempo reale tutte le informazioni che sono contenute in un modello di riferimento, e successivamente interagire con esso.

Tutte le tecnologie interattive e multimediali applicate ai musei virtuali sono realizzate con l'obiettivo di creare spazi educativi e ricreativi, percorsi conoscitivi vivaci e completamente personali.

Le persone all'interno del Museo possono seguire un proprio *personale itinerario*, un *processo fruitivo dinamico*, che permette di scegliere *diverse modalità di fruizione*, *diversi livelli di approfondimento* e una grande varietà di stimoli propedeutici.

Alla domanda che pone Maurizio Forte "ma perché è così importante la ricostruzione virtuale di un insediamento archeologico?", si può rispondere che al di là dell'impatto fortemente divulgativo, la ricostruzione virtuale è una informazione complessa e proiettiva dell'interpretazione che va oltre alla mera riproduzione grafica. Si tratta di una simulazione che permette di esplorare tridimensionalmente il modello attraverso infinite prospettive e in modo non intrusivo.

Le ricostruzioni virtuali permettono di fronteggiare numerosi problemi che riguardano i siti archeologici: aree non omogenee, edifici ormai distrutti oppure ridotti a delle tracce sul terreno e, non di meno, la possibilità di affrontare in modo concreto l'assenza di fondi necessari per interventi di restauro o manutenzione.

Il vantaggio nella realizzazione di una rete di strutture museali in Tunisia consiste nell'implementare i dati storici, scientifici e teorici in modo continuativo tanto da creare un sistema di saperi e conoscenze in digitale.

Un sistema che potrebbe offrire un layout chiaro e condiviso in grado di consentire a culture e mondi diversi di comprendersi reciprocamente, in modo tale da rendere ogni esperienza replicabile in altre situazioni e contesti che presentino analoghe situazioni.

3. Il Reverse Modeling come strumento di conoscenza dell'Architettura Antica (Andrea Manti)

Il processo di *Reverse Modeling* di una architettura consiste nella *traduzione digitale* del manufatto reale in una sua riproduzione virtuale, attendibile secondo una certa tolleranza. La *pipeline* metodologica prevede l'integrazione tra diverse tecniche di rilevamento, l'utilizzo dei dati rilevati come base di partenza certa per la ricostruzione digitale del monumento e l'interrogazione del modello virtuale per l'analisi degli aspetti

morfologici, geometrici, distributivi della struttura. I vantaggi nell'uso del modello digitale come forma conoscitiva dell'architettura si evidenziano, in particolare, nella capacità di poter interrogare i modelli, simulando forme di analisi non sempre possibili attraverso l'applicazione di tecniche di rappresentazione tradizionale. La definizione del modello digitale si ottiene mediante un complesso iter che richiede competenze nell'uso degli strumenti, nel controllo metodologico del processo stesso e nella interpretazione dei risultati, poggiandosi su una conoscenza eterogenea che spazia dai trattati dell'architettura fino agli studi sulle più avanzate tecniche di rilievo e modellazione 3D.

Nel campo del rilievo architettonico è sempre più ricorrente l'utilizzo congiunto di metodologie di analisi tradizionali con quelle digitali di ultima generazione. Questa ibridazione metodologica offre la possibilità di ottenere dati metrici strumentalmente differenziati che rappresentano un evidente arricchimento nella conoscenza del manufatto, poiché ne consente una lettura multi-dimensionale e multi-livello. Bisogna porre attenzione nel collegare i metodi di conoscenza tradizionali con quelli digitali perché un evidente svantaggio consiste nella possibilità di trovarsi in una situazione nella quale non si abbia una sufficiente conoscenza né dei primi né dei secondi. Tale condizione può portare alla possibilità di non sfruttare appieno le potenzialità di analisi oggi offerte dagli strumenti. Nell'ambito delle tecniche di rilievo digitale è essenziale quindi conoscere sia gli strumenti utilizzati sia la teoria che vi è alla base del funzionamento degli stessi, al fine di poter interpretare correttamente e valutare la qualità dei dati acquisiti. Questa pre-condizione risulta molto importante nell'utilizzo delle tecniche di rilievo 3D e delle tecniche di *Reverse Modeling* applicate nell'ambito architettonico. La nascita di questa materia è legata alle sperimentazioni avvenute fin dagli anni '90 in diversi settori scientifici. Nell'ultimo decennio alcuni dei processi contenuti nel campo del *Reverse Modeling* hanno vissuto una rapida evoluzione, legata principalmente agli sviluppi tecnologici in ambito strumentale ed in quello dei sistemi per la gestione delle informazioni digitali. In particolare l'applicazione delle tecniche di rilievo 3D da *laserscanner* e fotomodellazione digitale, hanno favorito l'estensione delle sperimentazioni anche ad altri settori come il Design e l'Architettura. In quest'ultimo campo sono diversi gli esempi che hanno segnato gli avanzamenti nei metodi di applicazione del rilievo 3D di manufatti reali a diverse scale, dal livello scultoreo a quello architettonico, dall'urbano fino al territoriale. Nella maggior parte di questi esempi risulta evidente come la sperimentazione di queste tecniche abbia avuto la principale finalità di ottimizzare il processo di acquisizione e modellazione delle forme, cercando di massimizzare le potenzialità degli strumenti e la qualità del risultato finale, minimizzando il tempo di elaborazione dei dati acquisiti. Gli esiti delle ricerche evidenziano la capacità di questa metodica di giungere a risultati eccellenti dal punto di vista della affidabilità nella ricostruzione digitale delle forme reali, fornendo modelli tridimensionali utili sia per la promozione del Bene Culturale, che per la sua analisi materica e dimensionale.

La fase di rilievo *in situ* si è concentrata sui resti dell'antico Teatro Romano di Dougga. L'esperienza, che è stata promossa dai docenti del Laboratorio di Sintesi Finale *Analisi dell'Architettura e della Città Mediterranea* della Facoltà di Architettura di Reggio Calabria nel Marzo del 2010, ha permesso di affrontare anche le tematiche relative alla modellazione tridimensionale e alle forme di rappresentazione digitale. Le analisi che sono state svolte hanno consentito di individuare dei moduli che regolano l'intero insieme. Il percorso seguito è stato quello di raccogliere tutte le informazioni utili per la generazione del modello tridimensionale dell'intero teatro, con particolare attenzione alla ricostruzione della forma originaria. In questa fase di analisi sono state integrate le informazioni provenienti dagli strumenti di rilievo con gli elaborati grafici tradizionali. La complessità del sistema architettonico ha richiesto un ulteriore passaggio: la scomposizione semantica del teatro nelle parti che lo compongono (gradonate, arcate, colonne, volte, ecc.), confrontando gli elementi individuati con i modelli dei trattatisti classici per verificarne la reciproca corrispondenza.

Il teatro è addossato alla collina che segna l'accesso principale alla città, tanto che è stato sfruttato il declivio naturale dell'altura per la costruzione dell'emiciclo e della cavea. Costruito intorno al 169 d.C. grazie al cittadino di Thugga, Publius Marcius Quadratus, l'intero organismo risulta a tutt'oggi ben conservato. L'architettura presenta le disposizioni classiche del teatro romano: gradini a semicerchio che formano la cavea per gli spettatori e una grande scena. La cavea è sopraelevata di 15 metri rispetto all'orchestra, addossata al pendio della roccia, per una evidente scelta di solidità dell'edificio e poteva contenere fino a 3.500 spettatori. Si compone di 19 gradonate disposte su più livelli e di gallerie di circolazione; il muro perimetrale presenta 5 porte. L'orchestra, posta sul boccascena, è relativamente piccola rispetto alla dimensione dell'intera struttura. Il teatro è dotato di alcune cisterne ricavate sotto il pavimento del portico, dato che la irregolarità e la pendenza del terreno aveva dato modo di sfruttare un discreto spazio sottostante. L'acqua serviva alle *aspersiones* per rinfrescare gli spettatori nei giorni caldi, come testimoniano le fonti letterarie. La *scaenae frons* presenta tre porte corrispondenti alle *valvae*, il *proscenium* doveva essere coperto da un tetto in legno che migliorava l'acustica e per realizzarlo si è sfruttato il dislivello di quasi 20 metri tra la base della nicchia e la cima dell'edificio, suddivisa su vari terrazzamenti. Nel processo di realizzazione del modello virtuale la tecnologia informatica ha avuto un ruolo fondamentale, offrendo la

possibilità di controllare nello stesso tempo il complesso sistema architettonico e i suoi singoli componenti costitutivi. Partendo dai dati del rilievo sono state estratte sezioni e viste ortogonali dei prospetti, che sono divenute le basi di partenza per la generazione delle primitive grafiche utili per approssimare il dato rilevato. Successivamente è stato quindi generato un modello matematico che rappresenta le forme reali, dotate spesso di imperfezioni ed asimmetrie per il processo di usura o di fabbricazione. In tal senso, il primo passaggio necessario è stato quello della riorganizzazione di tutte le informazioni raccolte durante la fase di rilievo dei resti del teatro attraverso la creazione di un *database*, all'interno del quale si è proceduto ad una pulizia di tutto ciò che non era inerente alla realizzazione del modello. Lavorando per parti modulari è stato composto un vero e proprio abaco di elementi singoli, il cui assemblaggio ha portato alla ricomposizione tridimensionale del corpo di fabbrica che possiede tutte le caratteristiche metriche derivanti dal rilievo. Per quanto riguarda la *texturizzazione* del modello si è scelto di attribuire a tutte le superfici un materiale neutro con l'intento di dare un effetto "*maquette*" all'oggetto, al fine di agevolare la lettura delle varie parti che lo compongono. Il percorso di analisi non si è concluso con la realizzazione del modello virtuale, ma sono stati redatti anche dei disegni bidimensionali dell'intero modello (pianta, sezione, prospetto), ottenendo delle rappresentazioni utili all'analisi di alcuni dei principali componenti dell'architettura. Questo "ritorno" alla rappresentazione bidimensionale dal 3D avvalorava un concetto sostanziale del *Reverse Modeling*, ovvero che il modello tridimensionale non sia il punto di arrivo dell'intero processo, quanto la rappresentazione iniziale di un complesso contenitore informativo che deve essere interrogato in funzione delle analisi che si vogliono effettuare.

* Le elaborazioni grafiche presenti in questo articolo sono state realizzate nell'ambito del Laboratorio di Sintesi Finale "Architettura e Analisi della Città Mediterranea" corso di "Rappresentazione dell'Architettura".

Exploration of the open spaces in Varna as a component of the cultural landscape

Prof.arch.Todor BOULEV, Assoc.Prof. Milena PETROVA Ph.d.Eng
Faculty of Architecture, Varna Free University "Chernorizets Hrabar", Varna, Bulgaria
E-mail: boulev@abv.bg, as@vfu.bg

1.City of Varna, Bulgaria

The city of Varna is the third largest in Bulgaria with population of approximately 500 000 people. Situated at the Black Sea coast, it is a major educational, industrial, sea port and resort centre. The various relief, the bay and the two lakes create an unique natural background (Fig.1).

The city is literally surrounded with the adjacent aquatic areas and forest-grown slopes and "plateaus". In respect to them, there have developed some historical and typical urban landscapes with many open green spaces, which create an attractive resort and tourism atmosphere.

For the preservation and renovation of this atmosphere, in particular, it is important that the qualities of the urban landscape should be recognized, safe-guarded and enriched.

Fig. 1: Satellite view

In 2010 – 2011, by assignment of the Municipality of Varna, a team of VFU "Chernorizets Hrabar" – lecturers and students with Head of Research, Prof. Arch. Todor Bulev, elaborated a special methodology to study and comprehensively evaluate the open spaces in the city of Varna as an essential supporting element of the cultural landscape – register of the open green areas of the city of Varna. The methodology defines a set of natural, urbanistic and cultural characteristics, which in their combination allow to make an overall evaluation of the characteristics of the open spaces (functional, ecological, aesthetical, etc.), by paying special attention on the biological components. The paper illustrates the methodology and the first stage of the studies on the territory of the city, namely, the street areas, and the smaller parks and gardens. The research was conducted on the basis of the available documentation, aerial photographs and terrain surveys. The materials from the study have been summarized in map-based materials according to the separate parts of the city and „passports” of the separate areas, which are presented on paper as well as in digital form.

Forthcoming is an analysis of the coastal cultural landscapes, the parks in the city and in the suburban areas.

Essentially, the register is a specialized information system for monitoring the condition of the open green areas of the Municipality of Varna, the various plant species therein, their exploitation, management and keeping. The register comprises the whole variety of green areas and all the territory of the Municipality, including the city parks and the territories envisaged for building suburban and countryside parks, as well as parks with special designation.

Employing the methodological approach, there are the principles set in the Register for: continuity and unity of the green system; for the comprehensive interdependence of the quality of the urban spaces, for their dynamics and development over time, and for the use of the register for efficient management of the green system in Varna as a whole. Therefore, the register contains not only system (base) data, but also a system of the necessary primary evaluations. Furthermore, it also allows (through the structuring and formalization of information) the performance of various analysis on separate problems and territorial units, facilitating the designing, programming, valuing, and management decision taking, related to the green system of the Municipality of Varna. The register will be used also in the elaboration of the integrated plan for regeneration and development of Varna.

The register of the open green areas serves to solve the following tasks:

- ❑ Comprehensive environmental assessment of the green areas;
- ❑ Evaluation of the potential of the spaces for creating the green system;
- ❑ Elaboration of an assignment for detailed structural plans;
- ❑ Elaboration of assessments of detailed structural plans;
- ❑ Elaboration of investment programmes for landscape gardening and shaping out the spaces, etc.

The first stage of the register elaboration provided also an idea of the great variety of nature and characteristics of the open spaces, the variety of the urban landscapes and their problems.

The elements studied at the first stage were the following: trees in good and bad health, and saplings, which have not been registered to date; registered trees, which have caught a disease; vanished or very sick trees; current condition of the registered trees; individual grass areas and grass areas on the streets and roads; bushes and groups of bushes; planting flowers, cachepots, flower pots; water taps, fountains, water areas, canals; low and high luminaries; waste bins and containers; single benches and groups of benches; kiosks, advertising panels and billboards; children and sports playgrounds; monuments; bus stops with and without a shelter. The changes in the street regulation have also been reflected.

2. Central Urban Zone (Fig. 2, Fig. 3, Fig.4)

Fig. 2: Central urban zone – satellite view

Fig. 3: Central urban zone – work sheet

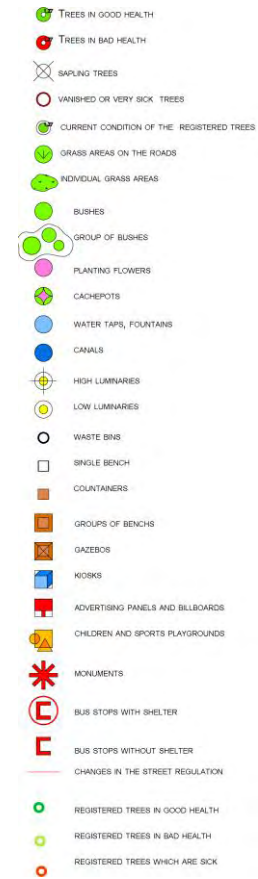

Fig. 4: Legend

Just as well as in a number of other Bulgarian cities (Sofia, Plovdiv, Burgas) the central core area is characterized by high level of construction density, small parameters of the real estates with individual landscape gardening and clearly outlined street spaces. Streets are comparatively narrow in Varna, wide just between 8,0 and 10,0 m. Sidewalks are 1,5 – 2,0 m wide, yet, nevertheless, they have trees planted on them, creating an unique atmosphere of „arches” of greenery. A major problem is their maintenance and the timely shaping out of their crowns. A lot of the trees are now in a very advanced age and they have to be gradually replaced. The area has a clearly distinct specific character of an urban area.

3. Residential district „Asparuhovo”(Fig. 5, Fig. 6)

Fig. 5: Residential district „Asparuhovo” – Fragment satellite view

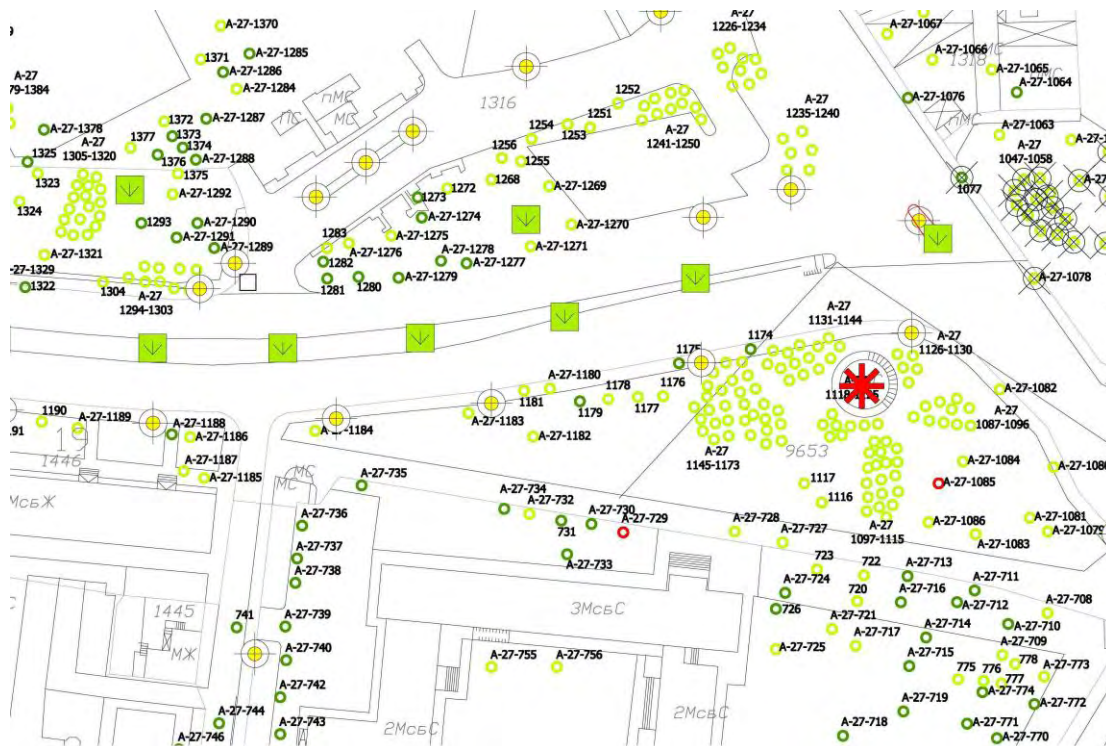

Fig. 6: Residential district „Asparuhovo” – work sheet

This district is an example of an urban zone, typical for the periphery of the big cities in Bulgaria. Originally, a village, cut off from the urban core – with large plots and lower level of construction, the residential district has been gradually urbanized; a public core area has been developed, as well as a park and a main street. Nevertheless, the urban landscape has preserved its spacious open areas, where street landscaping is dominating the view vis-à-vis the architectural shapes, and this specification renders it with a particular value.

4. Residential complex „Vladislavovo”(Fig.7, Fig.8)

Fig. 7: Residential complex „Vladislavovo” - Fragment satellite view

Fig. 8: Residential complex „Vladislavovo” – work sheet

The complex is a typical example of large-size housing construction, in specified urban territories, following the spirit of the Athens Charter, and oriented towards the large masses of city dwellers, while solving the housing problems, typical for the big cities.

The buildings are 8-10-storey high. They outline yards, which are sometimes quite big in size, where greenery is just yet to be imported and developed. Within those territories, important are not the streets, but the spaces between the apartment blocks, which create the characteristic urban landscape.

5. Garden square „The Red Square”(Fig. 9, Fig. 10)

Fig. 9: Garden square „The Red Square” - Fragment satellite view

Fig. 10: Garden square „The Red Square” – work sheet

Quite typical for the urban environment, which developed from the end of the 19th until the end of the first half of the 20th century, is shaping out small, local community or public gardens and garden squares. Some of them, just as the one mentioned here, have undergone many transformations, yet, they have remained those indispensable „oases” in the ever more dense urban development. The plant combination and network of alleys are carefully studied and create a typical atmosphere.

The research done in the Register allows making and carrying out characterization of the urban landscapes (Fig.11), as well as directions for the green system development. Particular interest presents also the accompanying study of the visual communications (Fig.12), which are yet another characteristic feature of the urban landscape, creating the spatial-visual interaction between the separate parts of the city. These researches have become a part of the General Structural Plan of the city of Varna, which is already adopted as a basis for the city development.

Jordanian Villages and Landscape: More Sustainable Planning, Less Physical and Social Degradation

Ahmed ABU AL HAIJA¹, Franca GIANNINI²

¹ Faculty of Engineering – Philadelphia University, Jordan

² Faculty of Architecture, University of Genova

E-mail: alhajja2@gmail.com, francagiannini@libero.it

Abstract

In traditional Jordanian settlements, the rapid urban development and the abandonment of most of the rural areas, due essentially to the lack of national policy in controlling the process of planning, has caused serious variation of architectural character and urban landscape. Local territorial laws and building regulations have contributed both positively and negatively to this accelerating transformation.

This paper illustrates some aspects of Jordanian villages concerning their typology and architectural traditional elements. Particular attention is given to the urbanization impacts on the local communities, in light of the transformation of rural activity due to the reduction of agricultural areas, which has negatively affected the physical integrity of the productive lands, altering the characteristics of the ecosystem and the social system. This process is irreversibly threatening the rural character and natural landscape of valuable and rare areas, whereas 97% of Jordanian territory consists of desert areas.

The objectives of this research are to highlight the importance of conserving the original habitat of these villages and to support the characteristics of their rural activities, introducing sustainable concept in Jordanian planning strategy. This research also advocates the need for the enactment of specific law for integrated planning -at different levels- and introduces specific guidelines for intervention methodology, concerning landscape and architecture, with scrupulous interest in European experiences (especially the Italian) in respect to the protection of tangible and intangible cultural human values, in terms of conservation of memory of places, traditional identities, in a process of sustainable development. Particular attention is given to the process of formation of the Landscape Territorial Plan with regard to the European Landscape Convention.

Keywords: Traditional Jordanian settlements, Rural transformation, Integrated Planning, Italian Landscape Experience

1. Introduction

Several historic populations have been established in Jordan since the Neolithic period (8000 B.C.). Traces signed by ancient objects like Dolmens, Gromlesh and different civilizations have been steeled in Jordan like Nabatanian, Persians, Greek, Romans, Byzantine, and Islamic (Abu Shmeis: 2008).

According to Ottoman tax registers, Jordan was well-populated until the 16th / 17th century, in which was produced a surplus of agricultural products. In the 18th and 19th century the Ottoman Empire declined and concentrated its armies at the western and northern borders to fight a series of wars. The villages of Jordan declined again and fell victim to internal strife and Bedouin raids.

Fig. 1
Source: <http://ar.wikipedia.org>

People left their houses and again turned to the way of life of semi-sedentary agriculturalists (Knauf, 1985). Semi-sedentary agriculturalists were confined to the mountain regions, while the nomads were located traditionally in the south and the east of Jordan.

As a consequence of the occupation of Palestine in 1948 and the war of 1967, more than one million refugees have mainly relocated to Amman, Zarqa and Irbid, causing rapid expansion of these cities, which has had effects on the rural communities from economical, cultural and social points of view (Potter, 2009). Many families left their agricultural lands and immigrated to the cities. As a result, numerous traditional houses were abandoned, deteriorated and demolished. The interrelation between the natural landscape and the traditional rural contexts altered profoundly in these years. The genuine nomad (Bedouin) lifestyle in relation with nature, habits and costumes has also changed. The source of their economy depends mainly on the state's aid and on some commercial activities created by the foreign tourists visiting the desert; their tents were replaced with cement blocks in order for them to be settled in the desert. As a result, the millennia-old natural habitat of nomads has been irreversibly altered in few years (Abu Al Haija, 2011).

This rapid urban development urged the Jordanian Government to institute territorial legislations in order to control and orientate this process, to conserve as much as possible green areas and historical centers. However, the planning system has only succeeded marginally in regards to the protection of natural resources and the historical fabric of the people. In fact, there is until now no applicable territorial plans work at the macro scale level to control the process of development, while local urban plans are generally created for land use zoning rather than strategic plans. Effectively, weak attention to public facilities in relation with appropriate standards is witnessed; in addition, the absence of sustainability concepts in urban development, weak housing and industrial polices, weak historical center conservation and lack of environmental and hydrogeologic protection plans.

The Jordanian current situation is also extremely difficult because of clear contradictions between reality and governmental intervention, as seen in the following examples:

- **Economically**, The shortage of agricultural lands in Jordan (only 3.1% of the Jordanian territory) (Al Gazou, 2008). The urban plans ignore this situation by permitting new models of horizontally huge cities (Amman, Irbid, Zarka, Madaba, etc.) which causes loss of agricultural lands, waste of energy and excessive infrastructure cost.

- **Socially**, the Jordanian society has strong tribal and social relationships. The tendency of the urban plans decreases this sense of community and relationships; importing western subdivision models of residential patterns also in the historic areas as well.

- **Physically**, the major part of the traditional Jordanian architecture was appropriate to the local situation, regarding available materials, technique, climate, etc.. The demolition of these agglomerations, rebuilding them with cement blocks is considered inappropriate, assuming also a chaotic aspect in relation with the urban context and breaking off the old center's physical integrity. Consequently, the typical Arab's urban fabric has been changed completely, establishing large streets and houses with several windows oriented to the outside, the disappearance of the patio and semi public spaces , and so on. (Abu Al Haija, 2008).

The administrative authorities and urban regulatory bodies (Ministry of Tourism and Antiquities, Ministry of Municipalities, and the various urban Municipalities) of the Jordanian territory are trying to improve the economic infrastructure and urban development strategy (see Ministry of Tourism, 2005). However, historic centers continue to be neglected and a comprehensive strategy to protect the old centers has yet to be articulated and laws promulgated. At the same time, the rare rural areas located in the south and northwest of Jordan are diminishing rapidly, and also the natural landscape character is transforming continually.

2. Framework of Jordanian Laws and Territorial Planning

2.1 The Jordanian Laws in Force Regarding Historical Centers and Landscape

Five Jordanian laws pertain to urban planning with particular reference to the conservation of the historic buildings and natural landscape. These laws are:

- a- "Planning the Cities and Villages Law" No. 79 (1966) and its amendments;
- b- "Agricultural Law" No. 92 (1966);
- c- "Antiquity Law" No. 21 (1988);
- d- "Protection of Urban and Architectural Heritage Law" No. 5 (2005).
- e- "Environmental Law" No. 52 of (2006)

Law No. 79 (1966) concerns regional and urban regulation in general and some references are dedicated to the conservation of historical buildings and urban fabric. The only article concerning the

protection of the historic buildings and centers states: “The conservation of sites, caves, buildings have archaeological or historical interest...” These references are very general; they do not clarify how to classify historic or archaeological elements; also they do not elaborate the meaning of preservation. As a result, the laws in force are vague and open to various interpretations as to the legal definition of preservation.

Agricultural law No. 92 (1966) deals with general indication in one article the duties and responsibilities of the Ministry of Agriculture concerning the agricultural land management.

Law No. 21 (1988) protects archaeological elements which are defined as “all constructions built before the year 1750”. Buildings which were built after this period are not protected under this law. As a result, it is important to recognize that a vast number of buildings in Jordan are less than 250 years old. Therefore, they are not protected under the law. Yet, the conservation and preservation of many of these is imperative for historical, socio-cultural and architectural reasons.

In Law No. 5 (2005) the Jordanian government recognizes officially for the first time the importance of the traditional (not only the archeological) buildings for the national identity and cultural heritage. Practically, no clear effective result protecting these categories of buildings is seen until now on specific maps because of several technical reasons, which could be reassumed as fallow (Abu Al Haija, 2011):

- The shortage of documentation regarding traditional buildings since there is no archiving system;
- Urban plans do not yet select and classify the traditional buildings according to their age of construction, historic and artistic value.

Law Number 52 of (2006) has established general indications in the conservation of natural resources and in respect of the environmental context in project elaboration and implementation. This law has also indicated the necessity to elaborate twelve technical norms concerning particularly the protection of nature, the environmental impact assessment, and the regulation of natural reserves and national parks.

2.2 Territorial Planning at Macro Scale Level as Practiced in Jordan

Although Law No. 79 makes reference to regional planning as a means to better control the territory, neither regional nor inter-regional plans have been adopted until now in Jordan. Only two territorial plans were elaborated in the last 5 years, but they are still not approved. The first one is the “Amman Metropolitan Growth Plan,” which has been presented to control the rapid development of the Amman Area. It is structured at several scales simultaneously in order to guide the planning process for an anticipated population growth of Greater Amman to 6,500,000 persons in 2025. The Plan has been prepared under the guidance of the Greater Amman Municipality Council, the Central Government Ministries, and the Mayor’s Roundtable.

Fig. 2: The new extension of Amman territory is about 1680 km² mainly on agricultural areas. Source: (Greater Amman Municipality - 2008)

The plan illustrates the location of existing areas accommodating residential and employment uses within the overall Metropolitan Area, as well as the preferred locations for the future expansion of settlement. It also details the projected future locations of new roads, public transit corridors, major natural heritage sites, and areas for more intensive mixed-use development. The plan has been developed according to different layers throughout its duration. Thus, the approval of this Plan also follows the ongoing development of these layers. The second territorial Plan, which is still not public but under revision, is Al Balka Comprehensive Plan.

The planning process in Jordan depends substantially on “Local Master Plans”. In reality, the experience of the major part of the Local Master Plans--adopted until now by the relevant authorities--demonstrated both methodological and technical problems. In these plans, the historic areas seem generally frozen. Practically, the development process is stronger in the old city centers than in the outlying areas. As a result, the development or the conservation in the old rural centers is generally less controlled than in the new urban areas. Other problems associated with these plans are the boundaries of the historical areas, which are not clear or not based upon a particular study or approach. Thus, the border of the historic areas is not precise or recognized officially by the Local Authority. This problem indicates that the historic areas are not regulated by specific norms and urban

regulations. The agricultural lands are under a huge process of transformation, but the physical plans in Jordan still don't consider the rural landscape as tangible and intangible heritage. Consequently, the local populations still need more awareness activity regarding their rural heritage without compromising the cultural, historical and landscape values.

3. Jordanian Villages

Before the establishment of Jordan as an independent state in 1946, the Jordanian population was mainly composed of semi-nomads who settled in villages close to the fertile lands of the country, and nomadic Bedouins who had previously wandered in the desert of Arabia (see: Bin Mohammad, 1999; Shryock, 1997). The traditional Jordanian villages represented places of stability for the semi-nomadic population, where emotional attachment and a physical context became the signs of local national Jordanian identity. These villages were a typical result of natural habitat production, where the community in certain circumstances collectively creates its own common culture, symbolic values and characteristic living environment, producing specific forms, typology and a compact urban fabric suitable to their habits and lifestyles. This production of the habitat proper begins with the initiative of a familial bond, evolving without any pre-programmed projects to authentically reflect the collective and individual needs. People had the capacity to create their own shelter depending on social collaboration, rather than through the intervention of the State or by following particular norms and obligations encouraged by any local administrations. The spontaneous urban texture and architecture in these villages reveals the necessities of having minimum spaces to live, reducing the size of units, openings, and structural forms, and inventing typologies that reflect particularities of the vernacular architecture in Jordan (Abu Al Haija, 2011).

Fig. 3: The Village of Dana in south of Jordan , Photo was done by Abu Al Haija in 2011

The semi-nomadic population has lived many hundreds of years in small settlements cultivating the fertile lands of the surrounded areas, grazing sheep and producing milk and cheese. Particularly, after the year 1970, several groups gradually moved to new quarters located close to their traditional villages. The lack of substantial services and public transportation in the original villages favoured the displacement and, consequently, the abandonment of these villages, which thereby provoked gradual physical deterioration of the buildings and place alienation among the indigenous populace. "Alterations negatively contrast with the authenticity of the pre-existing architecture" (Sidónio Parda). Figure n.4 shows some of the abandoned Jordanian villages located in the south, centre and north of the country.

Fig. 4: some abandoned Jordanian villages. a: Dana Village, b: Namteh Village, c: Hosban Village
Photos was done by Abu Al Haija in 2010

Recently, the problem of the major part of the Jordanian villages concerns particularly their transformation from articulated rural areas compatibly organized respecting the environmental conditions and cultural needs, to a total state of urban and architectural confusion. Most of the agricultural activities are abandoned and replaced with governmental administrative jobs. The transition from rural society to urban society has had a profound impact on population attitude and on the landscape. The younger generation has abandoned the traditional activities, selling their agricultural, inherited lands. But these regions, such as Ajloun in the north west of Jordan, are still very poor economically in comparison with the new urbanized areas mainly localized in the surrounding areas of Amman. This reality has led to dysfunctional spaces and landscape deterioration, due also to the over subdivision lands, which can be divided in 4000 square meters, in order to satisfy the heredities.

Therefore, the Local Master Plans do not adhere to any criteria or methodology to conserve or protect historical centers or buildings. For example, there is no technical report explaining the methodology of intervention in the old center (Abu Al Haija, 2008). Figure 5 shows the transformation of the local architectural style in the last century

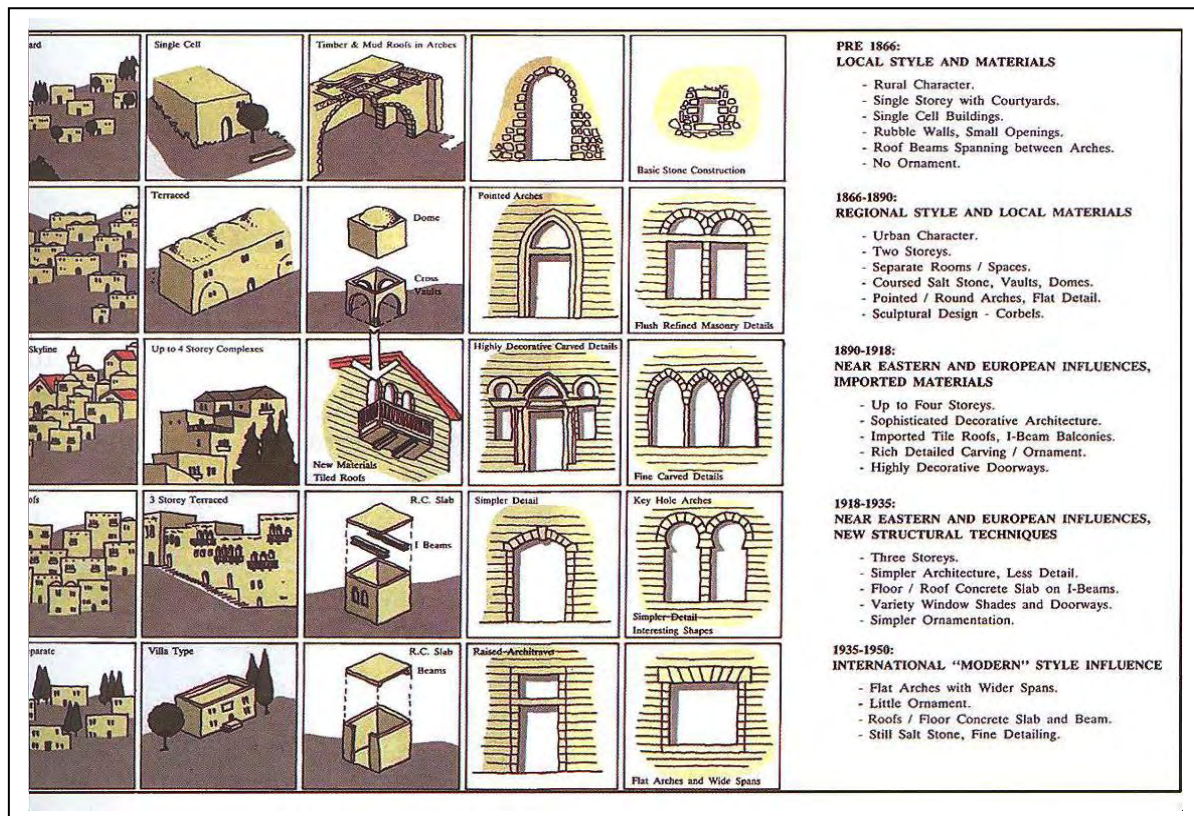

Fig. 5: historic development of traditional architecture in Jordan (Salt old center). Source: Khatib. R. 2008

4. The Italian Experience and the European Landscape Convention

4.1 The “Regional Landscape Spatial Plan” in the territorial governance process

The European Experience, in particular the Italian case, can constitute an important reference for the Jordanian State, which also has a valuable historical landscape and old settlements and cultural heritage.

The European Landscape Convention (2000) represents the most important legislative and cultural reference that the majority of European States is adjusting. It had influenced the territorial policies, integrated with the landscape theme.

One innovative aspect of this Convention deals not only with the extraordinary landscapes, but even with ordinary areas and deteriorated places, in order to establish a quality of landscape in all components of the territory. For a comprehensive survey about the situation after the European Landscape Convention a specific study (Voghera, 2011) can be seen, that discusses the legislative innovations, policies, plans and methodologies for evaluation which were developed by various countries during the ten-year period following the approval of the Convention.

In Italy with the “Italian Cultural Heritage and Landscape Code” or “Urbani Code” (2004), that promotes the landscape planning and regional laws, there is a completion of a normative codification for landscape that, at least in its statement of principles, seems to be one of the most advanced in Europe.

Now the “Regional Landscape Spatial Plan” is really the fundamental support of the territorial governance process. (Giannini, 2011). In the new context, the important theme of agricultural landscape and rural settlements is addressed, and there is an important production of the studies on historical agrarian landscapes and on types of rural settlements related to agricultural activity.

Italy's rural landscape, the fruit of several thousand years of history, has always been recognized as one of the fundamental elements of the cultural identity of that country, and there is an important production of the studies on historical agrarian landscapes and on types of rural settlements related to agricultural activity.

Rural landscape constitutes a fundamental resource, resulting in an added value for productions with designation of origin and forming a key element for the development of tourism and for biodiversity tied to the quality of the cultivated areas and species introduced by man, thus representing an aspect characterizing the quality of life in rural areas.

In recent decades, the Italian landscape has been affected by progressive deterioration, which is jeopardizing its qualitative features (Mantino, 2008)

The “integration” is the actual theme in Italy, also in reference to rural areas: not by chance the UNISCAPE (European Network of Universities for the implementation of the European Landscape Convention) is now organizing in Florence a seminar called “Rural Landscapes: Towards A Better Integration Of Rural Development Policies, Urban And Landscape Planning”. The aim of the seminar is to promote a debate on the current state of the research perspectives for rural and peri-urban landscapes. Particular reference will be given to the various contributions and knowledges that, with a trans-disciplinary point of view, confront this theme by challenging themselves to integrate spatial, urban and landscape planning with the guidelines of the agricultural and rural development policies.

The theme of landscape, whose importance is ratified in the Italian Constitution, requires an integrated multicultural approach, as recognized by the innovative contents – even on the cultural level of the European Landscape Convention, as well as by the evolution of the legislative framework and the various sectoral policies. One only needs to think of the landscape planning promoted by the “Urbani Code”, and the role of landscape as strategic objective in the National Rural Development Plan, 2007/2013 (PSN Piano di Sviluppo Nazionale) and in agricultural policies, 2014-2020.

In the presentation of the Seminar it is stated: “The pursuit of these objectives with coherent and effective actions requires the support of experts specifically trained and the multi and trans-disciplinary [sic] collaboration of experts from various sectors, as well as between the worlds of research, education and public authorities and professionals. Any action able to modify the quality of landscape contributes in fact in an essential way to economic development and to the improvement of the quality of the environment and life of the population. The most recent agricultural policies have stressed clearly how important it is that landscape becomes a paradigm of reference in various actions of planning, designing and managing the rural areas, also in relation to the increasing awareness of the social and economic value that a synergistic union between agricultural production and territorial resources has, as well as the potential worthiness of the agricultural sector on the social and environmental level for urban spaces”.

The Convention emerges as well from the definition of landscape (art.1) (“Landscape” means an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors”) considers the landscape as a problem of quality in all places of life of the populations and it concerns landscapes that might be considered outstanding as well as everyday or degraded landscapes. The Convention requires integrating landscape into its regional and town planning

policies and in its cultural, environmental, agricultural, social and economic policies, as well as in any other policies with possible - direct or indirect - impact on landscape.

The Convention states that “the landscape is a key element of individual and social well-being and that its protection, management and planning entail rights and responsibilities for everyone”. It explicitly calls for a greater involvement of the local populations in government of its landscapes.

4.2 The Theme of “Landscape” In the New Regional Urban Planning. The Apulian case.

The theme of “landscape” (in its most complete conception and as a dynamic process) is therefore experiencing an important moment in Italy for the need induced by the new Regional urban planning laws to integrate environmental and landscape content in territorial and urban planning and to evaluate the plans (general and by sector) in terms of environmental sustainability, through the instrument of Strategic Evaluation (VAS). Precisely, the landscape content requires furthermore, more than any other thing, to make reference to a method of co-planning between diverse levels, since it is not possible to confine it in administrative perimeters.

We are thus dealing with “work that is under way...”

In the very heterogeneous mosaic of the twenty Italian Regions, we have selected as a meaningful example the case of Puglia: a region that presents extremely varied and diversified “rural systems” that are characterized by the presence of a wide variety of naturalistic, landscape, architectonic, cultural, social and productive resources that, although with different levels of harmony and integration between them, they converge in qualifying themselves and rendering themselves unique.

Within the context of the different Italian Regions, which are very heterogeneous, but on their way towards revision, the Puglia region in particular is experimenting in a complete way the “new phase of Italian planning”, building in an organic and innovative way a new system of regional planning, in concert with the Ministry of Cultural Heritage and attempting co-planning at a Provincial and Municipal level.

The new conception of planning in Puglia puts the improvement of life quality at the centre of the political initiative, as well as the valorization of the territorial heritage, with great attention given to landscape, meant as a rediscovery and testimony of identity, synthesized by the natural and cultural values of the territory. In this new vision, the territory becomes an instrument of promotion and socio-economic development that is durable and sustainable and is not simply a mere physical support that is able to be adapted to hosting any type of activity, ignoring aspects of quality and vulnerability. (And in particular this has happened to the rural territory).

The lack of an efficient framework of general settlements in a large scale has until now impeded the construction of cohesive and shared scenarios of protection and development of the territory. In the knowledge of this long delay, for the construction of the new planning system, the Regional Administration founded its line of action upon the realisation of a basis of shared and certified knowledge of the entire regional territory and on the involvement of all the local institutions, with the conviction that institutional and social cooperation is one of the essential premises for the efficiency and sustainability of the decisions made (Barbanente, 2008).

As the scientific Coordinator of the PPTR (Piano Paesistico Territoriale Regionale) of Puglia, Prof. Magnaghi of the University of Florence states “a plan is, more than anything, a cultural event, in that the transformations that it is able to induce are not measured only by its technical normative adhesion (in Puglia scarcely efficient, given the historical management and applicative planning deficit), but also by its capacity of transformation of the culture of the actors who are producing the territory and the landscape on a daily basis.

4.3 The Regional Landscape Territorial Plan: Articulation, Strategic Planning Connotation

The PPTR, as a technical instrument is articulated in three sections: the Atlas of Environmental, Landscape and Territorial Heritage, the Strategic Scenario and the Rules. The whole apparatus of the Plan is available on the site of the Puglia Region (<http://paesaggio.regione.puglia.it>).

The “Atlas” constitutes the cognitive framework of the PPTR, which organizes the body of information deriving from the various fact-finding operations that were launched in the past, enriched by original investigations carried out by the Technical Secretary of the PPTR (M.Valeria Mininni Coordinator). The sections of the Atlas at various scales are articulated in analytical levels, with structural synthesis and descriptions of the objects of the heritage.

This cognitive structure is orientated to the description of the regional peculiarities and the highlighting of the settlement rules that they have produced.

The historical investigation tends to rebuild, in the long term, the major phases of territorialization to investigate the formation of the characters of the rural landscapes, assigning to some of them a “traditional” character; to analyse the forms of the settlement throughout its evolution, especially in the variation of the relationship between a built space and an open space; to define the “territorial and

landscape figures”, a unit of “minimum decomposition of the territorial individuality with a specific morphotypological structure”.

The Plan directs great attention to contemporary dynamics, in order to record the nature of their effects upon the major invariant structures that connote the regional territory.

The desire to highlight the “long duration” of the dynamics that have structured over the course of time the formation of the peculiarities of the landscapes of Puglia is an attention to the past that is directed essentially at establishing roots within the territory for the choices of the “Landscape Scenario” contained in the second part of the PPTR, a prefiguration of the medium and long-term future of the territory of Puglia. The scenario has served as a strategic reference for “starting processes of public consultation, actions, projects and policies, directed towards the realization of the future that it describes.”

The PPTR (Piano Paesistico Territoriale Regionale): The general objectives of the “Strategic Scenario”:

Objective 1: Realize the hydrogeomorphological equilibrium of the hydrographic basins

Objective 2: Develop the environmental quality of the territory

Objective 3: Valorize the landscapes and the long-term territorial figures

Objective 4: Redevelop and valorize historical rural landscapes

Objective 5: Valorize the cultural-settlement identity heritage

Objective 6: Redevelop the landscapes that have been degraded and the contemporary urbanisation

Objective 7: Valorize the aesthetic-perceptive structure of the landscapes of Puglia

Objective 8: Valorize the slow fruition of the landscapes

Objective 10: Define territorial and landscape quality standards in the development of renewable energy

Objective 11: Define territorial and landscape quality standards for the settlement, redevelopment and reuse of the productive activities and infrastructure

Objective 12: Define construction quality standards, as well as urban and territorial ones in the urban and rural residential settlements.

4.4 The Norms. The “Building Regulation”. The integrated projects.

The third part organizes the entirety of the Norms: there is a list of indications, directives and prescriptions that after the approval of the PPTR, will have an immediate effect on the utilization of the resources that constitute the landscape.

The PPTR has been among the first Regional instruments to test in the course of its drafting, active forms of participation in application of the European Landscape Convention. It started the production of “guidelines” and “integrated experimental projects” aimed at reaching the preset structures of the scenarios. Guidelines and projects have been aimed especially at planners and programmers, but in diverse ways they involve those who “produce” landscapes (builders, agricultural entrepreneurs, administrators, inhabitants united together in associations, etc.).

The guidelines, in part functioning within the integrated projects that attempt to create typologies, are drafted in the form of a datasheet-norm, with regulations aimed at particular management or construction aspects whenever the dimension concerns landscape aspects.

A protocol for the qualification of landscape and environmental development in a building regulation was signed with one of the Municipality (Giovinazzo), which proposed itself as a Regional regulation standard, with the introduction of qualitative rules on the building materials, the typologies, the colours, the insertion of the constructions in the urban and rural landscape, etc.

Another protocol regards the regulation for the National Park of Alta Murgia, agreed upon with the Park Authority, that oversees the morphotypological indications for the interventions of recovery and new construction, with the predisposition of an urban and building regulation for the construction and infrastructure activities both for recovery and for prevision of interventions of the single Municipalities in the Park area with specific prescriptions having a landscape character; and a priority Plan for recovery for agricultural, environmental tourism and residential purposes and for services for the agricultural villages that were abandoned by the Reform Body.

The Plan can be ready for other projects. For example, there are proposals for an innovative tourist guide based on the Atlas, that helps in the ecological and historical and structural understanding of the landscapes, and so forth.

4.5 The co-plan with the Rural Development Plan

The Plan, in the course of its drafting, oriented the active “policies” of the territory and regional landscape, opening a dialogue with the other instruments (the Infrastructure Plan, the Coastal Plan, the Plan for vast areas, the Territorial Plans of Provincial Coordination, the Rural Development Plan, etc.). The Landscape Plan chooses to co-plan with the Rural Development Plan of the Region the main transformations toward a “multifunctional” direction of agriculture

Fig.7: Schedule of "Network Systems" of the villages in the eleven "ambiti" of Regional landscape, from Abacus of "rural settlements morphotypes" Source: Landscape Territorial Plan of Apulian Region.

Fig.7a : Detail Area n.1 Gargano, "Aggregates of rural manufactured, placed in the ridges and far away , for safety reasons, from the commercial or military historic routes, most after the wear uninhabited as a result of emigration, which today are often populated during the summer".

5. Specific recommendation and Guidelines for Intervention Methodology, Concerning Landscape and Architecture

To sum up we advocate the need for introducing sustainable concept in Jordanian planning strategy, and the enactment of specific law for integrated planning -at different levels- and introduce specific guidelines for intervention methodology, concerning landscape and architecture. In accordance with our model of reference, we have taken into special consideration the guidelines of Puglia Region for the protection and development of its territorial and landscapes resources.

We would like to get the Jordan Government to take up these:

- promote rural repopulation in the context of multifunctional agriculture; among other things, to promote and give incentive to agriculture that is less water-dependent.
- promote deep knowledge concerning the rural architectural as tangible and intangible heritage.
- urge the local governments to develop awareness activity regarding the rural cultural heritage.
- revitalize, actively and economically, the rural heritage without compromising the cultural, historical and landscape value.
- intensify the debate on rural architecture and develop an educational role with the new generations
- encourage the active participation of owners in the decisional process of planning
- recover the rural buildings and the activities according to their morphological context
- promote sustainable techniques, recovering and rehabilitating the traditional building construction of houses, rainwater harvesting, and so on.
- promote an adequate project for restoration and rehabilitation of the rural unit
- adopt a general criterion for the use, re-function and administration of the rural unit

Consequently, in this step the role of the Jordanian Regional Authority should:

- coordinate and control the implementation of the guidelines in terms of urban landscape and recovering the architectural rural heritage
- collect and archive surveys of the rural buildings with particular architectural interest
- favour experimental rehabilitation and recovering of green building techniques
- support the training activity of technicians in the field of recovering the traditional techniques of construction

- promote the publication of manuals in the recovering of rural buildings
- encourage studies, seminars and conferences on rural buildings and agrarian and natural landscapes.

Cultural landscapes: materiality and spirituality in the mountains of Abruzzo

Caterina PALESTINI

Dipartimento ARCH, Facoltà di Architettura, Università "G. d'Annunzio", Pescara, Italia
caterinapalestini@libero.it

Abstract

The representation of the landscape involves a deep knowledge of the places and of the cultural and natural features on which it is configured. The perceptions resulting are aesthetic material factors, tangible and concretely visible, but also intrinsic, educational backgrounds that uniquely represent the environmental contexts of which they belong to. Among the many research applications pursued in this direction, the contribution proposes screening of samples that mark the immense wealth protected by Abruzzo's mountains, where materiality and spirituality are blended in a symbiotic reality represented by the perched villages enclosed in the broad valleys, now almost uninhabited, and to reconsider the logic of sustainable development.

Supporting the proposal of the study for the knowledge and the upgrading of these cultural landscapes, the writings of Ignazio Silone describe them as they cannot be understood without knowing the Abruzzo's mountains that form the backbone of the physical structure "the body", which is associated inextricably moral, "the saints and the poor people". The writer, on several tracks, provides the historical anthropology which reflect the physical and spiritual environment in which urban centers were built and several monasteries located between the mountains of Abruzzo, the current pictures and iconographic representations add informations that contribute to the knowledge and critical representation of the landscape in question.

Parole chiave: Landscapes, Heritage, Cultural, Knowledge, Representation.

1. Materiality and spirituality of the mountains. Knowledge and development of the Abruzzo heritage

Representation of landscape implicates a deep knowledge of the places, the naturalistic and cultural aspects on which it is shaped. Therefore, the perceptions which derive from it summarize material, tangible and concretely visible aesthetic factors, but also intrinsic, formative backgrounds which characterize the environmental contexts of belonging in a univocal way.

In particular, the analysis of the cultural landscapes tied in with the sacredness of the mountain induces one to search for meanings and experiences connected to this theme, in which spiritual paradigms, very different among themselves, united by an extreme mysticism sustained by austere and solitary lifestyles on the elevations.

An archetype common to many cultures perceives the mountain itself as an emblem of what is sacred and what is transcendent. In the collective imagination, the areas between mountainous elevations are considered particular places, the wide extensions which define them generate sensations of immensity and infinity; the height which draws them nearer to heaven, their harsh nature from which a hostile ecosystem derives which induces one to sacrifice, solitude and silence, have favoured the establishment of territories for meditation.

The mountain which the desert is in contrast with, are symbolically considered the most suitable places for meditation and spiritual asceticism as events concerning anchorites of various religions, Christianity, Hinduism, Buddhism testify, which, even though with different ideologies, share the habitat and analogous lifestyles. The ascetic phenomenon from the east spreads in the Mediterranean area, involving various cultural idioms equalized by the demand for meditation in solitude, in impervious, isolated areas, as referred to in many narrations: Those of the Tibetan monks such as Milarepa, who lived between the eleventh and twelfth centuries, who remained in complete isolation in a cave near glaciers to purify himself before professing his karma; those of Christian fathers such as St Onofrio, who lived in solitude in the desert for many years. Iconography shows images of stylites represented in settings defined by arid landscapes, seabeds with unexpected rocky caves from which they can be seen, represented in scenes of life which identify them. In this connection, the representations of the hermitages are interesting, which refer episodes of hermit saints, metaphorically united among one another in a single landscape context shown in a filmic way, in the interlinked series of a panoramic vision which synthesizes its spiritual essence in an ideal way. The Renaissance hermitages, attributed to Blessed Angelico and Paolo Uccello, are specifically set in mountainous landscapes containing scenes of coenobitic life. The former, a tempera plate dated about 1420, unfolds in a long view a mountain chain crowded with simple architecture, retreats and caves, accessible by means of steep paths dug out the rock, which allegorically communicate a busy hermitic presence, scattered among high tops lapped by the sea. Instead, Paolo Uccello's interpretation, which goes back to halfway through the fifteenth century, fixes onto canvas a limited portion of, still mountainous, landscape, in which he represents in a more detailed way analogous episodes referring to humble, industrious saints, who live between caves and steep, rocky spurs, in search of spiritual purity. The two temperas seem to be inspired by a component model deduced by a Byzantine mosaic, formerly used by Buffalmacco in a fresco in the cemetery of Pisa, which reproduces the same theme of the stories of the "holy fathers" recalled as moral allegories. The paintings supply a clear example of exegeses of cultural landscape. They show materiality and sacredness of the places contextually, specifically of some mountainous territories which, although they adopt the symbolic narrative formula of a Middle Ages type, find concrete parallels in real contexts that the contribution wants to highlight, by means of opportune comparisons and with different representative formulae. Going back to the importance of the mountain, it can identify the place in which heaven and earth meet and across which the so-called *axis mundis* passes, shows the ascension symbolically, delineated physically by the altitude, which allows one to overcome the physical space of human limited nature by means of spirituality. In various countries, one or more mountain tops exist to which this sacred role is attributed, among which are: mount Olympus, from time immemorial the dwelling of the gods, Tabor, Adam's burial place, Fuji in Japan, Kailash in Tibet. Alternatively, structures which recall mountains have been built: the Mesopotamian *ziggurats* of the paradigmatic monuments of Teotihuacán in Mexico with flights of steps which lead towards heaven like the mythical Tower of Babel. Also, the Tibetan monks identify some supposed "power places", some sites around which important energies and spiritual forces are concentrated, among which sacred mountains prevail, in which spiritual

Fig. 1: Beato Angelico, *Thebaïd* 1418-20, Tempera on panel (73,5x208 cm), Uffizi Gallery, Florence.

Fig. 2: Paolo Uccello, *Thebaid* 1460, Tempera on canvas (83x118), Accademia Gallery, Florence.

entities are present and near which caves for meditation are found and hermitages [1] in which charismatic figures, adepts, proselytes, founders of monastic communities lived.

In this sense, one single similarity unites the Tibetan mountains to those of Abruzzo because of the high concentration of hermitages present in the region; this spiritual and landscape symbiosis directed the request for a concrete project [2] presented to UNESCO for the development of the Majella as European Tibet, not only because of its naturalistic importance, but because of the cultural grouping preserved in it.

In reality, the sacredness of the Abruzzo *Montagna Madre* has remote origins. Popular legends testify to Italic cults, migrations and spiritual journeys on the steep, rocky walls, to reach ancient shelters, the caves into which the anchorites retired, inspired by fascination for the Majella, considered, precisely, the "holy mountain".

The mystic importance of the places, mentioned also by Petrarca in "De Vita Solitaria" as among the most suitable for spiritual ascesis, finds confirmation in the presence of numerous charismatic figures who spend some time there in solitude and among these Pietro Angelieri from Morrone, the anchorite who abandoned his mandate straightaway after his election as pope to continue the rigid principles of monastic life.

The famous "refusal" reinforces the fame of Celestine V, the saint who renounced papal power for the essentiality of hermitic rigour, thus favouring the arrival of followers and the subsequent establishment of local movements which increased the already numerous coenobitic structures present in Abruzzo.

In the severe setting, characterized by mighty mountain chains which cross the region and in the difficult conditions of existence established by them, the spiritual profile of Abruzzo Christianity took shape, its particular ascetic vocation from which forms of autochthonous monasticism have arisen.

Factors efficiently described by Ignazio Silone [3] who, in his writings, sustains that one cannot understand Abruzzo without knowing its mountains which represent its bone structure, the physical structure, "the body", with which the moral structure is associated indissolubly, that "of the saints and the poor people".

Fig. 3: *Thebaid of Abruzzo*, hermitic scenes deduced from iconographic works of fiction gathered in the background of the Majella.

“... The destiny of men in the region, which has been called Abruzzo for about eight centuries, was decided mainly by the mountains ...” In this way, Abruzzo was formed and consolidated “... safe from the immediate clash of historical events ...” The text continues, underlining how “the constant factor of the existence of the Abruzzo people” is established by a primitive element, the environmental one, of nature which constitutes the sum from which various connections derive and, among these, spiritual configuration.

The taking root of an extreme religiousness, in which Pietro da Morrone is “a borderline figure, an archetype”, therefore intersects with the survival of “myths and pagan customs” and with the rigour imposed by the mountain that, in itself, requires the condition of “permanent defence from a hostile physical environment”. The figure of the hermit in Abruzzo in many cases combines the meeting between what is sacred and what is profane, between the religious man and the shepherd who have approached each other, sharing among themselves the same shelters, the same places and caves at times evolved into walled structures which are able to house monks, followers of the rigid contemplative rule.

The harsh character of the environmental context and people, the unavoidable tie with places, the acute analysis of Silone, help one to understand the phenomenon from the anthropological-cultural point of view, making us frame the environmental setting and the role carried out by Pietro da Morrone, to be associated with the intrinsic sacredness of the Abruzzo mountains. From these introductory remarks, useful for defining the study of the places in question, research on the representations was started, on the images which were able to refer the appearance and the character of the landscapes imagined in hermitage form.

For the purpose of proposing a synthesis of the widest research on the representation, of the physical and cultural importance of the landscape, within the brevity permitted by the convention, the contribution shows the first step of the analysis carried out on the patrimony preserved in the Abruzzo contexts and suburbs.

Fig. 4: F. Paolo Michetti, *Gli storpi* 1900, tempera on canvas (380x970 cm.) Museo Michetti, Francavilla al Mare.

Fig. 5: F. Paolo Michetti, *La Figlia di Jorio* 1895, tempera on canvas (280x520 cm.) Province Palace, Pescara.

1.1 Iconographic representations

The interpretation of the sacredness of the mountains and rites connected with it was efficiently represented in various works by Francesco Paolo Michetti. By means of a series of studies, carried out with habitual visiting of the places of worship and with photographic experiments, the Abruzzo painter managed to capture the atmosphere generated by the religious scenes of a popular character. On the canvases, the intensity and charisma of the purifying rites are so picturesquely interpreted that, according to sacred and profane beliefs, they were perpetrated by ancient traditions. The representations deriving from a careful analysis from real life, sum up the sacred character of the places and events, communicated visibly by means of the emphasis generated by the devotional practices and emotional tensions which sprung from them. As in the case of the *Storpi*, shown in one of the long, tiring missions which were carried out in single file, among the inaccessible mountain paths, to reach the places of worship and ask for a blessing; or in the *Voto* in which the faithful venerate the patron saint, crawling on the floor, in a dramatic situation of mystic consternation.

The efficient pictorial synthesis includes in itself the research that the artist carried out with other intellectuals in an artistic coterie, together with the anthropologist, Antonio De Nino, the poet Gabriele d'Annunzio, the composer Francesco Paolo Tosti and the sculptor Costantino Barbella, with which he shared the project of

an avant-gardist laboratory which was able to eliminate the barriers between the various arts, integrated among themselves with reciprocal influences. Often successful hybridizations, as in the *Figlia di Jorio*, the prize-winning painting at the first Biennial exhibition in Venice in 1895, to which the homonymous D'Annunzio tragedy (4) set in the fifth scenic part of the snow-capped Majella, in front of which there appear the figures who communicate the language of elementary passions, staged on the background of the inviolable Mountain, which appears majestic and unyielding.

The subject, influenced by an event which really happened among shepherds, impresses on the scene an unusual "trueness" expressed by the two authors with their respective communicative formulae, compared between them in the symbiotic cultural projection of the figures to be represented who, as sustained by Benedetto Croce, came true figuratively in the paintings "... Michetti's painting colours the D'Annunzio vision of the Abruzzo people".

Also, a series of of postcards designed by Basilio Cascella are inspired by the theme of sacredness, aroused by these cultural landscapes, that efficiently retract a *pilgrim's stopover*, groups of people who, worn out by the walk, rest at the slopes of the mountains, where they went to visit the virtuous hermits and obtain spiritual support, exorcisms and blessings from them.

In conclusion, the contribution, centred on the understanding of the naturalistic settings and cultural groupings contained in them, wants to underline how research carried out by means of various informative, literary, anthropologic and iconographic sources, allow one to add important details to the complex chain of critical knowledge of patrimony, material and immaterial, comparing them to different and wider enquiry sectors.

The Abruzzo territory supplies an exemplary test bed for the study of neglected places, now little known, but rich in architectonic, historic and environmental importance to communicate by means of the integration of more than one representative formula. Renewing the spiritual charisma of these mountains, compared to the Tibetan ones, constitutes an occasion for investing on patrimony, on many abandoned suburbs, to be reconsidered in the logic of sustainable development.

Overlays in Amalfi Coast: *Less and More* of the elements in the landscape.

Luigi CORNIELLO

Facoltà di Architettura, Seconda Università degli Studi di Napoli
lcorniello@libero.it

Abstract

The search path suggests the study of the coast landscape of Amalfi, highlighting the values of the natural and man elements, creating a database, through which the knowledge, enables the management, protection and regeneration of the area. The mapping of the landscape is a key element discretization of knowledge and governance and is aimed at the enhancement. Through technology Corine-Land-Cover layers are of remote sensing of the cards stored in a GIS system becomes interactive and dynamic. In this respect the analysis of the tangible and intangible dimensions, interpolated in a process of recomposition anastylosis and allow the production of models LOD (Level of detail) in relation to the level of detail, discretizing the DLOD representations (Level Of Detail Discretizing) and proposing stages of mapping. The cognitive system on the environment of Amalfi takes shape through digital models organized hierarchically decomposed into sub-elements and through decompositions and aggregations aimed at multidisciplinary perspective. The overlap is the more and less understood of the landscape of Amalfi as addition and subtraction of numeric information in the GIS system.

Develops research oriented courses in history, architecture and environment, analyzing the skyline of the area, illustrating the landscape values through archival documents, the reading of images, the relative importance and performance.

Parole chiave: Amalfi Coast, Landscape, Knowledge

1. *Less and More*: the elements in the landscape

The search path mapping suggests the study of the coast landscape of Amalfi, highlighting the values of the natural and anthropogenic factors, constituting a database, through which the knowledge, enables the management, protection and regeneration of the area. The mapping of the landscape is an element of knowledge and discretization aimed at governance and valuation. The cognitive system environment Amalfi takes shape through digital models hierarchically organized and decomposable into sub-elements through decompositions and combinations aimed at multidisciplinary perspective. The overlap is the most and least understood of the landscape of Amalfi as addition and subtraction of numerical information. The research develops courses oriented between history, architecture and environment, analyzing the skyline of the area, illustrating its landscape through archival documents, the reading of images and its representation.

2. *Less e More*: the values of the landscape

The foundation of the coastal villages dating back to the decadence of the Roman Empire, as to the origin of names, the ancient Reginna Minor was called, from the river that flowed there, such a designation also designated the river of Maiori. In Sveva Age both lost the title of Reginna and were simply called Minuri and Maiuri. The Roman period is attested by the Minor remains of a large Villa of Augusto. The urban structure of the two villages, as they appear today, is typically medieval. The valleys, enclosed between two mountain slopes and open to the sea, take a vaguely triangular shape and end with a small beach with debris formed by rainwater and spring water. This geometry is revived natural setting-urban, which has its center of gravity on the boundary line between the town and the sea. In the reading area is of paramount importance to the knowledge of morphological structure in that both from a strictly natural integration of the intervention by man, is crucial for the use and did not consider an instinctive tendency intensive and extensive exploitation of the costs and resources, and can not prescindete from geomorphological features. The human intervention has from very early times in the construction of a vast system of terraced hills and mountains of the Valtellina of Pantelleria Island. He has contributed to the reclamation of wetlands and large rivers regimentation of the Etruscan and Roman. Then begins the policy of the construction of large, medium and small dams for water with different purposes from energy production to that of water supplies for agricultural irrigation. The natural environment has undergone profound changes over time natural and man-made. The multifarious nature of the Amalfi Coast is determined by the location, exposure, the elevation, the humidity and other elements that, over the centuries, have enabled the creation of different vegetation strips each of which gives rise to a specific ecosystem. The areas near the river have a type of vegetation favored by the abundance of water and the limited temperature: we find, beside the willows and alders, other species typical of mixed forest. A higher level of humidity than the shady ravines, the exposed areas to the south are dominated by evergreen oaks that once covered almost entirely in sunny areas of the Amalfi Coast. The oak forests were once forests, in the most dense, that prevented the passage of sunlight and greatly limited the formation of so-called underworld. The landscape plant, on the side least exposed to the sun, is completely different; species belong mostly to the family of deciduous and during the fall season adorn the forest with intense colors.

Fig. 1: Images of the landscape in the Amalfi Coast

3. *Less e More*: the coast defense is not utopian.

The coast towers, once used to guard the common Amalfi, were a warning system consists of robust construction firmly anchored to the rock and no ornamentation, apart from the battlements as the only design element terminal. Structures present on the Amalfi coast you can find two geometric forms: one circular and one square. The first can be traced to medieval times, which even before the Aragonese and Angioino. The validity of defense and visual connection remained unchanged for centuries, a phenomenon attributable to many circumstances and political-administrative and architecture: a cylindrical tower, of course, is easier to build, requiring no angular stones, and contains a surface equal upper perimeter of other geometric shape, does not require a specific orientation and reacts to ballistic impacts evenly. The towers when the system is square, mostly with raised truncated pyramid, possessed coverage plans similar to the deck of the vessels and therefore suitable to accommodate guns in battery. The interiors were used with multiple benefits of a military nature, sufficient to justify the adoption despite their higher cost. The escarpment is attributed to the need to object to the oblique ballistic impacts, to be ascribed to two reasons: the first static: changing the material of construction depending on the territory of which was to erect the tower, the second attributed to need to keep attackers away from the tower base and the relevant territory. The sighting took place in two ways: direct and indirect: in the first case the staff was having to give the alarm to the town, when sighted suspicious boat approaching the coast. The employees present in the towers had to consider the distance of enemy ships and the time required for their landing, in order to prepare the ground troops on the offensive and residents to take shelter in suitable places. The distance could be defined under the best atmospheric conditions, from the horizon to the beach, with $D = 3850 (h)^{1/2}$, where (h) is the height of the eye on the sea surface and (D) is the maximum distance visible. As a result of low coasts are resorted to structures with high vertical and average heights of the rocky headlands. Infact, note that the towers have a height Amalfitane not more than fifteen feet and allowed ten miles visibility, functional works of defense and the perception of the coastal landscape seen from the sea. Less obvious is the appearance of geometry and More coastal towers above the horizon. The many possible references to the Amalfi systems of towers, take a descriptive reference, the Tower of Fornillo in Positano, Praiano Tower, the Tower of Capo Conca in Conca dei Marini, the Tower of San Francesco in Amalfi, the Tower of Angelo in Maiori, offering their knowledge to a filing by map-based views of historical and current landscape shots. We analyze aspects of the configuration of matter in relation to landscape the site and supported by references to archival documents and aerial photogrammetric maps. The significance of the formal Amalfi systems tower take the reading parameters are interrelated, such as the geometry of buildings, location in the landscape and the specific communication function of the images, to perceive with reference to the natural beauty of places to protect it, the aesthetic forms and structures of the historic Amalfi system of towers.

Fig. 2: The Cetara Tower in the landscape of Amalfi Coast.

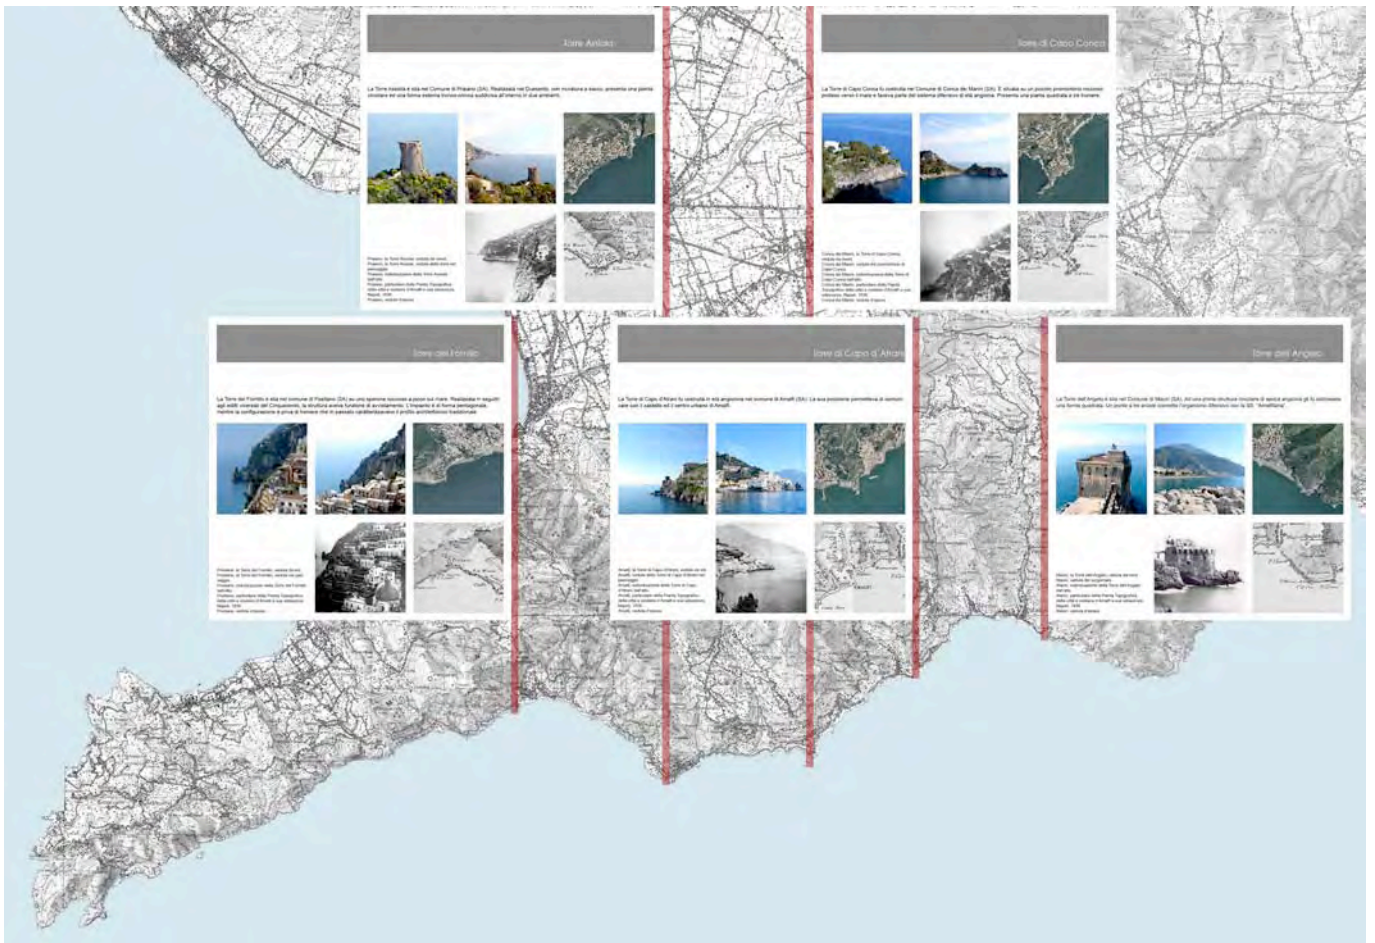

Fig. 3: The Towers of Amalfi Coast

4. *Less e More*: domes structures in the layers of representation

The coast can be like a real laboratory works in majolica pavements of the churches and cloisters, chapels and private villas. The views of small towns are dotted with bright domes and spiers of church steeples, covered with colored tiles arranged in designs frequently of meridians and parallels interpolating colors. You can see, the landscape values of the religious complex of Vietri sul Mare, Maiori, Atrani and Praiano through multiple relationships between form and color, environment and landscape, collecting notes on the architecture, the colourist on individual buildings assumed to emblem of ceramic decoration in his symphony of color and compositional effects that have defined this type of work "painted architecture" it is representative.

The glazed brick of dough, pressed dry, glazed in bright colors and slippery water are used as coating material for architectural works, creating multicolored robes reminiscent of the Byzantine and Islamic influences on the construction of the fishing villages, establishing a relationship with the topography of the place and putting themselves in the forms of the natural landscape. The vision of the natural environment in the viceregal era (Sixteenth Century - XVIII), included numerous domes and spiers covered with multicolored tiles, the curved line, with different colors ranging from yellow to green, brown to blue, arranged in patterns geometry. In a few hours of the day, the shimmer of multicolored coat, changing in relation to the path of the sun highlights the performance of buildings perched along the steep slopes of the places that stand out against the blue sea. The tiles, low cost products at the time, were particularly useful to take on the forms of monastic complex still facing our perception survey and historical documentation.

An example of a religious building with a dome is the church of San Giovanni Battista in Vietri sul Mare, which was founded in the late tenth century, destroyed by the Saracens and rebuilt in 1005. During the centuries it has undergone several changes and renovations in the styles Romanesque, Renaissance and Baroque. A Vietri, Giuseppe Salese, built on four pillars the dome, which at the beginning of this century it

was covered with majolica tiles produced by the brothers Tafani of Campania. Another church is Santa Maria a Mare that stands on a rock overlooking the town of Maiori. The transept is surmounted by a majestic hemispherical dome - completed in 1863 - whose soffit is crisscrossed by a grid of octagons punctuated by small diamonds. This has an internal diameter of 10.50 m and is constructed with a wall of constant thickness equal to 0.60 m, is devoid of drum and rests with plumes of four corner pillars. The dome has a hemispherical shape adhering to aesthetic reasons and structural reasons. The top surface is covered with yellow and green majolica tiles, with concentric lozenges harmonic patterns, and is crossed by ribs of dark ceramic, oriented in the direction of the meridians. The tiling is the work of artists of the second half of Vietri. At the top of the dome stands the cylindrical lantern with large windows, in turn surmounted by a dome covered with tiles, striped yellow and green. The dome of the apse, however, presents a linear decoration on the outer surface with alternating rows with three tiles of yellow and three green.

The architecture of the search path is added to the Collegiate Church of St. Maria Maddalena in Atrani that extends upward and toward the sea. It was built in 1274 on the ruins of an ancient fortress, by the people Atrani. At the center of the transept, a dome light spreads to the whole environment, and how those who hold the two side chapels, is covered with yellow and green tiles. Another interesting monument is the Church of San Gennaro in Praiano. Constructed in the Romanesque style - Renaissance, Latin cross, with round arches and domed oval on the cruise tiled majolica Vietri manufacturing. The coating of majolica tiles that glisten in the sun and the sober decorations inside were performed between 1771 and 1776. The colors of Less and More than the colors of the landscape.

Fig. 4: Domes in the landscape of Amalfi Coast

5. *Less e More*: a tool for mapping information.

A possible mapping in Amalfi Coast is an element of knowledge and discretization of the landscape which provides for protection and enhancement. In this respect the analysis of tangible and intangible dimensions, interpolated in a process of recomposition anastylosis and allow the production of models LOD (Level of detail) in relation to the level of detail, discretizing representations DLOD (Level of Detail Discretizing) and proposing stages of mapping.

The cognitive system can take the form of Amalfi through digital models and organized hierarchically decomposed into sub-elements through decompositions and aggregations in terms of typology and morphology. Interposing the amount of information with the scale of the representation is discerned a certain number of DLOD that constitute the different layers of the model LOD. This procedure allows a decomposition into individual elements and, through analysis, it is possible to lay down clear rules of composition related to the architectural language of signs in the landscape.

A perspective from a contemporary point of view medieval

Nadia FABRIS

Dipartimento DAD, II Facoltà di Architettura, Politecnico di Torino, Italia
e-mails: Fabris@polito.it, nad.fab@libero.it

The research is part of a series of insights through various readings which depart from the booklets of travelers to the manuals of architecture, comparing historical representations of their environment by analyzing the city in his heart. In this context we wanted to investigate the visual projection of its transformations emphasizing a point of view, the medieval tower at the front door of Turin, then comparing with the current view taken by different cameras made, which allow us to read the urban fabric of a capital city, with a view to analyzing ancient, through the eye of an ancestor, which he sees going transformations. Read the urban fabric of a capital city, analyze it with an old perspective, through the eye of an ancestor. Means a city set in the past and a view over a century, dealing with time and space in processing, capture, if it exists, the identity of a place, such as Turin, starting with an overview, as if we were from the top of a tower and below us we see the city scroll quickly for one hundred years of the 18th century. A view at 360 degrees, from the Tower of Acaia, inserted into the current Palazzo Madama, in the heart of Turin, orientate the prospect looking streets, squares, work, holidays, Royal Palace, the places of devotion, stopping the time in some decisive years: the beginning of the century, after the siege of 1706; the years of great works taken by Vittorio Amedeo II and designed by Filippo Juvarra for equipping Torino capital; at the end of the 18th century, when the ideas and the weapons of the French Revolution. Each capital lived these processes with sensibility and distinct rhythms, as it fits a pattern of net capital, Turin was the transition from a military Citadel, until civilian functions take precedence, political, cultural, which became particularly evident during the reign of Victor Amadeus II. This model was worked out definitively by the architect Filippo Juvarra from Messina between 1716 and 1719, responded to a more ambitious: Nineteen blocks, two squares, rectification of a street were the ribs that project would be realized in the third decade to become a model for future enlargements. For Torino capital, the facades of buildings, only partially violated the regularity and left leaked signs of wealth, as in the layout of streets and squares was celebrated the triumph of the principle of an orderly development, an essential beauty, that "nothing extremely beautiful, but all equal and nothing mediocre" that had registered Charles De Brosses passing from Turin, in 1740.

In Turin it was established the court nobility and the most recent service nobility and honor who had taken positions from the rank conferred by the Dukes while maintaining close links with the provinces, as in most European cities, including Turin throughout the eighteenth century and a moment of transformation.

The capital city is, therefore, a city in the harmonious baroque and rococo architecture and urban planning, churches, palaces and monuments. View, understand "this" Turin is not only to see the monumental complex: it is "seeing the form", walking along the streets, the wide straight avenues, many, many arcades, understand their perspectives and meanings. The great baroque palaces of the city become the Savoy, Palazzo Madama Palazzo Carignano, the palaces of the first capital of the Kingdom, a capital destined to remain so for a few years until moving to Florence.

Located in the heart of Turin, in what was to be the Roman fort, the Senate stands on that at the time of ancient Rome, was called Porta Decumana who had different life, being gradually incorporated into the castle that was erecting. At the beginning of the century this was the gateway to the city side of the Po, for its strategic position, was defended carefully: after the fall of the Roman Empire, the door was turned into a fortress, to act defense of the town, given the obvious importance of this way of communication, even if retained the original function of gate with the opening of the door in the ancient Roman wall Fibellona. Comparisons with the iconography and old photographs are immediate, where new requirements have subtracted the built, the *hall Madame Royale*, was demolished to facilitate the modern city, *the Mole*, which is imposed on the background of a city that wants to be European Union, the theoretical Guarino Guarini Baroque that leaves her diamonds with the chapel of the Holy Shroud and that of *S. Lorenzo*, who stand out as marvels of the time. And still the steeples of the monasteries represented by Friedrich Probst, still in the city built the gabled roofs of Turin valid in all ages, and tile roofs in Piedmont, preserved as a choice of

continuity leaves a warm color that blends with the brick buildings a view that brings out the color of the buildings of representation, with gold and copper tones.

This is part of ongoing research, including historical images and comparisons with today's reading, manuals and maps to lead to a conservative analysis is that perception of a historical setting, to give precedence to its essences stylistic points and enhance visual favoring a path and fruition that are not dictated by chance but by contemporary cultural angle.

The bibliography has provided key insights into the period and highlight the highlights of this part of analysis, while the cartographic and iconographic survey gives us the means of comparison.

Reflections on drawing the landscape

Abstract

In recent years the term “environment” has broadened its expressive content, until it reached the current meaning; a process of acquisition that has limited the historical conception of “natural environment”, leaving the field, more and more, to the wide meaning of “everything that surrounds (us)”.

Today, therefore, the environment is meant as “space/system”. This interpretation gives the term a value that tends to concept of geographical scope, that is: an ensemble of localized and specific natural and socio-cultural conditions which, layered over time in a certain place/area, are the common heritage of the local community and the territorial basis of its identity.

By virtue of this value, for some professions the environment is a sort of “hypertext” in which not only the territorial base of a specific community finds its place, but also, and above all, the substrate of the local development processes. Growth which if not commensurate with the environmental features, not compared to local needs, or if carried out with tight stops and in a senseless way, changes the dynamics of socio-economic modernization, always based on the man/environment relationship.

Through the elements that stimulate the process of shaping and transforming the natural environment, the text provides an overview of the representative system in an attempt to identify the most appropriate means of expression to the current needs of land management.

Keywords: drawing, landscape, survey, GIS

1. Introduction

The concept linked to the term “environment” is a complex mental representation which in a general sense indicates the sum of the physical biotic and abiotic (from *bios*, life) components surrounding living beings in interactive relationship with them. Therefore, in modern language the environment is the space of the picture of life, the common home, fundamental patrimony in which men live. It is obvious that where Man, who is aware of himself as a presence and territorial agent, is missing the environment would not offer landscapes to the eye but only spontaneous nature.

In the wake of this, the environment can also be interpreted as a space/system; a physical space in four dimensions (the temporal factor is as relevant as the dimensional one) in which a complex system of events exists or, more precisely, as a space in which a succession of events occur, each of which reacts to the variation of only one of the parameters of the events themselves. Such an interpretation attributes the word in question with a value tending towards the concept typical of the geographical ambit, that is, a localised and specific sum of natural and socio-cultural conditions, which have become stratified in a certain place/territory during the course of time.

By virtue of this value the environment is the subject of interdisciplinary studies and for professional researchers constitutes a sort of “hypertext”, in which not only the territorial base of a specific collective finds space, but also, and above all, the local substrata of developmental processes. However, this growth, if not in proportion with environmental peculiarities or local needs or if undertaken in rapid stages in an unmindful way, as in some Western societies, drastically changes the dynamics of socio-economic modernization, which has always been based on the relationship between Man and the environment. This change in behaviour is essentially due to the illogical thought characterising modern Man for whom the good, even less so the beautiful, are no longer his principal values, but the useful (which contrasts with both in that it subordinates them). Thus, nature is transformed into a laboratory in which Man experiments his intentions and kills it by using it as a raw material, leaving behind tangible signs of his works; signs which offend the territory, leaving deep wounds in the deepest layers of the earth which regulate the ecosystem. These signs reverberate in the uses and customs, in the history and economy of a place, disfiguring its historical identity [10].

However, it must be said, that recently I seem to be living a new season and the longed for change in the behavioural route taken by the human race thus far no longer appears so far off. In fact, in recent years, attention towards nature, initially the prerogative of a few sensitive individuals has grown in Man’s conscience and is today permanently fixed, to varying degrees, within each of us. This sensibility if solicited by dramatic events may trigger reactions of indignation and surprising operative solidarity, which when combined can provide the necessary impetus to defeat the passive resistance of those who, holding important political positions or heading the institutions administrating public assets, still show little sympathy for the environmental question.

However, while awaiting a sign that this change transpires, I believe that in the immediate future something more can be done to facilitate its occurrence.

I refer, for example, to the possibility of increasing territorial surveillance by involving pupils from all types of schools and citizens of all ages who show sensitivity towards environmental issues. One initiative, which suitably sponsored by national and international institutions present within the territory, could be the developed through periodic courses, structured at various educational levels, organised by the departments of institutes in which such a theme is at the centre of research with a high scientific content. Clearly, such courses would be tailored to help the public to see, to see in order to understand, with the aim of establishing a positive relationship with the territory in which they live, thus educating them to respect the environment as a collective asset and universal value. Such an initiative would constitute the first formative nucleus of the longed-for environmental culture, that which we may define as the “direct” nucleus, to certainly be echoed by the equally as important “indirect” nucleus, spontaneously activated by participants in the educational projects on their return to their families.

In order to make a greater impression upon Man’s conscience this system must be supported by another initiative, this time involving the institutions, which have some authority in this matter. I refer to the possibility of considering the field of research contextually from more than one point of view in order to highlight all of the stimuli which render it a dynamic, continuously evolving structure. In the first place, such an approach necessitates the identification of the disciplines comprising the entirety of knowledge and the subsequent creation of a system using their research results in such a way that the environmental resources relate and compare to each other in the heuristic-cognitive path. The idea comes from the observation that the environment is not always renewable and therefore is an asset to protect and safeguard by the appropriate management and use of its resources. Therefore, it does not constitute the private reality of individual owners, rather the physical support of collective and contemporary memory, an historical product containing references for the construction of a sense of belonging to places, which assumes a social importance that is also relative to economic dynamics. For this reason, every creative action that touches it should be guided by assiduous checks without being blocked by restrictive and protectionist laws, so that a sustainable development based on balanced and harmonious relationships between social needs, economic activities and the environment can be pursued.

In this interpretative and programmatic picture, the territory in its capacity as a space/container, is acknowledged with the role of coordinator of human activities, that is, guarantor for the safeguarding and recognisability of the natural values and identifiers of territorial communities, both in the landscapes of consolidated cities and in rural and natural landscapes, as stated by the European Landscape Convention, signed by 45 members of the Council of Europe.

All of this leads to the promotion of action to safeguard the figurative value and enjoyability of a territorial asset for which it is appropriate to identify the best implements for reading the characteristics of a place and the society residing there, as well as including its vocation for development and potential for transformation.

In the process of translation and comprehension of the richness of territorial diversity and complexity, the use of words is manifest, even if often evasive and interpretative, but what is even more obvious is the use of images, in particular graphic images in all possible forms. In fact, it must not be forgotten that drawing stands as a “useful” instrument for Man’s activities from the origins of civilisation as it consents reasoning on the image as a surrogate to reality [12]. Therefore, in the absence of a more immediate, more spontaneous expressive procedure which may take its place, drawing will continue to assist Man in his daily activities. Thus, its original function survives today, acting as an external back up to the mind and support for the imagination, in which ideas can be clearly formulated and then return to being part of thought through the mechanism of perception [20]. In this way, drawing is revealed as something more than an external instrument, something other than a “tool”, it becomes a part of the mind, a supplementary portion of the brain [8], and this occurs independently of how the graphic sign is achieved.

2. Some aspects of the expressive content of the term “landscape”

The word “paesaggio” (landscape) takes its meaning from the original root “paese” (village), intended as in the French *paysage*, made up of the substantive *pays* “country” and the suffix *-age*; the latter meant in the sense of “whole”, “vision of a whole”, “entirety” or “totality”. Moreover, the term “paese” originates from the verb *pango*, “I plant a stake”. Each “village” is therefore a marked place, an identification based on Man’s action as a founder. The landscape is therefore an aspect of the *ars aedificandi*; to explain the concept further we may say that the landscape is a portion of anthropized territory perceived in one glance.

From this exposition, it can also be deduced that the word “landscape” is a neologism for the Italian language. Over the course of time, this new term has fascinated numerous cultural figures and all, or nearly all have contributed to the spread of the concept of landscape, often also offering a personal interpretation which, modelled on their own needs and principles, gradually became enriched with new semantic content. Today, these interpretations constitute the idea of landscape in the various cultural eras.

To look back over the evolution of the metal representation of this word in order to identify which is at present the most recognisable to those in the design/planning cosmos, is obviously an interesting undertaking not without its surprises, given the many nuances contained within the concept of this word. It would almost certainly go beyond the limits of this study and the available editorial space. Furthermore, the use of such an approach would not resolve the confusion generated by the twofold character, which distinguishes this term. I refer to the reality of landscape-image, an artistic or technical representation, and that of conscience-landscape or spatial-visual reality, a real inhabited landscape starting from a “here-me-now”. In fact, as Franco Farinelli asserts, the word “landscape” is a «bat» word [9] (both bird and mouse, depending on how you consider it), which denotes the thing and at the same time the image of the thing, and in such a way that one cannot be distinguished from the other.

In the light of this, the reader should note that the idea of landscape in the guise of “symbolic image”, produced by what the eye can take in as it sweeps the horizon, but which according to a well-calculated ambiguity of meaning confers the word with the idea of “environmental whole”, therefore, will not be used throughout the rest of this paper. Thus, no longer landscape intended as an aesthetic appraisal of a section of anthropized territory, but landscape in which space has the dimensions of grand geographic scale, which, by virtue of its extensive nature, we can call the “geographic landscape” [3]. An original meaning which, immediately has the effect of overly dilating the confines of the observers gaze, until now linked to the visual capacity of the human race, and adopts the orthogonal method of representation using azimuthal projection, to the detriment of the perspective preferred in all earlier representation, a meaning which finds its logical and precise parallel in the essay by Vittorio Gregotti “Progetto di paesaggio” [13]. A landscape which has as a specific point of reference drawing directed more towards representation than portrayal; towards the production of graphics which, drawn up in relationship to the function “creativity + science = targeted product”, takes on a mainly decisional, and therefore design character [7].

It goes without saying, that in this interpretation the landscape is the place where Man’s history has taken place and left its traces, artefacts, hamlets, villages and towns. Here the landscape is conceived as «the theatre in which men live as actors» [23]. Although, not only. Here, the landscape also assumes the value of a territorial resource, an economic and social asset. Therefore, it must be appealing and for every type of intervention and territorial planning must be correctly formulated, with consonance of its parts and integration of the constituent elements of a place. There must also be respect for the site’s vocation and its cultural aspects, in other words, only if the identity of a patrimony is reinforced, as the new Codice dei Beni Culturali e del Paesaggio suggests (D. Lgs. 22.01.04 n. 42), can this be achieved.

3. Representation of the geographic landscape

We look at the landscape in many ways. We let ourselves be penetrated by the impressions the vision produces in us, or we try to understand what the landscape can tell us about men and the society with which they identify themselves.

This consideration provokes the idea, also shared by Turri, that to look at a landscape «is like reading a book or watching a play» [23], therefore, as in both these cases, a landscape also requires codes for its reading which help us give meaning to what is seen. Let us see what they are.

Usually, when we talk of reading we refer to a group of signs, for example a written page, a book, a series of graphic elements etc., of which we know the meaning and thanks to which a piece of news, an event, a thought or feeling is transmitted. The reading of the landscape is no different in that for one of the fundamental semiological formulas: each object, even if pre-eminently created as a thing to be used, at the moment in which it is recognisable as such assumes the value of a sign. As Roland Barthes writes, «The function permeates itself with meaning [function-sign]; this semantization is fatal: from the moment that society exists each use is converted into a sign of this use» [2].

For greater clarity let us look at some examples, making use of Turri's observations.

The Man's home is certainly not constructed to be a sign, but to be lived in. However, once inserted into the territory it becomes a sign, it indicates a function. In fact, we know that houses are not built simply on a functional basis. There is an attempt to make them beautiful, to express, taste, social standing, aesthetic sense and the private or collective ownership of those residing there through their form. The same goes for a field used for a crop, for a wood, which can become a sign if inserted in a certain territorial order, among fields, houses etc., as it assumes a precise function within that order, but the same goes for a church bell-tower or a clock tower. It is thus that the landscape, formed by numerous recognisable signs, can be "read" and interpreted. An interpretation which does not, however, regard individual elements, such as the words in a speech, but rather the context, that is the ways in which the single elements assume functionality and meaning as parts of a whole, the how and why they are connected within space, so as to make of them a sort of first draft.

This leads to the consideration that the search for dialogue, for a relationship between Man and the environment, is not a prerogative of the modern world, but arrived with the appearance of our ancestors on the planet, or rather, based on what the archaeological evidence tells us, was born with the appearance of *homo sapiens* as *homo faber*, given that from antiquity man has continued this search, even if in a rudimentary and conceptually very different form from that of today. Of course, today we cannot state with any certainty what the specific reasons are behind this need. However, we can make suggestions, perhaps not far from the truth, if we reflect on Man's inborn desire to know, to understand things, and to somehow perpetuate elements from the everyday scene in which he lives his life, almost as if to conquer a personal form of survival.

The "graphic sign" and the expressive language appointed to document Man's undertakings were mentioned in the introduction to this paper. In the description of the relationship between Man and environment, "drawing" is supported by "survey", which becomes the main investigative tool for determining the elements necessary for its graphic representation. Today, both methods have seen great developments in technique and technologies, mainly due to the close involvement with the renewed problems of space/environment. In fact, there is a growing awareness that the management of the processes of area development and regeneration of exhausted productive sites requires a critical and precise description of the territorial complexities. A synthetic description which, in origin, when our species belonged to the «cold» social structure [15], was narrated through the use of expressive techniques that were free and literate, auto-referenced in order to be shared only with members of the clan. However, today, in the modern era, so by analogy in the «hot» social group, this description is represented by a code shared and transmitted without impediment.

A substantial change in the approach to his fellow men, constantly matured by Man during his evolution, began with the introduction of new elements to the original graphic alphabet, obviously each with its own attribute. At the same time Man experimented with alternative graphic mediums having tested every type of resistant material close to hand, from animal bone, to stone and tree bark, the first to be experimented, to baked clay, papyrus, parchment and then paper, to mention but a few. Then from the last two decades of the 20th century, pushed by the technological innovation that marked that period, the representative system based on graphic signs climbed another evolutionary step: the analogical cord that had fed it from the beginning was cut and it transformed into the digital system.

Naturally, this change has not been without its problems. In fact, similarly to what occurred in other areas of human undertaking, the transition of graphic representation to the new technology was a road scattered with doubts and uncertainties. An almost immediate and significant consequence, was the decline of the

traditional graphic process (made of simple basic operations linked to specific execution times and tools, which, however different, still recalled the archaic in form and substance). Therefore, all those who in various ways were lovers of this language have had to undertake new training in literacy and familiarize themselves with the new tools (hardware, peripheral devices and software), which having lost the morphological and functional references to the old system of representation, appeared innovative and technological.

To have called the transition to digital technology an evolutionary step is perhaps reductive. In effect, it is plausible to imagine the final step along the developmental route of the graphic system as the most innovative and having the greatest impact. In fact, in a hypothetical classification of evolutionary steps it would not seem strange to many of us if this latest development was assigned a place, if not at the very top, at least very close to it. However, whatever its effective value in a developmental sense, we must ask ourselves whether or not, this has also brought innovation to the tools used for the representation of the geographical landscape, perhaps offering new ways of reading and understanding it, or, if in this sphere it is only the bringer of the latest change in tools and methodology with which graphic products are created.

Before answering this question let us get rid of any doubts that the question may raise in the reader. The query is not legitimized by the idea that the graphic mediums by which the geographic landscape has been represented to date are inadequate, that is, they do not manage to clearly transmit the message entrusted to them. Rather, it is legitimized by the desire to find alternative communicative systems, to place alongside traditional ones if desired, with characteristics that are more in tune with our present way of living and communicating, even capable of educating the less-well culturally prepared layers of society, or those less heedful of this subject, perhaps by bringing out their sense of belonging and of local identity which they are often missing. This sentiment originates from the bitter realisation that in our country considering the territory as a place to be plundered, ignoring the programmatic directives contained in documents, is a widespread phenomenon. Every day I am overcome with doubts about the actual existence of these directives, especially when faced with the absurd, uncontrolled building taking place throughout the peninsula, punctually highlighted by the force of nature when it periodically rebels.

In such a situation, there is no doubt that a valid promotional policy, such as that suggested at the beginning of this paper, would favour public sensitization towards such graphic products, and, therefore, towards their descriptive and prescriptive content, whose main aim, let us recall, is the safety of the public and assets, and at the same time that of maintaining an image of the geographical landscape that is more authentic and faithful to its history.

Having said this, let us answer the previous question. We asked ourselves whether or not digital technology has improved available tools for the representation of the geographical landscape.

Well, following such a long period of experimentation – about thirty years – the answer can only be positive. In fact, apart from digital technology's simplification, rationalization and acceleration of numerous of the operations typical of the graphic language, it has been possible to create innovative tools for the investigation and divulgation of information, which also find efficient applications in the reading of the geographic landscape.

As we know as a "document of culture", the landscape is of interest not only for what is visible, but also for what is implicit, for its ethnic, social and economic content, as well as for the game of natural forces meeting within it. Due to its peculiarities, it requires a method of reading capable of looking at its vastness and complexity, from its exterior to its interior; a reading that could be projected into space, above its background, in order to understand its being and history in the most objective and measurable manner possible. In other words, the geographical landscape requires a reading that is able to identify the fundamental elements, which constitute and characterise it and at the same time allows the recognition of their interrelationships, so that the themes linked to the vocation of places can be organised in a legible and comprehensible narration. A synthetic narrative which the thematic cartography developed from the post-war period until today has always provided but to the detriment of a quantity of documents that is at times embarrassing, which for the comprehension of the descriptions and prescriptions requires a considerable intellectual capacity and technical-judicial knowledge beyond that of the average individual.

This leads us to consider the representation of the landscape in a modern key as a synthetic expression resulting from graphic procedures with various properties, geometric and analytic on the one hand, pictorial, intuitive, perceptive on the other, forming a language capable of expressing not only metric and object quantities, but rather qualitative and relational parameters to describe the morphological complexity of places. Means of representation that can provide a global vision, of both a scientific and subjective nature, also transferring the empathetic and emotive aspects, provoked in its perception.

In this sphere of representation, what is needed is a type of graphic with feasible connotations, although already possible with digital technology, on condition that all the potential of the hardware and software available these days is exploited to the full. Obviously, an affirmation that such a system already exists

automatically means referring to GIS technology, the acronym for Geographic Information System, created by Ian McHarg and Howard Fisher. This analysis system offers the possibility of acquiring and dynamically managing data regarding the geographical landscape independently of their format (doc, dwg, tif, jpg, sde, shp, oracle etc.).

Such technology applies the principles of geography (intended as the study and unification of various sciences able to lead to a general understanding of the nature of the anthropized landscape) to the organisation and use of information, utilizing space as a field of action for the resolution of practical problems. Furthermore, similarly to geography GIS has as its focal point the manipulation and analysis of data regarding elements of the real world within a spatial-temporal frame. Most data manipulation and analysis, for example, the transformation of coordinates, analysis of closeness and contiguity, spatial aggregation, overlaying of polygons etc., are common to both GIS systems and geography. Both ambits also share some concepts and principles, such as georeferencing (the process of localising elements within a model of the earth's surface), geocoding (the process by which a geographical reference is applied to a non-geographical datum) and topology (the branch of mathematics which defines the relationships between elements, which assume the role of guide in the implementation phase of GIS systems).

Systems of this type also offer other advantages. Thanks to digital technology, with a few clicks of the mouse the data organised in a GIS becomes immediately available on-line for Web users. Furthermore, if developed by different subjects in different areas, but with identical geographical bases of reference and shared standard procedures of data acquisition, these tools are potentially able to communicate, assuring the exchange and integration of information, actually providing the possibility of having a picture of knowledge relating to the physical environment that is always up to date (for example, in geology, of instability, infrastructures, land use etc.). In this way, GIS systems can also constitute a sort of model of the real landscape which can be manipulated and analysed with the aim of obtaining information useful for decision making with regard to actions relating to the actual world.

These capabilities distinguish GIS from other information systems and render it attractive to many for use in numerous subjects as a support to the explanation of events, prediction of results and strategy planning, giving life to new trends in research such as, for example, that geared towards "business mapping", that is the possibility of producing thematic cartography providing immediate answers to industrial and commercial businesses in their dealings with ever more unpredictable markets in the contemporary world.

4. Conclusion

To synthesize what has been described thus far it could be said: the geographical landscape is a casket in which the dormant values of the collective conscience are deposited. A precious possession which together with the culture landscape constitutes the patrimony of a territory, for which it is dutiful, as well as useful, to set up a mechanism of defence and enhancement; an educative course which, naturally, must begin with knowledge, therefore, with representation.

However, as a collection of dialectic ferments and stimuli, the geographic landscape is as difficult to comprehend in its entirety, as it is to represent. This difficulty of expression can be seen in the reading of the variegated series of its historical representations – where an extraordinary graphic refining is maintained with intellectual constancy and rigour – capable of leading us from a conceptual, philosophical and generically allegorical symbolism, to a use of signs principally recalling, in the collective imagination, the drawing of the objects and the reality ever closer to the perceived elements. The present, growing attempt to use GIS as an instrument for reading, which extracts qualitative and quantitative data from "drawn maps", from photographs and satellite images and alphanumeric databases, shows this innate tendency, which in its progress through history has always aimed to eliminate all possible subjective interference with the reality represented by interpretative elements.

To conclude, the geographic landscape as a collective asset and a universal value can only be enhanced if all subjects involved agree on the method by which to do so. It is not possible that some limit themselves to making requests that others must fulfil. Each of us should be given the opportunity to take part in the organisation of the landscape in which, and off which we live. Such a necessity is even more urgent today as resources are scant and Man increasingly menaces the survival of other living beings. The protection of the landscape, if understood in the right way, could represent an opportunity for all. For this end, respect is indispensable: respect between men and for the landscape, which is not just nature but a living body in continuous evolution, better still a history book written across the millennia and which continues to grow, a book which can be read and in which the farmer, planner or "simply" anyone who observes and loves the landscape, can continue to write.

Abstract

In a critical moment as the one the world economies are crossing, the “contraction” seems to be the only way of exit, the only solution not overwhelmed by system collapse.

As a result, for the single person as for the great factory, the “decrease” (growth STOP), the actual password, influences every action and every medium term approach.

The interest caused by the question can be transposed to interdisciplinary areas, and it is demonstrated, for example, that a lot of words assume different meanings according to the scientific context in which they are inserted. In other words, terms as resilience, robustness, fragility, are contemporarily present in the engineering, in the informatics, in the biology field, indicating different phenomena (although a common “philosophical” matrix can be recognized). In this expanded vision, an integral part of conversation can also concern the natural phenomena, that seem to confirm the contraction theory, in which processes like the self-limitation (e.g. the trees) and the size effect are involved. In the same manner, the antropological systems, like the great civilizations that collapse, seem to confirm the theory according to which the expansion must necessarily be self-limited. It is easy to think for example to the collapse of the Roman Empire in the precise moment of its maximum size, in the precise moment in which every default seemed improbable: it cannot proceed more than a predetermined threshold.

Therefore, *less is more* is really the survival rule? This paper investigates the question from a different point of view, “lending” some theories of structural engineering, based on these general considerations, of purely socio/economic character. The aim of the study is the verification of the “robustness” of the statements out of the proper scientific scope, and contemporarily to evaluate the Mies’ assertion in structural ambit.

Key words: nature’s self-limitation, resilience, robustness, redundancy, compartmentation

1. Introduction

In engineering, the *resilience* is the capacity of a material to resist to sudden shocks without breaking; in informatic the same term indicates the capacity of a system to resist to usury in order to guarantee the availability of provided services; in psychology it is the men ability to deal with adversity, to overcome them, or to exit from them reinforced or positively transformed; in ecology and biology it indicates the capacity of an organism or an eco-system (included the human eco-system: the city) to restore the homeostasis, i.e. the equilibrium condition, after an external intervention that provoked an ecological deficit (i.e. the erosion of the resources consistency that the system is able to produce with respect to the load capacity) [1]. Recently the concept of resilience has been introduced in geriatrics also. In this field it is the unexpected ability to recover that some very ill elderly people seem to have, apparently under very compromised conditions, with respect to the usual care.

This quality is conceptually opposed to the elderly person *fragility*, that represents, on the contrary, a set of characteristics able to identify, in an early stage, the subject that risks to worsen his own life quality, but with appropriate interventions that possibility can be reduced [2].

In structural engineering, as it is known, the fragility represents the tendency in some materials to break suddenly without any deformations and yields previously occurred.

Again, the term *robustness* generally indicates the software or algorithm ability (obviously related to the programmer ability) to behave rationally in unexpected situations, not covered by specific indications. This type of situations includes errors and exceptions of various kind (uncorrected input data, failures of software or hardware external to the system and interacting with it, and so on). In this case the intuitive idea of robustness certainly implies considerations about the harmful effects that the system or the user suffer if the software reacts in a “no-reasonable” way in unexpected situations.

In analytical chemistry the robustness of an analysis method indicates its capacity to give good performances in a great variety of different situations. A study about the robustness of a given method should evidence all critical parameters, like pH, temperature, concentration, volatility, conductivity. The robustness of a measure is so that a tool index of how much little modifications in the analysis method (parameters variations), do not influence the tool reliability [1].

In structural engineering, the expression *robustness of a structure* describes the ability to avoid disproportionate problems (i.e. collapse) when the structure suffers serious local damage due for example to fires, explosions, collisions or consequence of human errors (Fig. 1).

The concept of robustness was formalized only recently, as aspiration to the realization of constructions able to involve all the resistance reserves, until collapse, through the activation of *alternate load path*.

In this way the aim is avoiding, inter alia, the generalized collapse danger, as a result of localized damage in the structure (progressive collapse), especially when exceptional events occur. [3, 4, 5]

2. Resilience of “small” vs. “large”

Less is more= small means robust. The Mies’s sentence seems to link itself with the natural law called size effect (or scale effect), according to which the system performances are inversely proportional to the physical dimension of the system itself. In other words, it descends from the observation that the surface/volume ratio, for any object with constant form, decreases with the increase of the dimensions. Considering for example a cube with 1 cm sides, if the surface and the volume are calculated, it is easy to note that increasing the side length until 2, 3, or 4 cm or more, the surface increases according to the square (6, 24, 54, 96 cm², ecc.), while the volume increases according to the cube (1, 8, 27, 64 cm³, etc.) and therefore the surface/volume ratio decreases with the increase of dimensions (6:1; 3:1; 2:1; 1,5:1; etc.). A lot of the forms existing in nature could not exist if their proportions were greater. An ant 10 times larger could not stand on its own legs. The heat emitted by a creature depends on the surface of its own body, and so, if the animals were volumetrically larger, they in proportion would have a smaller surface, and therefore they could disperse little heat, in a way that the internal liquids would end in seething. The animals of great dimensions in fact lose heat more slowly than the little ones. [4, 6, 7]

2.1 Economical systems, companies, banks

In the economical field the concern is the way to improve the “resilience”, that is the capacity to resist at the shocks of the financial system as a whole [8]. In this sense, a Masciandaro’s article, printed in June 2011 on *Il Sole 24 Ore*, is cited. The paper describes the role- according to the Governor Draghi- that the Italian banks, both small and great ones, have had as a support to the productive system during the year. *Il rapporto tra banche e imprese, nel modello tradizionale di banca commerciale, ha mostrato – non solo in Italia – notevoli qualità di robustezza. Prima della crisi era noto che l'intermediazione bancaria tradizionale riduce i rischi ma non assicura alti guadagni, a differenza di altri servizi finanziari. A livello globale, sotto la spinta della finanza anglossassone, è divenuto dominante l'imperativo per cui l'unica cosa che conta è la redditività; tanto, la stabilità è automatica. Infatti, se l'intermediazione è redditizia significa che è efficiente, e poiché sul mercato rimangono solo i soggetti efficienti, quel mercato alla fine sarà anche stabile. Per cui s'è imposto un modello di regole in cui la capacità di ciascuna banca di assumersi rischi è molto aumentata; fino a degenerare. Il Governatore ha ricordato quali sono state le degenerazioni della finanza. Sono stati progressivamente abbattuti, negli Usa come in Europa, tutti i divieti alle scelte imprenditoriali dei banchieri. L'assunzione di rischio sarebbe stata comunque monitorata e controllata grazie ai coefficienti di capitale, alla disciplina del mercato, alla supervisione delle autorità pubbliche. Oggi si sa quello che è successo. Coefficienti di capitale e disciplina di mercato si sono dimostrati due pilastri insufficienti, se inseriti in uno sviluppo non regolato di forme sempre più diffuse e complesse di indebitamento privato, grazie al contributo, decisivo e incrociato, della contabilità creativa, dei mercati finanziari non regolati, in generale del sistema bancario ombra.*

Large banking systems involve large risks and great debts, that are translated in greater possibilities of failure. Small systems can involve reduced risks and can deal with critical situations. Any contractor knows to

experience (but essentially to intuition) that the resilience of a small company or a small bank is really larger with respect to the resilience of a large system.

2.2 Social systems, great civility, urban centres

In parallel, in architectural and urbanistic field, the small villages whose growth remains “within the walls” due to logistical reasons (spatial impossibility to expand), have kept alive the conurbation sense, continuing to use its own historical centre as the heart, “the city” of the agglomerate, and maintaining the relationship with it. On the other hand, the great metropolis that have not been able to integrate (or could not integrate) their own historical centre in an evolutive part of the strategic and productive core of the town, lost the relationship with it. The centre is often reduced as a mere tourist route, decadent and discredited by the chief soul of the “city”, or transformed in a concentric development of suburbs increasingly marginalized (Fig. 2).

The town development accompanies the civility development and vice versa. It is demonstrated that the site influences the behaviour of the people living there. Sites and populations create together the social fabric.

The great civilizations, Egyptians, Persians, Greeks, Romans, even Barbarous nations, reached moments of maximum expansion and immediately after imploded. It seems like that an expanded organization, dual of the previous, was not equally robust and structured, and this was not equally credible.

The resilience, that on urban scale is translated in a core ability to preserve its own characteristics [9], is an auspicious concept for the modern metropolis. Their urban development needs an increasing amount of rules and/or indications for a guided expansion, or for stopping it, penalty the swiftly plunging in the irreversible metropolitan chaos, with all the known consequences from the sociological point of view.

2.3 Nature: bones, trees, snails

The above considerations seem to lead to the conclusion that the natural phenomenon of the growth self-limitation, product and re-product in the sociological and futuristic comprehension of the town, could suggest solutions for the resilience to the crisis.

An example can be the snail, as Latouche [10] points citing the Ivan Ilich’s metaphora, self-limits the growth of its own shell considering the costs/benefit ratio that a new spire implies. The snail shell grows in fact in exponential manner, so that an increase of space would involve an excessive increase of weight, related to the benefit (<<...C’est qu’une seule spire encore plus large donnerait à la coquille une dimension seize fois plus grande. Au lieu de contribuer au bien-être de l’animal, elle le surchargerait. Dès lors, toute augmentation de sa productivité servirait seulement à pallier les difficultés créées par cet agrandissement de la coquille au-delà des limites fixées par sa finalité.>>). Or the tree, whose intrinsic dimensions are confined during the life in such a way that the old plant stops growing, but nevertheless reinforces its own position on earth increasing its trunk circumference (Fig. 3). W. Goethe: “Es ist dafür gesorgt dass die Baume nicht in den Himmel wachsen” (it is noted that the trees don’t grow until the sky).

However, already Galileo, in his “Discorsi e dimostrazioni matematiche intorno a due nuove scienze (1683)”, wonders about the effect of the proportional dilatation of the creatures’ dimensions, and understanding that an animal so amplified could not stand under its own weight, concludes that the skeleton of large size animals holds a greater portion of its volume with respect to the case of smaller animals (Fig. 4). In other words, a small animal has more resistant bones, in proportion, than its giant dual (in sec. 2 the size effect = embrittlement of great structures, has already been mentioned) [11].

The scientific explication of this can be found in the definition of *fracture energy*, entity that, as it is known, depends on size, too.

Considering a fragile material sample under stress, in fact, the crack created in the moment of fracture depends on sample’s size (if the sample is small, the defect should be small too). The diagram in Fig. 5 results to be just a material characteristic: it represents the stress propagation through the crack versus the the crack opening.

This softening law indicates an impairment of the interaction when the distance w between the crack surfaces (or free areas) increases. When the limit value w_k is attained, the interaction totally expires, and the crack becomes a total disconnection that divides the sample into two distinct parts. The area under the curve represents the energy dissipated on the fracture unitary surface. This cohesive law is a material characteristic that depends on the type of structure, on the material damage mechanism, and on the fracture energy G_f , defined by the following relation

$$G_f = \int_0^{w_k} \sigma(w) d(w) \quad (1)$$

The cohesive law results to be an intrinsic property of the material. The energy, dissipated on the crack surface, is $G_f A_0$ (with A_0 area of the sample cross section). Since the energy dissipation occurs only in the crack, and not in the volume of undamaged material, the globally dissipated energy in the volume $A_0 l_0$ (supposed in the absence of hardening) is still $G_f A_0$ [12].

This shows, according to what has been said in sec. 2 (the volume increases with cubic exponential law, while the surface increases with quadratic law), that doubling the sample volume, G_f doesn't double proportionally, but increases "only" of 1/3. Hence, the ant 10 times larger than the normal ones could not dissipate the energy due to its body load, and its legs, although (the legs, too!) 10 times larger than the normal ones, should collapse under that weight.

3. The "lesson" by structural engineering (strategies for a "great" life)

Nobody can always self-limiting in size, as the trees and the snails, but sometimes "great" structures must necessarily be created and sustained. In these cases, Nature provides indications that, combined with the structural engineering studies, suggest strategies to give robustness. In fact, the same robustness that the "system building" requires can be expanded, as a concept, to the "system society", understood as a complex set of banks, cities, nets.

Generally, a complex structure is the one that cannot be reduced to a simple scheme without losing important aspects of the structural behaviour. The complexity of a system should be independent on the entity and the position of the external forces. Hence, a complex structure can be defined as the one made up by a large number of parts that interact in a non-simple way under an arbitrary loading scheme.

To describe the state system, the definition of *entropy* can be also used. The entropy, in a general definition, represents the amount of information required to describe a system. In the classical thermodynamic definition [13], the entropy is defined as the natural force which carries a system from an improbable to a probable condition. In statistical mechanics, entropy is essentially a measure of the number of ways in which a system may be arranged. It is often taken to be a measure of disorder: the higher the entropy, the higher the disorder.

Entropy increases with the increase of variety and uncertainty in the system. Correspondingly, a highly complex system requires a larger amount of information to describe its state. An increase of the complexity of a system, through increased disorder, variety and uncertainty, would be represented by an increase of its entropy, which, as stated, quantifies the amount of information required to describe the state of the system.

Some Authors [13] recently provided a definition of *structural complexity index*. The SCI takes into account the definition of information entropy formulated by the same Authors, and can be computed by the following formula:

$$SCI = -\sum_{i=1}^s \frac{\psi_i}{\sum_{j=1}^s \psi_j} \log_2 \left(\frac{\psi_i}{\sum_{j=1}^s \psi_j} \right) \quad (2)$$

where s is the (finite) number of load paths, i.e. fundamental structures, and ψ_i the performance index of the i -th load path linked to the deformation work performed on the i -th fundamental structure (defined as the statically determinate structure subjected to the loads and extracted from a statically indeterminate scheme).

Dually, the structural robustness is defined as the ability of a manufact into do not let propagate local occasional events (i.e. failures, lesions, explosions, terrorist attacks) up to the global scale of the manufact.

In this sense, an analogy with the concept of materials *tenacity* (namely the ability of do not propagate in a fragile manner a micro defect up to the macroscale) is done. The strategy to increase the structural robustness, therefore, can be reconducted at the same analogy with natural phenomena: **redundancy** of the elements in parallel, that is hyperstaticity, and **compartmentation**, just as some strategies of materials tenacity (especially the natural ones) are represented by the insert of reinforce fibers or crack arresters. So the human skull has crack arresters to partition the own shell and circumscribe the damages, the trunk of bamboo has a redundant texture in order to bend without breaking, and at the same time, to cope with unexpected events (i.e. a violent storm) (Fig. 6) [14].

So, in parallel with the *CSI* index previously defined, other Authors (belonging at the same work group) [3] recently proposed a *robustness measure*, starting from the **structure stiffness matrix norm**. In fact, decoupling the norm of stiffness matrix from the dimensional parameters (that make the measures "sensible" to the used metric scales, and impose to the structural designer an *a-priori* dimensional choice), the estimation of the matrix norm can be changed to the robustness evaluation. In a related manner, it can be related to the structural compartmentation, in order to develop a "rule" to design buildings able to survive to

the sudden and unexpected lack of one (or more) structural elements. In particular, some aspect of two different norms measures are evidenced, that is the robustness measures of Demmel [15] and Nafday [16], that appear of specific interest, although they were essentially developed for mathematical scope. In fact the first Author applies and perfects to the structural problems the results the other had previously computed from the essentially algorithmic point of view. Finally a third solution is proposed, able to evaluate the compartmentation degree, considered the first robustness parameter of the structure. The starting point is the diagonalization of the stiffness matrix.

The displacement norm, as robustness measure, can be analitically found starting from \mathbf{q} and \mathbf{P} , respectively generalized displacement and stress; in this case one has

$$\mathbf{q} = \mathbf{K}^{-1}\mathbf{P} \quad \text{or, in index form} \quad q_i = \sum_{j=1}^n K_{ij}^{-1}P_j \quad (3)$$

Assuming as unit values only the solicitations P_j dual of the searched generalized displacement q_i , one has

$$P_j = \delta_{ij} \quad (4)$$

thus, the same generalized displacement is

$$q_i = \sum_{j=1}^n K_{ij}^{-1}P_j = K_{ii}^{-1} \quad (5)$$

from which a natural definition of the robustness measure (or **displacement norm**), follows:

$$\delta_q = \frac{1}{\sqrt{\mathbf{q} \cdot \mathbf{q}}} = \left(\sum_{i=1}^n q_i^2 \right)^{-\frac{1}{2}} \quad (6)$$

eqn. (6) can be expressed by taking into account eq. (5) as follows, and then obtaining a formulation that depends only from the components of the stiffness matrix

$$\delta_q = \left(\sum_{i=1}^n (K^{-1})_{ii}^2 \right)^{-\frac{1}{2}} \quad (7)$$

3.1 Difference of robustness and vulnerability in random and scale invariance networks

In the '50, the two Hungarian scientists Paul Erdős and Alfréd Rény observed that a large part of the human phenomena can be represented by graphs: customers and suppliers, nerve cells, houses and telephone lines, towns reaches by trains, people linked to others via friendship. All that is linked, can be schemed, mathematically, with nodes and lines. The application fields are very vast, because all Nature, including the Society, is made by complex links and interconnections. So Erdős and Rény elaborated a general model of network built according a **random** connection (Fig. 7 a) of nodes. Unlike what Einstein believed, they supposed that the Case was the more uniform and perhaps "democratic" way to establish nodes and links in a network.

Adding an amount of isolate nodes and some random links between they, in a first time some couples of scattered nodes were formed. Gradually, random links are added and increasingly more little isolated groups are established, but at some point a giant cluster suddenly is formed, in which every node has at least one

link with another. All nodes have a link with the others, becoming a set, that is something qualitatively different from the previous. This phenomenon is a radical transformation that occurs after the qualitative and gradual addition of links, and it is defined “phase transition” by the physicists, similarly to the transformation of the water in ice (that just occurs with the increase of entropy [13]).

The ability of reaction (resilience) to attacks and errors, and the adaptability to the random failures of a network depends from its structure too. The nets theory perhaps shows, from this point of view, its major practical importance. In a lot of natural systems, a very high interconnection, together with a great capacity of self-tuning and robustness worthy of attention, can be observed. For example the eco-system, with the continual extinction of animal and vegetal species, shows an excellent fault tolerance. Instead, in a lot of human products, as the electric networks, the high interconnectivity lends itself to uncontrolled domino effects, like the black-out.

As a result the different sensibility at the events and the different robustness is not due to interconnectivity, but to the topology of these relationship. The **hub&spoke** system, that can be catalogued as scale invariance systems, is different from the random or not hierarchic system, because some observations about the cleavage. In a random network, if a node after the other is removed in a random manner, the net suddenly collapses in the moment in which it overcomes a given critical threshold. Barabási [17] summarizes the concept with these words: «La robustezza topologica ha quindi le sue radici nella struttura antidemocratica delle reti a invarianza di scala: i guasti privilegiano in modo sproporzionato i nodi più piccoli». The simple fact that there is a lot of small nodes and a few number of great nodes is a consequence. Therefore, if the nodes go out casually, it is more probable that this does not occur to the (numerical limited) hubs. So the great hubs are not damaged, but the small spokes are. If the higher probability is that the random collapse of a limited number of hubs doesn't provokes disasters, it is also true that the stopping of few hundreds of chosen hubs is enough to flake virtually all the network, whether they are airports or informatic. The networks signed by the power law are then **fragile** respect to targeted attacks. Their vulnerability is manifested when an action conscious and pre-routed occurs (terrorism?). Clearly, a random network does not run these risks, but it is much less resistant towards the normal difficulties and simple abnormalities [18]. The specific dimension and distribution (hierarchic) of the hubs (Fig. 7 b) determines as a result the network topology, its stability and robustness, and its dynamic behaviour.

4. Conclusions (theory of the decrease?)

The network theory and the contribution of the structural engineering are really simple attempts to operate a “previsional” function, or anyway a “control” function on the Society and on its sociological development.

In 2007 the economist Taleb wrote an essay titled “The black swan” (then followed by “Robustness and Fragility” in 2010), in which he described as the improbable, or rather the imponderable, governs every aspects of the life, from the economical one on global scale, until the social one on individual scale. Starting from the swan metaphora, Taleb [19, 20] demolished the human certainties confirmed by the empirical experience: <<basta un solo evento inaspettato>>... as the sighting of a black swan, precisely... <<per demolire certezze e schemi consolidati da secoli... così siamo indifesi di fronte all'imprevisto, si tratti di vita quotidiana o di mercati finanziari>>.

Properly because of these new, coherent theories, that are far from the attempts of global network for a total control, the structural engineering today proposes the development of concepts as the system “resilience”, that is a concept able to develop the adaptation ability to what will happen (and we aren't sure that today it can be defined) during the life of the structure/society. The development of the systems resilience, lent term by the material science, as well as the lesson of the structural engineering about the robustness recovery trough the redundance and compartimentation parameters, could represent a solution for the overcoming of critical social times, avoiding phases of contraction and decrease. In fact, if the Mies's assertion in the architectural field can imply a cultural revolution, above all contextualized in his age, in structural engineering we think also that “more is more”, and we aim to built ever higher skyscrapers, and ever longer bridges, although conscious that the challenge to the gravity results incompatible with the snail sapience.

CHAOTIC DEVELOPMENT AND URBAN MORPHOLOGY. THE SIGN OF THE ARCHITECTURAL ANARCHY.

Gerardo Maria CENAMO¹

⁽¹⁾ Facoltà di Ingegneria, Università Telematica Internazionale UNINETTUNO, Roma, Italia
g.cenamo@uni nettunouniversity.net

Abstract

This contribution aims to deepen the complex relationships between urban form and architectural design, such as defined by the documentation of some peculiarities of the built environment in the city of Naples, whose process of building was stratified by continuous comparison not only with the topography and orography of the city, but also with the phenomena of transformation for endogenous and exogenous causes, both natural and artificial, determining, as explained in this study, spatial organizations of preeminent originality and complex conurbations both linguistic and structural, "daughters" of a society considered itself an expression of strong heterogeneity and adaptability. During the first half of the seventeenth century the city experienced a chaotic demographic explosion: in the 1606 it passed, in only fifty years, from a population of about 270,000 inhabitants to 450,000.

The nucleus of the city, consisting of nine urban districts and seven villages, expanded itself volumetrically but, at the same time, it was limited within the same geographical areas, through a dense layering of makeshift homes as lows, warehouses, small supports, houses carved into the tuff, wooden shacks clinging to the tuffaceous spurs that littered the streets and that were mostly popular houses.

These were often different evolutions of the same structures of shops and stalls used as beds during the night. The changes brought about by rapid urban growth, detectable in the different historical processes of development and transformation, have strongly characterized the morphological development of the city, which had to relate both with a prominent archaeological heritage and with the particular geo-morphological, hydro-geological and bio-climatic system.

The growth of settlements has been placed around the manifold configurations resulting by geophysical activity such as valleys, hills, gullies and their transformation into foothill locations such as stairs and ramps, by the erosion of systems that have transformed progressively in big hollows, ditches, by the transformation of tuff as a result of mining activities in caves, and finally by an opportunistic and "imaginative" Neapolitan people's ability to produce extremely heterogeneous aggregations, which is outside by any canonical cataloging.

The main purpose of this study is, therefore, the reading of a complex and messy process of evolution, mainly declined through the research on the role of evolutionary processes in project design and urban transformation. I will also take into account, trying to value its effective weight, the relationship between complex morpho-urban development, historically decisive, and the evolution of part of the complex social body of the city, historically inclined to modus and customs often connoted by strong individualism.

Key words: form, city, development, morphology, aggregation.

1. Premise

Early Roberto Pane in his "Naples unexpected" explained a few places in the city cataloging curious architectural and environmental solutions made in the eighteenth century, introducing a search that may take even several interpretations regarding the processes of urban growth and transformation that the city has had in the past centuries [1].

One of the most "unexpected" thing that you can borrow from the title, even now, what about some episodes of residence found in some historical cities and especially in Naples, i.e. a particular type of housing that, conditioned by the morphology of the places, was forcibly influenced by several economic factors, social and existential forms, returning "not designed" for certain parts of cities, because of their peculiar configuration might seem peripheral and marginalized and contribute fully to the definition of portions of historic urban centers, constituting integration of their overall fabric.

The specific reference is to the dwellings of "luck", born spontaneously in Naples, along the steep walls of tufa or excavated in underground, dark and ancient paths of water, in the caves, natural or derived from the extraction of tuff, made from six hundred/seven hundred century to cope with population growth and the resulting housing needs. (Fig. 1).

These solutions have defined, for subsequent volumetric addition, the characteristic of real "hidden" villages, that are, only from the standpoint of the social context, urban boundary. Subsequent additions have resulted, in some cases, a formal result, an architectural language and a technology configuration that highlight very bold environmental solutions, original and creative ideas. (Fig. 2)

Ignored by official historiography, these settlements are now a cultural heritage of the People's ability to invent an adaptive housing types such as to define a new relationship between anarchy housing and urban morphology.

The work lies in the particular field of study (the larger problem of retrieval and urban renewal) for the rehabilitation of these micro-environments constructed which, for their size scale and their peculiarities conformative, were heavily penalized by the development processes of the city.

Fig. 1: Cavone a Piazza Dante: superposition of buildings.

Fig. 2: Vico Lepre a Montesanto: buildings in stone (tufo).

Fig. 3: Luigi Guerricchio, I Sassi di Matera, da B.Zevi "Dialetti architettonici, Milano 1966".

Fig. 4: Manila, Benvenuti a Death city, da Repubblica.it.

Fig. 5: I Trogloditi di Mergellina.

The objective of this study tends, in fact, the mending of these organic pieces “poor” with the remaining areas of “rich” by solving a dichotomy between different “modus abitandi”, ie between residential segregation and civilization.

In a lot of specialized vocabularies such properties are identified from time to time by such adjectives as “improper”, “precarious”, “luck”, “forced”, “rock” and others, but the common denominator that is always based on the trinomial poverty - marginalization - adaptation.

The history of these units is filled with examples of paradigmatic types, some of which have had the good fortune to have been investigated by the official culture of industry and others, such as those under consideration, which have been neglected due to physical and cultural isolation of city.

Just consider two extreme cases such as that of the "sassi di Matera" (Fig. 3) that is taken to the dignity of the UNESCO cultural heritage, and one that occurred in Manilla, where tombs, vaults, chapels and so have become housing for “underprivileged” (Death City-City of the Dead). (Fig. 4)

The theme of anarchy-residential construction is not new to Naples if you think that up to 1960/70 even in Mergellina some caves have been converted into homes, for which reason the inhabitants were called “the Troglodytes of Mergellina”. (Fig. 5)

2. The tradition of building as "Techne"

The study of these particular architectural episodes as well as a methodological approach towards the construction of anarchy theme, seems to have been customary, intended as an activity unrelated to the more canonical disciplines of architectural interest.

Beyond an overall research on the phenomena of chaotic architecture that developed in residential theme in the city of Naples with its continuity, the primary interest of this work is to define an approach directed towards this “architecture of necessity”, not necessarily attributable to already undertaken researches, but in order to recover our conscious reality that is often ignored or at least ignored by architectural and urban culture.

One of these concern approaches, surely, the “diversità” social, linguistic, productive and constructive architecture of hidden and overt Architecture of the city, revealing connotations and configurations closely related to processes of design, construction and building autonomous and differentiated.

The building unexpected architecture, not less than one designed, that follows “reasons” of laws and principles, have ancient origins: but while the second offers a more easily understood, because supported by an infinite analysis conducted under the most varied angles, in the first constructive engagement and building commitment is still to discover and understand.

At this point the chaotic architecture cannot express ‘the prelude to consider some aspects that, while being interesting manifestation of creativity, can not contribute to the definition of a canonized productivity process’, Anarchist designs and builds its own environment, subjecting only to its technical and cultural knowledge, escaping from any programmatic rule. [2]

The myth of the city as a dynamic center of cosmology and architectural symbolism, is scaled to the proper role of the contrappositive "out of town", where daily activities, spontaneous and creative weigh on culture and provide architectural elements and connotations associated with the processes of recognition the so-called "popular" culture. [3]

The city's architecture is reduced to the signs "understandable" and signs "incomprehensible" that splits and merges in forms more related to the paper, indecipherable to the "other architecture" that the "system" this aloof, elitist that does not allow dialogue with the "strong" poor, and whose signs of recognition and prioritization are provided on how much wealth the "decorative liveries".

In this sense, the opposition between "popular" and "noble" between "spontaneous" and "bureaucratic" between "creatività" and "restoration" and between "everyday" and "programmed" with rampant evidence rises to a concrete symbol of the deep laceration - political culture. [4]

3. The cultural references

The subject under study has not, to date, a bibliography canonical, so it is quite complex research of literary references that it can endorse the scientific credibility.

Nevertheless it is precisely this lack originality and interest provides bibliographic research; "Order and complexity in the design of the landscape" is the title of an essay by Rudolf Arnheim German psychologist (1904-2007) in which it is admitted that the "disorder can be attractive and desirable. It provides a form of raw and anarchic freedom, and as such can offer some relief to the victims dell'irreggimentazione". Indeed, the modern option is for "loss of center", the rejection of any hierarchy, the ongoing interest in the accidental, the unpredictable, the abnormal, the deformed, the monstrous, the eccentric. [5]

Second Bruno Zevi, as reported in the volume of cheap paperbacks Newton, architectural dialects (against the history of Italian), "the principle of dissonance remains essential. The constant is mechanically repetitive, as occurs in the curtain walls of the city, or complaint a more differentiated additive system that emphasizes waste, imbalance, disharmony, conflict".

For Zevi, the difference between settlement forced and planned settlement lies in the fact that while in urban outdoor spaces, streets, squares, visual take on the highest priority, architecture forced unity "home" has a secondary value, bought his first posed the "sequence" of volumes, if they were molded together with a single gesture.

We are faced with languages "zero level" says Bruno Zevi still on the aforementioned "architectural Dialects", without grammar or syntax, parks adjectives, basic existential dictated by events, by nature and from work. Words of immediate significance, placed side by side, no verbs: a communication architecture exactly the opposite of that academy, devoid of semantic and composed of stock phrases. [6]

Buildings are mostly illegal, but in their continuous development horizontally or vertically in grooves or protrusions paretali tufa, can be defined as self-sufficient: that is handmade and homemade. [7]

4. Environment and place

The cities, already from their origin are characterized by different parameters predominant, including the essence of the "genius loci" and the morphology of the place.

The first is to identify the social identity of the civil power (government buildings), religious power (the temple, the church), military power (military buildings) and economic power (buildings for business), the second identifies the "forma urbis", the morphology urban developed through the natural and artificial processes of transformation and urban growth.

Clearly in such situations, there was a symbiosis between cultural, landscape and urban form that has influenced the cities and ways of life.

The official history has, sometimes, neglected the analysis of the morphology of the places through the expansion projects, construction processes and the research of materials and natural resources that have local costruiron the form of the city.

This approach has resulted in a vision seemingly unitari of the built environment which, however, appears fragmented and cataloged in phases historical and sociological. Through the values considered, the meaning of "built environment" coincide with that of "urban place".

The environment, natural or artificial landscape, can be considered as "built by human, natural and artificial components." We can define the "place" as something more than an abstract location, as part of reality by environmental parameters recognizable by definite confines (houses, roads, buildings), then through "physical" limits that, in the case of this study, are represented by morphology and conurbation of the place. [8]

5. The case of Naples: the urban morphology

The causes that led to the construction of housing types unusual, fleeting referent to any architectural and structure, are to be found especially in some large city growth processes that have altered in some areas the balance between natural and built environment, forcing many people less fortunate, to be resigned to a condition of living "extemporary" and improvised.

In the particular case of Naples, the parameter most emergent and important to this type of analysis, it is precisely the morphology of the place, which has affected the development and then the final form of the city. Urban development has occurred within precise confines; the sea and the hills of Camaldoli, Vomero, Posillipo. The hill of Vomero is connected to the Greek-Roman archaeological settlement by ancient rivers and watercourses where they were subsequently constructed the neighborhoods of Petraio, of Cacciottoli, of Cavone, of Salvator Rosa, much like the hills of Capodimonte is connected downstream through the streets of S. Teresa, Museo, Stella, Vergini. These two systems converge in two main directions of Pessina and Foria. To the west the hill of Posillipo is connected downstream through the streets of San Antonio in Posillipo, Villanova, Fosso the Casale, Gaiola, Marechiaro, Riva Fiorita and Cordoglio crossing the homonym settlements.

In these areas there is the existence of multiple barriers "physical", which were their limits for social inclusion and urban organization.

They are indeed, in the tradition and typology of the city places, that even now composing the historical center of the city, are still "far apart" maintaining a hybrid role of "village" in an urban perimeter that can no longer consider them such suburbs.

We can refer in particular to the settlements "broken" by the construction of the important street Corso Vittorio Emanuele, as Montesanto, S. Antonio ai Monti, Cacciottoli, S. Maria Apparente, Petraio or those "broken" by the construction of S. Teresa street, such as Vergini, Stella, Sanità, Materdei or even those "broken" by the construction of the Posillipo street as Villanova and S. Strato.

And still the Pedamentina S. Martino or Calata S. Francesco, interrupted by the streets Tasso and Aniello Falcone.

They are all settlements dating between '600 and '800, where it denotes a constructive characteristic with brilliant and unexpected inventions and technological bold solutions.

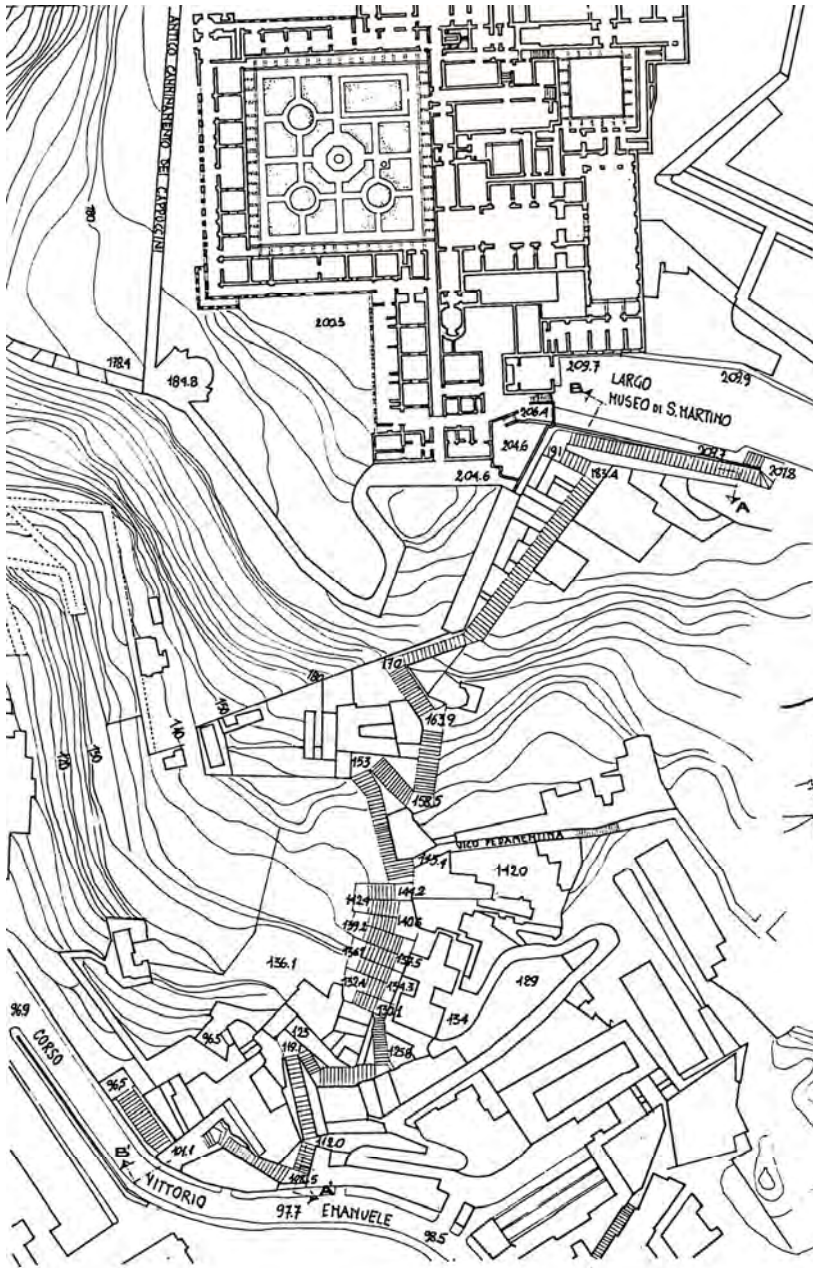

6. The project area

We study a piece of the city, the area of Montesanto confined between a section of the Corso Vittorio Emanuele (upstream) and the streets Pessina and Toledo (downstream).

The whole area is bounded to the east by street Pessina (from the Archaeological Museum to Piazza Dante), to the north by street Salvator Rosa (from the Archaeological Museum to Piazza Mazzini), to the west by road Vittorio Emanuele (from Piazza Mazzini to staircase of Montesanto).

The planimetric configuration of the area can be considered as an urban barycentre, which is a pivot around which to develop the directions of the district Materdei to the north-west and that of the Quartieri Spagnoli to the south-east.

The whole area is crossed by oblique paths starting from the hill of the Vomero run off downstream. One of the most famous oblique paths is, of course, the Pedamentina of S. Martino (from the homonymous Museum to Corso Vittorio Emanuele) and its natural extension, the staircase of Montesanto. (fig. 6, 7)

CONCEPITA NEL 1880, ESSA PRESERVA IL MONUMENTO DELLA CHIESA DI SAN CARLO DEL MONTE SANTO, RINNOVANDO LA STRADA DI MONTESANTO.

L'IMPIANTO È SCANDINAVICO, MA LA PROGETTAZIONE SPAZIALE NON È RAGGIUNTA PER LA PARTICOLARE COLLOCAZIONE CHE NON MONUMENTO DI EMERGENZA SE NON LA NUOVA STRADA.

IL TRONCO È PRESERVATO ED È DALLA SUA STRADA MANUTENZIONE LA SCALA SI TROVA IN CONDIZIONI DI NUOVE VITE DEGRADO.

Fig. 7: The Staircase: Montesanto.

The settlement of Montesanto is classified by the official historiography, as “middle” area of the historical city, where there are more buildings of historic character together at a strongly compromised by the chaotic development of past centuries with a static level of degradation and to limit the environmental compromise. The move away from the center of the city, over the years, a gradual but progressive deterioration of the housing stock, which in some cases, reaches the total degradation. This condition is shown above along those guidelines in which the building was excavated in downstream into the tufaceous walls, as well as the settlements along the descents and ascents that have been “cut off” from their street Corso Vittorio Emanuele. In fact, stopping the natural orographic “continuum” uniting these places, situated at the top, downstream towards the rest of city was determined to be an insurmountable barrier in terms of physical and social. Therefore it is changed also the way to inhabit these residual places, and in them there has been a chaotic buildings, anarchic, unregulated and unsupervised; it specializes in a manner of building and inhabit in a “hidden” behind the buildings noble or in natural cavities. Emblematic of this situation the street Francesco Saverio Correr, called “Cavone” at Piazza Dante. The “Cavone”, in fact, that was a watershed, the ancient river bed Sebeto hill, where the water had carved a canyon tuff in promoting intensive extraction. Sebeto disappeared, its river bed becomes a path, a street along which they settle many “fondaci”, where the merchants deposited their merchandise, which displayed in Mercatello Piazza (Piazza Dante) at the time outside the walls of the city’s defense. On either side of Cavone rise the tall walls of tuff are the border, to the east of the settlements of Tarsia and Pontecorvo, to the west of the settlements and streets Tommasi and S.Giuseppe dei Nudi. Along the sheer walls and on top of these can be found the buildings described, accessible only by stairs and walkways across the tuff. Housing in these areas, functions to meet a strong housing requirement and have found a particular type aggregative that defies the official consideration of architectural culture, because it is constantly changing and constantly changing urban design. They are buildings that relate primarily to the concept of “common vicinity” that is, the “modus vivendi” for which the street, the staircase, the ramp is an integral part of homes. These buildings are made from the assembly of functional systems typical of the traditional Neapolitan (verandas, terraces, patios, pergolas) that, with the Neapolitan yellow tuff, define an urban landscape a very special and worthy of attention and research. (Fig. 8, 9)

Fig. 8 – Juxtaposition between the natural and stone and artificial materials by buildings: S. Antonio ai Monti.

Fig. 9 – Juxtaposition between the natural and stone and artificial materials by buildings: Cavone a Piazza Dante.

7. The requalification program

The attempts to unify these places around the city, even with the advanced technology as the great staircase leading to the Corso Vittorio Emanuele, the funicular to Vomero, the stations of the subway and Cumana, were greater in the south, even marginalizing more concentrated in the northern area and areas around the terminals for connection (funiculars, staircars, station), the vast majority of economic activities and services such as hospitals, churches, banks, cinemas and theaters.

In recent decades of the area has been equipped with several services that have, in fact, tried to mend the rift between the two areas: the construction of the social park "Ventaglieri" (which took place in the years after the earthquake of 1980) and, more recently, the urban park on the former military hospital, and most recently the new station of the funicular railway and Cumana.

Since 1993 students of the Faculty of Architecture of the University of Naples Federico II, coordinated by the Department of Architectural Technology, have participated in a seminar on "The places of the contemporary city – Anarchy housing and urban morphology".

The seminar was studying three issues:

1. study of the urban development of the Cavone in Piazza Dante with a visit to S. Monica fondaco, to the fondaco "Fondachiello", to the homes built on the hillsides of tuff;
2. exhibition of the project proposals connected to toponymy and topography of Naples;
3. meeting and debate on the issues of the report.

During the same year the Institute of Technology of Faculty of Architecture Federico II drew up a research project with the CNR called "systems of the urban residential rehabilitation historical center and in particular the area of Montesanto".

The research, based on the study of the existing and the potential for redevelopment, was devoted to the problem of existing temporary housing area.

Unfortunately, all these cultural activities have had a practical application, so we must make a plan of reorganization of this built heritage aimed to a better integration of housing.

The retrofitting program, starting with strategies and methods of official culture of the sector includes research and survey of the most common types of housing, the analysis of morphological characters, the organizational criteria of space, character and functional performance, up to study all details of building components that characterize the architectural form.

Preliminarily will specify the role that morphological characters can play in the next work program retrofitting.

The research is the first part of the development of the whole work and may materialize in the cataloging of the "types", through a specific topographical and architectural survey, the study of materials and manufacturing processes, systems and processes of transformation adopted in phases construction.

Completing this first phase, the program will address the identification of new standards optimal models of functional organization, size and quality of interior space, corresponding to the different needs of users "in itinere".

The method of research, between practical and analytical model, first proposed a working hypothesis, through a series of adjustments approximated by:

1. adaptation of the method of work to socio-economic reality in which it operates, respecting the values and human and social conditions;
2. control of the typological scheme through interaction with the relative humidity and microclimatic models, light and sound;
3. adaptation to the local building systems, enhanced and updated appropriately, complying with the principles of simplicity, ease of construction, of creative freedom;

Through the sequence of adaptations, it leads to a range of models, organized for each of the single type of homes, obtained by extrapolating the self as a "living cell" from the context of urban reality, context within which they should go to intervene in the strategies for implementing.

Fig. 10 – Survey of the types of buildings and site.

8. Conclusions

The attention to quality urban environment involves a thorough evaluation of the urban environment in terms of creativity.

This results in a process of reconfiguration of the urban fabric that results in terms of reactualization and retrofitting extending the range of the project intervention also to the social.

The conclusion is that the balance in an urban environment like Naples is found in a situation characterized by morphological and environmental parameters: antigeometric spaces, informal, forming signs not rigidly preordained, not schematically concluded from points of view, in a sense that path leading to multi directional, variable, changeable, vertical, inclined, semi-closed as well as the dynamic relationships between morphological suggest a setra natural space and built space.

The regeneration program aims to integrate the few green areas, the organic integration of the roads to places where it exerts associational life, the capacity to create a utopia through the unification of the parties goes beyond the boundaries of urbanism of utopia to restore the city's past the marks of this.

It outlines a method for planning a redevelopment of the collective that could prefigure, through architecture, an environment more congruent.

Reaching places, connecting different heights, means developing a project, organizing the resources available for a revision and reinterpretation of the environment from which emerges a new spatiality, not only in figurative terms, which serves to shorten distances, integrate gardens, surpassing compactness of the logic to connect parts of the city to in itinere actions, mechanisms and kinetics multiple circuits, enhancing the integration of culture, art and projects.

Protection, Management and Sustainable Development : the "Grand Site de France" Experience

Anne VOURC'H¹

⁽¹⁾ Director, Grand Site de France Network, 9 rue Moncey, 75009 Paris, France
annevourch@grandsitedefrance.com

Abstract

"Grands Sites de France" network is a national association which brings together elected local authorities that are responsible for the long term and day-to-day action to conservation and presentation of cultural and natural sites, protected for their value in the landscape.

37 sites and 27 millions visitors, these two figures mean very strong pressures from tourism, and a major challenges: How to find and maintain the balance between the need to protect this heritage and its very attractive tourism potential ?

A national policy is currently carried out to manage sites with respect for the cultural or nature values of the site, the "spirit" (atmosphere) of the place and to seek solutions in cooperation with tourist operators through encouraging a quality experience for the visiting public and the participation of local residents.

Local authorities, in agreement with the State administration, are the main driving force to implement this strategy of sustainable development at heritage sites.

The State administration guarantees the legal protection of the Grands Sites, decides on their classification and issues authorizations for restoration or modifications within protected areas. But with the exception of a few major monuments which remain managed directly by the State, local agencies created and directed by elected local authorities are now responsible for the management of Grands Sites, in relation with participation of inhabitants.

Keywords: Heritage Site, Preservation, Integrated Management, Sustainable Development, Cultural Landscape

1. Introduction

"Grands Sites de France" network is a national association, which brings together elected local authorities responsible for both day-to-day action and long term evolution, conservation and presentation of cultural landscapes and other natural and cultural heritage sites, protected for their landscape value.

37 sites and 27 million visitors annually, these two figures mean very strong tourism pressures, and some major challenges for their managers: How to find and maintain a balance between the need to protect our heritage and its undeniable tourist potential? How to develop it in a sustainable manner? Via integrated management.

In France, a national policy is currently carried out in cooperation with local authorities to manage sites with respect for their cultural and/or natural values, the genius loci and local populations. The policy aims at creating local development in cooperation with local populations linked to the sites' values without damaging them. The responsibility for managing the Grands Sites in France has for many years been very centralized.

Fig. 1: Grand Site du Pont du Gard ©Réseau des Grands Sites de France, 2010

Nowadays, local authorities, in agreement with state administration, are the main driving force in implementing this strategy of sustainable management of heritage sites and their surroundings.

State administration guarantees legal protection of the Grands Sites, decides on their classification and issues authorisations for restoration or modifications within protected areas. But with the exception of a few major monuments, which remain managed directly by the State, local bodies created and directed by elected local authorities are now responsible for the management of the Grands Sites.

The Grand Sites are more than places of outstanding beauty and immense value, they are more than just the monument or protected area in their centre, they are territories where people live and work, they comprise fields, pastures, economic activities etc. and site managers integrate this reality into their management. Heritage Sites cannot be apprehended only as sites for tourists, but also as living spaces and the fact that populations are taking part in the Grands Sites' actions is essential for it brings better understanding and pride to the inhabitants, better preservation and a better base for sustainable development. We always need to think of a site in its environment.

This paper will present the global goal of this policy, and practical accounts of on-the-ground managers. It will focus on the key role of good governance for a long-term and a sustainable preservation of living-heritage sites.

2. The challenge: Finding and Maintaining a Balance

This article is based solely on the experience of the Grand Sites de France Network in the field of sustainable development of regions via an integrated management of heritage sites.

Answering the question of balance is not easy in France, a country that is the world's leading tourist destination (with 82 million international visitors annually), and which has strong domestic tourism (growing with the economic crisis we experienced during the past three years). The concentration of natural and cultural heritage sites is very strong in France. They form the basis of the tourism economy, accounting for 6.2% of GDP.

What are the problems the heritage sites face? The majority of these sites are protected by a powerful law, but sometimes with poorly integrated infrastructures, with insufficient regard for the environment and with no

managing bodies for many of them. It has been recognized for some time now that we must change the way these sites are managed. What other problems are the sites facing today and what measures are being undertaken to improve things? We face invasion of cars and coaches, undesirable levels of crowding disrupting site's atmosphere (genius loci), obtrusive shopping outlets which are becoming the same wherever you go, souvenir shops with products that are anything but locally produced, local residents depending solely on tourism or, on the contrary, residents who object to the influx of tourists and develop hostile attitudes, regular visitors who no longer want to come to sites that have become "tourist traps". In short, many heritage sites are victims of their own success – a success that is not sustainable

Fig. 2, 3: Illegal parking at the Grand Site des Roches de Solutré-Pouilly-Vergisson before parking installation ©Grand Site des Roches de Solutré-Pouilly-Vergisson, 2001 and A shop with standardized and low quality products at the Grand Site de la Baie du Mont Saint-Michel ©Réseau des Grands Sites de France, 2008

The national "Grand Site de France" policy has been implemented for 30 years. The Ministry of the Environment and Sustainable Development operates this policy and it concerns natural and cultural sites, protected for their landscape value by a long-standing and powerful law dating from 1930. This law relating to "the protection of natural monuments and sites with artistic, historic, scientific, legendary or picturesque character" allows protection of sites covering very large areas, often including important monuments which are themselves protected as historical monuments. The Grands Sites often include areas of recognized ecological importance as well. These are subject to national and/or European laws on the protection of biodiversity such as Natura 2000. They are very popular and well known in France, and in some cases worldwide. They form the bedrock of tourism in France and you will no doubt be familiar with many of them, such as the Mont Saint Michel and its Bay in Normandy or Mont Sainte-Victoire in Provence, made famous by the paintings of Paul Cézanne. The Grand Sites attract large numbers of visitors: the 37 sites in our network attract 27 million visitors annually, whether local, regional, national or international. Some of them are also included on the UNESCO World Heritage List, like Mont St Michel and its Bay, the Roman aqueduct of Pont du Gard, the fortified City of Carcassonne, and so on. In every case, the values and key concepts of the World Heritage Convention inspire our actions, independently on the status of the sites.

Local authorities and public bodies managing the Grands Sites wanted to join in a network to share their experience and good practices, overcome their difficulties, move forward together and construct joint projects. Therefore, our association was created through a bottom-up initiative and not a "top-down" decision; managerial bodies join us on a voluntary basis. We have no authority over those local bodies,

members of the association, as our role is to facilitate their moving forward together, learning new skills, exchanging on good practices etc. We are recognized and supported in this by the state, especially by the Ministry of the environment. We work closely with other heritage networks, such as national parks, natural reserves, various associations of historic towns etc.

 Sites labellisés GRAND SITE DE FRANCE
 Sites engagés dans une démarche visant la labellisation

Le label GRAND SITE DE FRANCE est décerné par l'État, au gestionnaire du Grand Site, pour six ans. Il vient reconnaître que son action est conforme aux principes du développement durable.

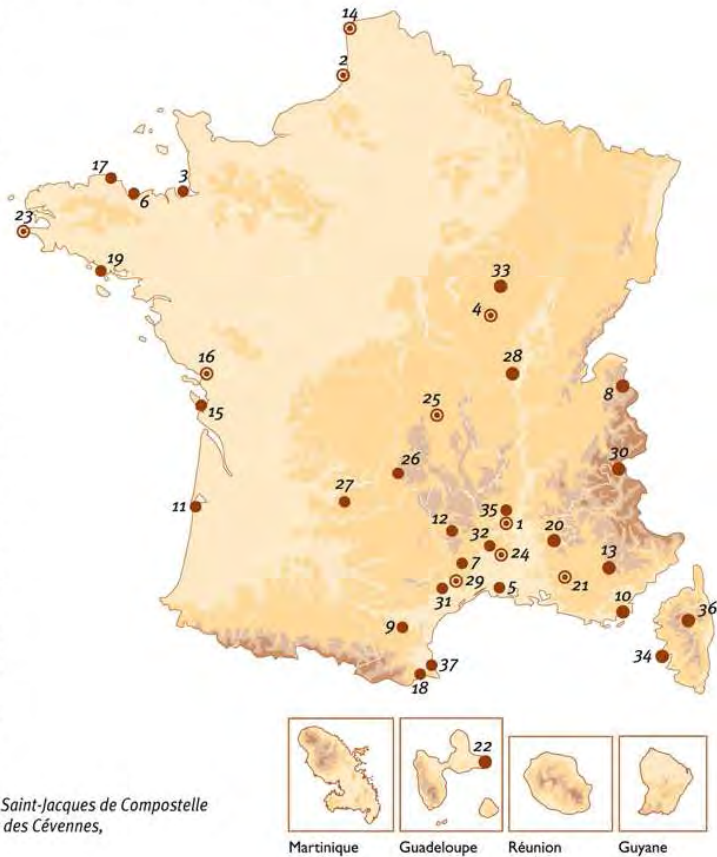

Fig. 4: The Grand Site de France Network and its members as in January 2012 © Réseau des Grands Sites de France, 2012

Studies carried out with our public show that nowadays, visitors do not appreciate being drowned in a crowd any more, preferring to be treated in a more personalized manner. Our visitors want human contact, they want to meet the residents and workers of the places they visit or stay at, they want to eat local food and buy local products (food, pottery, carved wood, local stories etc.

Fig. 5: Modern architecture which blends well into the surrounding landscape loaded with history – Museum at the Grand Site de Bibracte – Mont Beuvray ©Réseau des Grands Sites de France, 2011

In a Grand Site, they are looking for a new, interesting and enriching experience, something unfamiliar and in a way overpowering by its magnitude, beauty and identity, but also relaxing and shareable with friends and family, especially their children. Heritage sites are important places for inter-generational relationships and for value transmission from parents or grandparents to younger generations. Therefore, information about the site, its values and its inhabitants must be accessible and adapted to visitors with a wide range of cultural expectations and backgrounds, and programs for young visitors are to be developed. One expression comes up often in surveys carried out with the French public: "Don't over-develop these sites!" Culturally, public is attached to the notion of heritage as a common asset with a local anchorage which should not be turned into business.

3. Sustainable Management to protect sites and create local development

Local authorities, in agreement with State administration, have decided to react to the problems encountered by the Grands Sites they manage. They have all worked to change site management methods in order to adopt a strategy of sustainable development, to manage sites with respect for its cultural and/or natural values, the "spirit" (atmosphere) of the place, to work in respect of and in coordination with local populations and to promote local economic development. Many tourists want to have an intimate experience with the place they are visiting and they are more and more numerous to care about the impact their visit may have on the site – positive in terms of local economy and negative on the protected site itself.

The State administration supports local authorities and has recently created a label to distinguish the sites that have achieved a level of excellence in sustainable management (socially, economically and environmentally); a national label "Grand Site de France". This label is given for 6 years, and its renewal is possible only after an evaluation.

GRAND SITE

DE FRANCE

Fig. 7.8: Two of the ten Grands Sites which have obtained the Grand Site de France Label: Grand Site de Saint-Guilhem-le-Désert – Gorges de l'Hérault ©Olivier Arsandaux, Communauté de Communes Vallée de l'Hérault and Grand Site des Deux Caps Blanc-Nez Gris-Nez ©Réseau des Grands Sites de France, 2011

Grands Sites' experience shows that protection laws, however powerful they are (and the legal arsenal regarding these sites is very powerful in France), are essential but not enough to protect this emblematic heritage. It's not a case of "tourism versus protection" or "visitors versus locals". On the contrary, the healthy management of heritage tourism is central for the Grands Sites' protection. We cannot protect these sites if we are not acting according to principles of integrated sustainable development and we cannot offer a "real" experience to tourists if we cut them from local populations and vice-versa. The appreciation of the other comes with knowledge.

Local authorities have wide-ranging powers and have responsibility for policy coordination across their territory (town planning, economic development, environmental policy, local transport, etc.), which allows them to have a global vision and to act globally on both the site AND its environment, and not only on the protected zone. This broad vision allows the managing bodies to act towards local economic development via heritage sites.

It is important to state that tourism may play an important role in local economic development but it cannot be the unique way to take. It is the managing bodies that draw up the strategy of presentation and transmission, including congestion management, and the site management plan, while respecting rules of protection and in close cooperation with the culture and environment state bodies at the national or regional levels and local inhabitants and workers. Local authorities are also in charge of day-to-day running of the Grands Sites and the reception of visitors: Information, guidance, services, facilities, ticketing, designing maps and interpretation tools, programming cultural events, public relations and site promotion, carrying out necessary work, and so on.

4. Three examples of local development

The three examples are: Grand Site du Marais poitevin (Poitevin marsh in Western France), Grand Site du Puy Mary – Volcan du Cantal (biggest extinct volcano in Europe) and Grand Site Sainte-Victoire.

Grand Site du Marais poitevin is a cultural landscape of canals, fields, pastures and villages in Western France. It used to suffer from short-term tourism (1.5 days in average) concentrated in the heart of the area. The only attraction used to be visits of the canals in small boats. Agriculture was being abandoned since extensive agriculture – the only possible in the area, was not profitable any more. This meant that the landscape started to close itself and the visitor could not live the experience he came for, this feeling being emphasized by the over-concentration of tourists. The managing authority did an important work with local populations and local economic actors (mostly farmers and boatmen). The marsh landscape got back and is keeping its beauty via the renewal of traditional agricultural practices. The boatmen follow a quality chart, which guarantees a quality experience for the visitor. This work on quality and on diversification of tourism (400km of cycling paths were built for example) paid off. In 2011, the average length of stay was of 7 days – visitors stay longer, spend more money in the region and the tourism flow is dispatched in the entire site. Both the tourist's experience and local economy have improved. For its exemplary sustainable management, the site got the "Grand Site de France" label in 2010. That same year, the site got the "European Destination of Excellence" award for sustainable tourism development.

Fig. 9,10: Cows boarding a boat at the heart of the Grand Site du Marais poitevin ©Réseau des Grands Sites de France, 2008 and the cultural landscape of the Grand Site du Marais poitevin ©Réseau des Grands Sites de France, 2006

Grand Site du Puy Mary – Volcan du Cantal is part of the largest extinct volcano in Europe. It is a very big site (approx. 36000ha with 10000ha strictly protected). Its location in a very rural and remote area played an important part in the economic decline of the region in the second half of 20th Century. By the 1990s, population density dropped to 4 inhabitants per km² and there were very few young people left in the villages around Puy Mary. For almost fifteen years now, Grand Site's du Puy Mary managing body has been working with local mayors and local populations to create a new project for the region. Nowadays, local actors and populations are strongly engaged in the project. Several new small scale tourism amenities opened around Puy Mary in the last few years – mostly restaurants and accommodations. By playing the card of authenticity and cosiness, use of local products and a "back to basics" approach, they managed to attract large numbers of visitors throughout the year. Visitors sensitive to authenticity are mostly sensitive to the environmental and landscape values of the site, which is a real plus. The managing body accompanies the local businesses in their implementation and boosts the project with interpretation centres that are for visitors and locals alike. Local economy got a new start.

Fig. 11,12: Making the children understand the Grand Site du Puy Mary – Volcan du Cantal and its integrated management via a game workshop ©Réseau des Grands Sites de France, 2010 and the landscape of the Grand Site du Puy Mary – Volcan du Cantal ©Réseau des Grands Sites de France, 2007

Grand Site Sainte-Victoire, a site located in the direct vicinity of Aix-en-Provence, is best known for the numerous paintings Paul Cézanne did of it. But it is also a site with rich biodiversity (Natura 2000) and an inhabited territory with a common goal – to preserve, manage and promote the site in a framework of sustainable development. Local populations take part in the project. The managing body recently commanded a study of the site's impact on local economy. Since there is no entrance fee, all benefits are indirect. The attraction of Sainte-Victoire brings tourists to the region (not only to the site itself). 60 million euros are spent annually by the visitors. They also generate 700 jobs and 9 million on local taxes. Sainte-Victoire's name also generates impacts in terms of brand value and in terms of real estate value. Even though the impact of a heritage site on local economy is very difficult to measure, it is always positive, there can be no doubt.

Fig. 13,14: Hiking at the Grand Site Sainte-Victoire ©Philippe Maigne, Grand Site Sainte-Victoire, 2006 and Local products in the "Maison du Grand Site Sainte-Victoire" (interpretation centre and boutique) ©Réseau des Grands Sites de France, 2010

It should be underlined that a heritage site's public management structure is usually financed by the profit from related services and merchandise (for example parking, guides, souvenirs sales, etc.), as well as from public funds. Few are the sites with admission fees to the site. The site has a duty to function efficiently as a public service, but it has no obligation to be profitable. Even though it is sometimes difficult to understand, heritage sites' impacts on local economy are important but indirect and will be attained only through management in a framework of sustainable development and if a site is well managed, all funds being invested in it contribute to the economic development of the area.

5. Conclusions

Based on our experience, management of heritage sites needs to be regulated by a local body representing public interest, in co-operation with state administration, local populations and scientists.

The challenge is to combine good public policies with private involvement with an important share of local involvement and investment, on the ground of shared values. Heritage site's managers and states shall always bear in mind that integrated management is the best option for the sites and the surrounding regions and that preservation, management and tourism promotion should be in balance and that there is a need to work towards a harmony between visitors and 'locals'.

It is necessary to bear in mind that heritage sites are not attraction parks hence short term economic profitability should never be a site manager's first aim. Heritage sites are also to be taken and treated as a whole with territories/regions that surround them and tourism is not the only means for local development.

For more information, do not hesitate to visit our website www.grandsitedefrance.com.

6. A new project since 2010

Since 2010, the Grand Site de France Network has been opening to international perspective. The International Francophone Centre for exchange and training of heritage site managers was created in 2010 in the framework of a wider partnership: In 2010, the Monitoring Committee comprised the World Heritage Centre of UNESCO, the Association of French World Heritage Properties, 3 French Ministries (Foreign Affairs, Culture and Environment), the Regional Council of Burgundy, the University of Burgundy, the Ecole Arts et Métiers ParisTech of Cluny, the Centre des Monuments nationaux and the European Centre of Archaeology in Bibracte, France. In 2011 ICOMOS France joined this committee and Convention France-UNESCO did so in 2012.

It is intended for French-speaking site managers worldwide, whether they come from French-speaking countries or not, who wish to manage their sites in a sustainable manner, confront their views and share their practices with peers who face similar issues.

Three major themes are in the competences of the Centre: 1) international network and information resources platform, 2) place for training and 3) twinning creation. The first intensive training took place in December 2011 under the auspices of the French National Commission for UNESCO.

For more information: <http://www.polepatrimoine.org>.

On the Soundscape of Folk Festivals as Intangible Cultural heritage

Luigi MAFFEI¹, Maria DI GABRIELE¹, Saverio CARILLO¹

⁽¹⁾ARV_Architettura Luigi Vanvitelli, Second University of Naples, Aversa, Italy

Abstract (Arial – 11 pt – grassetto – allineato a sinistra)

With the international convention for the *Safeguarding of the Intangible Cultural Heritage*, UNESCO recognizes “Intangible” as “cultural heritage”. The main criteria for inscription of intangible on the UNESCO *Representative List* is their representativeness of human diversity and creativity. Moreover, the convention establishes the safeguard of intangible *in situ*. The soundscape of town folk festivals can also be considered as intangible cultural heritage, as it is unique or possesses qualities which make it specially recognizable by the people and makes these events tourist attractive. Currently, the Italian “Rete delle grandi macchine a spalla” is candidate for the inclusion in the List. So far, the nomination and selection of an intangible property in the UNESCO List do not require any acoustic criteria and the “sound” is not considered as an intrinsic value of cultural heritage that contributes to perceptual experience of the event. In order to characterize the sound environment of some town folk festivals marked by the music rhythm, video and binaural audio recordings were carried out. Rhythms and frequencies of sound events have been analyzed and correlated with other rhythmic elements as part of its overall perception. Binaural audio recordings taken during different folk festivals have been then compared to determine their sound characteristics and to establish the recognition by the community.

Parole chiave: soundscape, intangibile heritage, multisensory perception

1. Soundscape as Intangible Cultural heritage

The close correlation between tangible and intangible cultural heritage was already recognized in 2003 by the General Conference of UNESCO. The *Convention for the Safeguarding of Intangible Cultural Heritage* [1] in fact consider these properties as part of the cultural heritage, just as for the tangible goods.

The above Convention extended the concept of cultural heritage, already established in 1972 by previous agreement about the *Protection of the World Cultural and Natural Heritage* [2], meaning by *intangible cultural heritage*: “practices, representations, expressions, knowledge, skills – as well as the instruments, objects, artefacts and cultural spaces associated therewith – that communities, groups and, in some cases, individuals recognize as part of their cultural heritage”.

All these are forms of culture that communities have always practiced and that without a written codification have been transmitted orally from generation to generation.

The recognition of intangible as world heritage involves the recovery of all manifestations of culture defined by Alberto M. Cirese *volatile* [3]. Constantly re-proposed by the communities these give them a sense of identity and continuity and promote respect for human creativity and cultural diversity in an historical period in which the process of globalization on one side encourages cultural exchange and dialogue among the people, and on the other side cause the loss of historical memory and cultural identity.

Local communities play an important role in the protection, promotion and revitalization of folklore in all its manifestations.

In the last years an increase of nomination by States members of the *Committee for the Safeguarding of the Intangible Cultural Heritage* for inclusion of intangible properties in the *Representative List of the Intangible Cultural Heritage of Humanity* has been registered. This inclusion should be supported, among other, by a management plan programming all interventions to be implemented for the safeguarding of the heritage.

Italy, despite being one of the richest countries of folklore, rituals, traditions and folk festivals in the world, only in 2007 ratified the Convention [1] and in 2008 applied for the intangibles in the UNESCO Representative List.

So far only the Sardinian "Canto a tenore" and the Sicilian "Opera dei pupi" were included in the list, although were already declared *Masterpieces of Intangible Heritage* [4] before the entry into force of the Convention.

At the present time the "Rete delle grandi macchine da festa" [5] (Gigli di Nola, Macchina di Santa Rosa di Viterbo, Caldelieri di Sassari, Varia di Palmi), designed and coordinated by dr. Patrizia Nardi from University of Messina, is candidate for inclusion in the UNESCO Representative List of the Intangible.

They are folk festival of ancient tradition having in common the use of scenic and gigantic festival machines carried on men' shoulders according to a specific practice.

So far the management plans of tangible cultural properties (such as historic city centers) or intangible ones (such as popular festivals), do not take into account the protection and valorization of the soundscape as an intangible property of the site or of the event since unique, recognizable and attractive feature.

Furthermore, so far the nomination and selection of a site or of an event for the inclusion in the World Heritage List do not require any kind of sound criteria and no international official document drawn up by UNESCO or ICOMOS pays proper attention to the "sound" as an intrinsic value of cultural heritage that contributes to its perceptual experience.

Moreover UNESCO establishes the safeguard of intangible *in situ*. The concept of "cultural space" was already established in 2001 with the *Proclamation of Masterpieces of Oral and Intangible Heritage of Humanity* [4] as "an anthropological concept that refers to a place or a series of places at which a form of traditional or popular cultural expression occurs on a regular basis". These places, will continue to be alive thanks to the presence of community that hand down locally forms of folklore.

"A real environment, such as an urban street [...] is sonically far more complex than a single wall [...]. The composite of numerous surfaces, objects and geometries in a complicated environment creates an aural architecture", namely "the unifying concept of the aural influence of space on the social, behavioral and musical activities of the inhabitant" [6].

The literature on the soundscape has also clearly shown that the judgment of the pleasantness of a sound depends not only on low noise levels, but it is influenced by other aspects of subjective perception. Its acceptability also depends on expectations and involvement of people in the event [7-8].

In the last decade many studies have been carried out on soundscape of tangible properties, such as historical city centers [7] or archeological areas [8]; the results are regularly reported in the literature [9].

Up to now no specific research has been conducted on the soundscape of folk festivals, although these involve a strong participation of the population. Moreover researches on the topic of "folk festivals" are in progress and approached in a multidisciplinary way.

In the present work a first part of a more complex research aimed at the characterization of the soundscape of some events of the folk tradition, marked by the rhythm of music and song, is presented. As case study the unique "ballata" of Gigli di Nola along the traditional path in the historical city centre was selected. Infact, a historical analysis has enabled the identification of some invariants of Gigli di Nola Festival, strongly marked by the key role played by the music, which disciplines the movements and performances of the machines along the whole path.

In summary, according to the authors, the soundscape of a place or of an event is recognized as an intangible property, if three important features coexist:

- Historical tradition
- Key role of the music
- Population involvement.

2. Case study: Gigli di Nola

2.1 Historical tradition

Every year, on the first sunday following Saint Paolino celebration, the Festa dei Gigli is celebrated in Nola. For the locals, this celebration has a deep religious meaning, as it is directly linked to Saint Paolino and to the Saint's devotion.

According to the tales [9] told by travelers who visited the Festival, we can observe how the obelisks have changed during the years, the birth of more and more new equipments and outfits and how the whole atmosphere has changed during the years along with them.

Although earlier stories provide important information on evolution of the shape and the frame from basic “cereos” [10] to more sophisticated “Mai, o Gigli” [11], from the tales dating to the nineteenth century though, we can get more details about the celebration itself. The highly educated Gabriele Quattromani, in 1838, told about “certe macchine che hanno la forma d'un campanile, e molti campanili sono minori di questi portatili che si chiamano gigli [...]. Ciascuna di queste macchine ha su di sé i suonatori ed è illuminata di modo che la gente passa la sera tra la fiera e 'l vederle, e sentire la musica [12] (trad: bell shaped obelisks, whereas the very local bells were even smaller than the obelisks themselves. On each obelisk there were even musicians and the light illuminating the obelisks allowed visitors to properly see them and to enjoy the music).

In 1853 the German Gregorovius got to Nola and was drawn from a whole crowd moving and swarming towards the city; “fu colpito da uno spettacolo mai visto prima di allora. Da una strada laterale a suon di musica venne fuori, oscillando, un singolare mostro [...] un'altissima torre che, agitava di qua e di là sulle spalle di circa trenta portatori [...] nel piano più basso sedevano ragazze incoronate di fiori, al centro un coro di musicanti con trombe, timpani, triangoli e cornette eseguivano una musica assordante [13] (trad.: He was highly impressed and mesmerized by a show he had never experienced before. From a lateral road he saw a creepy monster staggering out according to a rhythm, a huge tower which would swing hither and thither from about 30 men's shoulders. On the lowest story beautiful flower-crowned women were sitting, in the middle a choir of noisy and rowdy musicians play trumpets, drums, triangles and cornets).

The towers, coming to the cathedral from different sides, could be seen over the local houses' roofs though and heard through the “musica rimbombante”. (trad.: noisy rumbling music). “Appena un obelisco era giunto al duomo cominciava uno spettacolo singolarissimo: la gigantesca torre si metteva a ballare al ritmo della musica rimbombante. Davanti ai portatori camminava un uomo con un bastone e mentre egli indicava il tempo, quelle torri si muovevano secondo il ritmo, di qua e di là” (trad.: As soon as an obelisk was taken to the cathedral, a very strange show would take off: the huge tower would even start dancing according to the noisy rumbling music; the towers were swung hither and thither by several men, according to the indications by a man who stood at the very front, waving a stick).

All these descriptions can provide us elements which have not changed during the centuries: the Giglios' parade, the “paranza” (the outfit of men which got and brought the obelisk on their shoulders), the “maestro di festa” (which would be the celebration's master), the “capo paranza” (who would order the rhythm to both the musicians and the “paranza”), and of course, the music itself.

Music is definitely the crucial element of the fest: it not only entertains, but also brings all the movements about, as well as the original and fascinating obelisks' shows.

According to an iconographic and bibliographic analysis we can date back to the very origin and the evolution of this element, that is music and its whole arrangement. In 1700 and up to the first middle of 1900 the obelisks' shows were accompanied by fanfares, which were put on the obelisk itself, usually on the first story, as testified by a 1700 carving, reported on [9] (Fig. 1 a). The carving shows musicians holding breath-instruments (recorde, flute, horns) standing at the front of the obelisk, as well as other musicians holding percussion instruments (cymbal) on each side of the obelisk.

Other pictures from 1900 though, show the presence of the singers (usually two on each Giglio) on the Gigli, plus more new instruments. Moreover, on the obelisks new special device to amplify and increase the music can be made out. Other images from the fifties show the “capo paranza” giving orders to the musicians through microphones, which sometimes were even installed in front of the middle wooden bar, as well as loudspeakers fixed along the first part of the obelisks (the first portion of six, located immediately above the base). Their collocation and their bents upon different heights is not casual: they are in fact meant to guarantee the creation of a rumbling climate which is to cover the whole city and to convey the blaring music on the carriers who are galvanized, inspired and urged by it (Fig. 1 b – c – d).

At least up to the seventies both the breath and percussions instruments represented a form of respect of the tradition, notwithstanding the introduction of other items along the time, like saxophone, clarinet and accordion.

In the nineties even electric instruments, such as guitars and keyboards take place on obelisks, sometimes substituting the most traditional instruments (Fig. 1 e - f).

If on one hand these musical instruments and technology products can be elements of discontinuity with the tradition, on the other hand they did not make any fundamental change to the overall atmosphere of the festival, which continues to be characterized by loud music and cheering and joyful people.

Fig. 1: Pictures from different historical periods, showing the evolution of the music and its arrangement: a) carving from 1700 (from [9]); b) 1950 (from [14]); c) 1960-1970 (from [15]); d) 1968 (from [15]); e) 1980 (from [15]); f) 2011.

2.2 The role of the music

Musicians and singers, at least from the mid sixteenth century are located on the Giglio. This feature of this festival is not found in other folk events in which giant obelisks are carried upon the men shoulders according to different rules and the music is placed in front of or under the obelisk. This disposition highlights even more the great harmony that between the “paranza”, “capoparanza” and musicians have to be established. “Paranza” and musicians taking orders from the “capoparanza” send each other the rhythmic through the structure.

In regards to the music of Gigli, every year the “maestro di festa” chooses the best lyricist and music master to compose the musical repertoire that make distinctive his Giglio.

In last decades, in addition to new music repertoire, some commercial songs are arranged to give rhythm to the “girata” or “mezzo passo” and “marcia”.

The most important song is written for the “aizata”, an exhibition that is to raise the Giglio with a single movement performed synchronously by all carriers under the command of “capoparanza”. Actually this movement is made several times during the festivals, or to restart after having stopped and “posato” the Giglio to allow the carriers to rest and/or to prepare them for some spectacular exhibition, or to enable the “capo paranza” to order some particular movement aimed at correcting the position of the Giglio when its stability is compromised.

Some traditional movements of the Giglio, in fact, require a special musical accompaniment that follows its own time and rhythm. In general the music played on the Gigli for accompanying their performances are in 2/4 and 6/8. Actually, sometimes music following other rhythms, such as 5/4 or 3/4, is also played but only when the Giglio is still.

The 2/4 rhythm is used for performing the traditional movements called “aizata” and “girata” but also for the “spallatta”. These performances are carried out by Gigli on the place, without moving forward.

When performing the “aizata” and “girata”, the Gigli follow a music in 2/4 rhythm, but it is played more quickly in the first case and more slowly in the second one. The “aizata”, infact, for the above outlined reasons requires a strong beat, well marked and recognized by all the carriers which have to run synchronously the single movement.

The “girata” is a special exhibition in which the “paranza” shows its great ability, by rotating the Giglio of 360° on itself several times in an open areas or in other very characteristic and unique places of historic centre of Nola, sometimes very narrow, making the whole performance without touching the walls with bars.

The “spalletta” is a lateral movement of the Giglio performed to improve its position, for example to place it in the center of the road and make also easy the path to the carriers on the sides.

In fact, the song of the “aizata” is composed of about 4-5 parts (each part comprises verse and chorus) and all the carriers already know that traditionally after the second part the “capoparanza” commands the “aizata”.

A music in 6/8 time is played to perform exhibitions called “mezzo passo” and “marcetta”. These performances are showed while the Giglio is moving forward.

In particular:

- “mezzo passo”, the Giglio moves forward while performing small rotations on the right and left sides. Together with the “girata” is one of the hardest performances.
- “marcia/marcetta”, the Giglio moves forward performing jumps.

Another traditional movement is the “posata”: at first the capo paranza stops the music and every Giglio’s movement and later he commands the band to perform “2 attenti” corresponding to a double sound of sax. After some second of suspance he orders the carriers “cuonce cuonce e 'jettele” and they all, with a single synchronous movement, put down the Giglio in a way that its weight is evenly discharged on the four cantons (Fig. 2).

Fig. 2: “Paranza” in action during the performances of a Giglio.

2.3 People involvement

Audio binaural and video recordings were carried out during the Festa del Giglio by an operator following the Giglio’s parade along the whole path in the historic centre of Nola (Fig. 3 a).

Fig. 3: a) Planimetric excerpt of the Nola city center showing in red dashed line the path of the Gigli’s “ballata”; b-c) people involvement in the Festival.

Binaural recordings were aimed to characterize the soundscape during the spectacular event and to identify sounds mainly heard by participants to the event. The audio binaural recordings, were taken with microphones placed on an headset put on the experimenter's head and connected to a two-channels sound analysis system. These audio recordings were taken in positions very close to the obelisks but also in other positions from which the obelisk could not be seen. The sound pressure levels measured in the proximity of the Giglio can reach values $L_{Aeq} = 104,1 \text{ dB(A)}$, while in more distant position $L_{Aeq} = 79,9 \text{ dB(A)}$, as shown in Fig. 4 a) and b) respectively.

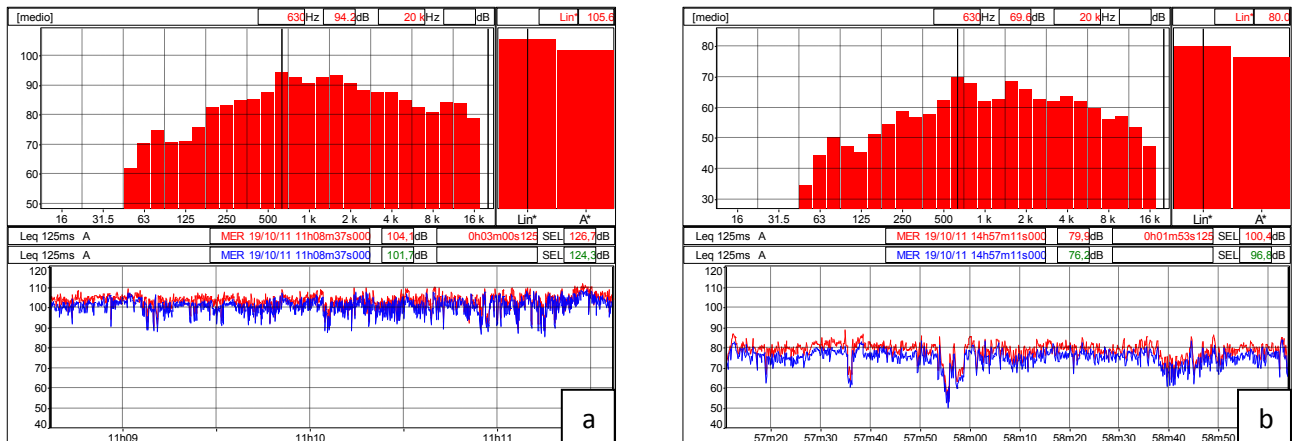

Fig. 4: a) Time history and 1/3 octave band spectrum of the binaural audio recordings carried out a) in a position very close to the Giglio; b) in a position in which the obelisk could not be seen.

Considering the presence of nine obelisks in parade along the same path, each one with its music and its crowd of rejoicing supporters, is almost impossible to find locations not influenced by the sounds of the festival. The main sound sources are not only the music located on the Giglio, but also the loud voices and shouts of the cheering people from the street and from balconies and windows of the buildings bordering the path (Fig. 3 b – c).. Furthermore, the spatial conformation of the Nola historic center, and in particular the area where the Gigli's "ballata" takes place, is largely made up of narrow streets and small open spaces creating a series of sound reflections. This leads to a strengthening of the sounds and also a condition that the sounds can be heard even without seeing the source. This justify also the high sound levels acquired in position far from the obelisk.

However, despite the high noise levels recorded during the festival, the involvement of the population is still so high as in the past. In fact, people are not annoyed by the deafening atmosphere perfectly as they are in tune with the music and the event.

3. Conclusions

Since 2003 UNESCO has established the safeguarding of intangible cultural heritage just as for the tangible one. They are the manifestations that constantly re-proposed by communities promote respect for human creativity and cultural diversity. UNESCO establishes also the safeguard of intangible *in situ*, introducing the concept of cultural space as place where continuously forms of intangible culture take place.

So far the soundscape of tangible and intangible heritage is not taken into account as intangible property contributing to their perceptual experience as so to protect and enhance.

Local communities play an important role in the protection, promotion and revitalization of the folklore and of its manifestations.

The soundscape of a place or of an event has to be recognized as an intangible property, if three important features coexist: i) Historical tradition; ii) Key role of the music; iii) Population involvement.

It was demonstrated that the Gigli di Nola Festival fulfills the above features.

An analysis of historical tradition has enabled infact the identification of some invariant elements of the traditional "ballata" of the Gigli di Nola. Audio and video recordings taken during the event permitted to characterize not only the soundscape but also identify the sound sources contributing to the overall atmosphere of the event.

Acquired data show that even if sound levels are very high in different positions, people are not annoyed and enjoy the festival.

Therefore, the authors believe that the Gigli di Nola Festival can be inserted in the *Representative List of the Intangible Cultural Heritage of Humanity*.

Further developments of the research will consist in i) interviews in situ in various subjects involved ("cullatori" namely men carrying the Giglio on their shoulder, citizens and tourists) in order to obtain information on the subjective perception of the event and ii) laboratory tests aimed to understand if the soundscape of a folkloristic event can contribute to its recognition by the community.

1.

Istanbul, a great City enhanced by historical treasures and natural gifts, a settlement of 3.000.000 people few years ago has lately been drawn under the unplanned influx of 10.000.000 more settlers immigrating from rural areas. Today, %70 of the City's building stock, mostly in the form of squatter housing, is without buiding and/or occupancy permits. Problems such as air, noise, light pollution, security weaknesses, ethnic crashes, loss of historical, cultural and natural entities, and a congested traffic are commun in Istanbul.

The dense circulation today has become the nightmare of the people and the City's economics. Each day about 700 cars obtain new license plate and join the traffic. It takes around 3 hours to travel from one to the other side of the City. The congested circulation constitutes potential treath in case of a serious earthquake.

In order to cope with the traffic problem, in 1973 the Government built a suspension bridge over the Bosphorus, the Straits bordering Europe and Asia. Yet, soon after the Bridge and its highways have become congested. The 2nd Bridge, intended to establish a speedway for transit and peripheric traffic was erected further North in 1988 and has been connected at both ends to TEM (Trans European Motorway). It has become congested, too in a short time. On the other hand, the construction of the 2nd Bridge and TEM have accelerated the northwardsly rapid, yet unplanned, urban growth transforming 250.000.000 m2 of green areas into ugly, mostly illegal concrete structures.

Today, confused with the traffic problems, the Government proposes a 3rd Bridge over Bosphorus even further the North towards the Black Sea. Yet, since northern lands of the Bosphorus house the last green zones and water sources of the City, we believe building a third belt on the North will repeat the same cycle experienced with the 2nd Bridge and eventually turn the City towards the desertification trend, endangering the remaining 500.000.000 m2 forrest zones of the Metropole.

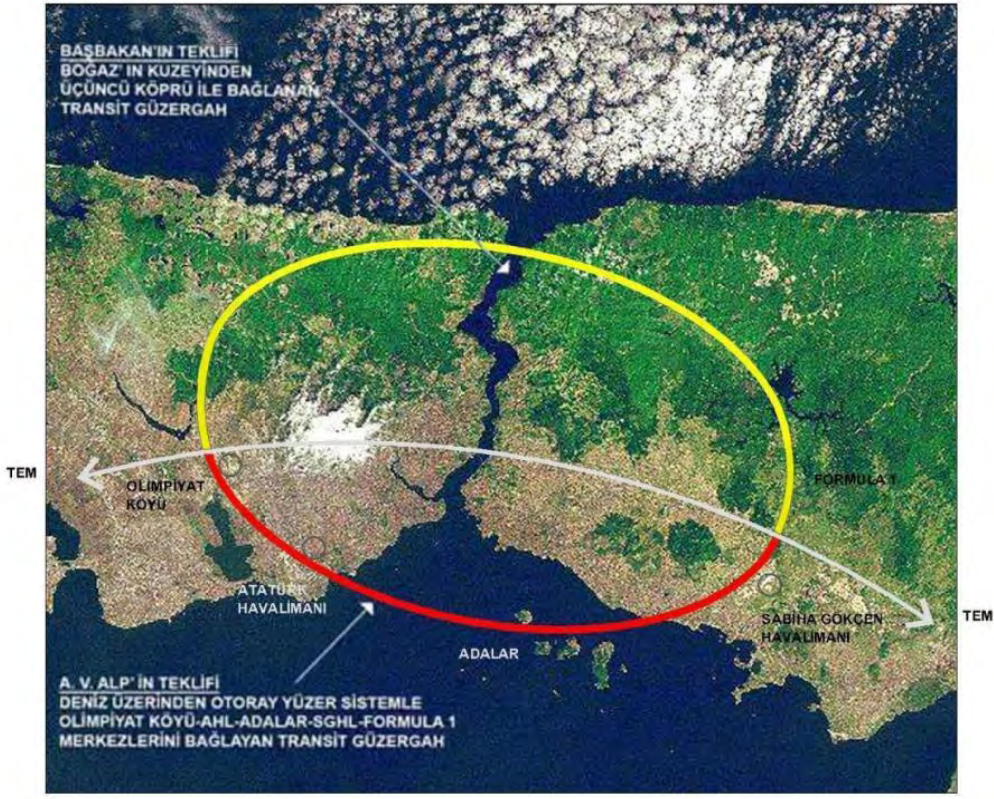

TRANSMAR has born from this point. Since the north of Bosphorus is not suitable for a new highway system due to natural entities, and since south of Bosphorus is also not suitable for a new bridge due to its dense urbanization and historical, cultural and natural treasures, the only reasonable solution was to go more south on the Sea of Marmara and built a bypass floating rail-road viaduct linking Europe to Asia across the water. TRANSMAR begins on the European side from the Olympic Village, intersects the TEM, passes by the Ecological Village Project by Architect Dr. Ken Yeang, goes under the Ataturk International Airport, leaves the European shore as a 9 km viaduct on pilotis at 25 m above sea level ,continues as a 6 km floating viaduct. The 2 km double span cable-stayed fixed bridge at 65 m altitude allows large sea traffic. It is followed by a 14 km segment as a floating viaduct. The system sits on land on the Kinali Island which serves as a service and emergency center. The system leaves Kinali again with a 14 km floating viaduct segment and approaches the Asian shore with a 6 km viaduct on pilotis. It enters the Asian coast near the urban project by Architect Zaha Hadid in Kartal, reaches the International Sabiha Gokcen Airport, reintersects with the TEM, and finally terminates at Istanbul Formula-1 Park.

It is expected that daily 100.000 vehicles will use TRANSMAR at a max speed of 100 km/h. The rail shuttle within the structure runs at 200 km/h and links the two Airports of the City in 15 mnts. The Project's cost is estimated about 4 Bln USD and the payback period 12 years.

Advantages of TRANSMAR compared with the Government-proposed 3.rd Suspension Bridge accross North Bosphorus

- . It takes the transit, heavy weight and peripheric traffic out of the City
- . It does not destroy the northern water sources and forrest zones of the City
- . It does not harm Bosphorus' unpredecated historical and natural entity
- . It helps and supplemets the intercity urban circulation network
- . It does not allow for urban land speculation
- . It does not permit illegal construction and squatter housing
- . It does not need land privatisation
- . It does not cause noise and air pollution fort he City
- . It directly links the two major airports of the City in 15 minutes
- . It may be erected fast and economically
- . It helps the traffic of the Olympic Stadium and The Formula-1 Park
- . It allows emergency evacuation from Prince Islands in case of natural disaster
- . It is not affected by seismic activity
- . It enhances the underwater life of the Sea of Marmara

Similar long sea passages are numerous in the World. Floating systems, making use of the off-shore petroleum platform technology, appear to get momentum. They are not under seismic risk, they are much more economic than conventional systems in deep waters, they are fast to build and, finally, they make use of the sea instaed of the congested urban land.

RECYCLING URBAN SPACES. AN ALTERNATIVE ACTION RESEARCH ON SUSTAINABILITY AND CREATIVITY IN IVRY-SUR SEINE

Silvana SEGAPOLI,

GERPHAU Laboratoire Philosophie Architecture Urbain, Paris. Ecole Nationale Supérieure d'Architecture de Saint-Etienne, France

e-mail: silvana.segapoli@st-etienne.archi.fr

This study has the object of comparing the Mediterranean project of Officiamuseum in Pompeii with a French project located in Paris outskirts, Ivry-sur-Seine. Ivry-sur-Seine City Council has commissioned internationally renowned French artist Stefan Shankland to engage Ivry-sur-Seine communities through an artist's process and to foster a continuity of practices/projects in a large building site area (ZAC du Plateau). TRANS305 is the name of the program created by Shankland to perform the changes of this area and it is also a platform of experimentation, action and research in the framework of urban transformations and cultural and political-social practices.

This collaborative initiative is based on an urban recycling operation in order to promote a new idea of relationship between culture, contemporary art, eco-production and territory. A pavilion is open to different activities (from artistic production to exhibition), acting as a temporary demountable urban structure, a shelter, a landmark and new urban medium. This last task appears essential in the transformation process to be undertaken in the Paris' banlieue.

To create still unfathomed links, activate unknown aggregations and find devices that may translate emotions and *desired* collectives into forms, in other words means structuring the territory with modifiable models, following the Italian architect and critic Andrea Branzi's principles of weak urbanization, identifying what Edward Lorenz (American mathematician and pioneer of chaos theory) would have called "attractors", towards which dynamic systems evolve in a determined temporal arc.

Keywords: Urban Interventions, Artistic Process, Recycling Systems, Transformations, Temporary

The TRANS305 project has come about following a series of important transformations along the frayed fabric of a major arterial road, the former "Route Nationale 305", connecting Ivry-sur-Seine, a municipality in the first ring of Parisian *banlieues*, to the capital. The city of Ivry is located right on the hinge between the south-east edge of Paris, a sector subjected to a series of interventions of profound urban transformation for at least twenty years or so, and a territory that falls within a boundary that has been the object of the highest attention at a national and international level. Indeed, this is one of the segments of the Grand Pari(s) program of renewal and rehabilitation of the urban belt and neighbouring zones.

The Atelier 305 project represents a specific phase of the TRANS305 program, an intervention procedure that envisages an interchange between artistic practices in an urban context and territorial policies.

It is a pilot operation of cooperation between art, architecture and urban planning, promoted by the municipality of Ivry and managed by an artist, Stefan Shankland.

Beginning from the 2006, the artist has been engaged in an artistic support process of an immense territory undergoing change, following the principles of the lead artist.

The zone in which his activities are being undertaken is called "ZAC du Plateau"; this represents one of the great lines of transformation of the Parisian periurban territory: a vast area of comprehensive planning that foresees a series of demolition and construction sites that will take place over an arc of more than ten years.

Atelier 305 is an ephemeral construction created within the construction site for an office building destined for the Ministry of Public Finance of Paris. The construction firm, together with the urban planning office of the municipality of Ivry, has agreed that part of the site should be allocated to an artist. However, the firm is furthermore committed to participating in the artistic operation by building the reinforced concrete platform on which a construction that can be dismantled will be installed, Atelier 305, envisaged as a observation point that is accessible to the public, with a view over the building site itself and the changing landscape. The platform is being erected in the area in which, following the project, a public space to be integrated with the offices is planned.

1. AN EPHEMERAL PROJECT FOR A CHANGING TERRITORY

The project is presented in principle as a transitory work operating as a kind of filter between the inaccessible space and time of the construction site and the space and time of the public and the road. Other interesting connotations have come about over time and still constitute the object of study.

Atelier 305 was constructed in June 2010 and from November 2011 the elements making up its structure were taken apart following the planned procedure, moved and re-used for different purposes in another area with a building site within the 'ZAC du Plateau' perimeter.

The city that Shankland illustrates in this operation is the icon of a new frame of mind, already in ferment starting with the experiments carried out from the 1950s by Jean Prouvé and Richard Rogers, among others, on the first houses that can be disassembled or by Cedric Price and Yona Friedman on the city linked to movement and events. But today more than ever, through experiences of this kind, it is becoming increasingly apparent that what is needed, much more so than rules, in the contemporary city is the "idea-instrument" (Franco Purini, 2010).

A city made up of fragments to be reassembled, habitable cells to be stacked like boxes in a warehouse; a city with new scenarios and differentiated temporality that continually reinvents itself, changes and has the power to liberate itself from the inherited and reassuring image of a dense nucleus to be preserved and maintained as an immutable order. An elliptical concept of 'permanence' therefore emerges, no longer bound to forms of rootedness, but rather connected to mechanisms of reproducibility and of unperturbed cyclicality.

This experience has highlighted the possibility of a dual life of the building site, at both a city and territorial scale.

Nomadism, reversibility, ecology and recycling are the key concepts that place this intervention within the channel of weak urbanization, a line of thinking that has opened up the way to *temporary use* as the spazialization of the ephemeral. The concept of cyclical use and reuse of spaces implies a transitory quality that is conceptually opposed to the innate stable quality in the programmed use of managerial policies. *Temporary use* aims towards the dissolution of the criteria that support the culture of the master plan, using modest time spans and reduced spaces.

1.1 LIFE-CYCLES AND CYCLES OF USE. FROM THE TERRITORY TO THE OBJECT

The project of the TRANS305 atelier is undertaken by Stefan Shankland in collaboration with the architects RAUMLABORBERLIN in a kind of continuous flow of exchanges of experiences, of cross-referenced workshops between Ivry and Berlin, involving students of several schools.

If the loss and lack of references connoting the landscape of the periphery motivated reflection in the first phase of design and planning, urging the creation of a sculptural element in the landscape in the form of a visual attraction, in the successive stages the problem of making works of art to be inserted in a context leaves room for a more interesting question: in what way and with which instruments to enable a kind of meaning to emerge from the context? It is in this way that the project embraces a broader critical dimension.

Atelier 305 is modular architecture, conceived like *Lego*, according to a line of thought with an ecological basis that pursues sustainable creativity and cleaner production. All the elements to be composed come from a known cycle of use, from demolition yards or public works in the area or neighboring areas. All the elements have therefore been reused or recycled and may still be taken apart and used elsewhere. Containers, pallets, scaffolding and kits of building sites have been mounted during the course of training workshops for a public of apprentice students and trainee architects.

Atelier 305 may be considered an exchange platform at the crossroads of interests of contemporary creation and the territory in transformation.

As a workshop for young creative artists, an itinerant element linked to cultural events, scores of artists have made it a place for encounter, display and exchange. Students of all ages and different geographic, cultural and educational backgrounds have participated, covering different dynamics of appropriation of the territory and the urban space.

This tension between durable and ephemeral, proving to be an integral part of the new ways of city action,

has moreover contributed to raising the issue of the sense of display places, of appointed places, the spaces dedicated to culture and likewise the concept of the place of creation education, culture and exchange.

2. ARTISTIC PRACTICES IN THE PROCESS OF RENEWING THE URBAN PROJECT CONCEPT

The formal disorderliness, the altered temporality and the more rapid cycles of mutations constitute the grounds for research and terrain for a new aesthetics. It is for this reason that the critical and analytical instruments of art are coming closer together and at times intersect with those of architecture, giving rise to a genealogy of phenomena codified by Anthony Vidler (historian and critic of modern and contemporary architecture) as “intermediary art” (A. Vidler, 2009)

If on one hand, architects like Diller & Scofidio, Asymptote (Hani Raschid & Lise Anne Couture), dECOi Architects (Mark Goulthorpe), NOX (Lars Spuybroek), R&Sie (François Roche & Stéphanie Lavaux) and Andrea Branzi, are pursuing a path punctuated by frequent interactions with the world of art, on the other hand, artists like Tadashi Kawamata, Toba Khedoori, Vito Acconci and Thomas Saraceno, claim a sensitivity for the architectonic space and a procedure that attests more to the motifs of tectonics than those largely to single artistic disciplines.

If, as Vidler claims, the disciplinary crossover is undertaken in the two directions and by many with different approaches, it is important to note that the artists' interest in architectural planning and urban spaces takes on an ever greater importance in the context of urban practices, often acquiring a sociological connotation. For more than a decade now, artistic actions have increasingly focused on peripheral ambients. This incursion of the real into art, without a hint of the transcendental, has led to an ontological change in the concept of the work of art and artistic intervention.

The issue of artistic practices in the urban context falls within a precise strategy, intent on finding alternative, though not substitutive, forms of action on the territory. Forms that are innovative with respect to a culture of the architectonic and urban project grounded in traditional systems of intervention, and finally released from the figure of the architect or the town planning demiurge.

Creative action shifts from the project to the process, from the object to the strategy. A shift that does not imply or mean challenging every material practice, nor a separation from phenomenal reality, but rather a strengthening of the process-like nature of planning: the work is not contextualized, it is the very work that constructs the site, that weaves relationships with the inhabitants by closing the gap separating those that live there from those doing the planning.

This activist *coté* of current artistic and interdisciplinary planning practices developed with the dawning of anti-urban movements, which challenged an era marked by the first urban project experimentations and the last undoings of a disastrous planning at various scales.

Pacifist groups of “urban warfare” and interdisciplinary collectives are today engaged, often through artistic practices, in processes of profound renewal of the concept of intervention or city project, focusing their actions starting from the archipelagos of the peri-urban, floating outside the dense territory of the city or between the more hidden folds of the urban area. They are the areas of greater flexibility, overflow zones one might say with a geographic metaphor, that ensure the possibility of constant evolution and continuous adaptation. Their cartography is patchy. In some ways it responds to the idea of a city that renews itself, that revives its centre chiefly by revitalizing the entire periphery and acting on its landscape. A broad production of interventions, mainly in the peripheral context, is bound to a refusal of rigid programming and constitutes a solid framework of a kind of militant anti-urbanism, an agile and flexible response to the need for a radical approach.

FROM URBAN SPRAWL TO ECO-COMPACT CITY: THE URBAN RENAISSANCE

Luigi MOLLO, Rosa AGLIATA

Department of Civil Engineering, Second University of Naples, Aversa, Italy
architettura.technica@unina2.it

ABSTRACT

The alienating and uninhabitable suburbia of European and American cities is the manifest utter flop of modernistic architecture and urbanism, who lead to a mortification of principles and a huge waste of resources. This paper aims to show the more actual concept of urban design, based on the traditional urban design. The standards and principles of the new traditional urbanism, called "Urban Renaissance" in Europe and "New Urbanism" in USA, are designed to make areas more livable and people-oriented. These "eco-compact cities" are built and developed in balance with the natural environment and with an optimum ratio between social mingling and sustainable use of buildings, soil and other resources, assuring safety and accessibility to pedestrians, bicycles, cars and public transport. This model is based on the concept of organization in polycentric towns, where population density is such as to guarantee a good life standard, the presence of retail business activities, the creation of an efficient public transit system, the optimization of the use of natural resources, reducing pollution, and the reduction of government and social costs. At the same time, this logic can reinforce the sense of place, of community, of belonging, restoring civic pride.

Key words: eco-compact city, urban architecture, mixed-use

1. Architecture of the history

If it is true what philosopher Emanuele Severino wrote "to decide to escape out off the Western History is like willing to jump over our own shadow" [1] then, it is certain that this rather absurd experiment has been already done by both Modernist architects and their heirs, with all the consequences that are evident to everyone, and that, unfortunately, have not yet finished to produce countless practical, economical, and cultural damages. Therefore, we can agree with Renato Rizzi – the brilliant introducer to the works of Severini – that "contemporary architecture is the most efficient and concrete example of Western nihilism. Besides being its revealed metaphor and its accurate and desperate theatrical representation" [1].

From Licurgus to Stalin, from Plato to Leibniz, passing through all the idealists in more than 25 centuries of urban history, the city has always expressed the up-to-date petrification of a precise system of thinking, organic to the urban community, the coherent relationship between ideal and practical needs and its formal representation; at the beginning of the 3rd Millennium there is no doubt that "nihilism" destroyed any logic-demonstrative system. The typical unitary thinking, plenty of remnants and consequences, has been completely shattered. The architectural space is everyday getting more hybrid. It often contradicts the fundamental needs of a civil society, while the architect's freedom of expression and conception turn into the abstraction of an endless variety of forms conditioned by the absence of an organic thinking. As a consequence, the adaptability of the system codified by the millennial experience turns into a kind of arbitrary and unlimited pluralism of forms that have anymore nothing to do with the concept of living within communities organized through a common culture. The design autonomy thus leads to a mortification of

principles, the establishment of a new arrogant pattern, a huge waste of resources, and finally to a big disappointment.

The contemporary architectural culture, states Rizzi again, identifies in the theory of ontology "the tyrannical form of both oppression and command, the condition of being forced to live under the weight of a vertical wisdom, which is hierarchical and, therefore, outdated in respect to the horizontal request formulated by the <mobility> of the formal sprawl" [1]. Thus, "the architecture passes from the evolution of forms to the revolution of the shapelessness", the "monotonous inequality" leads to the "loneliness in which the built works are relegated" [1].

In addition, this also destroys the principle according to the aesthetic quality has to be determined not by an individual judgment, by the unlimited invention of forms, but by the presence and relevance of permanent elements. Because they are part of history, incorporated into the local tradition and culture.

In fact, we are all aware of the richness of physical, technical, and operational resources that are at our disposal in the contemporary world - and many individuals would be capable of designing, calculating, and building vertiginous skyscrapers, gigantic concrete shells, innovative metal structures, in every context, for any given circumstance if only they accepted to break with a responsible self-discipline. Yet, we know too how a selfish, unrestricted and hazardous employment of those resources can severely damage the civil society instead of contributing to its development.

Here is the contradiction: while the democratic institutions, the economic systems, the working methods and tools are actually being coordinated and regulated on the basis of successful experiences, the urban space is being disintegrated day after day. Cities are losing their rooted functional and aesthetic features, architecture is evaporating in a unlimited collection of arbitrary and abstract forms produced by lonely inventions, and the human being - the citizen - is being mortified by the absence of any kind of respect towards his/her real practical, ideal, and cultural needs.

And this rather strange phenomenon does happen to please particular unlimited ambitions and specific economic interests, too often with the enthusiastic support of a generation of media always searching for shocking novelties. Sometimes, even with the encouraging attitude by the academic world, that misunderstands the right to research and experimentation (however not "at people's expenses") with the logic of professional education.

Finally, it is rather surprising to notice that those who oppose "globalization", support and push the destruction of any urban structure created to improve the human condition.[2]

2. The Urban Renaissance

"The Urban Renaissance is a term attested since the first Bologna Triennale in 1992 in order to emphasize a project culture based on the traditional principles of the urban spaces and the constructive techniques of the European city.

These years of experiences, observation, studies, books, concur us to assert that we are inside a new age of Urban Renaissance. Sure this "vision" appears clear to people working on it, more uncertain to the common citizens, or the readers of monotone reviews of architecture. Today the city is damaged and, at the same time, a different concept of planning and constructing is asserted. An Urban Renaissance which is introduced in opposition to the sprawl of "modern" periphery left to us in inheritance from the past century.

The images of the Rebirth pass from the extraordinary experience of the reconstruction of Bruxelles capital city of European Union, to the recent experiences of re-urbanization of the periphery of Paris, of London and Berlin, touching every latitude of the Old Continent: from Saint Pietroburgo to the architectures of the Portugal on the Atlantic sides, to the new cities constructed in Turkey, from Stockholm and Oslo to the Mediterranean architecture of the new villages constructed in the islands of the Aegean. In continuity with the tradition of the occidental city, using local materials, valuing the peculiar aspects of every site, stretching the hand to the styles of the place.

The Urban Renaissance does not want to be a school, a movement or a tendency, but the occasion to regain the heredity of the culture of the European genius.

The aim is not that one to impose a new ideology, but to convince and to demonstrate through projects of evident quality, that an alternative to the functionalist culture exists, as it should be in a tolerant and democratic civilization.

All the modernist planning seemed to forbid, is now used in these pages: the reconstruction, the styles, the buildings aligned on the street-edges, the public realm, that never-ending-variety of complex urban-spaces born from the combination of simple parts typical of "healthy" traditional urban development.

Today the problem of good part of our peripheries and of many modernist buildings is not only on their existing, but rather than various architects and ideologists want to make to believe us that their construction was and is unavoidable, necessary also in the future.

In democracy also the architecture and the urban planning are a whole of choices, without no obligation. Anyone who refuse the existence of choices is undemocratic, totalitarian and, consequently, "not-modern", for how much futuristic and technological his building, his skyscraper, and his mall could seem.

Today a massive return towards solutions of good sense still exists, according to the philosophy of A Vision of Europe network, and with the American current of New Urbanism correspondent, in Europe, to the Council for European Urbanism" [3].

The standards and principles of Urban Renaissance are designed to make areas more livable, more vibrant, and more people-oriented, and to build community pride in the city and the work of its developers [4, 5]].

This is a Copernican revolution: the people, and not the cars, must to be the centre of the urban develop. The towns and the buildings are designed for the people and not as a monument to the "progress" or to the presumption of architect. In substance the principles of Urban Renaissance are resumed in applied of the principles of Traditional European Urbanism that governed the city grow in Europe during the last twenty five century.

The consolidated urban environment already has its own natural predisposition to suggest and to accept as its own and in its own way the new elements so that every new event is introduced in its vital space, put and interwoven in its body. In this way every deformity, an abuse, an inconsistency introduced in a plan will become – and this is the worst damage – similar to a deformity, which remains and multiplies once it has been introduced in a living body. The enlargement of a town too is already potential in its organic structure and in its natural position. It is up to the architectonic designer to carry it out by means of suitable typologies by including and expanding the existing town so that every quarter meets its function on the whole and creates an order, a breath, a subordinate and harmonic autonomy in its units and links; so that neither the functions overlap without any coordination nor the new quarters rest on the old city centre by thickening, overcrowding and chocking it.

From this point of view, New Urbanism represents a concrete answer. In November 2003, in Stockholm, after a few years of work, during the annual general assembly of the Council for European Urbanism (CEU), researchers, engineers, architects, designers and entrepreneurs signed the Charter for European Urbanism.

The Charter proposes a new traditional way to design livable, sustainable and ecological towns, quarters and villages and a new way to give life back to suburbs. CEU started from the remark that metropolis, towns and countries are continuously menaced by phenomena of social exclusion and isolation, dispersion, waste of natural and cultural resources, mono-functional development, lack of competition and of whatever respect for local cultures; it defined as its priority objectives: the need to promote a urban designing supporting diversity of usages and social mingling; the promotion of an effective and sustainable use of buildings, soil and other resources, assuring safety and accessibility to pedestrians, bicycles, cars and public transport. Towns and quarters must be territorially defined during each step of their development. They must have streets and spaces defined (surrounded) by an architecture complying with local conditions – culture, tradition, climate and landscape – and must have a variety allowing the development of a society, of its activities and of its built shape.

CEU promotes the valorization of the distinctive and typical features characterizing towns, suburbs, villages and countryside in Europe; it encourages keeping and strengthening regional identities and citizens' aspirations; it supports the creation of new towns, quarters, suburbs incorporating, if suitable, these objectives; it stimulates requalification, formal renewal and transformation of outskirts and suburbs on the wane in poly-functional and active areas; it encourages the respect for natural environment and for human habitat; it promotes the protection of natural and building heritage. As towns, suburbs, villages and rural areas are a reflection of the social, political, economic and environmental context in which they have developed, physical requalification is not enough. Every intervention aiming at improving the physical quality of the environment must be considered as part of more complex policies aiming at improving the quality of the European population [6].

This reasoning leads to suppose a model of development based on a logic of sustainable globalization founded in the organization of polycentric towns, of towns organized in urban quarters, districts, suburbs and

villages, of towns where population density is such as to guarantee a good life standard and at the same time to support the presence of retail business activities. As Gabriele Tagliaventi wrote, *“the challenge of architecture is creating the physical conditions for the development of a world in which towns express local*

realities, enriching the experience of an age of globalization through the plurality of visual and morphological experiences. This technically means studying urban shapes and local settlement typologies with no prejudice, but being open to the introduction of all those innovations consistent with the base framework and fit for improving it, according to the principles of traditional architecture.” [1]

The study of urban typologies represents also a way to analyze the demands not directly expressed by citizens, but “*de facto*” written in the town’s stones, which represent the history and the civic conscience of that community. It makes it possible to everybody to take part, even if indirectly, to planning. This way of acting can lead to the definition of projects which cannot be shared by citizens because they are based on its political, economic and social demands, in their turn, grafted on a definition of urban spaces realized on the basis of the typological evolution that the town has undergone in relation to its natural, economic and socio-anthropoc environment [7].

In order to achieve this objective it is necessary to act at the different scales with a direct knowledge of the urban setting of reference in order to determine the unchanging typological elements – typological invariants – giving its character to the city and reinterpret them in building of new interventions (a quarter, a building or even a single building element). In this way the vital transformation of the city is obtained and at the same time the perpetuation of its peculiar, unique and unrepeatabe historical connotations. The research for typological invariants has to be performed already in the step of planning devising, since already during this step it is necessary to define the typological features that the building intervention has to adopt at the different scales, from the urban scale to the building detail, in order to be bound with the building tradition of

the area. These objectives can be achieved by drawing up an instrument to manage the intervention, called urban code. This code is based on graphic tables which classify the typological invariants determining and regulating the development of that specific physical context at the different scales. The code works since on one side it is a useful and simple tool to carry out the necessary quality controls on the final product and, on the other, it guarantees the historical continuity of the built-up structure.

Synthetically, the Urban Renaissance promotes building of eco-compact cities. These are cities built and developed in balance with the natural environment; they are cities with clear boundaries and with an optimum ratio between density and network of open public space defined by urban mixed-use blocks [8, 9].

They are cities made of a federation of organic urban neighborhoods and districts, but they can also be a metropolis (i.e. Paris). The optimum density that characterized the eco-compact city allows the existence of a rich system of small retail, while allowing the creation of an efficient public transit system. The eco-compact city allows its inhabitants to live within a pedestrian friendly environment, that encourages pedestrian movements, the use of public transportation, and discourages the intensive use of automobiles. The main goal of this urban design concepts is to create a rich-interactive urban environment that optimizes the use of natural resources and dramatically reduce the pollution of both the air and the natural landscape.

During the last years, the concepts and ideals of a new traditional way to build towns were spread.

In the figures included in the text, it is possible to see more examples of new towns or interventions of urban Renaissance designed or built in Europe. It is interesting to note that there is not a specific geographic or cultural area of diffusion but all European countries are investing by this new wind of change [10, 11].

3. Structural and social benefit of the Urban Renaissance

In consequence of application of these ideals, the cities have a smart growth with the subsequent addition of eco-compact urban neighborhoods that provide the following benefits.

Mainly, they give people without access to a car, such as children, the elderly and the disabled, more safety and independence in their world. In second time, making mixed use neighborhoods, more dignified and rich of historical references, it preserves and promotes community character, increases urban liveliness and citizen access to culture and, at the same time, it reduces the need to escape to suburbs, therefore reduces the necessity for costly and useless sprawl and mall development. Really these new traditional ideals help restore of historic structures instead of leaving them in favor of parking or large suburban shopping center. Substantially they reduce government and social costs - especially because they reduce the costs for services (public transportation, garbage, welfare services, etc.) and for maintaining of infrastructures and, at the same time, they reinforce sense of place, sense of community, sense of belonging and restore civic pride [12, 13].

In this new urban space also edifices are built for permanence instead of structures designed, as too many contemporary structures are, for a short life. These permanent edifices promote flexibility and integrate income groups by mixing housing types and providing a public realm available to all incomes.

In these new traditional towns, streets are designed to slow traffic because travel choices are increased and the length and number of vehicle trips are reduced. In this way it promotes neighborhood and community self-sufficiency and, therefore, sustainability and reduces per-capita gasoline consumption and air pollution (C.E.U. - Oslo Declaration on Climate Change and Urban Design). Recently a European Union research showed that normally a car trip for 2 or 3 hours for day (from house to work and back again or similarly from house to mall), during the remained 21 hours it is parked on the streets or in the garages. So the urban system based on an irrational use of cars while in the traditional cities, as well as Paris or Rome or Annapolis, there is a balance between the needs of the car and the needs of the pedestrian integrated by public transportation system. The extraordinary key-factor of an eco-compact urban neighborhoods is also its high performance in term of walk ability. It is right the dispersion of small retail through the network of streets and urban blocks that allow citizens to easily shop on foot to the different type of contemporary shopping typologies: department stores, stores, small shops, etc., without using car. And the daily flow of citizens throughout streets and squares offer another dramatic advantage in term of security: the famous "people watching people" effect. The contemporary presences of cars and pedestrians on streets guarantees the presence of small retail. In the same time, the large presence of small retail on streets and squares allows an automatic and high performing type of surveillance for pedestrians. It is the main reason that led many American cities to adopt a special legislation to guarantee small retail on street; the small retail is therefore declared as "public utility", thus qualifying for a special tax exemptions [14, 15].

4. Conclusion

The Urban Renaissance is a term used in order to emphasize a project culture based on the traditional principles of the urban spaces and the constructive techniques of the European city. In fact it represents the most modern concept of urban architecture based on the traditional and historical western ideals of liberty, democracy and participation of the citizens to the development of the city.

At the same time, the development of traditional eco-compact cities allows a pedestrian oriented neighborhood with permanent edifices built with traditional typologies and mixed use; it reduces per-capita gasoline consumption and air pollution, encourages growing of retail in the urban space and, so, puts "eyes on the street" and promotes "citizen surveillance" of public places where citizens watch over their collective security, crime is reduced, as are public law enforcement costs. This is, briefly, the reason to consider the traditional way of making urban architecture as the best answer to build today true sustainable cities.

Abstract

In the article we deal with a recent survey mission – in collaboration with the Magdala Project and promoted by the Custody of Holy Land – in the evangelical sites next to the Tiberias Lake in the Holy Land. The activity concerned the survey of the new archaeological site of the city of Magdala and the visit of other places of evangelical interest (Tabgha, Capernaum). The mission involved the integrated use of different survey techniques and suggested how a more systematic cultural approach to knowledge and documentation of the places – of strategic importance in history of mankind and civilization – could certainly promote a further social and economic development.

Keywords: survey, documentation, development, economy.

A mission for the survey of the ancient town of Magdala on Lake Tiberias, subject of a stratigraphic excavation project directed by P. Stefano De Luca, took place in recent months; the mission is part of a collaboration agreement signed by prof. Cesare Cundari (one of the authors of this communication) and by P. Stefano De Luca, scientific director of the *Magdala Project* which is held under the auspices of the *Studium Biblicum Franciscanum*, Faculty of Biblical Sciences and Archaeology in Jerusalem. The organizational part of the mission was provided by the ISI Engineering srl of Rome.

The study of the site, as well as for the evangelical events, is also important for understanding the historical stratifications that occurred, contextualized in relation to near Lake Tiberias and settlements that have sprung up along its perimeter (fig. 1: map of the Lake with highlighted Magdala, Tabgha, Capernaum). The ancient city of Magdala was a thriving commercial center also favored by its strategic location in the intersection of major roads of communication, just remember that it was crossed by the "sea route", a road leading up to Egypt along the valley of the Jordan.

The site has been undergoing major stratigraphic excavations between 2007 and 2011; research results have already been published, especially by P. Stefano De Luca himself [1].

The mission, which was attended by many scholars [2], had the purpose to carry out a systematic and widespread campaign of metric detection and photographic documentation in order to return (graphically and infographically) the physical reality of the ancient site and allow for their representation in the main steps of transformation. In carrying out the activities we used a complex of photographic equipment (calibrated or not), a laser scanner Leica C10 (specifically made available by Leica Geosystems), and a total station available in the area for a sample check of a very dense topographical network already made in previous months.

The activities of restitution and processing infographics related to the ancient city of Magdala will go on for the next few months.

The main purpose of this communication, however, is not so much to popularize the activities of the mission but, rather, to make known that, with his conduct, it was also possible to perform a careful survey of some

other biblical sites not far from Magdalene as Tabgha and Capernaum; it was also possible to start the survey activities of the main historic episodes in the two places and to lay the foundation for a systematic study and documentation which can be possibly extended to the main religious settlements that have sprung up along the banks of Lake Tiberias.

Fig.1: Tiberias Lake and the sites on its shores

Fig.2: The Church of the Primacy of Peter and the Lake's water level in the Seventies

Fig.3: The Church of the Primacy of Peter and the Lake's current water level

Fig.5: Survey activity in the ancient Beatitudes' church

Fig.4: Inner view of the Church of the Primacy of Peter

Fig. 6: Tiberias Lake seen from the ancient Beatitudes' church

It's hardly necessary to emphasize that the objective of the research is not only the documentation of the various buildings and sites; it should be clear to the reader the fact that the Lake Tiberias is located along the river Jordan, which flows in a valley that, as a whole, should be considered a rich palimpsest of evidence of ancient civilizations; from that - along with a careful reconsideration of the history of people who have inhabited - should suggest a careful critical analysis and enhancement that disregards the current political divisions to consider those aspects (of unifying type) that are strategic for economic and social regeneration, among which water supply is of primary importance.

In this regard, suffice it to say that a photo of 1970 (Fig. 2) certifies that, near the Church of the Primacy of Peter at Tabgha (which stands almost on the shores of Lake Tiberias), the water level of the Lake has lowered (fig. 3), during these years, of about 6 meters. It's also true that the whole area was not exempt, over the millennia by earthquakes.

The opportunity during the mission, to visit, among others, these biblical sites, showed that some of them are still the destination of pilgrimages and undoubtedly retain an aura of mystery and mysticism certainly linked to the sites; this is what you feel on the lake shore near the Church of the Primacy of Peter, or aiming the steps of the rock from which the story is that Jesus has appointed Peter's role in the foundation of his Church.

It's, then a + marking architecture (also built with simple and basic techniques) and an environment capable of transmitting even today, after two millennia, an undisputed historical significance (Fig. 4).

Others, indeed, deserve a better fate, as the place where traditionally you want the conversation of the Mount took place (or speech of the Beatitudes); on the road that goes from Tabgha to Capernaum, the Franciscans discovered in 1935 the remains of a religious building with a beautiful mosaic floor dating from the end of the fourth century and restored in the Byzantine era. Today, the building is quite recognizable in the plant (mutilated by the route of the road) on top of a hill, not far from the site where stands the church of the Primacy of Peter. Being there - even to make some basic measurements (Fig. 5) - made it possible to imagine, even in this case, the charm of ancient environmental conditions (Fig. 6); we regret to have to mark it with a - in the hope that the place can be recovered to the usability of pilgrims for its outstanding landscape value.

To be for long days in those places, however, allowed to experience the difficulties of a situation of latent and constant conflict that is matched, however, with the geo-political situation; we believe that a better understanding of the histories of nations may certainly contribute to mutual recognition and establishment of better living conditions. To this we can greatly contribute with our ability to engage an intelligent and prudent strategy of survey, documentation, dissemination. From this belief comes the desire to continue the action undertaken.

SPECTRAL ANALYSIS OF WAVE CHARACTERISTICS ON THE BACK OF SUBMERGED BARRIERS IN THE MEDITERRANEAN

Giuseppe D'ANGELO⁽¹⁾ – Maria Cristina MIGLIONICO⁽¹⁾

⁽¹⁾ Facoltà di Architettura, Seconda Università di Napoli, Italia
E-mail: giuseppe.dangelo@alice.it, mcristina.miglionico@unina2.it

Abstract

In the last decades of the just spent century, the worldwide scale degradation of the coastal environment has spread out in all its seriousness. One of the most important aspect of such a degradation is given by the recession of the shoreline and the erosion onset. The Mediterranean coasts are not affected by this emergency, according to recent Ministry of Environment report. Most of coastal heritage (45%) is currently threatened by erosion.

It is firstly necessary to have in mind that the shore line is the last most mutable sign of the natural landscape. The causes of its backward movements are affected by various aspects. Generally, this phenomenon is always due to the simultaneous presence of two factors: natural and anthropogenic.

The possible solution is the downstream action of the phenomenon, with the creation of defensive works facing the eroding coasts.

Such a paper puts in relation the geometric features of the structure (height and width of the ridge, slope of the vestments, permeability) and of the incident wave (height and period) to magnitudes. These quantities are also relevant for sediment transport in the protected area, and it is considered the parameters for the definition of magnitudes which represent the hydraulic response of the barrier. In particular this work deals with the influence of the building geometry and the wavy accidents characteristics:

- Primary spectral parameters;
- Low frequency waves;
- High frequency waves;

Key words: Environment, wave spectrum, submerged barriers.

1. Introduction

In the last decades of the twentieth century has exploded in all its seriousness, the degradation on a global scale, the coastal environment. One of the most striking aspects of this degradation is given by the recession of shoreline and since onset of erosion. The coasts of the Mediterranean have not been spared from this emergency, according to recent reports from the Ministry of Environment most of coastal heritage (45%) is currently threatened by erosion.

Always, to our coast is recognized as a valuable asset, whose natural beauty and economic performance should be preserved as much as possible over time. Nevertheless, since the late '50s, the Mediterranean coastal strip is used as an inexhaustible well, indestructible and its delicate balances are put in danger,

constantly, often irreversibly, by a large number of works and infrastructure. These two opposing trends have, over the years to the construction of various works of defense, which have had the role of interventions "buffer", under the pressure of urgency. Today, as a result, we have that our coasts are defense works of all kinds, created to meet the different needs, but too often constructed as a response of a careful design.

Bear in mind, first, that the shore line is, the signs of the natural landscape, one of the variables. The causes of its backward movement are varied and, in general, this phenomenon is always due to the simultaneous presence of two or more factors. Wanting to identify the main causes of the evolution of coastal profiles, you must make a distinction between the "natural" and those related to human activities.

Among the natural causes, the most important is certainly represented by the progressive rise in mean sea level (eustasy), which produces what is commonly called "erosion on a large scale." There is evidence that, from the Roman era, the average level of the Mediterranean has increased by about 2 m, with an average of about 1.2 mm per year. Among other possible natural causes may include also the effects of subsidence and bradism (Phlegrean Fields).

The anthropogenic causes are, of course, more numerous and dangerous. They produce what is usually called erosion "long term" (or "structural"), largely due to the positive gradient of the solid flow rate longitudinally along the beach and is typically fatal. Among the most common human causes include:

- The construction of harbors and breakwaters;
- Destroying or tampering of the coastal dunes;
- The extraction of gas, oil or water from underground, and the consequent problems of artificial subsidence;
- The reduction of fluvial inert sediments, due to the extraction, sometimes wild, near the mouth (the case is emblematic of the Volturno, whose bed was plundered for years for the concrete production);
- The construction of dams;
- The arrangement of mountain basins.

On many of these factors is, as we understand, impossible or useless act. The only possible solution is therefore the action downstream of the phenomenon, with the creation of works of defense in the face of eroding coasts.

In the design of barriers offices are generally available only two equations. The first concerns the stability of the boulder with cabinet and is used for structural design; the second concerns the transmission coefficient and provides an estimate of the total incident wave energy transferred in the protected area.

In this paper we relate the geometric features of the structure (height and width of the ridge, slope of the vestments, permeability) and the incident wave (height and period) to magnitudes that are also relevant for sediment transport in the protected area, and we consider the parameters for the definition of magnitudes representative for the hydraulic response of the barrier, and, in particular discusses the influence of the geometry of the work and the characteristics of wavy accidents:

- The main spectral parameters
- Low Frequency Waves
- High frequency waves.

2. The frequency spectrum

Observing the "real" sea surface we note that it has a pattern (in time and space) extremely irregular.

A "state of the sea" schematization by means of a monochrome wave train (or regular) characterized by a single value of the period T (or of the frequency $f = 1/T$) does not result always physically satisfactory.

It seems more realistic to assume that the real surface is constituted by a large variety of waves of different amplitude, frequency, phase and direction of propagation.

It follows that the actual wave is no longer periodic, neither in time nor in space, for this reason that it is defined irregular or random.

Analyzing a random signal, and using for example a window of the type box-car of length T , to determine the analyzed segments, it is possible to obtain different spectrum estimates, that, in general, do not coincide, either in the peak, or in form.

It is possible to shown that the resulting spectrum from a direct analysis of a random function is also a random function. In fact, if the expression of the Fourier series:

$$\eta(t) = a_0 + \sum_{n=1}^{\infty} a_n \cos n\omega t + \sum_{n=1}^{\infty} b_n \sin n\omega t$$

with:

$$\begin{pmatrix} a_n \\ b_n \end{pmatrix} = \frac{2}{T} \int_0^T \eta(t) \begin{Bmatrix} \cos n\omega t \\ \sin n\omega t \end{Bmatrix} dt$$

where $\eta(t)$ is a normally distributed random process, even a_n and b_n are normally distributed random functions, and so the spectrum:

$$|F_n|^2 = \frac{1}{4} (a_n^2 + b_n^2)$$

To derive a statistical estimate of the spectrum, is needed what is called a smoothing operation. The methods to carry out the smoothing of the spectrum tend to reduce the estimated spectrum bias, $B(f)$, defined as the difference between the estimated spectrum and the spectrum of the actual process:

$$B(f) = E[\tilde{S}(f)] - S(f)$$

the estimated variance of the spectrum:

$$\text{var}[\tilde{S}(f)] = \frac{S(f)^2}{T} \int_{-\infty}^{\infty} \omega_p^2(\tau) d\tau$$

Between the methods of smoothing, the most and widely used is the method of Welch. This method consists in:

- 1) split the set of length T , into K subintervals of length $M = T / K$
- 2) to estimate the spectra of individual subintervals $\tilde{S}^{(j)}(f)$, $j = 1, \dots, k$.. (each subinterval has a frequency resolution of $1/K$, or K/T , while the entire series would have a better resolution of $1/T$)
- 3) calculate the average of the whole spectrum

$$\bar{S}(f) = \frac{1}{K} \sum_{j=1}^K \tilde{S}^{(j)}(f)$$

This method increases the bias (because it reduces the observation period), then reduces the frequency resolution, but reduces the variance.

It is possible to define the moment of zero order:

$$m_0 = \int_0^{\infty} S(\omega) d\omega$$

that represents the area under the spectrum curve. This time indicates the energy associated with the spectrum.

3. Laboratory data analysis

The data relating to only measures of recorded wave height are processed first by adding data relating to the acquisition time and, after, using the methodology proposed by Yamashiro (Yamashiro et al., 1999).

Fig.1 Wave off frequency spectrum.

The figure shows the trend of a typical wave off spectrum, it represents the concentrated energy around the peak frequency f_p .

Spectral density

Fig.2: frequency spectrum of the wave after the barrier impact.

The figure shows the trend of a typical spectrum of the waves on the reverse side of the barrier. Analyzing the power spectra, from wide to coast, it is noted that the energy decreases thanks to the intervention of the barrier. The spectrum has two peaks, one at a peak frequency f_p and the other at a frequency $f > f_p$. It has, the formation of two populations of waves: defined "low frequency" waves and "high frequency", with the peak frequency f_p , which remains unchanged. Away from the barrier, the class formed by the high frequency waves of energy increases ("reforming"). It is possible to calculate:

- The zero order momentum, defined as:

$$m_0 = \int_0^{\infty} S(\omega) d\omega$$

- The meaning wave height, defined as:

$$Hm0 = 4 * SQRT(m_0)$$

with: $SQRT(m_0)$ the square root of m_0 .

- "Transmission coefficient K_t " the ratio of the transmitted wave height and the one incident:

$$K_t = \frac{H_t}{H_i}$$

- where H_i and H_t represent the meant heights waves calculate with "sea states spectral" method, in absence and in presence of the hedge respectively.

Once time determined the energy spectrum and their associated parameters, using the Yamashiro theory, it is possible to divide the energy spectrum in three parts:

- the included part $0 < f < 0.5f_p$ (frequency impossible to find in the nature)
- the included part $0.5f_p < f < 1.5f_p$ (*“low frequency area”*);
- the included part $1.5f_p < f < 5f_p$ (*“high frequency area”*)

The figure 3 shows the spectrum in the 3 defined areas.

Fig.3: Divided energy spectrum following the Yamashiro theory.

After it is possible to calculate the values of m_0 for every area of low and high frequencies, by indicating with:

- m_0 High the value of the zero order momentum referred to the spectrum interval $1.5f_p < f < 5f_p$;
- m_0 Low the value of the zero order momentum referred to the spectrum interval $0.5f_p < f < 1.5f_p$;
- m_0 Total the value of the zero order momentum referred to the spectrum interval $f > 0.5f_p$;

Afterwards, it is possible to calculate the wavy characteristics:

$$\frac{m_0 \text{high}}{m_0 \text{tot}}$$

$$e \quad K_t$$

on the basis of the geometrical characteristic of the hedge:

$$\frac{B}{gT^2} \quad \frac{H_t}{gT^2} \quad \frac{R_c}{B}$$

For "short" berms, with $B=1$, the ratio

$$\frac{m_0 \text{high}}{m_0 \text{tot}}$$

tends to decrease with the increase of the quantity $\frac{B}{gT_p^2}$. For "long" berms, with $B=4$ the ratio

$$\frac{m_0 \text{High}}{m_0 \text{Tot}}$$

remains constant while the ratio

$$\frac{B}{gT^2}$$

varies.

With the same quantity of

$$\frac{B}{gT^2}$$

the ratio

$$\frac{m_0 \text{High}}{m_0 \text{Tot}}$$

of the less submerged hedges, with $R_c=-0.2$, results greater than of the more submerged hedges, with $R_c=-0.4$.

It is important to observe that with the same value of R_c the ratio

$$\frac{m_0 \text{High}}{m_0 \text{Tot}}$$

decreases with the increase of the quantity

$$\frac{B}{gT_p^2}$$

this means that for structures with low

$$\frac{R_c}{B}$$

the ratio

$$\frac{m_0 High}{m_0 Tot}$$

results quasi constant, independent from the wave height off $Hm0$. Increasing the transmission coefficient (K_t) and at same time increasing the transmitted height wave, increases also the range of the ratio:

$$\frac{m_0 High}{m_0 Tot}$$

It is possible to obtain best results (lowest transmission coefficient) for the structures with longer berms and less submerged. For the structures with short berms it is not possible to say about K_t in function

$$\frac{B}{gT_p^2}$$

4. Conclusions

Spectral analysis shows that the energy spectrum is modified slightly first by interacting with the bottom, after it changes substantially with the passing of the structure.

The analysis show that the peak frequency remains unchanged to back off from the structure and the experimental data is rather a tendency, the transmitted peak frequency, doesn't exceed one incident in about 75% of cases the ratio

$$\frac{f_{i,p}}{f_{p,t}}$$

is less than the unity, and mostly for wide ridge structures. From the study carried out on the peaks frequencies shows that the variation of the frequency peak is less than 4% of that of large for most of the tests, which are normally carried out and, as regards the low frequencies, it is accepted that this percentage of energy spectrum transmitted, associated with long-wave enters significantly involved in the mechanisms of creation and modification of the forms of the bottom.

For high frequencies, however, has been analyzed the variation of the relationship between the time of zero order of the high frequencies and the total one, as a function of dimensionless parameters that refer to characteristics of the wave and the geometry of the structure, noting that increasing the transmission coefficient K_t , therefore, the increase of the transmitted wave, increases the range of variability of the

relationship $\frac{m_0 High}{m_0 Tot}$.

Management models of sites of excellence in France for the rural landscape in the province of Caserta.

Alessandro CIAMBRONE¹

Abstract.

The landscape of the province of Caserta, in the centuries-long succession of historical events and up to World War II, has been not only the expression of a rural culture but has also focused on innovative agricultural processes through a conscious attitude of man towards this extraordinary natural heritage. Over the last decades, the dissipated use of space has damaged the image of the “beautiful landscape”, that has been greatly appreciated in the past by foreign travellers. Not taking into consideration the shortcomings of local administrations willing to propose operational landscape management tools as well as the uncontrolled and unauthorized building interventions that have gone unnoticed by the institutions, the author believes that the most serious problem lies in the lost sense of identity and attachment of the local communities to the historical matrices of the place. In order to avoid repeating the same mistakes, the creation of a “local tourist system” for the province of Caserta has been proposed, with planning strategies aimed at enhancing the rural vocation of the territory as well as the involvement of local communities, as sustained by the European Landscape Convention and the Budapest Declaration on World Heritage. In this context, several management models of sites of excellence in France can stimulate strategies to be adopted in “*Terra di Lavoro*” (Land of Work): *Val de Loire patrimoine mondial, le Schéma de Cohérence Territoriale de Montpellier, les Grands Sites de France de Saint-Guilhem-le-Désert, Pont du Gard et Bibracte*.

Keywords: rural landscape, territorial management, cultural heritage, local community, public participation.

The landscape of the province of Caserta, in the centuries-long succession of historical events and up to World War II, has been not only the expression of a rural culture but has also focused on innovative agricultural processes through a conscious attitude of man towards this extraordinary natural heritage. Over the last decades, it is passed, in a short period, from agricultural to industrial use, denaturalizing the natural vocation of the territory. This has involved a meaningful variation in the models of life and fruition of the area [1]. Not taking into consideration the shortcomings of local administrations willing to propose operational landscape management tools as well as the uncontrolled and unauthorized building interventions that have gone unnoticed by the institutions, the author believes that the most serious problem lies in the lost sense of identity and attachment of the local communities to the historical matrices of the place. This has effects on the social and economic aspects. The inhabitants of the area have turned away from politics and public institutions, delegated, in general apathy, to make planning choices. In this sense, looking to realities that have been signed by history in a similar manner to that of the province of Caserta, and which are considered models of territorial management for the real involvement of local communities as well as for proper landscape planning, can stimulate ideas and considerations on strategies to be adopted. The province of Caserta has been defined as an “immense Mediterranean garden” from the travellers of the XVIII century [2] and *Terra Laboris*, for its characterization linked to agricultural production and extraordinary fertility of the land as well as for its exceptional underground and superficial water apparatus. It is represented in its logo

by two cornucopias, symbols of abundance, filled with the fruits of the earth's labor. The allegory of fertility is found in the *Mater Matuta*, holding in her hand a pomegranate, earth product and symbol of fertility, the only exception of tufa statues *Matutae Matres*, women with one or more babies in their arms, exposed in the Museum Provinciale Campano and realized, from the sixth to the first century B.C., from Oscan populations. The rural vocation of the territory, characterized by urban centres of extraordinary historical and artistic interest, can be read in different historical stages and through different signs that have marked its landscape: the consular roads and subsequent *centuriatio* in Roman times, the fortified architectures during the Middle Age and Renaissance, the convents and the agricultural colonies of the Benedictine monks, the Bourbon royal palaces, water infrastructure and major roads, implemented and expanded in following periods [3]. The Romans, besides the construction of the streets of communication with Rome, also organized agricultural land by taking the usual division into sectors of equal size squares, oriented according to cardinal directions denoting a quite evolved technique. These traces are still visible in numerous roads, including, Capua, Santa Maria Capua Vetere, Caserta and Casagiove [4]. Later, the presence of the Normans in the territory marks a period of economic and political stability, also guaranteed by an effective system of road monitoring, based on the construction of castles, fortified structures of defense and elements located at strategic points in the network. These are interwoven with rural dependencies and farms, managed by the Benedictine monastic communities, for the control of large areas subject to drainage and subsequent agricultural use. Subsequently, the Swabians introduce the productions and sales of local crops in national and international circuits, thanks to the regulation of monopolies, customs and the opening of fairs and markets [5]. From 1500, the Aragonese are substantially involved in the rehabilitation of vast areas of wetlands and construction of roads, especially for agricultural transport: they had the idea to make the Volturno river navigable in order to establish a connection between Capua and the sea. Since mid-1700, the best territories of the province are utilized for agricultural experimentations, which are considered a driver of economic development. These are promoted by the Bourbons, through a network of residences, the "real sites", spread over a large area [6]. The most important among these for the protection of the agricultural productions is the royal property of Carditello, destined above all, to the breeding of equine and bovine races [7]. The rural landscape in the eighteenth century, is strongly marked by extraordinary works of hydraulic engineering: the Regi Lagni, a massive irrigation canal that runs through the hinterland to the sea: and the aqueduct of Vanvitelli, declared World Heritage property in 1997 with the Royal Palace, the royal gardens and the industrial city of San Leucio characterized for its production of silk. The program of "rural urbanism" of the fascist period - focused on the reclamation and colonization of wetlands, especially along the Domitian coast - serves as a propaganda by the government, which exalts the virtues of rural life as a sign of a renewed morality to oppose to the industrial urbanism, seen, on the contrary, cause of population decline, disorder and social anarchy [8]. Today, the rural architectural heritage, which has significantly defined the landscape of these places, as already said, seems severely compromised and in a serious state of abandonment, both physical and functional. In recent decades, the uncontrollable urban and industrial expansion, the construction of several and massive highways and, in general, the unsustainable use of space have destroyed the image of "beautiful landscape", widely celebrated in past centuries by foreign travellers [9]. In addition, in line with the data diffused by the national drainage and irrigation association [10], the agricultural land was significantly reduced because of overbuilding in the area and changes in the conditions of work activities linked to traditional land use [11]. The province of Caserta should have tried to preserve these landscape features at least similar to some areas of southern France. These consist of a strong classical influence, a Middle-Ages connotation influenced by the Arab-Byzantine culture, and important episodes of architecture related to the Renaissance and Bourbon periods [12]. The rural landscape of *Terra di Lavoro*, if properly valorised, could encourage the economic development of the area, not linked solely to agricultural production, but also to cultural and gastronomic tourism in search for authentic experiences, outside of the international circuits of mass tourism. In this sense, "it is crucial to understand what are the identity matrices of places in order to advance hypotheses of design able to protect and manage the territory by creating a balance between the spaces of the past and present needs, offering innovative solutions to meet the different requirements in terms of sustainability" [13]. The international comparison can provide positive elements to implement strategies for heritage protection, even to export to other contexts [14]. Thus, the author believes that the strategies to be adopted for the management of natural and built heritage, must involve local communities so that the future sceneries of territorial modification could be compatible with their expectations, as advocated by the Landscape European Convention and the Budapest Declaration on World Heritage [15]. In this planning process, we support the idea that "the roots of the gene are fertile ground for producing innovation. This does not transform but modify, sharing that biological culture, natural and evolutionary, which will fulfil against any implementation of predetermined patterns, a sort of regenerative function, we would say "stem", as produced by the same complex identity of places" [16]. It is impossible to

recover the whole artistic, architectural and landscape heritage related to the rural history of the territory, in consideration, above all, of its exceptional qualitative and quantitative wealth and, also, for the limited economic resources devoted to protecting and enhancing the natural and cultural assets. Different forms of land management would be able, however, to avoid that the mistakes of the last decades are repeated. We think, for example, of establishing a "cultural district" or "local tourist system", as defined in the "Tourism National Reform" law (L.135/2001, article 5), connected to the World Heritage property of Caserta, for its international recognition, and characterized by the revaluation of the territorial rural vocation as an important stimulus of project for the socio-economic development of the area. Even the minor heritage, in this case associated with architectures and rural landscapes, in line with article 12 of the World Heritage Convention, included in a network, could assume and enclose in itself the Outstanding Universal Value, inseparable condition from the concept of World Heritage property. This could be promoted within a complex proposal of tangible and intangible values in which the province is extraordinarily rich. This project should involve the main stakeholders of the territory, as we can learn from the best practices on heritage management worldwide.

Fig. 1: Roman theatre of Sessa Aurunca, province of Caserta (source: Alessandro Ciambrone)

In the UNESCO site of the Loire Valley, the involvement of local communities assumes great importance for the choice of territorial planning. The property, which extends along the river and includes 2 regions, 4 departments and 164 municipalities, is endowed with an innovative system of management. In 2002, the regional, departmental, municipal and local advisory agencies signed a "charter of engagement" with the aim of increasing the attractiveness of the area in terms of landscape, environment, tourism and cultural services. The State and local authorities, upon request of the World Heritage Committee, have established a system of site's management consisting of three bodies:

- the Territorial Conference, which is composed of representatives of institutional, national and international agencies. It draws up the guidelines;
- the Development Committee represents the main actors of civil and business society in the major domains of economy, tourism, environment, education, heritage, culture, education and research. The

Committee has advisory competences and the proposals are submitted by thematic working groups during the annual meetings; and

- Mission Val de Loire, which is the operational body. It has the task of transforming the guidelines and proposals, approved by the involved institutions, in concrete projects. The Mission is delegated by the State for the management of the label, linked to the identity values of the place that have allowed the property to be included in the World Heritage list [17]. The politics of land management developed through the synergic operate of these bodies, aim to protect specialized crops as well as preserve the natural environment, which strongly characterized the landscape of the Loire, considered "Garden of France". To enhance it, within the territorial planning instruments, agricultural protected areas have been established (ZAP - article L.122-2 du Code Rural). These aim to avoid the negative effects of contemporary agricultural sectors, which often stimulate the production of major crops at the expense of those typical. They regulate the relationship between urban sprawl and rural areas. The ZAP became operational, for example, in the metropolitan conurbation of Angers and in the municipality of Montlouis sur Loire. In general, along the river, scenic routes, related to local agricultural products, have been established, encouraging the development of cultural tourism. The landscapes of the Loire Valley, characterized by vineyards – the main crop of this territory - were included in the international circuit, the Vitour network, which connects through a wine tour, seven European vineyards included in the World Heritage list [18]. The idea of preserving and enhancing the rural landscape structures le *Schéma de Cohérence Territoriale* (SCoT) of Montpellier, related to the agglomeration of the city which includes 31 municipalities and 410 thousand inhabitants. The urban plan of the inter-municipal cooperation became operational for the first time in France in 1999, thanks to the law Chevènement. In the same period, the law Voynet, *d'orientation pour l'aménagement et le développement durable du territoire* (LOADDT), established the legal institution of "agglomeration contract" to articulate local development projects in cooperation with State and regions. Finally, the law Gayssot-Besson (2000), *Solidarité et renouvellement urbain* (SRU), improved, over the scale of town planning, a tool of orientation and design – the SCoT - which promotes the social and special integration in homogeneous territories belonging to contiguous municipalities.

Fig. 2: Saumur, Loire Valley (source: Alessandro Ciabrone)

The *Schéma* of Montpellier – forecasting 100,000 new inhabitants and 40/45.000 new residences in the next 15 years - plans the urban expansion outside the agricultural space, which becomes an impassable limit to be protected and a productive resource to be valorized. The area designated for new residences of project, occupies the middle of the space with respect to that used for the same number of housing units built in the years immediately preceding the approval of the SCoT. Therefore, the logic that agricultural land and natural sites are perceived as a variable to be adapted to the needs of urban expansion is reversed, in favor of a vision that, in contrast, envisages such areas as expression of the identity of the places and vector of economic development. The urban development is planned along a directional axis - the "sea route" - which projects the city on the coast, with large planned spaces dedicated to nature and agriculture [19]. In this logic, the concept of dense city is preferred. This is opposed to urban sprawl, spread over a wide area and result of a speculative land planning linked to little attention at the sustainable use of the soil.

Fig. 3: coastal area of the agglomeration of Montpellier (source: REICHEN, Bernard et ROBERT, Philippe & Associés. Schéma de Cohérence Territoriale (SCoT) de Montpellier. Agglomération de Montpellier).

The SCoT foresees three levels of housing intensity for the realization of the new residences. The number of planned constructions is greater in the urban centre and decreases in the periphery and in the vicinity of agricultural areas. This approach, in line with article 52 of law 2 February 1995, aims at the protection and enhancement of the French natural environment. Additionally, design solutions are proposed to facilitate short distance travel of limited environmental impact. For new construction, the SCoT envisages the reduction of the number of parking spaces near working areas and the construction of garages in residential centres, starting from the analysis that these measures encourage alternative travel with public transport, or through pedestrian and bicycle paths [20]. A similar attention to the enhancement of rural landscape, understood as the engine for sustainable development of the territory, is projected in the management plan *du Grand Site de France de Saint-Guilhem-le-Désert et Gorges de l'Hérault*, which includes 5 out of the 28 municipalities *de la Vallée de l'Hérault*. The label *du Grand Site de France*, is a prestigious recognition, attributed by the State, for a management that combines preservation of the landscape and "spirit of the places" as well as quality of the reception and participation of local communities in the preservation of cultural and natural assets. The five villages (Saint-Guilhem-le-Désert, Saint-Jean-de-Fos, Montpeyroux, Aniane Puéchabon), which host a population of about 5,000 inhabitants, receive from 650 to 700,000 visitors per year, with peaks of 12/13 thousand visitors a day during high season among the localities of Pont du Diable, Grotte de Clamouse and the village of Saint-Guilhem-le-Désert [21].

Fig. 3: Saint-Guilhem-le-Désert (source: Alessandro Ciabrone)

Thematic itineraries have been realized to avoid human pressure due to excessive tourist loads. These depart from the *maison du Pont du Diable*, reception centre and gateway to the territory as well as point of exposition and sale of local agricultural products. From here, it is possible to reach, among the local cultivations, the nearby potters village of Saint-Jean-de-Fos, where there is *la maison de la poterie*, interpretative space of a famous local handicrafts. In addition, through a riverside nature trail, it is possible to reach the village of Saint-Guilhem-le-Désert [22]. The landscape *du Grand Site* is characterized by designed and cultivated terraces bounded by local dry stone walls. The protection of agricultural and pastoral areas is

the goal of the "local program of concerted management", drafted in 2004, which is joined by the association of landowners "*Les Terrasses de Gallon*", constituted for the law 1901. The farmers have dealt with the recovery of the two-thirds of the olive cultivation of the territory from 2005 to 2007, and production and sales of olive oil since 2006. The community of municipalities in the Vallée de l'Hérault, has extended the management policies related to the rural identity of the territory to all the 28 municipalities constituting, among other things, a photographic observatory on landscape. The local photographers and association *Les Panoramistes* have captured 60 points of view, which are taken each year through pictures in order to inventory and constantly update the transformation of places [23]. In the framework of the policies of management for cultural and landscape heritage, the *Etablissement Public de Coopération Culturelle* (EPPC) is an innovative institute of governance adopted by the UNESCO site and *Grand Site de France du Pont du Gard*. In this organizational structure, the general manager is responsible for coordinating all the institutional representatives at different spatial scales, who are components of the board of directors. Additionally, the director has the executive power, under delegation, to implement the strategic actions approved by the board. This facilitates and makes shorter the long and complex bureaucratic processes which often prevent the management of properties under the control of national and international constraints and guidelines, for their own particular state of "excellence". A scientific council oversees all research activities, also related to the virtual exhibition on the Roman world, the largest in France, set up in the interpretation centre, gateway of the site [24]. The modern structure, of minimal environmental impact, is not far by the Roman aqueduct and is designed to not be perceived, in its own perspective axis, from the valley where the aqueduct is located.

Fig. 4: Pont du Gard (source: Alessandro Ciabrone)

The strategic choices for the enhancement of the site are oriented to the protection of its identity and landscape, including agricultural spaces, with the recovery of a natural area of 15 hectares adjacent to the Pont du Gard and the construction of a pedestrian promenade through it. *Mémoire de garrigue*, this is the name of the thematic path, guides visitors to the rediscovery of the Mediterranean landscape characterized by stone walls, local crops and medicinal plants as well as activities related to farming and forestry. Besides

unquestionable aesthetic enhancement of the landscape and the important cognitive function of the place, the project has contributed to the definition of a "cultural district", which, in a few years, has allowed a significant increase in economic revenues linked to cultural tourism for the site and the whole region. The number of visitors has increased by 100,000 units in three years, from 1.3 million in 2008 to 1.4 million in 2011. In the same period, the business figures have increased by 87% and the auto economic maintenance of the EPCC, compared to the allocation of public funds, increased from 50 to 73%. Pont du Gard moves an economy on a large area involving 1500 people engaged in cultural activities and tourists' reception, and produces an economic revenue of 140 million per year in the Languedoc-Roussillon region [25]. The archaeological site of Bibracte, located on Mont-Bouvray in the regional natural park of Morvan in Burgundy, is managed through the legal institution of *Etablissement Public de Coopération Culturelle*. Bibracte, considered the most important Gallic city at the time of Caesar, is a large proto-historic fortified agglomerate bounded by 12 km of walls that enclose an area of 200 hectares within the protected forest of Mont-Bouvray. The site has received the labels of National Historic Landmark (1985) and *Grand Site de France* (2008) for its landscape and historical prerogatives as well as for the concrete actions to protect and enhance it. Particular attention was dedicated to the preservation of the landscape characterized by its centuries-old forest and agro-pastoral activities typical of the area. A landscape management plan, with a projection-time of one hundred years, orients the scenarios of future archaeological excavations within the area as a function of the biological rhythms of the natural environment [26].

Fig. 5: Museum of Bibracte (source: Centre archéologique européen, Bibracte)

The fortune and development of Bibracte are linked to the political choices of president François Mitterand who proclaimed it, in 1985, the *oppidum*, site of national importance, and, in 1989, included it in the ambitious program of the "great works of the State." The investment of 215 million francs had two objectives: to make the archaeological site a model for research on *oppida*; and to highlight its importance for the French and European history [27]. In the following years, there will be a research centre, a museum and two residences that host for free researchers and students of the partner universities, which have signed international agreements of cooperation with the EPCC. Even the tourist management policies are related to

the protection of the landscape, through the organization of numerous guided tours, especially with local schools. Moreover, a promotion campaign of the property has been launched, aimed at regional and international visitors interested in authentic and natural experiences, related to the suggestive conservation of the natural environment. Best practices in France can promote possible forms of management for the establishment of a local tourist system in *Terra di Lavoro* (province of Caserta), which on the traces of architecture and forgotten landscape may find the "meaning" to design strategies for its future development [28]. The management of the considered French properties is oriented to define plans that exceed the individual involvement of local government, and involve institutional representatives at different territorial scales, including international institutions of reference. In the case studies mentioned above, organisms able to make the projects operative have been highlighted. For example, in the Loire Valley, the Mission is the operational body that deals with the implementation of joint projects approved by institutional representatives (*Conférence Territoriale*) as well as representatives of society and local entrepreneurs (*Comité pour le Développement*). Also, in the EPCC of Pont du Gard and Bibracte, the general manager is delegated to the implementation of projects approved by the board of directors, with all that this implies in terms of shortening and accelerating the long bureaucratic procedures, which, in contrast, often slow down the planning processes in Campania. Additionally, the planning process is oriented to the rediscovery of the historical identity of places that, in the French case studies, refers to landscapes strongly characterized by their rural and natural prerogatives. This is the case of the large-scale landscape design of the Loire Valley, which focuses on the affirmation of the values that have allowed the property to be included in the World Heritage list. The SCoT of Montpellier takes ownership of natural and agricultural areas that become the limit to the urban expansion, which is projected through a green axis, toward the sea. At Bibracte, Pont du Gard and Saint-Guilhem-le-Désert, the strategies for the protection and enhancement of the rural landscape become a stimulus of attraction for tourists in search of authenticity. In all the French properties appear clear and essential the involvement of the local collectivities in the processes of territorial modification and re-appropriation of its identity values. Finally, the best practices analysed suggest that if it is not feasible to recover all the historical, architectural and landscape heritage, as in the case of the province of Caserta, for who is involved in management of assets become a concrete option to re-create the memory through a virtual itinerary. For example, it is worth considering the creation of an interpretative centre which allows to read the layers of historical stratifications and the identity of the places [29], in a cognitive process of re-appropriation of values shared by local communities [30].

Knowledge and representation for landscape re-design: the area of Lago Piatto in Castel Volturno

Nicola PISACANE¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Italia
nicola.pisacane@unina2.it

Abstract

This paper presents a project related to the study for the sustainable development of a site in the region of Campania (Italy): the city of Castel Volturno, in particular the area of Lago Piatto. The research is about the census of all the building and street of this area characterized by the presence of an unauthorized district in an area near the sea coast and the river Volturno with a high hydraulic risk. The activity has involved the census of about 4000 buildings. For each buildings were surveyed both quantitative and qualitative data in order to be able to evaluate not only the quality of the place but also to provide for an intervention of protection in a site with an high environmental and natural valence, but highly degraded by human action. The data acquired by existing documentation and detected by the working group were incorporated into a GIS platform, and then associating to chart a given database with the information acquired. The use of GIS technologies for creating a Geographical Information System of the whole area has made it possible to combine all the physical and intangible components with a view to safeguarding and enhancing the site for landscape re-design.

Key words: Landscape, Geographical Information Sysyem, Survey, Census, Castel Volturno

1. Landscape drawing, landscape design

Investigate a territory, measure its multidimensional components in order to seek out traces of its evolution, analyze its constituent elements are fundamental moments of the landscape knowledge. The landscape, in fact, "is a document, a mixture of words, ideas, images, in which the system was forced to disband because of its elastic stiffness to adhere to the complexity of the problem" [1]

The survey of a landscape allow to analyze and to evaluate its quality, the aspects that damage its image, the changes that have taken place over time and which have changed positively or transformed negatively the environmental, perceptual, historical, geographical aspects and all other components that create a place " whose character is the result of the action and interaction of natural and/or human factors". [2]

To represent the complexity of the landscape, which goes far beyond the mere summation of the various components that compose it, it is essential to understand and analyze the relationships between the articulate and dynamic components trying to identify, through knowledge, the topological relationships of the changes that have affected the landscape that we are analyzing.

The dynamic study of the landscape provides a criterion of interpretation and analysis of n -dimensions that constitute it, to describe it in summary, based on the most significant changes, the peculiarities and the problems, the talents and the compromise, the fragility and the landscape vocations. The multidimensional analysis and the identification of changes and transformations of the past can guide the destiny of the

territory through the description of evolutionary trends to program the various actions of control, protection, management and re-design. The dynamics of landscape changes analysis and the direction of modifications based on a study that predict the future of the landscape, puts the researcher in front of highly complex phenomena that are supported by the tools offered by technological innovation driven by specific knowledge. Very different is the reading of the landscape - natural and/or built - carried out analytically and investigated by the specialists of the matter, in relation to their skills.

Environmental studies, in particular disciplines which refer to the earth sciences and biological sciences, allow to obtain a deep and comprehensive knowledge of both abiotic environmental factors, ie the character of the land and natural support that determines the good conditions to the development of life, both biotic environmental factors, ie the complex system of relationships that establishes a living community with the space in which it is born and raised and, therefore, the mechanisms that govern the life of our planet.

The different skills deepen, in various ways, knowledge of human activities and events in its evolution: the numerous and complex problems and phenomena, natural and cultural, related to the organization of the territory, the management of natural resources and cultural heritage; the birth and development of settlements, scattered buildings, the roads, the crops, the social organization and the technical knowledge of various community groups and local modes of utilization of available resources in various places, in addition to studying the ecological systems, anthropogenic and non anthropogenic modification and used for the sustainable management of landscapes

2. Degraded landscape

Among the major innovations introduced by the European Landscape Convention, is certainly worthy of note that the extension of landscape idea also to places that do not have exceptional values but for which quality can be traced in a hidden quality although strongly affected by anthropic actions who have completely transformed its aspects. In fact, Article 2, indicating the scope of the Convention, states: "This Convention applies to the entire territory of the Parties and covers natural, rural, urban and peri-urban areas. It includes land, inland water and marine areas. It concerns landscapes that might be considered outstanding as well as everyday or degraded landscapes".

An innovation of considerable conceptual and operational value that represents a significant excess of the previous vision of landscape, land and environment. It has therefore developed a new and complex landscape discussion on the issue: reflection that led to recognize a physical entity in the landscape.

The result of the interaction between culture, human activities and development of natural reality, undergoes spontaneous events and human actions, infused by cultures and traces of the historic building and by premises of future mutations, is an important document which recognized the landscape -with numerous cultural, economic, ecological values- an important role in promoting European identity and the relationship between man and his living environment.

In fact, trying to classify landscapes according to their aesthetic value, according to Annalisa Calcagno Maniglio, it is possible to identify four classes related to their value: the landscapes of exceptional value that must be preserved and should not be changed, the landscape of high general value that can undergo the transformations that we can not find anywhere else (for example, the expansion of a mountain village for the needs of residents or the construction of a road) with particular care to minimize the loss in value; the landscapes of common values that may undergo too large, provided that such changes do not diminish the value and, if possible, increase; degraded landscapes in which the transformations are necessary to achieve an acceptable quality.

Landscape and environment thus become two points of view of a single problem that is identified with the perception and the existence of relations between man and the context of transformation related to three spatial dimensions of living: the domestic space and the close relationship, the city and the space of social relations and the territorial activities.

The landscape then becomes a place where characters are identifiable thanks to parameters that can be found in perceptual sensitivity and mentality of the community. It is therefore a place concrete, jumble of signs and meanings, and presence of tension that builds up over time-course of relentless change and intangible assets.

Fig. 1: Castel Volturno, Lago Piatto, Degraded landscape

The landscape is geographically, historically and anthropologically specific, knowable and governable. It is a relationship between form and motion everlasting life, nature and outcome of the layers of memory and all the projections into the future.

Cultural Landscape represents the symbolic expression of cultural heritage in a modern way. As wealth spread on land, cultural heritage signifies the set of tangible and intangible heritage as a resource for common identities of a territory and of people who inhabit it.

The cultural heritage that make up this collective entities include material, concepts and representations, specific aspects of community life and land, as a synthesis through which people reproduces the concepts that are used for their identification and representation.

The word 'culture' is therefore a sense of a cultural traces that need 'protection' of a particular region or spatial domain, regarded as a cultural town. It is clear, however, that the problem now is extended to larger areas, especially if we think of a small planet like ours, a mere artifice, which is important, not only protect but also to improve and redevelop brownfield sites, abandoned and degraded areas in order to transform urban public space, most vital assets.

The need of coming back to give to places lost quality through interventions that have compromised the characteristics to eliminate what has been the result of actions not aware, within the meaning of Koolhaas, junk-space. The junk-space is the residue mankind leaves on the planet. The product is constructed of modernization is not modern architecture but Junkspace.

The Junkspace is what remains after modernization has run its course or, more precisely, what coagulates while modernization is in progress. Modernization had a rational program: to share the benefits of science, universally. As its individual parts are the result of brilliant inventions, lucidly planned by human intelligence, their total marks very clearly the end of the Enlightenment. The Junkspace is the sum total of our current achievements, we have built more than all previous generations put together, but for some reason we can not be measured on the same scale. [3]

Fig. 2: Castel Volturno, Lago Piatto, Environmental and natural presences

3. Analysis and survey tools

Using G.I.S. as a tool for the government actions of the territory gives a multiple meanings in which terms as information system, land and government have different meanings. Territory Management considers territory in its global and unit aspects, such as complex apparatus composed of heterogeneous elements that coexist in a certain space (the building stock, population, workforce, economic activities, services, soil, etc.) but all these elements are interconnected by cross-influences, consisting of trade in goods, services, money, image, people. Identifying territory as a real system immediately places those who want to govern it two sets of problems:

- The description of the system using a model for many parts of the informal, which sets individuals, relationships and behaviors;
- The ordering of the constructed model by means of precise and rigorous formal tools, such as mathematical equations that express the dynamics, or computer systems.

G.I.S. use who manage multidimensional data enables the creation of a dynamic platform fully implemented and queried to support the activities of re-design the landscape from its own resources.

Besides representing a strategic variable, the preservation, conservation and enhancement of specific sites constitutes a tool for long-term (i.e. widespread and diversified) and sustainable development. Indeed, an economic process based on local resources ensures a higher multiplicative effect on income; in their turn, wealth and well-being create the conditions for further growth and preservation

The information will be inserted in a geo-referenced database using GIS technology. The database was designed to be a dynamic system for supporting integrated and interactive knowledge

4. Case-study

Lago Piatto area, located in the town of Castel Volturno, just in the north of the river that runs through the city is strongly characterized by the presence of low-value construction settlement. The high landscape value of the site shall be given over by the strong links with the mainland of Litorale Domitio [4] by the closeness of historical, architectural and natural presences: the San Castrese Village, the Lago di Patria and Variconi Oasis. Emergencies in stark contrast with the area in question which emerges in a landscape devoid of a particular design and developed without a plan and through the construction of buildings mainly abusive, made with shoddy construction techniques and materials, and especially without the quality that characterized the site before the settlement of the Lago Piatto district. The constructions, made largely without requisite authority, and the almost total lack of any basic services and infrastructure that would ensure quality housing, transform this area of the town of Castel Volturno in a place characterized by physical and moral degradation of the people who live or frequent the place.

The survey conducted in this area is intended to be an inventory of resources and about the consistency and the situation of the housing and transportation infrastructure.

Employing the opportunities offered by technological innovation, the phase of the census involved the filing of physical characters and intangible assets of approximately 4000 properties. The filing and local survey was followed by the construction of a data-base to support the graphical data of Geographic Information System. In particular, for each building has been classified not only quantitative and metric data (height, number of floors, extension of the built and of that discovery, etc.) but also the consistency relate to the quality of the building (use for each plan, maintenance status, presence of appliances, etc.). Then was done, through a comparison chart, a check on the legality of the construction, comparing with the cadastral map and aerial orthophotos to verify any regularity.

It is therefore a genetic document of the area [5] of lago Piatto area that give us significant data on the value of the area and about the strong anthropic and not sustainable action realized in few years in an area of high environmental value. The value of the site still shows even if hidden by intensive construction activity and the abuse that undermines every piece of land in areas of high environmental and hydrogeological risk: the line of sea coast, the bend of Volturno river and the areas close to lake. Man action is realized in contrast to any prescription and any environmental constraints and urban security.

Knowledge action becomes finding the essential foundation for hypothesis to re-design the area and for the recovery of the landscape and its resources. The census has indeed found that just over 50% of buildings in the Lago Piatto area are shown on the cadastral map and some of the settlements insist on areas not

divided into lots. Another important finding concerns the almost total absence of commercial facilities and transportation services in support of a high-density housing development. The few commercial appearances are in fact placed at the ground floors of the residences on the main road, parallel to the coastline, crossing the entire area. Residential presence are above all isolated houses of two floors, surrounded with an open area used as a garden. The state of preservation and maintenance is largely poor, due also to constructions made of low quality materials and technologies and to widespread state of neglect and decay.

THE PROCESS OF THE PROJECT BY MARCELLO PIACENTINI OBJECT TO THE CITY: CLARITY AND EXPRESSION FOR WISE AND BALANCED USE OF PROPORTIONS.

Fabio Converti

Dip. di Cultura del Progetto, Facoltà di architettura "Luigi Vanvitelli", Seconda Università di Napoli, Aversa (CE), Italia,
fabio.converti@unina2.it

Abstract

The harmony of the invisible architecture of Piacentini, indicates, in the facades of his main works, details of plastic resulting thickness of the walls with altered geometry and modulated surface. The articulation of the various projects is always controlled by the rules of proportion between full and empty, indicating a relationship with the modules and submultiples with evidence in detail of construction and the continual comparison with the carrier.

These works lead to an overall effect that tends to bring out the details and the signs of Appeals as a element of modular measurement.

This assembly determines, in effect, decorative elements derived from the modular size of materials, which are expressed with mathematical rigor, leading to a shift from general to specific to the geometric logic of the organic project.

The Piacentini has expressed his own work on architectures for social shaping public spaces and / or relational spaces, consisting of a multiplicity of urban elements with a strong relationship between the shape of the history and structure of the city.

For Piacentini was of primary importance in urban redesign projects, to defend the town center, enhancing the city's identity, preserving as much as possible the diversity of activities of the place.

The research aims to identify and enhance, through specific aspects, achievements and entries in relation spaces, in the architecture of Piacentini, clarifying, models, values and functions that he intended to express in his long and varied production of works architecture.

This search leads to highlight a fundamental element, which the study design and analysis of extremely complex processes, including the approach, method and procedure for the success of these works with unique characteristics, with a harmonious relationship between mathematics and geometry.

Keywords: Representation, Project, Piacentini and City

1. Introduction

The dominant values, which characterise a given culture, tend to permeate the specific rules of each category and situation that are part of the system, and in which they are applied.

In the construction of the objects which make up the qualities of urban space, the concept of crisis in the contemporary cultural values can be attributed to the multiplicity, ambiguity and indeterminacy of the values that govern the operational choices, forms, reports, the symbolic meanings transmitted, which then impinge on the behavior of the inhabitants of the city. The signals arriving to the individual, in general, don't communicate a coherent whole, so they don't combine themselves into a system. The result is often an ambivalent, incoherent, disordered, reality that is the result of the application of a wide range of possible standards following combinations and variations without coordination, within processes of transformation and continuous spread.

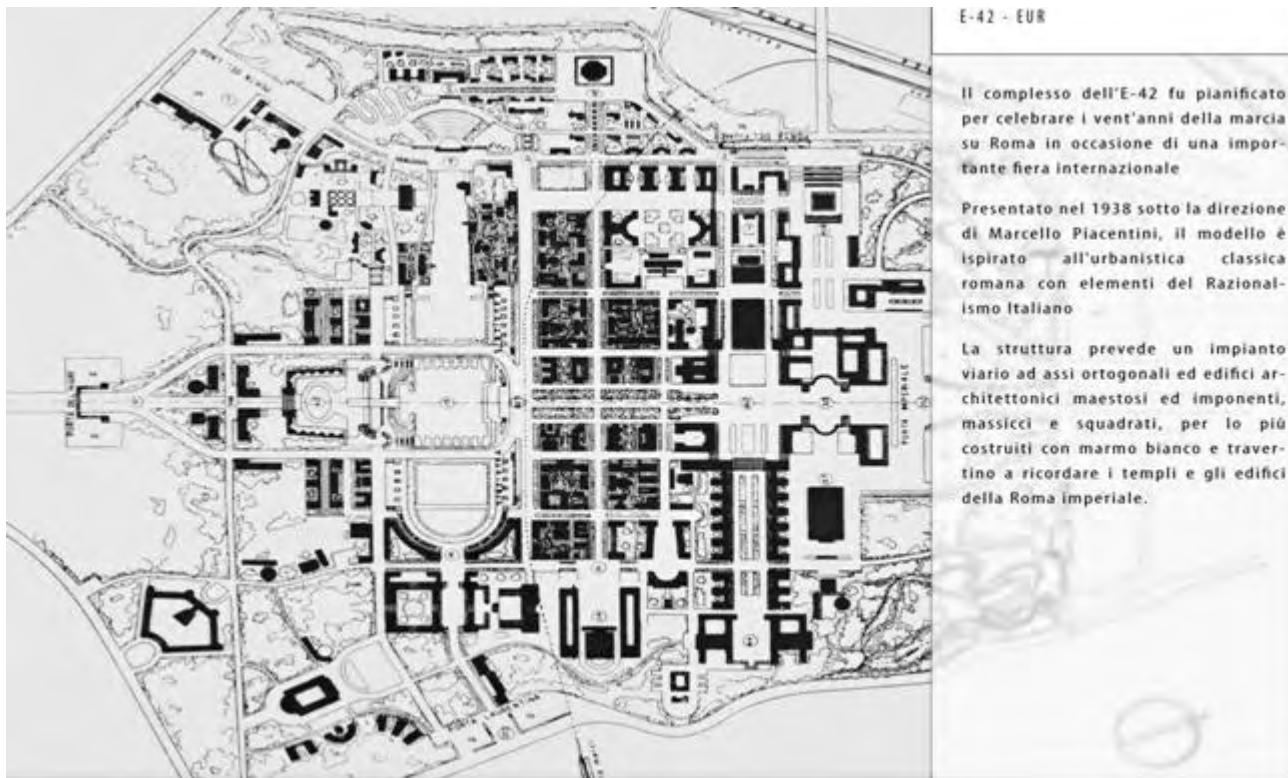

Fig. 1 Rome, Piacentini Eur Plan

If its possible to assert that organization of city spaces is inseparable from the whole of its social manifestations, are the relational processes, which are developed in it, which can be revised to incrise and improve the quality of urban environment, and its beauty, only by creating systems of reading territory that express and show the complex phenomena of ancient and contemporary environment.

If a new quality of reality is produced, as a result of an encounter which makes hybrid transforming which is actually placed in it, in any case it's usefull underlining that any definition of identity is a process that concerns the interaction between object and subject. If the first process reaches a stable condition, the manner in which the latter perceives that identity, even of beauty, therefore, it instantly shows temporary, changeable, as in any construction process, the result must prepare to questioning and to be able transformed into something different.

Consequently the architecture, whose legitimacy is now a prevalent reason for being in the aesthetic dimension, rediscovers the value of the emotion, the involvement of the senses, the reflection surface, the reverberation in his relationship spaces, and new forms of urbanization is increasingly built on the principle of union between ancient and contemporary meeting as short and engaging, surprising and emotional, a maker of stories, experiences and emotions.

2. Research field

Architecture, like all other aspects of human culture is a product of the general model adopted, generated by the basic symbols, which of course identifies also the relationship which the individual has both with the "function" and the "shape" , understood as the basic components of the environment. So the architecture itself becomes a model which, once organized, tend to strengthen the symbols that are generated indirectly, by creating additional symbols. Those places that do not notice the symbolism is not emotionally charged and are therefore foreign to us.

The investigation of these forms of representations consist, therefore, a question from several points of view on the morphologies of the country as a reinforcement of new ways of use of urban space: the signs of geomorphology are transformed from internal to external to the new city extended. May represent the primary elements of new urban structures based on a system of plural different architectures, united by a strong body of places: structures at the same time old and new, who kindly join the "object" of architecture and the city.

Fig.2 Rome, Via della Conciliazione Project, Piacentini's and Spaccarelli's project.

So, the act of representing the city by Piacentini, evidently, was not only a technical and graphical matter, but it was characterised by the willingness to symbolize, treating it as an artifact, a work of art, a masterpiece that has its own identity, and a own spiritual plastic. In fact, subject and object are no longer separable elements to analyze in isolation. Instead they are the two poles of an indissoluble relationship. In this perspective, the process that leads to the formation of systems which observe, it's also the same process that forms the observed reality. The two processes are distinct, they are only two ways of looking at a single principle in evolution. A system becomes able to recognize certain signs because these signs exist, but the fact that the system can react to them is the condition of existence for those signs. In fact, into Piacentini's architecture we witness the "coming into being" of new forms each time it's made a match between observer / observed. In the course of evolution (in the phylogeny of the species) are seeing a continuous growth in the number of forms recognized and reproduced. The shape determines its recognition, and its recognition determines the shape. Into Piacentini's work prevail some elements such as the use of architectural forms and materials with precise symbolic meanings, the use of a particular material would never happen by choice or by calculation, but only by intuition, such as the desire the enhancement with coating materials such as marble and stone, the return to the basic elements of classicism, which then brings up to date with his sensitivity and new interpretation, the attention paid in the views and perspectives, the use of small scale and then get to large scale. He also rejects the monotony, which considers typical of American cities and those of the nineteenth century speculative. Still, it enhances the values of the change and harmony. This is the result of aesthetic sensibility, is reducible to numerical relations, and obtainable only with a design of three-dimensional symmetric and varied. Piacentini criticized the two-dimensionality, he has even exceeded the three-dimentional interpretation of architecture, giving an high value on the fourth dimension, time, considered as a means to manage a plan.

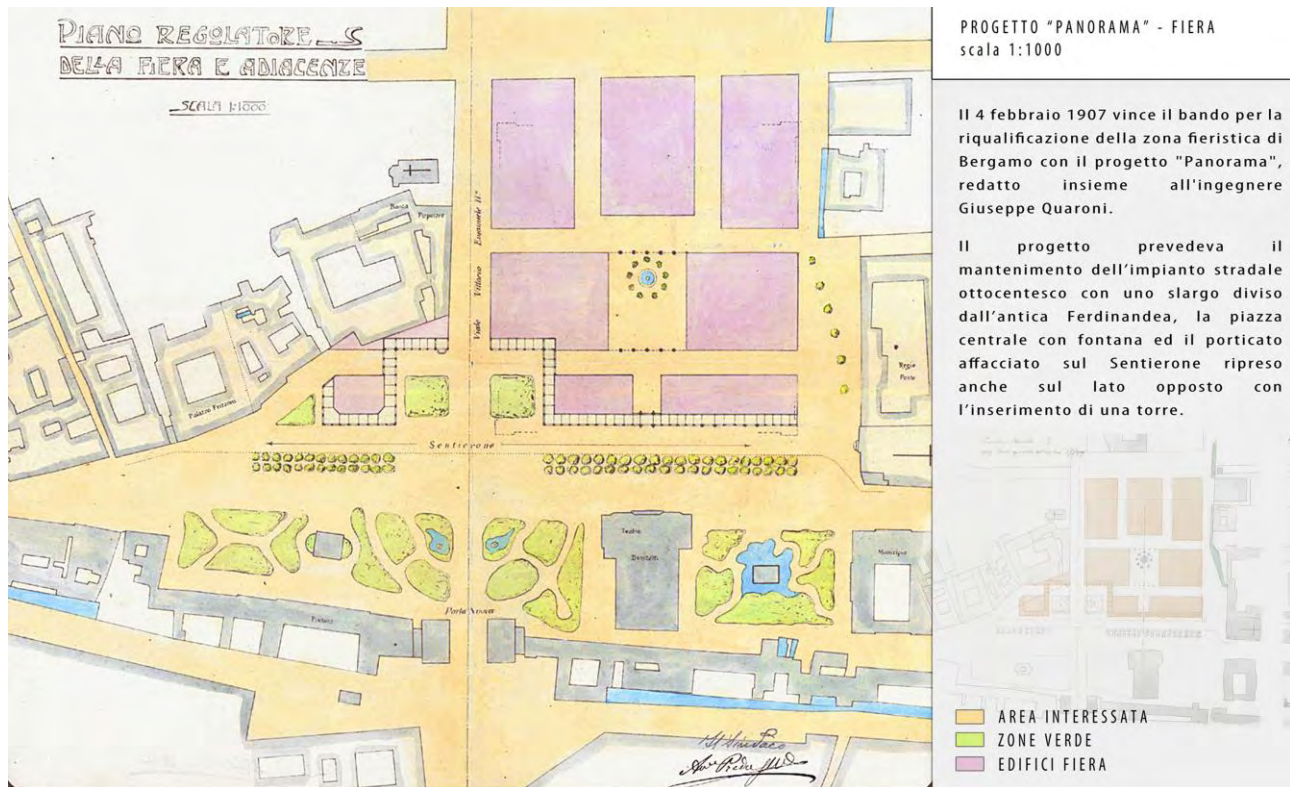

Fig.3 Bergamo, Piacentini's Project exhibition area

3. Objectives

Such as human language, in which a large part of the communication is free from the formal rules of the verbal code, so also in the urban language elements of communication are many, varied and multidimensional (or polysemantic).

The exploration of various ways of representation of an urban landscape can start with a representation of its "boundaries" that have been proposed and / or designed in studies and acts of planning. These areas, which cut in a different way the territory, often doesn't overlap between them, because of their derivation from nonequivalent scales and reading criteria for the interpretation of spatial variables, or often purely physical morphological. Otherwise the spatial contexts, within which individuals and local operators carrying out their main functions to which they belong or believe they can give "name", appears also different. Knowledge of the spatial structure and urban pre-modern forms is the starting point for further knowledge acquisition.

In order to better understand Piacentini's production is worth deepening the role of design in the twenty-first century.

The combined use of different materials, the diversity of information they contain allow a broader, detailed and careful survey of Piacentini's projects . The cross-reading offers images and reveals conditions and items not otherwise visible or not fully understood.

Piacentini reserves to his works a careful study that involves proportions, unlike the studies of metrology, a precise search of the affinity (dimensional and design) between the individual parts of one or more objects.

Therefore the study of Piacentini's graphic documents, together with the analysis of the text, have highlighted the crucial role of representation in dealing with architecture, specifying each time the design aspects of purely geometric, graphic or forecasts of the buildings constructed.

The interest in the images of Piacentini's projects comes from the fact that today these have assumed a key role in changing the culture and reality, but also by the fact that never before has the relationship between image and reality has a sticky and this complexity to make it the center of architectural thought and planning.

Fig. 4 Rome, Piacentini's Palace of Civilization and Labour at Eur

4. Design process

Piacentini's architectures are defined by a set of signs is of both numbers: the firmitas is abstracted in the number, the venustas remains line.

Subsequently, with the knowledge of the formal potentiality inherent in the new building systems, it was given life to rationalism, where the formal expression is obtained only by playing with the basic technical elements and their physico-mechanical: it is the "no style", the "necessary architecture", the new real "Order" after the Doric. In some cases Piacentini, using the supporting structures of buildings, gave functions not only to building envelope but connoting loud and clear the building.

For Piacentini, already in his time, were considered important the connections of the various components that contribute in the construction process: in fact in its plans the amount of different materials and components used were different with a high number of connections.

In architecture of today the ornament understood in the traditional sense no longer find a place, here, as L. Kahn said, the richness and expressiveness of a formal architecture also lies in the clarity of the connections between the parties and the readability of their autonomy as well as in the Piacentini's architecture.

Fig. 5 Brescia, Piacentini's Urban General Plan

This does not mean that the technique performed can only legitimate architecture, the technique, as the function, is necessary but not sufficient to create architecture! The process of the project must have information, order, recognizable and also critical for creating a history of the project.

The design procedure goes and defines itself through the plane of the drawings, while responding to the same nature of the drawing to be a code - then as guarantor of information competence and its transmissibility - to making himself structure within the design process, so its narrative nature, places him as plot, network, web of meanings, layers of cultural contextualization of a concept, an expression of choice direct.

Just through the drawing act, the most interesting architects have built processes which establish relationships between the parties, between the intentions of the project. Relationships that have helped to establish working conditions, to discover constraints and ask and answer several specific questions.

The formation of each of them is the place of exchange and also the center of a ritual of approximation, in which the drawing brings with it the general rules and personal intentions that are the plot. The training becomes beyond the place of provenance of individual discoveries and knowledge, the experience of "how" the experience of "doing". The exercise on the critical reading, to re-write continues where it requires the choice, "Complexity and Contradiction", individual and generational, social and cultural being incorporated in the drawing make it unique, personal and collective.

Design drawings are, therefore, a further element on the study of Piacentini's work though reading the signs by which theoretical and design intentions.

Within a single element of the composition can be read all the characteristics (composition choices, linguistic, formal, identity) that are found expressed in a larger scale. Consider for example the windows, rectangular geometry, the building of the Palace of Justice in Milan: in it are well aware of all the assumptions and motivations that drive the architect to design and bring their buildings to simple geometric shapes. This means that the design of a building structure is something extremely logical and consequential damages, so the "whole" is found to vibrate in a small scale, even within a single element of detail.

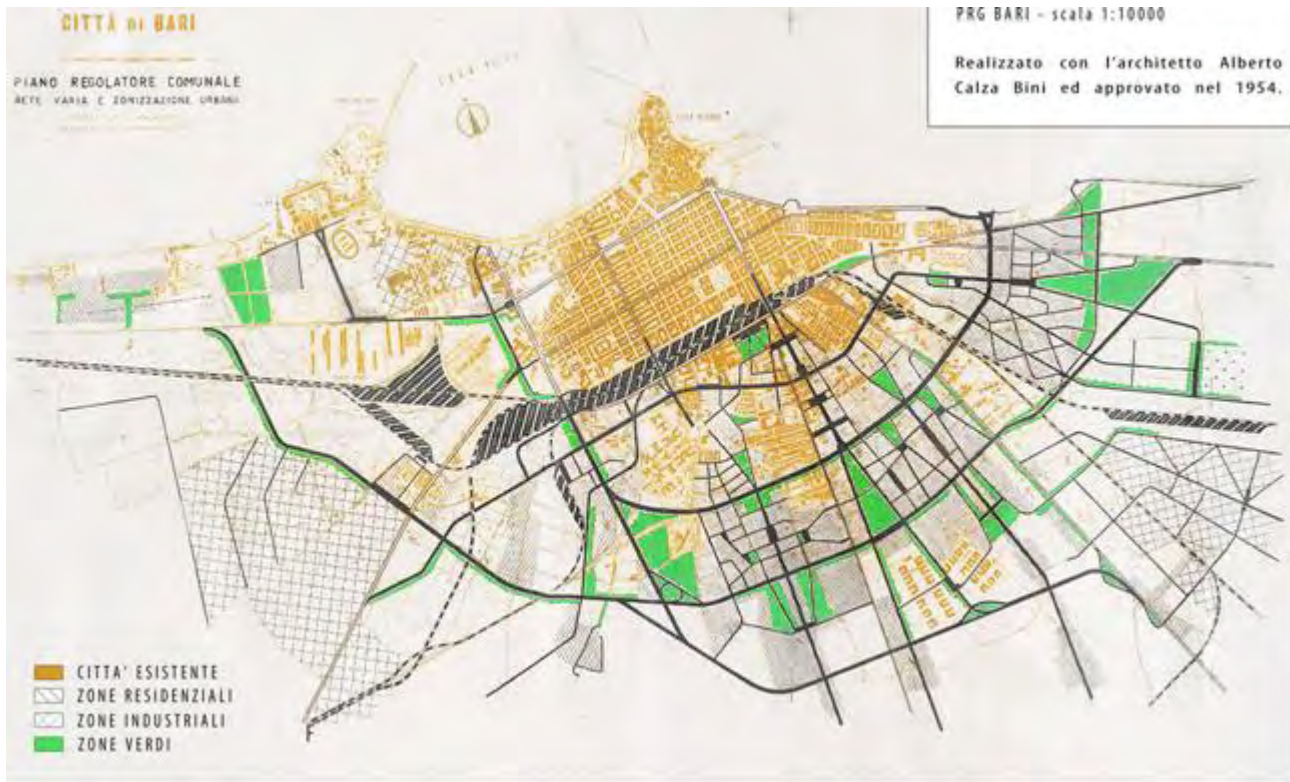

Fig. 6 Bari, Piacentini's and Calza Bini's Urban General Plan

Such sets out a framework of relationships extremely delicate and complex within which it must fit design process, where architect knowledge and awareness must find its expression and freedom, while responding to very specific rules and laws.

The delicate harmony and balance full of tension which Piacentini came reveal strategies skillfully conducted to containing forms and signs to resolve the relationship between free and great light transparent parts, between immobility and movement.

The first element in common is the constructive need that determines the perfect adhesion between the shape of a building and its contents, which in this case is the function, making it unnecessary to any decorative tinsel applied to the structure.

Next to the plastic sense of Piacentini's work, expressed by the elaborate compositions of pure volumes, the new aesthetic arises with simple surfaces, not weighed down with decorative motifs, bare walls, such as industrial buildings, distinguished only by calibrated relationships between solids and voids and linear profiles, which are enhanced by the use of materials such as concrete and marble.

5. Conclusions

Piacentini's works reveal concepts and ideas realizations, with architectural shapes and chromatic values that reveal, in their entirety, the psychological state of an entire society. This psychological state also comes into play in communication, making it one of the most showy elements of urban language. So, if drawing is language and memory, into Piacentini's work it's remarkable his study and his observation, that identify a constant work method that, in this case, was able to create a shape in Rome architecture, through its drawing and design.

Finally, the multidimensionality of the relationship with the place is not limited, of course, to physical aspects of the geography of the area. It presents its structural features, the so-called ancient/new relationship: into such interrelation between different economic roles and forms and modes of production within the territory of man-made.

Fig. 7 Ideal City 1951

According to Piacentini the ancient center hasn't to become a paralyzed element that fails to establish itself as a matrix of development of the urban core, but with his studies on "unified aesthetic concept" brings to decompose and recompose the whole structure of the city to create a sense of the whole. Finally into Piacentini's work it can be immediately notice his attempt to create a new design method that is the union of two cultural planning processes, one sensitive to the historical memories and the other extended towards new achievements.

The Gisbusiness as a tool to manage change and innovation

Competitive scenarios are changing swiftly and oblige firms to abandon definitively defensive strategies to become effectively leading to global markets. The challenge is not more in improve outcomes compared to its past, as in the know and be able to compare with the best competition. The recovery of competitiveness should be placed at the center of attention in the country, in the awareness that being competitive is a community value and brings benefit to all. Recovery of competitiveness which should concern businesses, in their role as a vector of development, but also of the entire countrywide system, with far-reaching reforms that can support such development. We need a leap equal to the magnitude of the changes that we are experiencing. This quantum leap, paradoxically, must be harmonious, pervasive and synergy between the world of research, business, educational system, labour market, infrastructure, services and policies for businesses and the market. It is therefore essential to highlight the importance of spatial data and geography in almost all industry analysis to manage change and innovation. In fact Through the Customer Management (CRM) Relationship hooked to geographic information systems (GIS), you can "do" Gisbusiness and represent the data stored on a map, highlighting on the same business opportunities in the territory. Project management takes on a strategic importance in the management of change and innovation, through the design of new products/services but also internal asset market positioning, the entry into new business, in the synthesis of the design challenge.

Parole chiave: Gisbusiness - Knowledge Factory – Market – CRM - GIS

1. The Gisbusiness as a tool to manage change and innovation

The competitive sceneries are changing in rapid times and they force the enterprises to definitely abandon defensive strategies to become indeed protagonists on the global markets. The challenge doesn't consist of improving the results in comparison to the anymore really past, how much in to know him and to be able to be compared with the best competition. The recovery of competitiveness must be sets to the center of the attention of the Country in the awareness that to be competitive is a value of the collectivity and door benefit to everybody. Recovery of competitiveness that must concern the enterprises, in their role of vector of the development, but also of the whole system-country, with reforms of great course able to support such development. We need a leap equal to the magnitude of the changes that we are experiencing. This quantum leap, paradoxically, must be harmonious, pervasive and synergy between the world of research, business, educational system, labour market, infrastructure, services and policies for businesses and the market (taxes, privatization, research, finance, etc.). It is denominator common of it the ability to plan together the common growth. The is not enough anymore already difficult assignment to govern the complexity. They serve competences, wish and tools to manage the modification, to choose with decision the innovation - in his ampler meaning - what competitive weapon. The international competition is intense and aggressive more and more, on open and global markets more and more. The Italian production system is

compressed between countries that are leading innovation and Countries benefiting from lower system costs. Given that we do not undermine but rather to improve our standard of convenience, the choice is obliged: to stand up in the value chain, through more investment in research, innovation, knowledge and appreciation of this heritage " Knowledge Factory " (Gambardella 2010) that it characterizes our history in the sector of the culture of enterprise. Knowledge Factory as value as wealth that it produces wealth as ability to promote the modification and to manage the future projects. It is not a case that the principal competitive assets of which we prepare and that they cannot be purchased on the market I am really the ability to produce and to develop projects. It appears as the best guarantee to face with success the competitive dynamics, to anticipate the markets, to gather the evolution of the consumptions to exploit the technological opportunities in the products. Insofar, the human resources are considered what the true capitals of the firms, but of other song the market of the job results that more rigid. This has always forced the Italian enterprises to aim at the innovation of trial rather than on that of product, producing more and more and more in way efficient mature products, lifting so in comparison to our competitors the levels of technical immobilization and the thresholds of gone out of current productions, consequently reducing the profitability of the invested capital, that is struck at the end on the same occupational perspectives. From a side it always assumes great importance the economy of the knowledge that is at the base of the recent technological revolutions of the information and the communication, with, for instance all the potentialities of the net Internet still to express him in terms of widening of the markets and approach between producers and consumers; from the other side our quota of products high tech on the total one of the manufacturing assistant value is among the lowest of Europe and our exports of product to high technology and intensity of knowledge I am of big long inferior to those of the Countries mostly industrialized. It appears therefore inevitable that in a Country that has the most elevated rate of entrepreneurship but the lowest number of great enterprises, it goes deeply reconsidered where in a market the integration and the intensity of the competitive challenge they are redefining the markets: in other terms, must be questioned the competitive lever of the small but flexible one goes. The small one and it mediates enterprise it possesses as a rule a deep competence of the product and his productive trial, and it is notable also the direct knowledge of the potential buyers, rather than of the dynamics of the question and the competition. The innovation of the fittings and the machineries not by chance, prevails on that of the product and of the way to present on the market. Insofar the strengthening of positions of leadership of based niche on the quality, the attainment / maintenance of a status of excellent supplier, the integration of a system of firms, shape a great necessity to face the change through the for activity, the planning, the operazionalizzazione of the opportunities could be said, in the context of bright results gotten in the current management and in its flexibility. In fact the new sceneries that open introduce risks, but also enormous opportunities. It is up to therefore to the system of education and the search the strategic assignment to form the decisive resources. those human. and to develop that tools that better can sustain this binding challenge "on the new one" (Gambardella 2010). The project management assumes then a strategic importance in the management of the modification and the innovation, through the planning of the new products/services but also of the inside assets, of the positioning on the market, of the entrance in new business, in synthesis the planning of the challenge. It is therefore fundamental to underline the importance of the territorial datum and the geography in almost all the analyses of sector to be able to manage the modification and the innovation. In fact Through the Customer Relationship Management (CRM) hooked to the Geographical (GIS) Informative Systems it is possible "to do" gisbusiness and to represent the data memorized on a map underlining on the same one the opportunities of present business in the territory. It is already said previously that to study a datum in geographical key they are necessary his geographical coordinates, hooking a managerial business to a geographical informative system. The greatest part of the information that they are gotten by a managerial they are attributes that give a strategic importance to the territory. We use, to this intention, the necessary tools for the visualization of some analyses typical of a firm:

- The georeferencing of the model sold for zones would allow to develop a precise strategy of sale thanks to the gotten visualization. Can we wonder the reason for which in that zone that model is sold rather than another? Which morphological, social, economic and demographic characteristics do they characterize that territory? The whole the products could be optimized for single point in operation sale of the relative location and to improve the distributive net of the single points sale; to plan advertising countries and in operation promotional actions of the location of the proper target; to esteem the potential expressed by one determined geographical area for a specific market sector, to define and to analyze the basin of use of a store, in base to the construction of areas represented with different colorations;
- The georeferencing of the billing of the clients (annual, quarterly or monthly according to the demands), getting the immediate perception of as the sales is going on the analyzed territory;

- The georeferencing of the billing of the agents (annual, quarterly or monthly according to the demands); you/they can be defined objective of sale, for agent or for area, to individualize the possibilities of commercial penetration of the net sale and to develop new strategies;
- The georeferencing of payment and discount; visualizing the zones in which the payments are regularly made and those where instead present are more unsolved an important indicator it is gotten for developing careful analyses of the market of reference;
- The analysis SWOT (or Strengths and Weaknesses, Opportunities and Threats) delineates the critical points of strength and weakness inside the firm compared with the external environment and studies the threats and the opportunities of the market of reference. Purpose of this analysis is to allow to anticipate important developments that could have repercussions on the enterprise. For this type of analysis, the visualization on a map of the usual clients and those potential constitutes a tool of more punctual analysis of that that to everything today it has available a firm. To represent the sales for typology and characteristics of model can clarify us on the why in you determine areas some models they sell him and not others considering of it, for example, the color, the particular ones, the customizing and so street. To visualize the location of the stores and to have a precise knowledge of it, guarantees the immediateness of the information on the nearer points of assistance for the final client;
- Market segmentation, which can be geographical (country, region, province, city, neighborhoods, etc.), demographic (age, gender, family size, income, occupation, education, religion, race, nationality), psychographic (for social class, lifestyle, personality) and behavioural (for ease of use, the benefits sought, situations, the intensity of use, brand loyalty, awareness, attitudes towards the product) makes sense, the multiple benefits derived from these data on a map. Can be circumscribed areas of analysis to study in detail the market their product and to assess any penetration strategies. To view customers on a map you must hook up the data that are in the CDB with geographical database data; consider the following fields from the CDB: business name, the street, the city, and a unique code (e.g. that ISTAT that uniquely identifies a town, a municipality, a province and a region). From geographical databases will take the coordinates of the municipalities and/or provinces and/or regions, which define the location, geographical boundaries through points or polygons, connected cities, and to ensure that the data is represented, the coupling between the code and the GIS management. If we wanted to do an analysis to model customers bought, you could connect the different tables, whose field of Union is the unique code (linked always to the CDB by the ISTAT code GIS or similar); the data that we represent the model and its features, price and quantity purchased, the city where the customer resides, and finally, the date of purchase will be displayed, in a simple and immediate. It is useful to georeferenced suppliers (both regular and potential ones) because through this analysis can be identified part of logistical costs, such as travel to collect the goods, by reducing the same with the grouping of suppliers to zone (vehicle routing). To analyze another important part logistic costs is an important representation of deliveries (Origin - destination array) through the merger of the following fields: name of the carrier, the city, the cost of transport, the product quantity transported, the consignee of the goods, the city and the date of delivery. The most suitable tool for this kind of analysis is definitely the GIS. You get increased speed and security of the same: the data displayed surely makes it easy, with the possibility of changing views with additional questions on different data depending on the results you want to achieve. Surely it has a higher quality of services offered; Whereas such as corporate meetings with agents, architects and business executives, the analysis data can be explained with a territorial view or be sent to the format map. The choice of variables is large; you can select several fields and columns in the database, it is possible to select different records and on the choice of geographic detail assumes importance in relation to the outcome you want to achieve. Visualization of analysis that you get through them, showing the GIS tools used and the possible detail analysis. Reported applications are only indicative and may be extended in size and in number. GIS is a tool that supports the common marketing decisions, including primarily those settlement lots, segmentation and targeting. An important element of the ability to understand the use of GIS is tied to the way in which technology can also be used to carry out traditional activities; a particularly important case for analysis of marketing mix in each of the four components of the product (which also relate spatially attributes of products with groups of customers/consumers); price (and it is known that through the study of local markets the geography influences the price); place (in which decisions on the modalities of settlement lots and distribution are among the first to benefit from a systematic and efficient use of geographic data); promotion (whose efficacy can be analyzed not only globally but also distinct in different regions highlighting, as often happens, the results varied reasons for geographical areas of customers). In all these cases, the GIS allow quick integration of different data sources, without this technology, it would be very difficult. Therefore it is clear that the benefits obtained or assessed through the use of GIS technology duly integrated with CRM systems and with a multidimensional analysis (Genomics) you can do gisbusiness

is to highlight the potential of an undertaking is to manage appropriately the possibility of territorial development.

Cultural Landscape and Culture of Landscape

Gaia GIORDANO

Abstract

All Landscape deserve the title of *Cultural Landscapes*. Nevertheless, this *Cultural* epithet is preferably applied to landscapes that express a particular harmonic relationship between the society and the environment, in the spirit of what we call, today, sustainable development and that are representative of a certain culture or civilization. The Cultural Landscape, indeed, is defined as a complex entity formed by the synthesis of physical, environmental, historical, social, economic and political issues that characterize the identity of a place. These are cultural aspects that contribute, in the course of history, to change the material and immaterial dimension of the territory, of signs and sediments to which they connect the immaterial forms of perception, are signs and sediments in which they connect the immaterial appearances of perception. The Cultural Landscape represents the symbolic expression of cultural heritage in a modern way. As heritage diffused on territory, the cultural heritage take the overall meaning of the material and immaterial goods that are the source of heritage and identity to a common area and to the people who inhabit it. The cultural heritage that make up this collective entities include material, concepts and representations, specific aspects of community life and the land, as a synthesis through which individuals reproduce the concepts that are used for their identification and representation. The adjective “cultural” would be perceived as the presence of cultural traces that need 'protection' of a particular region or spatial domain, regarded as a common good cultural. However it's clear that today the problem extends to much broader area, especially if we think of a small planet reduce to a mere artifice, like ours, which is important, not only protect but also improve and redevelop brown field sites, abandoned and degraded to transforming them into urban public space, a most vital assets, mostly endangered.

Keywords: Cultural Landscape - Representation - Identity

1. Natural Matrix and Generating Action

All Landscape deserve the title of *Cultural Landscapes*. Nevertheless, this *Cultural* epithet is preferably applied to landscapes that express a particular harmonic relationship between the society and the environment, in the spirit of what we call, today, sustainable development and that are representative of a certain culture or civilization. The Cultural Landscape, indeed, is defined as a complex entity formed by the synthesis of physical, environmental, historical, social, economic and political issues that characterize the identity of a place. These are cultural aspects that contribute, in the course of history, to change the material and immaterial dimension of the territory, of signs and sediments to which they connect the immaterial forms of perception, are signs and sediments in which they connect the immaterial appearances of perception. (Gambardella, 2010). The Cultural Landscapes represent a multidisciplinary conceptual framework that attaches to the landscape dimension, already characterized culturally, an even more pronounced characterization towards the interpretive and representative action that culture has on the land, they are the

result of relationship that companies have established with the environment over the centuries in order to meet their survival needs and social. Therefore, they are products of history and culture. The concept of Cultural Landscape allows you to reposition the human activities and the area within a framework full of meaning and cultural identity, the most appropriate category to indicate territorial space is the 'place', understood in its anthropological sense of the scope of *identitary*, *relationally* and *historical*: (Augè, 1993): *identitary* because for each birth, natural and symbolic, is realized in a place that acquires an additional value given by the sense of belonging that contains the original dimension, *relational* because the sites are configured in relation to the actions and relationships that they house, *historical* because they settle in places the traces of social forms, settlement and production of the populations in the course of time. The place is so different from space, giving the dimension or function of geophysical additional meaning, expression of specific cultural values. In places, indeed, "we identify ourselves, we have our social ties, our dead, our memories, our vital interests, as to be the starting point of our knowledge of the world, a reflection of our action, the measure of our lives the territory " (Turri, 1998). The Cultural Landscape represents the symbolic expression of cultural heritage in a modern way. As heritage diffused on territory, the cultural heritage take the overall meaning of the material and immaterial goods that are the source of heritage and identity to a common area and to the people who inhabit it. The cultural heritage that make up this collective entities include material, concepts and representations, specific aspects of community life and the land, as a synthesis through which individuals reproduce the concepts that are used for their identification and representation. The adjective "cultural" would be perceived as the presence of cultural traces that need 'protection' of a particular region or spatial domain, regarded as a common good cultural. However it's clear that today the problem extends to much broader area, especially if we think of a small planet reduce to a mere artifice, like ours, which is important, not only protect but also improve and redevelop brown field sites, abandoned and degraded to transforming them into urban public space, a most vital assets, mostly endangered. The geographer Otto Schluter is credited with having used formally for the first time, the term as a Cultural Landscape academic term at the beginning of the twentieth century. In 1908, Schluter argued that the definition of geography as *Landschaftskunde*, would have given the science of landscape, from the logical point of view, a subject of study is not shared with any other discipline. He defined two types of landscape: the *Urlandschaft* original landscape, or landscape that existed before major human-induced changes, and *Kulturlandschaft*, cultural landscape created by human culture. The main duty of geography was to trace the changes in these two types of landscape. It was, however, probably Carl O. Sauer, human geography, the most influential scholar who promoted and developed the idea of Cultural Landscapes. Sauer was determined to emphasize the action of the culture as a force capable of shaping the visible features of the earth's surface in limited areas. As part of its definition, the physical environment remains a central meaning, as the means by which and through which human cultures act. His definition of cultural landscape is as follows: "The cultural landscape is fashioned from a natural landscape by a cultural group. Culture is the agent, the natural elements are the means, the cultural landscape is the result". Since the first formal use of the term by Schluter and the real promotion of the idea by Sauer, the concept of Cultural Landscape has been variously used, applied, debated, developed and refined in academia , until, in 1992, the UNESCO World Heritage Committee decided to organize a meeting of specialists to advise and assist the rewriting of the Operational Guidelines of the Committee to include the Cultural Landscapes in the World Heritage List is not characterized from one form neither purely natural nor purely cultural. The adoption and use of the concept of Cultural Landscape by the UNESCO World Heritage Committee has seen many specialists in the world and many nations to identify, evaluate, include in the list of assets, manage and actually make known and visible to the world the Cultural Landscapes, with very practical ramifications and challenges. The theme of Cultural Landscapes, debated for a long time in Anglo-Saxon countries and in Europe, it also raises the attention of Italian society, equipped with various facets and complex, it offers a point of balance between the need of an environment on a human and memory and the desire of a landscape area. The term itself, however, would seem to indicate a difference between cultural landscapes and other landscapes, forcing a confrontation between different points of view: on one side protected by the ideology of the Cultural Landscape Conservation, careful to the established values of the community, on the other hand those landscapes fast processing, places in which the city is lost and blends into something else, the object of attention from the disciplines of geography and territory. In the current cultural and scientific debate, then, the landscape is becoming more and more importance and significance. A deep cultural innovation has in fact characterized by a completely new interpretation than in the past, considering it good to be protected as an expression of social-ecological transformations occurred on the territory by the community. Any culture not only interacts with the landscape as if it produces with its practices and relationships are often intangible, but also because he perceives it, is reflected on it and gives it meaning and particular and changing values, also the psychological one Consequently, a cultural landscape, in a given historical moment, shows always

different stages of development of a society. Identify and represent the culture of a community in the heritage of symbols made in the course of history gives way to explore her deepest identity and draw together the visions of its humanization and its network of values. The landscape and its cultural representation are a central theme for the recognition of the intrinsic and absolute value of the culture of a place, culture rooted in a territory which has its own geographical dimension, a physical space. This main theory leads to represent the culture as a story of symbols attributed to places and living spaces by the community. Places, symbols and living conditions are, therefore, the conceptual terrain within which proceeds the cultural representation of the landscape. We are now faced with the need to equip ourselves with new eyes, new instruments are sensitive to these intangible assets needed to find and understand the cultural dimension of the landscape, to highlight the weft and warp of the relationships between places and people in a given geographical area. It can ultimately say that the action of culture is the force capable of shaping the visible parts of the earth's surface in limited areas, to define the landscape changing physical and natural environment through human actions and coined the cultural landscape, shaped by a natural landscape by a cultural group. Culture is the agent, the means of the elements, the cultural landscape is the result.

Speculations on the Future City

Dr. Fatih RIFKI, Professor

Montana State University, U. S. A.

E-mail rifki@montana.edu

Introduction – Questions and Axioms

Today, the 'information age' is an increasingly urban age, because, since 2008, more than half of the world's population can be called "urbanite". In this second decade of the 21st Century, urban population in the world as a whole has reached 7 billion and still continues to grow at a fast rate. The 'digital society' on the other hand is a society, which is mostly domiciled in cities and metropolitan regions.

Given this state of matters, a prudent question one may be prompted to ask is what the current nexus is (and in the future would be) of the rapid acceleration of the use and the phenomenal advancements in the capabilities of digital technologies, particularly information processing and communications on the one hand, and the intensifying urbanization of the planet on the other. That is one may ask what the impact of these technologies is on the contemporary spatial, social, economic, geographical, political, and cultural processes urbanites are engaged in mostly in urban areas of the globe. Or more succinctly posed: is there -a cause-and-effect relationship between digital technologies and urban life? If there is, which is the cause and which is the effect? Are (or aren't) the ever-ubiquitous digital technologies and urbanization constitutive elements of broader processes of modernization, internationalization, globalization, industrialization, restructuring, and cultural change? These constitute the main questions this paper attempts to answer.

Cities continue to be, as they have always been, where financial and human capital is concentrated as more and more of the regionally or nationally focused, if not internationally oriented firms and institutions, flock. At the global scale, these cities attract people with higher disposable incomes who initiate, demand, and nurture cosmopolitan and multicultural social environments. Further, cities are increasingly becoming mediated by flows of electronic information and symbols, as evidenced by the progressive digitization of money, services, media, information, education, and logistics. In light of these, at the very basic level and a priori to the above questions, isn't it prudent to explore the ways digital technologies help facilitate, nurture, and intensify the urbanization processes at the global scale? Conversely, how do the demands of the contemporary urban life, work, and play; initiate, sustain, and nurture innovations in digital technologies? These two questions reflect the title of the paper.

Three main axioms can be cited on the nexus of digital technologies and urbanism:

First, digital technologies encourage urbanized entities, mainly service and manufacturing as well as cultural centers, to mostly locate in cities and facilitate them to extend their markets, powers, and control to over ever more distant regional, national, international, and even global hinterlands. Cities after all have the infrastructure to facilitate this influence and consequently affect urbanity. Urban infrastructure in turn helps bind, integrate, and add economic dynamism to the vast, extended, and multi-centered urban settlements, corridors and regions of our age.

Second, in an intensely complex, multivalent, and currently volatile global economy, and the growing speed, complexity, and riskiness of innovation in all sectors, cities seem to attract a parallel concentration of creative assets and nurture an 'innovative milieu' to sustain the ongoing competitiveness. Creators and innovators of the digital technologies still need to be in the proximity of one another, i.e., 'in the thick of the innovation process', even though their products can often be instantaneously sent online to distant markets and users as well as to local urbanites.

Finally, demand for digital technologies -mobile and land-based telephones, satellite and cable TVs, computer networks, electronic commerce, Internet services, is overwhelmingly driven by the growth of metropolitan markets. Global cities, which rely on digital technologies, drive most aspects of innovation and investment necessary for developing and sustaining digital technologies. After all, urban social and economic processes that take place in cities require speed and mobility and in turn result in complexity and dynamism.

Previous Scholarship on the Nexus of Digital Technologies and Urbanism

From the mid 20th century up until the early 1990s, the complex links between cities and the digital information processing and communication technologies had generated a curiously meager body of scholarship in urban studies, mainly because of the relative invisibility of these technologies compared to physical communications systems. Information and communications studies, on the other hand had traditionally tended to neglect the dominant role of modern cities, again until the last decade of the 20th century. There were few, but significant exceptions to these in literature and film, particularly in late 19th and early 20th centuries and most of these had a science fiction slant.

Since the mid-1990s however, notable theoretical, empirical, and policy research on the links between the ever developing digital technologies and the changing nature of cities and urban life has rapidly emerged in urban studies, anthropology, geography, planning, art, sociology, architecture, cultural studies, and transport studies, as well as in information, communication and media studies. So much so that a "sub-discipline" seems to be emerging as scholars are positing the reciprocal impact of Internet, mobile phones, Geographical Information Systems (GIS), and Virtual Reality (VR) on urbanism. Currently, urban scholars are particularly interested in the mutual influence of the forms, processes, experiences, and ideas of urban life and the digital technologies in a wide variety of contexts across the world. Nevertheless, debates about both the implications of digital technologies for cities and urban life, and the effects of the cities and urban life on digital technologies, have yet to move to center stage on urban research agenda.

Against the widespread assumption from the 1960s to late 1990s that electronic communications would necessarily work to *undermine* if not outright *threaten* the very existence of cities, notable empirical evidence suggests that the two realms are actually supporting each other. So much so that nowadays coming across counter claims such as the ones that posit that the current and potential use and application of digital technologies within and between cities constitutes a critical, strategic, and positive nexus that underpins the development of human societies, settlements, and, indeed, civilizations is no longer an isolated occurrence in the relevant literature but is more commonplace than the contrarian view.

However, it was only a few decades ago, mostly during the second half of the 20th century, that "dis-urbanists" dominated the urban discourse taking place and this was occurring mostly in the western world. Many commentators, business writers, futurists, novelists, utopians, media theorists, architects, planners, and social scientists portrayed digital technologies as being effectively at war with any urban-based activity, which generated the need, or desire, for geographical concentration of people and economic and social processes in cities and urban regions. Their critical justification was that conventional, i.e., face-to-face human interactions would be gradually replaced by growing flows and capabilities of electronic communications. This, it was alleged, might even lead to the gradual 'dematerialization' of advanced societies resulting in a post-urban fantasy. For example:

In 1964, media theorist, the late Marshall McLuhan, known for his aphorisms such as "if it works, it is obsolete" and "[turn on, tune in, drop out](#)" (by way of Timothy Leary who wrote a book that had this as its title), suggested that the coming of the 'global village' would inevitably mean that 'the city as a form of major dimensions must inevitably dissolve like the fading shot in a movie'.

Urban theorist and professor emeritus at the University of California, Berkeley, the late Melvin Webber argued, around the same time, that in the near future, 'for the first time in history, it might be possible to

locate on a mountain top and to maintain intimate, real-time, and realistic contact with business and other societies. All persons tapped into the global communications network would have ties approximating those used in a given metropolitan region'. Reflecting on the complexity of urban development in an age of rapidly growing communications and mobility, he challenged the conceptual foundations of urban studies, postulating that urban planners and transportation analysts should focus less on the notion of place and more on the linkages and connections, both physical and informational, that bound together what he called "non-place realms." Seeing the city as, in effect, a giant switchboard, he anticipated the 'networked society'. In the light of new forms of communication and the prevalence of the automobile, he argued that concentrated, denser urban forms were not necessarily more desirable than more dispersed settlements.

French philosopher, cultural theorist, and urbanist Paul Virilio, best known for his writings about [technology](#) and credited for the often-referenced quote "The speed of light does not merely transform the world; it becomes the world; globalization is the speed of light" also speculated about the urban future shaped by digital technology. In 1993 he observed that the diffusion of digital technologies into cities would mean that 'the city of the past would slowly become a paradoxical agglomeration in which relations of immediate proximity give way to interrelationships over distance'.

And at around the same time, i.e., in 1995, Nicholas Negroponte, then the Director of MIT's Media Lab, asserted that 'digital living' would include less and less dependence upon being in a specific place at a specific time, and the *transmission of place* itself would start to become possible. Soon, he believed, homes would be equipped with 'electronic windows' allowing him, from Boston, to 'see the Alps, hear the cowbells, and smell the (digital) manure in summer'. Thus, while being in Boston, he would, in a way, be 'very much in Switzerland'.

Martin Pawley, an influential British architecture critic, pronounced in 1997 that, 'in urban terms, once time has become instantaneous, space becomes unnecessary. In a space-less city, the whole population might require no more than the 30-atom diameter light beam of an optical computer system'. He foresaw a society with ever-greater technical means of communication becoming paradoxically more insular and dysfunctional.

Finally, British writer Charles Leadbeater pronounced that 'at the moment (in 2000) it is as if we occupied two worlds at once, especially in our congested cities: the physical world of clogged roads, which is inefficient, slow moving, and rigid; and the immaterial world of computers and communications, in which we can work at the touch of a button. The ease of use and responsiveness of the new, immaterial economy will make us increasingly frustrated with our experience of the cumbersome old economy of physical machines and roads'.

Building on these and many other suggestions broadcast by writers that new technologies would overcome the need for spatial proximity, many more authors implied that the spread of digital exchanges at the speed-of-light pace, and the explosion of digital domains, would necessarily imply some catastrophic collapse for cities.

The implications of these predictions seemed depressing for those who cherished and valued vibrant cities in all their physical juxtaposition, conflict, unpredictability, and their social and cultural diversity. If such scenarios were to be believed, human reliance on urban places, urban infrastructures, transport flows, and even the corporeal presence of human bodies could, and would, ultimately be transcended. After 8,000 years, urban life, with all its messy and material ambivalence, its clashing territorialities, and its associated congestion, poverty, conflict, violence, pollution, and social problems, was on the way out. Crudely put, the pure, clean, and limitless realm of (post postmodern) 'cyberspace' would rescue us all urbanites from the dirty, polluted, contested, finite, (modern) city. To believe such authors was to believe that a new post-urban age was being ushered in, which would finally allow the rural utopias of the twentieth-century architects like Frank Lloyd Wright to be realized.

Four "Romantic Visions" of Post-urban Fantasy

Place - Breakdown of Materiality - Cyberspace

The romantic vision of the demise of cities, in favor of place-less (non) urbanism stressed the technological basis of a post-urban societal revolution. Rather than seeing the digital technologies as means to be seized upon, shaped, and readily adopted within the fine-grained practices of everyday urban life, such technologies

that enabled cyber-spatiality, were cast as a 'dazzling light,' 'holy grail,' and 'shining' above everyday concerns of urbanism.

Replacing physical movement in and around the city would be the limitless domains of dematerialized cyberspace -the digital domain that results from the convergence of computers with digital telecommunications and new media technologies. First coined by science fiction writer William Gibson, the term cyberspace has been defined as 'a parallel universe' or 'a new kind of space, invisible to our direct senses, a space which might become more important than physical space itself'.

The period these romantic visions became the most common was the last two decades of the 20th century when the "information age" reached its pinnacle with the rapid growth of the Internet and world-wide-web, as computing power was doubling every two years and microchips were starting to saturate every domain of life. It seemed very possible that soon every equipment, instrument, appliance -even human bodies, would be fitted with digital technologies and turned into globally connected digital appliances or terminals linked by broadband telecommunications services over fiber optics and global satellite links.

The "master narrative" or the 'teleology of cyberspace' suggested that digital technologies would transform 'information from something separate and contained within computers to a space we can inhabit'. The world of cyberspace, invariably, was pictured in this romantic discourse as 'a world that exists in the future ... a hope, an expectation, for future fulfillment'.

Architecture scholars who espoused this romantic vision, like Michael Benedikt, a professor at University of Texas-Austin yearned for a future when 'materiality' was 'cast away' because humans could 'inhabit' a virtual world of pure information, while software engineer David Gelerntner predicted that 'reality' such as cities, would be replaced gradually and piece by piece by its 'software imitation' i.e., the 'virtual reality'.

Because the software produced reality was immaterial, infinitely extendable, and an absolute substitution for all forms of physical mobility and corporeal presence, 'cyberspace' was thus seen as a force for decontaminating the natural and urban landscapes, redeeming them, saving them from the chain dragging bulldozers of the paper industry, from the diesel smoke of courier and post-office trucks, from jet fuel flames and clogged airports, from billboards, trashy, and pretentious architecture, hour long freeway commutes, ticket lines, choked subways - from all the inefficiencies, chemical and informational pollution, and corruptions associated with moving information attached to things, across, over, and under the vast and bumpy surface of the earth rather than letting it fly free in the soft hail of electrons that was cyberspace, declared - yet again- Michael Benedikt.

By late 1990s, the explosion of wireless infrastructure promised and began to deliver the unhitched computing and communications from fixed locations, as cyberspace advocates predicted. In its wake, a non-spatial world beckoned where digital streams of information, data, images, and video - manipulated and processed through an infinitely complex global skein of computer networks, pervaded every domain of contemporary society.

Process - Dawn of the more Egalitarian, Capitalistic, and Ecologically Sensitive Societies - Cybernetics

The second romantic vision of the post-urban discourse involved utopian assumptions that the shifts away from place- and city-based lives made possible by digital technologies could meld communities and mediate democratic processes in ways that would completely replace the political, social, and anthropological roles individuals and communities have played and continue to play in urban places. It was often uncritically assumed that such a development would automatically lead to shifts towards more democratic, egalitarian, decentralized, and ecologically sensitive societies. As a matter of fact, the digital "revolution" would yield a cultural revolution because information could be transmitted and transmuted in fundamentally limitless ways, enabling the successes already being witnessed in digitally processed economic transactions. A global neoliberal marketplace where individuals engaged seamlessly as consumers with the entire planet based on globally stretched digital technologies was no longer a utopia.

Beyond the tangible, digital technologies would offer the priceless intangibles of friendship, community, and understanding leading to a new democracy dominated neither by vested interests of political parties nor of

the crime syndicates or oligarchs. It could narrow the gap that separate capital from labor and it could deepen the bonds between people and planet.

Advocates declared that with reduced (or altogether eliminated) need for face-to-face encounters and interactions; tools to (re)-install some form of idealized Athenian or Jeffersonian democracy were now available in the national and global digital infrastructures. With the capabilities of the digital technologies that would support bi-directional and decentralized communications, communities, and democratic links could be forged irrespective of geography, resuscitating democracy itself.

People - End of the Actual Being and the Complete Substitution of Corporeal Presence - Cyborg:

The third romantic vision of the post-urban discourse was the most bizarre of all: the progressive blending of digital technologies with human bodies! Society would effectively be dematerialized, as urban activities would effectively migrate into the ever-extending domains of virtual interaction. Thus, cities would become increasingly and conspicuously “old-fashioned” and unfit as political, social, and cultural expression of the time. As a matter of fact, it was claimed, cities would gradually be complemented, and eventually be replaced, by a fast-expanding universe of virtual realities, virtual communities, and digital economies, as well as unlimited and electronically constructed and maintained domains accessible from anywhere and at any time.

In a direct challenge to the human experience of “actual” place, “virtual” domains would increasingly evolve to be experienced immersively through Virtual Reality (VR) technologies. These “places” and the digital media would fuse with the human bodies and nervous systems of their cyborg (cyberneticorganism) hosts ever more seamlessly. Such ‘terminal citizens’ could, in a sense, ‘leave’ their physical bodies (‘meatspace’), and their local geographies, ‘behind’ the arrays of technology they used to create, to inhabit the new simulated, replaceable, and infinitely extensible, virtual worlds. Richard Coyne, who is a Professor of Architectural Computing at the University of Edinburg, put it this way: “in a virtual world you can have instant access to any coordinates in data space. You can be here, there, or any/everywhere, unlike the limited spatially constrained world we usually experience”. Expressions such as this summarized the critical seam of the discourse prevalent in this romantic vision, often called Technoromanticism. More and more in this context, the concept of a person or of human beings appears to depend on the attenuated possibilities of cyberspace.

For better -and certainly not worse, the crude and in most cases, bleak fantasies of a complete substitution of corporeal (i.e. bodily) presence and movement within and between urban places to habitation of a virtual domain are now less ubiquitous than during their heyday from 1960s to 1990s. Nevertheless, ‘at the turn of the twenty-first century’, anthropologist Caren Kaplan, currently Professor of Gender and Women’s Studies at University of California at Davis, has argued that it is still ‘the rhetoric of cyberspace and information technologies that we hear and read, and the discourse is heavily reliant ‘on a hyperbole of unlimited power through disembodied mobility’. Whether we encounter theorizations of new cityscapes published by university presses or are exposed to advertisements in magazines, references to boundless space, unfettered mobility, and speedy transfers abound.

Time - Collapse of Geographical and Temporal Constraints - Cybertime

The last romantic vision emerging out of the post-urban revolution that is relevant here, involved the assumption that digital technologies would entail a generalized collapse of temporal constraints –mostly manifested by distance- on urbanites’ interactions, which urban life is about. After all, people always chose to establish themselves in cities to overcome the “separation in time and space”, i.e., distance, with other people whom they engage with in urban processes (service, trade, cultural partake, etc). The city had evolved for 8,000 years of urban history by concentrating human life in geographical territory. Through minimizing space constraints, cities had allowed the time constraints on physical human interaction to be reduced. Even in major metropolitan regions physical, face-to-face contact could be achieved within a reasonable time. The prediction was to continue witnessing the exponential growth of the communication technology in capability, scale, and sophistication to such an extent that they would directly displace, and substitute for the city. It followed that, in the future, the key relationships in the ‘digital age’ or the ‘information society’ would not link a person or a group and his/her or their home, their neighborhood, their city, or their nation, by rather, the urban relationships would continuously telescope between the individual and the integrated and planet-wide, digital civilization as a whole. Thus, parallel to the death of cities, the death of distance, by way of cyber space, was presented as both logical and obvious. Inevitably, the digital

technologies would be detrimental to the future of urbanism. Since the digital technologies of communication would facilitate 'real time' interactions to occur: time -as a significant inhibitor of human interaction- would thus be no longer relevant in urban life. The underlying logic of this romantic vision was founded on the equating of distance with time.

Critique of the Post-urban Fantasy

In the dialectic discourses that have been taking place in the last half of the 20th century, as posited by the romantic visions delineated here, the digital technologies and urbanism would diverge into polar opposites. However, these visions of the post-urban fantasy were far from being a single or even a unified discourse. They varied significantly in their assumptions, bases, arguments, and even in conclusions, save for the common belief in the death of cities –as we had come to know and experience them. A complex range of philosophical and theoretical antecedents served as bases on which each were put forth. Many had futurism, cyberpunk science fiction, media, and critical theory as their source, though architecture, planning, and urban studies were significant fields of study from which many of the discourses drew their genesis. A significant number of discourses, particularly the ones coming from science fiction, had bleak, cynical, and a pessimistic view and critique of the direction global political, economic, and technological change predicted to take place.

Nevertheless, all the depictions of the future, predicated on the speculated advances in digital technologies, had one commonality: they were based on a general, and thus uncritical, use of the metaphor that cities would simply be 'impacted' by new technologies, particularly those that pertained to communication, and this impact would be in the same way planets are impacted by asteroids. In all the above accounts, digital technologies were portrayed as arriving from 'out there', as a transformative 'force' or 'shock' hitting the fabric of urban society.

To regard new technologies as 'largely unproblematic and even autonomous in shaping the life and form of urbanity reflected the long-standing tendencies within the contemporary culture, and this may be held as the foundation for -and fountain out of which sprang the four "Romantic Visions" of post-urban fantasy outlined previously. In all, digital technologies were generally portrayed as some disembodied, external 'wave' of change which, quite literally, transformed cities and urban life single-handedly. Alvin Toffler, the author of Future Shock, even used the metaphor 'Third Wave' to capture the latest digitally based societal revolution, following on from the First (agricultural) and Second (industrial) revolutions.

This view reflects the classic, deterministic view of the role of new communications and transport innovations in which 'changes in technology lead inexorably to changes in urban form' and urban life, and not the other way round. In this view, the fledgling networked infrastructures like the Internet become little more than 'progenitor[s] of new urban geometries'. Such rhetoric assumes a simple, linear, cause-and-effect chain where the technology itself is as the direct and single causal agent of urban change. Commonly, this intellectual perspective is quickly translated into the broader use of technological and infrastructural depictions of historical urban 'ages': from the 'hydraulic civilizations' of the first urban centers in Mesopotamia, through to the 'steam', 'electric', 'auto', the 'nuclear', and 'information age' metropolises of the past three centuries.

Thus, the critical problem with the romantic fantasies is that they tend to portray technologies as having overwhelming power in ushering in simple and discrete societal shifts, which seem to amount to some naturalistic process of urban and societal evolution. In the process, the parallels and congruencies between historical periods tend to be underplayed or completely disregarded. Further, in the fantastic scenarios of place, processes, people, and time, each romantic vision also implies that all cities would somehow be 'impacted' by digital technologies in similar ways, irrespective of their starkly contrasting geographical positions, sociologies, economies, cultures, political structures, and histories, because technology it is assumed to operate in the same way in the general and at speculative levels. The tendencies of newer technologies to overlay, and subtly combine with, rather than replace, earlier ones are often ignored. And the forms and processes of city life tend to be simply read off as the deterministic result of the intrinsic nature of the new generation of technology.

Such 'technological determinism' - the reading off of the universal effects of technologies from their intrinsic properties- is nevertheless attractive. It helps to create powerful scenarios, clear stories, and tangible predictions however simplistic they all are. It makes good copy for the media and creates glamorous notions

of a new electronic 'frontier' awaiting colonization by those hardy pioneers that are up to the task. Such rhetoric seems to tally well with the early periods of the diffusion of a new set of technologies and practices. This is because, at this stage, people literally see the social world, and the urban landscape around them, gradually filling up over time with new equipment, new artifacts, new practices, and new ways of organizing human experiences -as if coming from nowhere. Above all, technological determinism and the metaphors of their impact accord well with the dominant experience in the Wild West in the U.S. several centuries ago.

What is unfortunate however is that the pervasive reliance on 'technological determinism' leading to end of city visions actually obscures the complex relationships between new communications and information technologies and cities and urban life that have emerged as these have diffused to be embedded in real everyday lives and practices.

Many urban scholars find the digital technology-related shifts in everyday urban life occurring now to be more intriguing than could possibly have been predicted solely by the generalized scenarios pumped out between the 1960s and 1990s. The architecture critic and Yale University professor Keller Easterling for example, argues that 'the explosion of changes to the world's markets, cities, and means of shipping and communication [are] far more strange and unpredictable than any of the swaggering futurology scenarios'. Thus, there is a desperate need, as many sociologists suggest, to move beyond the deterministic discourses about the 'impacts' of 'cyberspace' on society to look in rich empirical detail at the complex ways in which digital technologies are being used in real ways, in real urban regions, and in the real world. This is imperative.

Far from being a complete and revolutionary break with the past, most advances in digital technologies retain many intrinsic qualities of and maintain intimate connections with old media, old technologies, old practices, and mostly electromechanical old infrastructures and spaces e.g., telephone systems, broadcasting systems, electricity systems, highway systems, streets, airline systems, logistics systems. The so-called 'information age', then, is best considered not as a revolution but as a complex and subtle amalgam of new technologies and media fused onto, and 'remediating' the old ones. They are allowing for the subtle 'remediation' of TV, newspapers, magazines, radio, telephones, publishing, books, art, video, photography, face-to-face communication, and the social and anthropological experiences, and construction of place. This is happening as established practices subtly combine with, rather than disappear all together, in socially constructed technological patterns. There are a great many more continuities and synergies than many romantic visionaries of the post-urban fantasies would have us believe. We are not experiencing some wholesale and discrete break with the urban past ushered in by the 'impacts' of new technology. Rather, we are experiencing a complex and infinitely diverse range of transformations where new and old practices and media technologies become mutually linked and fused in an ongoing blizzard of change. 'Cyberspace' is very much a part of our contemporary world and it is constituted through a series of remediations. As a digital network, cyberspace remediates the electric communications networks of the past 150 years, the telegraph and the telephone; as virtual reality. It remediates the visual space of painting, film, and television; and as social space while it also remediates such historical places as cities and parks as well as 'non places' such as theme parks and shopping malls. Like other contemporary tele-mediated spaces, cyberspace refashions and extends earlier media, which are in and of themselves embedded in material and social environments.

The first problem is obvious: deterministic end of city accounts are simply, empirically wrong.

End of city discourses studiously ignore the fact that fast pace urbanization and growing digital technology use are actually going hand in hand.

The beginning of the 21st Century marked the milestone of the world population being more urbanite than not.

End of city perspectives also ignore the rapid rise in all forms of physical mobility at all geographical scales. These have actually grown in *parallel* with the application of digital technologies; they have not been replaced them.

The growing gridlock of city streets; the staggering rise of global automobile ownership; the exponential growth of airline travel; intensifying levels of consumer and business tourism; growing energy consumption; and a general acceleration of flows of goods, commodities and raw materials at all scales across the world.

Cities of all types across the world continue to be not only the powerhouses for all aspects innovation, research, application of digital technologies, but their demand and installation.

However, current processes of economic, political, social change mostly facilitated by digital technologies, are radically affecting cities. There could be no denying that cities are becoming more diffuse just as the condition of all spaces within societies becomes more generally urban.

The second problem with digital technology-based end of city visions is that they ignore the very material realities that make the supposedly 'virtual' realms of cyberspace' possible. 'Cyberspaces' do not exist on their own; the many supposedly 'virtual' domains and worlds are brought into existence, and constantly facilitated by massive and globally extended sets of material systems and infrastructures.

Because the material bases for cyberspace are usually invisible they tend only to be noticed when they collapse or fail through wars, terrorist attack, natural disasters, or technical failure. Thus, in contrast to the vast and land-hungry infrastructural edifices that sustain transport, electricity and water flows, the myth that cyberspace is an ethereal, unearthly and even immaterial realm continues to retain power.

The third problem with the utopian and anti-urban predictions of end of city visionaries is that they massively over-generalize. They imply that all experiences are the same anywhere and that digital technologies relate to all cities in the same way at all times.

Tough the digital technologies are helping to facilitate significant reconfigurations in the geography, mobility patterns and social economic and cultural dynamics of cities, and in the ways in which urban life is represented, lived and managed, these changes are subtle. They are often counterintuitive and they tend to involve many other processes of change.

The fourth problem with deterministic end of city predictions is that they tend to dramatically overestimate the capabilities of digital technologies to mediate human relationships. At the same time, they dramatically underestimate the complexity, richness, and the continuing anthropological and cultural power generated by co-present human bodies in places, which are predominantly urban.

The penultimate problem with end of the city scenarios is that they -at least in their utopian incarnations- tend to promote simplistic, biased and glossy ideologies of the so-called 'information age'. Many of these have been relentlessly used to improve the public relations profiles of governments and digital media and telecommunications firms.

The final problem with end of city visions is that, in their depoliticized depictions of cities being 'impacted' by waves of autonomous, future technology, which seem to arrive from elsewhere, they imply that there is little or no space for policy innovation in cities, urban regions, or nations and supranational blocs.

It is the irrefutable reality that the twenty-first century will be a century marked by *both* the deepening urbanization of all parts of our planet *and* a growing reliance on fast-advancing information and communications technologies.

Four Romantic Visions on the Future City

Place - Breakdown of Materiality - Cyberspace

Process - Dawn of the more Egalitarian, Capitalistic,
and Ecologically Sensitive Societies - Cybernetics

People - End of the Actual Being and the Complete
Substitution of Corporeal Presence - Cyborg

Time - Collapse of the Geographical and Temporal
Constraints - Cybertime

“Carolino” Aqueduct landscape

Gilda EMANUELE

Dipartimento di Cultura del Progetto, Facoltà di Architettura, Seconda Università degli Studi di Napoli, Aversa, Italia, gilda.emanuele@gmail.com

Abstract

The insertion in 1997 in the UNESCO Heritage Sites has urged a great attention on this magnificent work. This action has solicited a greater attention on this magnificent work that from the Taburno it comes up to Carditello.

In 1750 the architect Vanvitelli, that was getting great comparison near the pontifical and noble clients in Rome, was entrusted from the sovereign Charles of Borbone so that realize a stately palace to Caserta, the new political capital of the kingdom and to contextually see to resolve the old problem of the water provisioning. The jobs of the stately hydraulic work, began in 1753, after the presentation of the project to the sovereigns and it lasted until 1770, with a total expense of around 700.000 ducats. The denominated “Carolino” aqueduct, in honor of the sovereign, it is long around 40 km and it crosses the territories between the provinces of Benevento and Caserta, it depart from the sources of the Fizzo up to the falls of the Palace. The water pipe was entirely buried, except external lines on the bridges, and the path was signalled by 67 turret, square building with pyramidal coverage, together with the other works of service, collectors, gathering tanks, mills, ramifications for the water restocking, signal the presence of it and they constitute the element “meaning” of what we could define “the *Carolino* landscape.”

keyword: “Carolino” landscape

The modification of a landscape

Prigogine writes “the science is a dialogue with the nature, but the knowledge passes through the time. It implies a becoming, a difference between present and past. It implies an universe under construction and a life that he evolves. These concepts can be conceived in a very vast horizon and extended the term, but if we want to analyze the meaning of anthropization. In more real sense, it needs to consider the various ecosystems on our planet formed from: water, earth, atmosphere.

The anthropization begins with the appearance of the man on the earth. The first great civilizations, nevertheless, despite some imposing works as the Pyramids or the control of Nile course in Egypt, the capital terraced with great hanging gardens in Babylon and the beautiful states been in Greece they didn't provoke great environmental changes. An example of balanced environmental insertion were nobles Romans villas that exploited the characteristics of the places. Also in the Middle Ages and in the humanism

the architectural and rural environment was of great harmony. Only in the last centuries the demographic increase was creating a great impact on the rural environment.

The built environment must represent the fusion of the natural element with the human intervention. And' that "new system in harmony" that magically Wright was able to build and every planning of the built environment must aims to it.

On the basis of what results to be the management and the modification of the environment in modern sense, the "Carolino" aqueduct was realized.

This infrastructure in 1997 was inserted in the UNESCO Heritage Sites. This action has solicited a greater attention on this magnificent work that from the Taburno it comes up to Carditello.

In 1750 the architect Vanvitelli, that was getting great comparison near the pontifical and noble clients in Rome, was entrusted from the sovereign Charles of Borbone so that realize a stately palace to Caserta, the new political capital of the kingdom and to contextually see to resolve the old problem of the water provisioning. [1]

After the aqueduct, built in the first years of Six hundred by the Acquaviva of Aragon, reacting and strengthening by the introduction of some sources, denominate Small Waters, you displace on the surrounding Mountains in the plain of Caserta, he made the course of the water still resulted insufficient and decide to realize a new structure [2], an aqueduct that, according to the Charles of Borbone ambitions, it was able to furnish water to the building, to the gardens, to the new city that was forming, to feed the turbine of St. Leucio twisters of, to the mills, drinking trough, to Carditello estate and to increase the preexisting Carmignano aqueduct that supplied the city of Naples. The aqueduct would be become the symbol of Charles sovereignty to emulate ancient Romans works devoted to the great Cesar. [3]

The searches of sources was long and hard. The sources should have rise in a site higher than Royal Palace, so that the water arrive with necessary pressure. A rich zone of sources was found at stratum of Taburno, 254 mt above sea level, on Airola's property, belonging to the prince Riccia, that subsequently gave him/it to the king.

Different solutions were introduced for the realization of the path to the Palace, that don't seemed him easy both for nature land that for the same length, 26 miles, about 38 km.

The jobs of the stately hydraulic work, began in 1753, after the presentation of the project to the sovereigns and it lasted until 1770, with a total expense of around 700.000 ducats. The denominated "Carolino" aqueduct , in honor of the sovereign, it is long around 40 km and it crosses the territories between the provinces of Benevento and Caserta, it depart from the sources of the Fizzo up to the falls of the Palace. The water pipe was entirely buried, except external lines on the bridges, and the path was signalled by 67 turret, square building with pyramidal coverage, together with the other works of service, collectors, gathering tanks, mills, ramifications for the water restocking, signal the presence of it and they constitute the element "meaning" of what we could define "the *Carolino* landscape."

The paths of the "Carolino" aqueduct :

- The aqueduct has origin from the sources of the Fizzo and continues downstream toward Faenza river (current Isclero) where it was built a bridge with three arcs layers, 7 meters high and 190 meters long. (1. Source. Bridge on the Isclero).

- After the bridge on the Isclero the path widens toward S. Martino and Cervinara to lace other sources and then it returns within earth in a tunnel about, 2 Km long, in the hill called Prato. After the crossing of Mount Ciesco Mountain it comes on another deep valley crossed by Faenza river and it crossed with a bridge. The "Carolino" continues for the territory of Sant' Agata de' Goti trough Mount Castrone, of the Acquavivola, of the Sagrastia, of the Cacosca, of Stella Maggiore, of Fico Fano, of Traugano (Mountains belonging to the chain of the Taburno). (2, bridge on the Isclero. Sant'Agata de' Goti)

- The path continues still crossing the Mountains of FicoFano and of Traugnano and then Durazzano. valley Where there is a bridge with 5 arcs, 60 meters long and 19 high. It continues until Cascione torrent and then it meets Mount. Longano The road of the Longano end with the splendid scenery of the Bridges of the Valley. (3.a S. Agata de' Goti. Mount Longano)

The most famous line that countersigns the hard-working project of the aqueduct is certainly the imposing building denominated "Bridge of the Valley" of Maddaloni.

The project developed to overcome what seemed an insuperable obstacle in the time: the vast valley that separates the Mount Longano from the Garzano. Once that it was easily understood that water could not go down from the slope of a Mountain and to go up again the other without water lost the necessary pressure to reach Caserta, it was decided to build a bridge to overcome the obstacle. The work was very hard in the time, as revealed by the many letters that the architect wrote to his brother Urbano

The Bridge, 2000 palms (529 meters) long, 220 high (95,3 meters), was built on three levels of arcs, progressively 19, 27 and 43. An inside passage allowed to cross in all the verses the three orders of arcades,

strengthened by buttresses.

The grandeur of the work, especially in the aerial line, it didn't miss to strike the foreign travellers of the epoch that crossed Naples kingdom; it constituted an exceptional show, in the middle of a solitary valley, All of a sudden rise the magnificent bridge to three orders of tall arcs, that majestically cross the valley on one side to the other. (3. b The Bridges of the Valley - 3.c a war memorial).

Once trough Maddaloni valley, the aqueduct crosses the Mount Garzano and it continues along the slopes of Tifatini Mountains. The walk continues in depth of 6 Km and than two collectors, allows the clearing of the water in smaller plumbings. (4 Mount Garzano. Mount Briano)

Minor water system is constituted from three small aqueducts: The Old Duct, the Sant' Elmo and the Giove-Fontanelle. (5. Minor water system) [4]

The "Carolino" aqueduct can be seen as a monument that once it has lost its functional value (utilitas) has continued to live and to be appreciated for its landscape and monumental value (venustas).

This is the the case in which "the architecture is what it makes beautiful ruins", as asserted August Perret.

The known aphorism of Perret introduces us to brief considerations and critical reflections.

This work is assimilable somehow to the Greek temples, that are everything today admired in how much, despite their native aspect it is perceivable only, it remains in them the beauty (venustas) and their architectural and constructive quality.

In the downfall of a true architecture we recognize the expressive character, the constructive system, the idea that has produced him/it the osmotic relationship that he is istaurato with the landscape.

In the bare structure, deprived of ornaments, architectural identity appears today still us unchanged, rather strengthened in the expressive eloquence of the naked construction.

This is the motive for which the visits of Louis Kahn on the different European sites of ancient ruins represented for him the key of time in its formation. Its architectures are in fact daughters of a resistance to the banalizzazionis of the modern one and the "flagwaving" technological ends to if same. They are creatures that are born from the almost devoted respect for the man and the nature.

The architecture should not be a mass in scene of a show that once ended it not only loses its functional value but also its identity and its ability of it stuffed to move, quoting her Corbusier we can say that "The architecture is a fact of art, a phenomenon that arouses emotion, out of the problems of construction, beyond them. The Construction is for tener on: the architecture is for moving."

Too often the contemporary architecture is an architecture-installation in which it seems to prevail the attitude to put in scene, to communicate an image, that becomes only with the time old, but not ancient, once that you/he/she has reached the condition of ruin, it loses every value of his and it doesn't even purchase that of "beautiful downfall."

Unfortunately this is a condition common to so many works of contemporary architecture, that don't converse with the surrounding environment.

The greatness of a work as that of the "Carolino" and particularly of the Bridge of the Valley of Maddaloni, it is in the being entered symbiosis with the landscape and to have emphasized him/it with his/her assistant value. it is a monument that he/she lives in osmotic relationship with the landscape, alive in symbiosis, it interprets him/it and it melts him with it.

The manufactured article in this case is a car, it is an anthropological system that valorizes the natural environment; the architecture and the environment constitute a non referable unity to the sum of the parts, but to the totality, that has in itself the assistant value that is gotten with the union and it loses him in the separation of the elements; and it is together that form the monument as Roberto Pane intends him/it. In fact, as he/she quotes the art. 1 of the 1964 Venice Paper, "You notion of historical monument includes as so much the isolated architectural creation the urban environment or landscape that constitutes the testimony of a particular civilization, of a meaningful evolution or of a historical event" and it is for this motive that the safeguard of the manufactured article implicates that of its environment.

In 1972 the UNESCO Convention on the Protection of the World Heritage defines "monument", or better, "Heritage" both the architectural manufactured article is the site, or rather "every complex both work of the man that of the nature, that has historical value, aesthetical, archaeological, scientific, ethnological, anthropological or remarkable physical characteristics, biological and geological, that justifies a protection and an exploitation" The fundamental action that precedes the exploitation of the cultural and natural Heritage is the knowledge of the architectural manufactured article and the landscape in which is inserted.

In this point it makes space for the drawing becomes a means of representing the complexity. The architecture, the land and the environment can't be represented simply by returning three dimensional, but at this canonical method, plus a multidimensional approach, it follows, so that all the elements constituting the landscape should be investigated at different scales representation and, above all, in both forms, extensive

and intensive, that is, entering into the body of the object and know its constituent elements. The objects are then discretized by the knowledge that is traversed in order to be re-established and capitalized.

The evolution of research lies in the limit, in this dynamic place that allows extensive information from entering the body of the objects, and enriching the information, determines the evolution of the representation as a project. Understanding through drawing marks a fuzzy boundary between relief and the project as the relationship between the object detector determines not only knowledge, but also foreshadows the fate.

The desire to recover the historical memory, the deep roots of the place, the traces of the past reveal that the vocation of the place (*genius loci*), must accompany any systemic approach aimed at understanding the changes, so that the knowledge of the past suggests a continuity with the present and a future in which tradition and development have been merged in the process of economic and social modernization.

For the protection of the landscape and the environment must take two levels of actions:
protecting and regenerating the construction of quality works.

For the protection necessary to engage in an activity intended to measure and capitalize the infinite reasons of nature and recognize the environmental context of the gene.

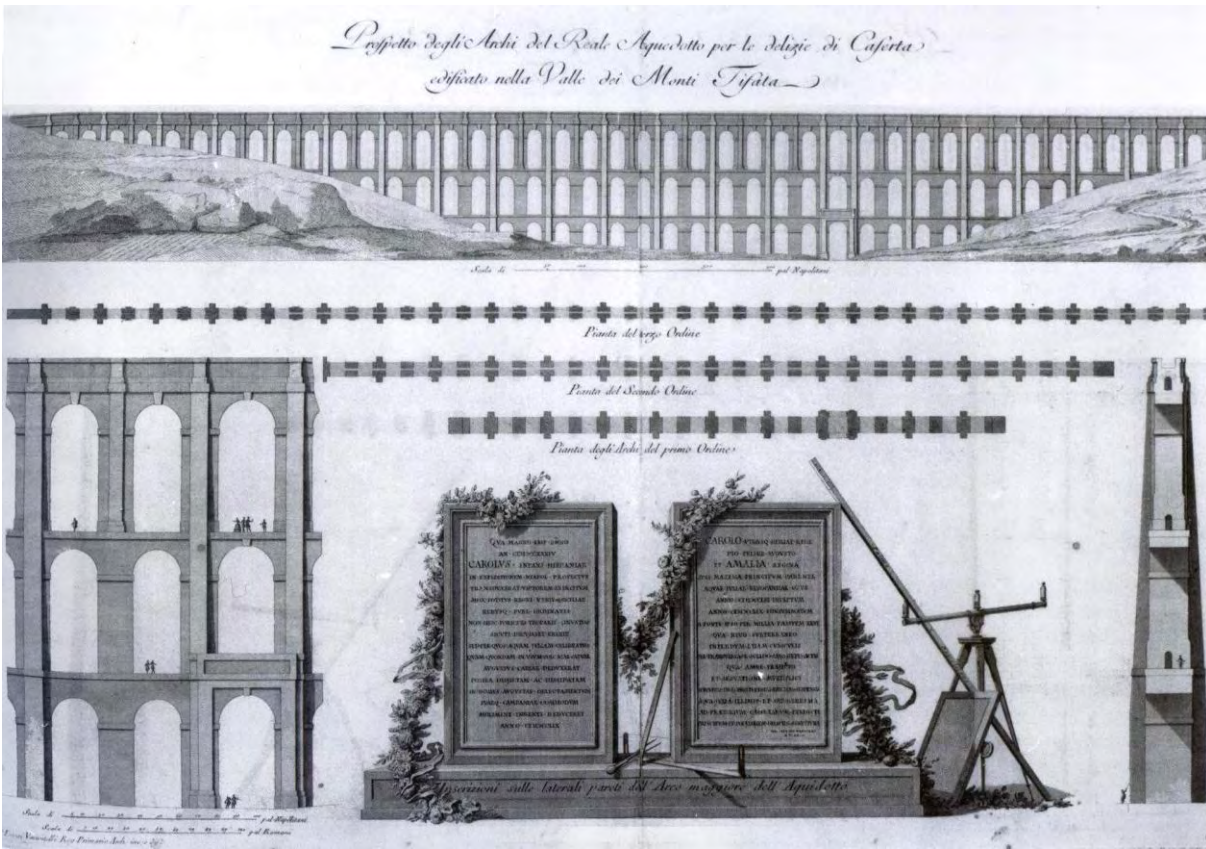

By measuring and drawing changes pass to the next track and intangible assets, favoring quality works through a process of modification of the territory, and not of transformation that involves action taken to overcome the limits imposed by knowledge.

Transformations, a tangible sign of the unstoppable anthropization soil, often beyond repair may have altered the landscape: from cultural and social (think of succumbing to the peasant culture than the urban one), the ecological landscapes. Less well known, at least in the Italian tradition, but the action is "positive" in the process of territorial change in order to improve or increase the same landscape quality of certain urban areas or territorial waters.

The man works characterize the period, representing the memory to date on an evolutionary process that each sign contains a bio-design.

To be able to get a more complete protection activities must regenerating the natural environment and built to live and develop into the progressive change of the human experience so that the landscape appears as a result of today than yesterday and the becoming, through the project, will be of chief importance to abstract and extract the archetype, defined as geometric matrix of the foundation, the transporter rule knowledge, discretizing in all parts together in agreement.

Through the representation metabolizes the past and lays the foundation for change that respects and recovers, the relationship between archetype and nature, comparable to the value of a stem cell regenerator (borrowed from biology) that is produced by the same complex identity of places. [5]

Contribution of technological innovation to reinforce the multidimensional knowledge of environment and direct its development

Lina ABATEGIOVANNI

Department of Culture Project, Faculty of Architecture L. Vanvitelli, Second University of Naples, Aversa, Italy
lina.abategiovanni@gmail.com

Abstract

The main theme of this research is about the awareness and recognition of the territory, with particular attention to the possibility of an integrated approach of different techniques and technologies, as tools to establish forms of sharing territorial data between different disciplines, which may tend to its development. Requisite for the enhancement is with no doubt its knowledge, which passes through measuring action and management of resources that belong to it.

The aim of this essay is highlighting of a method of investigation and a analysis that provides a good introduction to the multidisciplinary study of the territory and its multidimensional reading, made possible by a skillful integration of innovative techniques.

Keywords: territory, heritage, multidimensional knowledge, development, technological innovation

1. Introduction

The territory appears to us with higher obviousness as expression and outcome of the complexity of nature and culture, of human actions on landscape and their setting and their existing impact. To understand the general organization of places, but above all, to prefigure the protection and regeneration, it needs an innovative approach to the study of area based on the integration of skills and knowledge articulation. The contribution of the current technologies that allow us to integrate and to network the knowledge products make us able to show the thought of man, the project in its complexity, as it had never been possible until now, by moving the point of view above, below, on each side but also in the territory. The territory, therefore, constitutes a fundamental reference point of our identity and quality of life, then, a more active consideration of it involves action at several levels. To speak, or rather, to write about the territory in relation to new technologies means addressing the issues of values, identity, perception, the expectations of individuals and the interdisciplinary approach.

1.1 The importance of use of joint disciplinary skills and new technologies

The technological solutions made available by today's contemporary Geomatics disciplines, provides an opportunity of great interest for the detection of the territory and its cultural heritage, both for the relief time and the issues concerning the representation of objects architectural, artistic, archeological things.

The field of cultural heritage has attracted in recent years a growing interest by the scientific community often refers to the science of detection. UNESCO and other agencies and authorities of the field now arise more and more attention to the digital meter of archaeological sites, historic centers, complex building of historical and architectural importance, archaeological remains; then it is spreading the idea that knowledge of an asset may not involve only its artistic history, but it must also include the characteristics of position, shape and geometry.

New technologies offer the possibility to detect an item in a very short time and with high degree of detail and precision. The quality of modern instruments, the possibility of integration and flexibility they allow, are combined with the expressive power provided by modern techniques of representation.

The disciplines of surveying, over the centuries, in this regard have refined measurement techniques tailored to the situations and the potential offered by technology, by more simple and effective methods, means of direct relief to those derived from primary descriptive geometry and, finally, today with the great potential offered by electronic and information technology and, therefore, the tools offered by modern Geomatics.

In this reading, and in a multidisciplinary perspective, it is easy to understand the meaning and significance of modern development and renewal that are attributable not only to technological advances but also to a new and modern way of dealing with it.

Today's technology are guided by a survey method based on multidimensional knowledge that allow to "capitalize" the territory, its resources and to enter in the body, bringing back the value of identity.

It is amazing see how using the tools of modern technology, it's possible to represent a UNESCO site, study its components and measure them in a complex management.

The measure, therefore, is the basis of knowledge and every representation of physical and intangible values of reality and documentary traces of man in his biological evolution as a function of environmental context in which they live. Measuring and capitalizing the endless reasons of nature mean to recognize the genetic heritage, the identity of places.

The knowledge of the culture, supported by technology, can allow you to resume a comprehensive and challenging debate, especially if the researching areas are supported by developing sceneries, the recovery of new opportunities that this land and cultural treasure can offer to contemporary society. Consequently, it achieves a new survey, whose task is to describe the complexity of the critical factors that affect the urban reality, the natural environment and the entire antropic space in which it occurs top plan out conservation and adaptation to the needs of survival and human welfare.

For a full exploitation of the territory, taking into account its immense heritage, the set of new technologies is now an unavoidable tool for the acquisition and use of geo-referenced information to the government and the innovative management of land and environment.

It is therefore necessary to know the basic concepts underlying computer technology for the processing of data and territorial and environmental information, as well as learn about the technological resources now available to use its specific characteristics in relation to the different territorial problems. The integration of the techniques allows to obtain a fair amount of controllable data, in spite of their heterogeneity, and different processing, to support the different purposes programmed in the conservation project.

The new techniques and digital technologies offer, in fact, the possibility of obtaining new products new products not only by the relief's activities but also in the representation and in the view, with the purpose of having a metric accurate description of the whole territory.

In order that this complex procedure show its full effect it needs the shortest possible time switch from the "cognitive dimension" to the "time of use" of information. It is therefore essential aspect of the *geo-referenced* data: that is the operation to assign to each element of the territory, its real spatial coordinates compared to a known reference system, in such a way that the scale of representation is uniform and allows to consider the territory equivalent to a map (Figure 1).

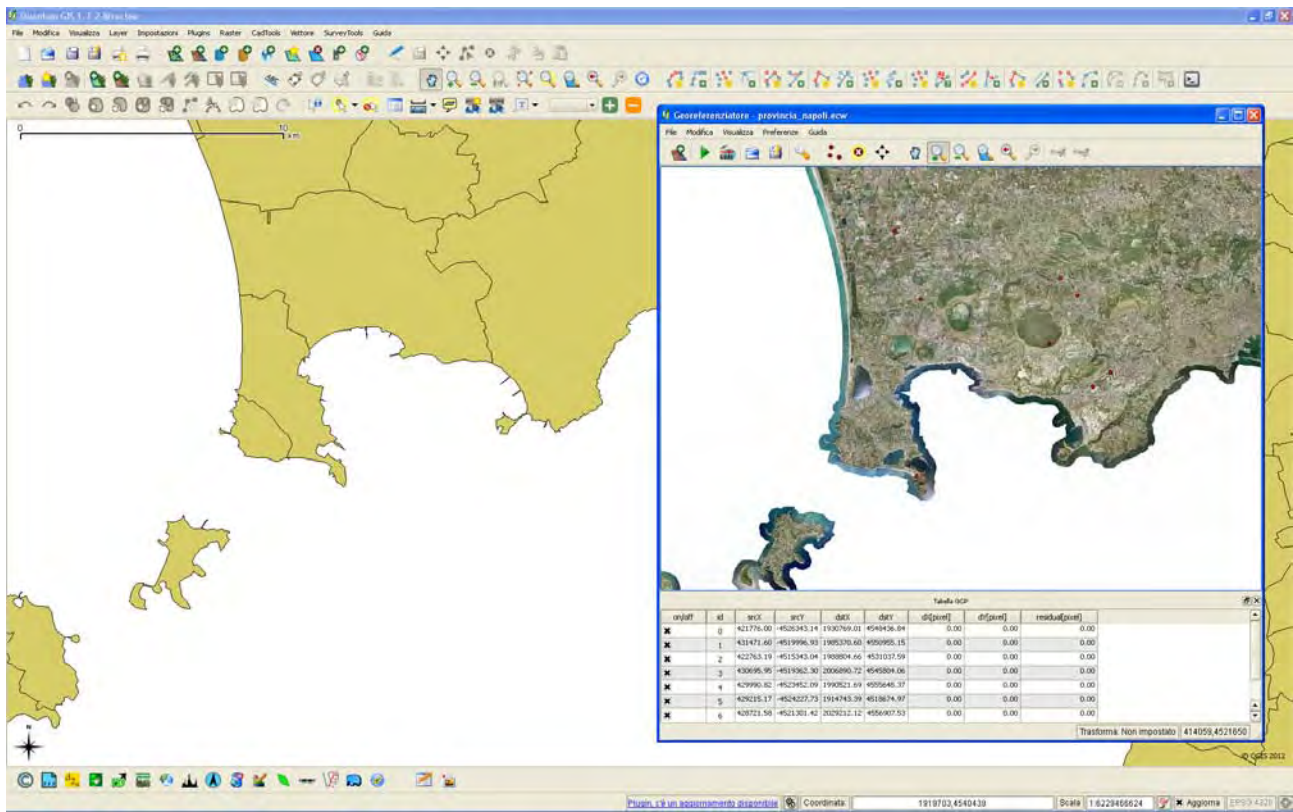

Fig. 1: Georeferenced territorial method thanks to ArcGIS software.

The necessity to prepare in a short time, restorative models that allow to combine the rigor of the investigation of metric knowledge with the need to effectively serve as a tool for understanding the values and to communicate the meanings of the site, new relevant technologies are eligible to handle large quantities of spatial information, but require an integration and joint use by the operator.

Among others, the *laser scanning* technology is playing an increasingly important role in the relief, thanks to the advantages it offers especially in terms of speed of acquisition, the amount of measured data, however, the ability to immediately provide the user a 3D representation.

The surfaces prepared starting from the clouds of points acquired by laser scanners, they describes not only the size and arrangement of architectural elements in the territory but can give back the material consistency, making it readable masonry equipment, materials degradation and injury and give the ability to segment the data into logical levels, dividing the architectural structures, as well as the elements that characterize the territory, into simple elements, then apply them different procedures for surface modeling.

The spread of laser scanning techniques is relatively new and certainly is one of the technologies that will find a larger expansion in the near future. As known, a scanning laser system provides as a direct result of the measurement session a set of three-dimensional coordinates, usually in a reference system linked with the instrument, referred to a very high number of points that are hit by the laser beam; the cloud of points thus describes the surface of the scanned object. Jointly to the measurement of the distance, these tools are generally able to also measure the reflectance of each point-object to the frequency of the beam and, in some cases, to acquire the RGB image recorded with the laser (Figure 2, 3).

Fig. 2: Scan performed by terrestrial laser scanner and displayed in the form of points of cloud.

Fig. 3: Scan performed by airborne laser scanner and displayed in the form of points of cloud.

In recent years, laser scanning techniques have been widely used in various fields of metric survey, from the architectural and cultural heritage to the land one. The ability to collect and process high amounts of data very quickly has deeply changed the philosophy of metric survey, which was based on practice and on a relatively small number of extremely accurate measurements, requiring long time and remarkable skill. Today, however, you run the risk when you rely on packaged software in a superficial way, that this change in attitude may reflect a loss of control by the operator on the individual data and the various stages of processing. This means that you can get high quality results without being aware of the strategic importance of the different techniques and the integration of many existing high-tech tools with different disciplinary skills.

The integration of the laser scanner with *digital photogrammetry* offers a valuable tool to respond the specific requests for relief, in this way, it's possible to operate according to different modes and scales.

The techniques and experiments that have exploded in recent years in all phases of the photogrammetric process are numerous and difficult to categorize and list.

The photogrammetry without a doubt has a key role in the generation of maps for historic urban centers, archaeological areas and building more or less extensive. The role of photogrammetry as a modern and rigorous technique in the cultural property field is undisputed, its characteristics of being a technique that requires no contact with the object, of rapid acquisition, with a considerable flexibility of use and excellent metric accuracy in determining the geometry and shape of objects of all kinds, have made it spread more and more, now much enlarged by the possibilities offered by digital (Figure 4).

Today we wonder whether photogrammetry is still makes sense compared to laser scanning: the answer is definitely positive. The two techniques are not in competition but complement each other or rather should integrate with their different characteristics.

Fig. 4: Method of photogrammetric survey on digital orthophotos.

New technologies, combined with the use of geographic information systems (GIS), are integrated together in order to achieve fast and rigorous multi-scale relief, from the territory, through its heritage and up to each individual element.

The future of the science of detection, then, lies in an approach that would merge data from different techniques, made possible primarily by the sharing of a single reference system that allows the reading and understanding of every subject of interest not only in itself, but in the context in which it is.

It needs, in other words, involve different types of knowledge to contribute and present overlapping *layers* that compose the state of the art compared to a “cumulative knowledge”.

The dynamic request includes the need to merge the different levels of knowledge in a database (regional, provincial and local) which must constantly update and monitor in real time “discoveries” and events, natural and/or anthropogenic, that added to the previous ones.

The multidimensional knowledge, then, must be understood as the primary basis for planning and cross-articulated between functions and uses of our time and memory resources of the past, between the status of fact, the transformations and developments in progress, supported by contribution of technological innovation, more and more integrated into our daily reality.

1.2 Observations and expected results

Correlate the cultural heritage with technology and innovation is an important strategic action that could produce positive results in many fields, generally, in the economic development one.

New technologies can break down, analyze, evaluate and manage the land, they also can bring people to cultural heritage, revitalize cultural contents and transfer them to the public in the form of new ideas and encouraging creativity and involvement reviving the past and, at the same time, plan the future.

It needs to promote the use of technologies that are used to rebuild the characteristics of the property, to constantly monitor their status and plan a more effective maintenance.

Furthermore, in developing programs and funding, priority must be given to those interventions that better integrate the assets with different technologies, rewarding those projects that have groundbreaking elements, paying close attention to the expected results. The technology must, therefore, represent a stimulus and a help making culture affordable for everyone.

It arises the need for a new way to address the representation and protection of property that the area has provided, the awareness of its cultural assets with the aim to bring added value given by its knowledge.

It appears the compulsory study of an innovative methodology capable of defining territory, on several levels and on different levels of knowledge, traces of past and present needs through a multidimensional approach that takes account of a variety of sizes and material, immaterial, perceptive, intrinsic values allowing the transition from the simple addition of different knowledge, of its multidisciplinary, to full knowledge in which any information is amplified by a added value by knowledge itself.

With the help of new technologies and the creation of a knowledge network based on the integration of knowledge and analysis of multidimensional, the objective is to aim at the forefront of territory protection and enhancement of its heritage, exploiting all potential.

Abstract

“The Project “cultivate in the Faculty” means the necessity of deferrable “Growing culture”: the garden as an opportunity to regain the own land or giving it back its best value landscape / environmental, economic / social / educational training, perceptual / sensory or the value deeply ethical and aesthetic that belongs. The monumental complex of San Lorenzo in Aversa ad Septimun - Faculty of Architecture SUN - surrounds with its walls about 7000 square feet outside the carelessness of the time and different priorities in the restoration of the plexus has eroded and compromised. Like most urban spaces, the area outside Abbey has hosted open dumps in the spaces taken from the collective benefit, and wasted by neglect abandonment. In 20 weeks we have realized our dream: the dream of translate into action our genetic local ethics; the dream to regenerate the connective tissue nature / culture, the dream of participating in a collective project and work with teachers, students, farm laborers than another ortho ‘Intra Moenia’ working quietly for several generations; the dream of planting Our vegetable cultivars and biotypes tracking local dream recover the ancient well without wasting a single drop of water, the dream slowly replacing all “now” global universe that is needed and in time of local ground, the dream of offering our first harvest at the table brotherhood of the Shrine of Saint Lucia a Mare, the dream of understand that outside the virtual experimentation of tastes, odors, perfumes there is a real perception of places that “listen” with our senses, a dream not to waste space community and use the products in the Garden of the Faculty buvette km 0 away. The dream of allowing nature to one long long Travel to the culture. Specialist skills were involved in the process of regeneration - not just formal-of the “vacuum” of the Abbey: morphological / Dolores Morelli, soil / Andrea Buondonno, agronomic / Gaetano Pasquale and Alberto Cappelletti, Mathematics / Cristina Miglionico, eco-alimentare/Eugenia Aloj, culinary/ Salvatore Genovese, quality control and food / Luca Rastrelli. And together we “sown” the “Laboratory Gardens of San Lorenzo” to explore and draw with students of Architecture and Design “the secret law of nature “of which Goethe speaks, extracted from the leaves, by vegetables, fruits geometric matrices, the golden section, the Fibonacci series, fractal geometry, traces of an archetypal project that goes from nature to artifice: bags that evoke the form drag of “pummaroce”, banana peel as shoe covers for ortho, libraries inspired the structure of the leaf according to the process of representation suggested by Munari articulated shelves on the Fibonacci series and a bicycle ecological drawn on the snail to “speed up” sustainable mobility [0 <miles < 0.0298258] by the short food chain [km 0] average speed of the snail [0.0298258 miles]. A slow, gradual, starting from the involvement of students, not only of our faculty, students of schools high school and elementary school children involved in virtuous cycle of recovery of common ground”[1].

Key words: land, design, children, garden, school, love

Abstract

Soil is the common earthen parchment upon which humanity’s cultural signatures are imprinted. Reading the complexity of a soil profile from the pedogenetic point of view is equivalent to read the peculiar history of a site. The aim of the present work is the pedo-semantic analysis and the reconstruction of pedo-historical identity of the soil of “Orto di San Lorenzo *ad Septimum*”, at the Faculty of Architecture of Second University of Naples, Aversa (Italy). On the basis of field observations and laboratory measurement, it is evident that the soil: i) is characterized by an extremely complex horization, including a whole of 17 horizons with several buried layers, and, ii) its formation is the outcome of three main genetic Cycles driven by natural and/or anthropic events/impacts. The 1st, older and deeper Cycle (14.9 to 3.9 ky b.p.) formed by Volturno and Clanio rivers flooding, starts after Neapolitan Yellow Tuff formation, and closes with “Avellino Pumices” eruption; the 2nd middle Cycle (3.9 ky b.p. to 1807 a.D.) includes Roman finds and the authentic “Abbot’s Garden”, detected by organic carbon and phosphorus peaks; the recent 3rd Cycle (1807-today) consists of past and recent anthropogenic layers. The pedo-semantic analysis reveals the very complex and fascinating history of “Orto di San Lorenzo *ad Septimum*”, confirming the impressive relevance of soil in the human life, and also highlighting the intriguing traits and the proficiency of the multidisciplinary cooperation among Architecture and Soil Science.

Key words: Orto di San Lorenzo; pedotechnique; pedoarcheology; buried soils; HTMs.

1. Introduction

The different pedological and bio-chemico-physical nature of soils has determined and determines different settlements and developments of human civilizations and societies, resulting in a biunique correspondence between soils and landscapes. From this standpoint soil is also accredited as depositary of historical, cultural and artistic heritages of mankind. As known, the early Latin derivation of *Homo* (Latin for man) was *hemo*, meaning the earthly one; akin to the Latin word for earth or soil, namely, *humas*, and the Latin, word for humans, namely, *humanus*. The history of humankind, and our ancestral Homo species, is the history of our relationship to the Earth and its environment. Archeological evidence in many parts of the world reveals our penchant to alter the environment, be it to our boon or bane. Soil is a major component of the natural resource trinity (soil–sun–climate) from which humankind’s sustenance is rooted. And soil is the common earthen parchment upon which humanity’s cultural signatures are imprinted [1]. In other words, reading the complexity of a soil profile from the pedogenetic point of view is equivalent to read the peculiar history of a site. The aim of the present work is the pedo-semantic analysis and the reconstruction of pedo-historical identity of the soil of “Orto di San Lorenzo *ad Septimum*”.

2. Materials and Methods

The investigated soil profile is located in the garden of the Benedictine Monumental Complex of San Lorenzo *ad Septimum* in Aversa (Caserta, Italy) (Fig.1), an area which represents, since Roman age, an important human settlement place. Recently, as of 1992, it is the seat of the Faculty of Architecture of Second University of Naples (Tab.1). In 2010 the garden of this Abbey has been subjected to pedotechnical intervention aimed to its environmental and functional restoration (Fig.2).

2.1. Site description

The geo-lithologic substrate consists of pyroclastic products of recent volcanic activity of Campi Flegrei (Phlegraean Fields) District with irregular intercalations of fluvial deposits such as limnic materials [2]. From a pedological point of view the investigated site is situated in the “Phlegraean Piedmont Plain” Subsystem that encompasses very urbanized areas with well drained volcanic soils classified as Pachi-Vitric Andosols, MolliVitric-Andosols [3].

2.2. Soil sampling, analysis and classification

The soil profile was sampled, described and classified using standard soil survey methodologies [4, 5, 6]. Soil samples were air-dried and 2 mm sieved for laboratory analyses according to the Italian procedures [7] and international standards [5]. Total Organic Carbon (TOC), Total Extractable Carbon (TEC), Humic and Fulvic Acids (HA+FA) and Total Phosphorous (P) were taken into account as reliable clues for the identification of the so-called “buried soil”, *i.e.* ancient soils covered by more recent soils, superimposed by various natural and/or anthropic events/impacts, and past human activities [8, 9]. From the taxonomic point of view, horizons along the soil profile are denominated according to the latest Keys to Soil Taxonomy [6]. In particular: (i) the “caret” symbol (^) indicates just mineral or organic layers formed by Human Transported Materials (HTMs), *i.e.* natural (soil filling materials) and/or artificial materials (limestone gravel, amendments) moved horizontally onto a pedon from a source area outside of that pedon by directed human activity usually with the aid of machinery; (ii) the letters “A”, “B” or “C” designates, respectively, mineral surface, sub-surface, or deep, poorly pedogenized horizons; (iii) the subscript “u” denotes presence of artifacts created or modified by humans such as materials derived from excavation activities; (iv) the subscript “p” warns a pedoturbation, *i.e.* a mixing within a soil or sediment profile by various natural/anthropic processes, such as animal burrowing, tree throw, freeze-thaw cycles, manual/mechanical movements or transports; (v) the subscript “k” indicates an accumulation of visible pedogenic calcium carbonate; (vi) the subscript “b” denote the presence of identifiable buried horizons.

3. Results

The synoptic comparison of field observations of soil horizons, laboratory measurements, and the distribution of TOC TEC HA+FA (Fig.3) and total P (Fig.4) along the investigated soil profile, clearly reveals that it developed under three main pedogenetic cycles -at least-, and suggests a preliminary reconstruction of its pedo-historical identity (Fig.5). The polycyclic and polygenetic genesis shows a complex and anisotropic horizonation, characterized by many lithologic discontinuities, *i.e.* significant changes in particle size distribution and/or mineralogy of parent materials (identified by Arabic number prefixes).

The first deep Cycle, from -185cm to -130cm, made up of poorly pedogenized sediments, is subdivided in two subcycles: (i) the I.1 Subcycle, from 7C₂ to 7C horizon, was formed after the “recent cycle” of Campi Flegrei volcanoes, which produced the Neapolitan Yellow Tuff (14.9 ± 0.40 ky b.p.) [10]; it includes limnic materials, likely associated to the common floods of Volturno and Clanio rivers in ancient times, when the whole area was a marshland named *Maremma Litternina*; (II) the I.2 Subcycle, 6C_k horizon, formed by volcanic materials of the “Avellino Pumices” eruption of Vesuvius, 3.9 ky b.p. [11].

The overlying horizon sequence, *i.e.* 5B_b, 5C_u/B_{kb}3, 5C_u/B_{kb}2, 5C_u/B_{kb}1, 5B_b2, 5B_{bk}1 and 5A, from -130 cm to -40 cm, identifies the second Cycle. The evolution of its deeper horizons may be contemporary to the *Via Campana* building, dated at about 400 a.D., as supported by the presence of earthenware fragments of Roman times, lime mortar and artificial concrete. This Cycle ends with the 5A horizon, which likely represents the original soil surface of the “Abbot’s Garden”, which performed its functions from 1777 to 1807, when Napoleon laws dispossessed the “San Lorenzo *ad Septimum*” Abbey of its assets. Indeed, this assumption is strengthened by the remarkable peaks of TOC, TEC, HA+FA and total P (Fig. 3, 4) in 5A_b, clearly evidencing that such horizon was at the surface of the “Abbot’s Garden” soil.

The recent third Cycle, from -40 cm to field level, represents the modern *man-made* horizons of “Orto di San Lorenzo *ad Septimum*” made up by HTMs, horizonated as [^]A_{upk}1, [^]A_{upk}2, [^]A_{upk}3, 2[^]C_u/A.

In this third Cycle the whole lithologic discontinuities is associated to very abrupt colour changes (Fig.5).

This Cycle is subdivided in: (i) III.1 Subcycle, from 1807 to 1992, formed by 4[^]CB_{ub}/A_b 3[^]A horizons, and (ii) III.2 Subcycle from 1992 to present, which represents the final result of pedotechnical interventions.

4. Conclusions

As guessed, the pedosemantic analysis of the investigated polycyclic soil profile revealed the very complex and fascinating history of “Orto di San Lorenzo *ad Septimum*”, from the age of the dramatic last Phlegraean Fields activity, to the contemporary pedotechnological era, through Roman, Mediaeval and Modern times. Such outcomes not only confirm the impressive relevance of soil in all the aspects of human life, but also highlight the intriguing traits and the proficiency of the multidisciplinary cooperation among Architecture and Soil Science.

1. The trunk of the “Orto di San Lorenzo ad Septimum”

Last year, the trees planted in the orchard of the Abbey of San Lorenzo were very small, almost unrecognizable. As these vertical wires are thickened, have begun to branch out and below spring leaves, flowers and fruits. The trunk, as Munari said, is the thick branch , because "every leaf on top of branches, has a tube that goes back to the trunk and keep in touch with the earth. With this tube sucks its nourishment: the trunk is the set of all these tubes, this is bigger than the other branches [1]. "The trunk is composed of several parts, the outer bark, protection of the plant that allows gas exchange needed for its life, the sapwood consists of living cells that make up the circulatory system, the book contains the vessels that carry nourishment synthesized; the exchange, the thin layer of tissue responsible for the production of the new wood; the heartwood, the inner part of the trunk, the most valuable formed and stable, the bone marrow, the central part of the trunk, generally not very differentiable from the heartwood that contains it; unmistakable, and concentric circles convertible in the horizontal section, link structures constantly in vertical section.

The trunk represents the height phase of the Landesign project "seeding in-formation into Faculty" and all the children from the schools of different levels are the tubes, mentioned by Munari, who visiting and doing creative sensory experience of knowledge in San Lorenzo's Garden in the Faculty of Architecture of the Second University of Naples contributes to give the project his lifeblood.

The university is the place to teach "universal knowledge", where "to concentrate on bringing intelligence", "educate the know" to form men who can "feel at home in any environment ... End the university will not is the creation of new genes, or political leaders immortal authors - although many of them arise within its walls - but you can form mature personalities, endowed with freedom, equity, moderation, peace and wisdom, "wrote John Henry Newman promoter and first president of the Catholic University of Dublin (1801-1890) in his book *The Idea of a University*. Newman called this kind of training 'liberal education', whose purpose is to train gentlemen. Newman aspired to an university education where each discipline was given taking into account the contributions of others and the general context where all belong; that education has in itself the ultimate reason of his "useful" education, which is required for each good moral life, but insufficient by itself to cause it.

The relevance of Newman's thought comes from the fact that his is not a model of university, but a model of education for person, able to the bottom with its personal implications of determining an attitude "of its own" in front of the world, to others, his conscience: for this, his "Idea of the University" is still a suggesting reflection.

The project starts with the idea of pursuing these conditions by opening the architectural spaces of the Abbey of San Lorenzo ad Septimum in Aversa in the Faculty of Architecture of the S.U.N. to children, youth, vulnerable groups, elderly and disabled, structured educational exploratory workshops open to schools of all levels and all those who want to participate in this shared project which acts to spread the love, care, respect, the value of their land, thereby making the design as a moment of collective around a table at work where children interact with students and teachers.

The 16 laboratories, grow a chemistry set; I investigate the earth; watch the sky; recognize the architecture; the clay model; supporting bio-energy; “green-gym”; experiment with bio-energy; dance and song tradition; vibrating with the sounds; drawing tastes; exploring flavors; eating well; seeding the city; collect, play, differentiated and recycling design, are designed and organized by a team composed with faculty members, experienced in teaching baby, research doctors, graduates, farmers, interns, college students engaged in the role of tutors, are aimed at school children and adults, divided into age groups (3-5y.o.; 6-11y.o.; 12-14 y.o.; 15-20 y.o.; 20-100 y.o.), group synergy of disciplines (science, technology, computer science, physics, Italian, history, art history, art and drawing, image education, physical education, anatomy, theory and composition, education and sound music, dance history, technology and farming techniques, art, civics, art and representation techniques, technology and computer science) and modulated sensory perceptions.

The format of the 16 laboratories involves three phases: *historically_* 'Benedictine Abbey of San Lorenzo; *naturally_* sharing the redevelopment of degraded with the project by seeding and planting trees in the Orchard of the Garden; *creatively_* the early phase introduced by tales, games and debate, leads to the elaboration of drawings, models, mosaics made from natural or recycled products on the themes of nature, and his extraordinary potential. At last children and teachers are called to give an assessment of the three stages of presentation, in-training and design of the laboratory report.

The project "seeding in-formation into Faculty," supports the student creativity, sport through lessons on the recovery of folk dances, concerts and evening parties in order to involve young people with the vision of musical performances at local, national and international musicians blending the traditional Italian cuisine with music, speeches responding to a renewed material culture, the needs of the body and person, its mobility, the criteria of sustainability and globalization with the help of technology and telematic. So are planned workshop activities and sport, attentive to the disability in respect of ease of management and regulations, accessibility, security, usability, comfort and environmental well-being, choice of materials and equipment "risk free".

The phase out of the project Landesign "seeding in-formation into Faculty" proposes to establish a network of virtuous school buildings who want to decline the project to restore degraded areas and to establish their own educational and exploratory workshops with the aim to achieve and maintain daily green spaces turned into orchards or gardens horticultural farming.

obiettivi

Insieme comprendiamo la trasformazione degli elementi naturali per scoprire i piccoli tesori della terra.

modalità [2 ore e 1/2]

Nel Laboratorio della durata di 2 ore e mezzo sperimentiamo la trasformazione della materia, partendo dalla raccolta di campioni di suolo e di elementi vegetali dell'Orto di San Lorenzo. Dopo un'analisi visiva e al microscopio, cataloghiamo gli elementi naturali, distinguiamo un fenomeno fisico da una reazione chimica, prevediamo il comportamento della materia, progettiamo e conduciamo semplici esperimenti per produrre benessere.

modalità [3 ore]

Il Laboratorio, della durata di due ore, è strutturato attraverso esercizi pratici-motori, supportati da un video delle attività. Riflettiamo insieme sulla conoscenza, sul funzionamento e sulla potenzialità del nostro corpo. Il Laboratorio si svolge nell'Orto di San Lorenzo per "ri-ascoltare" gli odori e i colori della natura.

[3-6 anni]: attraverso il gioco sviluppiamo la coordinazione e la mobilità.

[6-10 anni]: attraverso giochi strutturati consolidiamo ed ampliamo le attività motorie di base, sviluppando la coordinazione e la respirazione.

[11-14 anni]: attraverso attività motorie sviluppiamo la coordinazione specifica, oculo-motoria, oculo-podolica, della forza, della resistenza con obiettivi a breve e lungo termine.

[15-100 anni]: attraverso attività statiche recuperiamo e potenziamo schemi motori di base, miglioriamo la mobilità articolare e la coordinazione, sviluppiamo la forza e la resistenza garantendo risultati funzionali di benessere.

obiettivi

Insieme proponiamo progetti di smaltimento, trasformazione e riutilizzo dei rifiuti finalizzati all'acquisizione di comportamenti eco-compatibili.

modalità [2 ore e 1/2]

Le parole della poesia di Gianni Rodari "Un poco di prato... Signori architetti che fate progetti di case e palazzi di torri e terrazzi... Un poco di prato l'avete lasciato? Su, siate gentili: fate anche i cortili. Pensateci un poco ai campi da gioco... Lasciateci appena lo spazio, che poi a far l'altalena pensiamo da noi: sarà cura nostra farci anche la giostra" introducono alle attività del Laboratorio, della durata di due ore e mezzo, avvicinandoci con gli alunni alle problematiche dei rifiuti, al loro smaltimento, alla trasformazione e al riutilizzo. Con attività ludico-progettuali adottiamo l'Orto di San Lorenzo e produciamo "energia" per mantenerlo in vita; lo spazio diventa un luogo magico progettando e realizzando un percorso flessibile, dinamico, pronto ad essere modificato assecondando e riproducendo il ciclo della natura, utilizzando materiale di riuso.

obiettivi

Insieme giochiamo con i bambini per condividere storie sull'educazione ambientale e la sostenibilità.

modalità [3 ore]

Il laboratorio della durata di tre ore è incentrato sul tema della progettazione collettiva introdotta attraverso la narrazione, il gioco, la discussione e le attività laboratoriali.

Saranno parametri guida nella fase di progettazione le seguenti fasi:
Le mani dell'albero: Evanescente quanto trasparente, un telo si anima di colore quando le impronte delle nostre mani si uniscono a comporre un grande albero. L'orto siamo noi: Immagini e parole che scorrono sullo schermo ci raccontano la storia di un progetto, i suoi protagonisti e le loro motivazioni.

Naturalmente: Guidati da un esperto viviamo l'esperienza della natura ed impariamo a discriminare frutti ed ortaggi coltivati in facoltà.
Creativamente: La magia dell'illusione ci introduce alle "bizzarrie" di Arcimboldo: giochiamo a creare volti con le sagome di vegetali.

2. The branches of the “Orto di San Lorenzo ad Septimum”

Hugo Cabret, the last great movie by Martin Scorsese, it's an extraordinary metropolitan tale.

The town is represented as a gear whole and each castor means something inside and between the others. If the machine go stuck the only way to unblock the instability of the “urban system” break, it's the love: that driving force that heals every neurosis and disease in man and in the city. Children are given the task to act for common good, to control the flow of time, to switch passivity and resignation in excitement and concrete actions to regain possession of the past accelerating ethical and poetic conversion. In some large contraption jammed cities rotate large attractors / detractors and a series of smaller widespread wheels: the schools, places where children spend most of their time, are usually gray, sad and resigned places, which will certainly affect the scope and immensely perceptive and emotional in every single child, which becomes adults in amorphous areas, with the risk of an addiction to bad, forgetting that, to quote Fierbach "we are what we eat" (with eyes, ears, nose, touch, taste).

The applied research led with students of Urban and Environmental Survey of the fifth year of Architecture and architectural design Laboratory of the first year aims to rethink the city focusing on the redesign of outdoor areas, particularly schools as priority anchors for re-composition of the urban mosaic. Downstream of several memoranda of understanding between the Faculty and schools, with students, pupils, the children clean up the voids municipal solid waste, we adopt the school, we design and build "smart gardens": priority areas for reasons of external brevity (proximity to the Faculty, the residence of students, particularly disadvantaged places and needy immediate concrete actions).

"Landesign: from Gardens of San Lorenzo to the “smart-gardens ” is a process of co-design and co-production: degraded areas of the city become resources, raw materials for redesigning spaces and minds, the square and people are plus ethical and aesthetic value, declining the good practice implemented in the Garden of San Lorenzo, home of our Faculty of Architecture.

L.A.N.Design [Local Area Network Design] is therefore to reflect, share, draw, tell, spread the wealth of resources in people and things.

Local, in the sense of a project that has its roots in the place of reference in which the land, with which and from which to extract traces, signs, fragments, for the design of places that become events;

Area, soil resources the common good, limited non-renewable, physics surface that we see, touch, hear, taste, we perceive;

Network, as a network of meetings, incentives for real people who share a path of making it part of their land according to a fractal metaphor.

We begin to change the color of the landscape, with students of design, thinking the interior. We enlive along the corridors, classrooms, gyms, cafeterias, a participatory process that acts to change - developing it - the concept of design, not classifiable with the product life cycle "project, production, sale and consumption" (De Fusco, 1990).

In this renewed ethical dimension of the urban areas involved in emotion found in which the beauty becomes inducer of comfort, but also social. The Vitruvian triad (form, function, technical / feasibility) and the three dimensions that fall in physical assets (economy, ecology and emotion) are the basis of a positive process for you to take root in the Garden city, town and give himself to be a good practice to decline in the empty school buildings, aware that the space (the city, the school) is about us.

We want that "observed the flavor of the green, and not see the black waste; listen to the scent of the leaves, and not hear the noise of car horns; enjoy the story of the lettuce and not eat a bar code; breathe the color of nature and not smell the ignorance, neglect; tap the sound of the earth and do not click on a pc mouse"[1].
