Peer review Scholars has been invited to submit researches on theoretical and methodological aspects related to Architecture, Industrial Design and Landscape, and show real applications and experiences carried out on this themes. Based on blind peer review, abstracts has been accepted, conditionally accepted, or rejected. Authors of accepted and conditionally accepted papers has been invited to submit full papers. These has been again peer-reviewed and selected for the oral session and publication, or only for the publication in the conference proceedings.

Conference report 220 abstracts received from:

Algeria, Brazil, Bulgaria, China, Cuba, Denmark, Egypt, Estonia, France, Germany, Greece, Holland, India, Indonesia, Iran, Italy, Japan, Jordan, Kosovo, Malaysia, Malta, Mexico, Netherlands, New Zeland, Poland, Portugal, Puerto Rico, Russia, Saudi Arabia, Spain, Taiwan, Turkey, United Arab Emirates, United Kingdom, USA

More than 350 authors involved.

163 papers published.

Preface

Less, often leads us to reducing considerations and its linguistic application, generally, characterizes a condition of inferiority, decay or deprivation. If we make reference to the scope of our researchers, Architecture, Industrial Design, Landscape and to their deeper meanings, and if we use “less” before them we might involve a critic situation, or homologate a century.

An example is from the historical period we are living in, where Western economies are generically dealing with their budgets by cutting down on expenses rather than investing on their own heritage in order to create richness and workplaces.

On the contrary, our Researchers, Scholars, Businessmen and Civil Services Representatives want to use less to promote a shareable cultural reflection about the reduction of the waste of goods (raw materials, human resources, assets). That’s why we are going to arrange the X International Forum “Le Vie dei Mercanti”. In this perspective Less does not mean less investments or cuts, but to identify a hierarchy of relevant sustainable investment funds based on the search for the know-how.

Less in Architecture, Less in Industrial Design, Less in Landscape subsumes more if we are able to supply regenerative models based on integrated system visions.

Consequently, More research in Architecture, More research in Industrial Design, More research in

Landscape if Local Human Resources are set up to create an efficient training education to be involved in the management, protection and regeneration of raw materials and human needs.

All along the past editions of the Forum I have drawn people's attention on our heritage as expression of "actual developing" (modernity).

Modernity, in fact, is an integrating part of history, an inexhaustible mine supplying raw materials to the Factory of Know-how which, as mentioned above, must get the same local physical geometric connotation as the generative humus about the production of fascinating items for Architecture, Industrial production, Landscape.

The projects our Faculty has dealt with, "Pompei Fabbrica della Conoscenza 0079/2013" or "l'Atlante del Cilento", witness as by sizing tangible and intangible heritage we can give rise to a productive factory aiming at art works and competitive Cultivated products and services.

So, scientific contributions aiming at collecting and spreading out the best practices and paradigmatic sustainable projects about system activities and elaborated in an assembly International dimension, are expected. Such contributions must be useful at enhancing an increasing Research process characterized by a constant learning and a great Know-how passion.

Less/More Architecture, Design, Landscape

Carmine GAMBARDELLA

ARV Architettura Luigi Vanvitelli, Seconda Università di Napoli, Italy
carmine.gambardella@unina2.it

The “Le Vie dei Mercanti” Forum is now in its tenth edition. I would like to recall the reasons for the title, chosen the first time ten years ago to address the climate of cultural fervor that during the Renaissance, through its calculations, inventions and economics managed to define a new way *ante litteram* to combine scientific research and business. The merchants, in the middle of the fifteenth century, at the margin of international trade, united research and training in new ways, realising the value of the territory as a resource, promoting the redevelopment and reclamation of wasteland. [1]

Luca Pacioli, a versatile figure and best known as author of the essay *De Divine Proportione*, as tutor to the Venetian family of merchants, Rompiasi, invented the double entry in order to not only create a language to be shared by both researchers and the outside world but also to produce wealth and assets by applying the concepts of proportion and proportionality to economic development. [2-3]

Fig. 1: *Pacioli e Leonardo alla corte di Ludovico Sforza.*
Fresco by Nicola Cianfarelli, 1841.

Humanism succeeded in integrating good governance and knowledge that, in the declination in physicality, took shape in the City and Renaissance Architecture. A global project of society that led to the *Res Publica* of statesmen such as Coluccio Salutati and Leonardo Bruni, the mathematician Paolo dal Pozzo Toscanelli, to name a few, Leon Battista Alberti, who reminds Paolo of the ancient lesson, with innovation not only being of *homo renatus* but also *homo civis* in a single consideration that goes from *De Re Aedificatoria* to the *Libri dell'Economia*.

The conference venue, the island of Capri, is the same as where the first “Conference of the Landscape” was held 90 years ago, in July 1922, organized by the Municipality of Capri, with the then mayor being the engineer and writer Edwin Cerio. The politician Giovanni Rosadi, undersecretary of Fine Arts, and promoter of the law in defense of Antiquities and Fine Arts dated June 20, 1909, inspired the Congress as well as supported the work of the Cerium,

The “Conference of the Landscape” was the most important cultural event held on the island of Capri in the first half of the twentieth century, and was attended by eminent speakers such as the Deputy Director General of Fine Arts, Luigi Parpagliolo, the Secretary to the Prime Minister Giovanni Porzio, as well as Filippo Tomaso Marinetti, author of the famous Futurist Manifesto. [4]

The conference ended with the approval, unanimously, of several orders of the day. One of these, presented by Filippo Tomaso Marinetti, and Luigi Parpagliolo, condemning the continuous disfigurement of the Italian landscape, expressed the commitment, while recognizing the needs of modern life, that the use of new materials and construction methods respected the environment and were in harmony the local landscape.

Another appealed to the Ministry of Education to study the possibility “of a least weekly propaganda” that, beginning in elementary school and continued into the middle schools, spread “the cult of heritage of the beauty of Italy”.

Fig. 2: Ruins of the Certosa in Capri. From: E. Cerio, *La casa nel paesaggio di Capri*, Ed. Alfieri e Lacroix, Roma 1922.

These are cultural references which the Forum recalls, as denounced 90 years ago by the First Congress of Landscape, with the resolutions that were unanimously approved having been completely disregarded. They can still be considered targets of primary importance both with regard to the fight against the disfigurement of the environment as well as the need for public education, starting at school, and respect the protection of the landscape and the environment at all levels.

In the current era characterized by the economy of knowledge, the cultural identity of places is an essential asset in the learning process in order to raise human capital as well as render the territory competitive and attractive. The identity of places is the result of the memory of ancient traditions and knowledge as well as the material evidence of the past that has shaped its physical form.

In order to preserve historical continuity, guaranteeing man a better living environment, a balance between the spaces of the past and present needs should be created, offering innovative solutions to meet the different needs in terms of sustainability.

The historical centres, monuments and even the degraded landscapes are the raw material of our investigation, the *hardware* on which the consideration and integration of the competencies act like a *software* to develop a repertoire of solutions appropriate to return to those areas of the community through a protective regenerative action.

In this context, international confrontation is vital so as to share virtuous examples of the protection and management of monuments, sites and historic environments, in which conservation and development coexist in positive role models and that can be exported to other contexts.

Hence the reasons for the choice of the theme of this year's Forum, *Less/More Architecture, Design, Landscape*.

Less, almost always leads to reductive considerations and its very linguistic application, for the most part, characterizes a state of inferiority, degradation or loss. In fact, when referring to the areas of interest, Architecture, Industrial Design, Landscape and other categories that include these terms, *less* could mean a state of crisis, or approval to an era, like the one we are experiencing, in which the economies of Western countries are aimed at readjusting their budgets by cutting their expenses, rather than investing in its assets to create wealth and jobs.

With *less*, however, we want to foster a common consideration of academics, researchers, entrepreneurs and representatives of the Public Administration on the creation of a development based on the reduced waste of Assets (raw materials, human capital, resources). In fact, *Less* does not mean less investment or general cuts, but rather the identification of a hierarchy of significant investments supported by knowledge.

From *Less is More*, Mies van der Rohe's motto and rationalist architecture, we take the idea of an architecture based on material honesty and structural integrity, but expanded, assuming the idea of an honesty in investments as well as in the realization of objectives truly capable of being the driving force for local development, and above all integrity in design ethics.

We also agree with his idea of shortening the distance between professional and research activities, and his words on architecture as a tool to educate young people. "The aim of architecture is to educate architects with the necessary knowledge, but also to train man educating him, and enabling him to make the right use of the knowledge acquired. Thus, teaching is aimed at a practical purpose, while education aims at values. In fact, the meaning of education is to train and mobilize, it must counter those personal opinions that do not undertake the obligation of exact knowledge, it must lead from the sphere of the arbitrary and random balance to that of clarity of a spiritual order".[5]

From the more recent, *More with Less*, reworking the motto of Mies by the Spanish designer Campo Baeza, to emphasize his research on essentiality through a subtraction of material and addition of significance, we take the idea of rigor, to avoid the excessive and ephemeral in favour of truly innovative solutions that can meet the needs of man and enter into a relationship with his environment and culture.

More with Less also deals with the issues of sustainability, where living spaces, designer goods, orchards and gardens, introduce new ways of behaving in search of a balance between man and nature, demand and resources, in a time when everyone is becoming aware of the environmental, economic and ethical unsustainability of the lifestyle that has characterized the West over recent years.

Attention should therefore be directed to the great mines that surrounds us, the raw materials of the *Knowledge Factory* that are the resources of the territory in which we live and work which, if crossed by

knowledge, can produce attractive products as well as a competitive global marketplace, guaranteeing work and quality of life.

The *governance* of the production cycle, understood in its regenerative and modifying action of the infrastructures, landscapes and products can only be substantiated if the complexity of the values of our identity are discretized and measured by knowledge, in their dual activities of multidimensional knowledge of the physical produced and to be produced, and returned as a heritage to citizens and stakeholders of the territory to take up economic activities at different scales of sustainable investment. This results in products that will be more valuable, the higher the degree of knowledge that can be transferred to any part of the production cycle is.

The city of the future, therefore, is characterized more and more by the city of the present, as the town planner Italo Insolera recalled, [6] in a future that has an ancient heart, where the roots of the genetic heritage of our sites are the reassuring refuge and fertile soil to envisage innovation that does not transform it actually changes, sharing the organic, natural and evolutionary culture, and therefore always contemporary, which, against every transplant of predetermined patterns, accompanies a regenerative stem cell function, because it is removed from our own identity.

Less in Architecture, Less in Industrial Design, Less in Landscape, includes the *More* if we are able to provide regenerative models, based on integrated visions as well as the system.

Therefore, *More research in Architecture, More research in Industrial Design, More research in Landscape*, means preparing the Human Capital of the Territory through effective training in order to be included in the management, protection and regeneration of the raw materials as well as the needs of those who live in Cities and Territories.

Since I strongly believe in the importance of training, the students of the Faculty have been involved with these issues throughout 2012, through a series of meetings, national and international, with planners, designers and landscape architects. The aim of these meetings was to avoid any academic self-referentiality, offering students the opportunity to meet with those working in architecture, industrial design, landscape, as well as explore different points of view and experiences.

Even the choice of hosting the first day of the Forum at the Faculty, intended as the final event of this year of reflection and research on the theme of *Less/More*, aimed to involve our young people and open them up to the experiences presented by researchers from around the world.

Fig. 6: Some of the meetings organized about Less/More Landscape.

As for the practical experience, the example of the projects carried out by our Faculty, “Pompeii Knowledge Factory 0079/2013” or the Atlas of the Cilento, show that starting from a measurement of the tangible and intangible heritage of the places, it is possible to transform the environmental resources of an economic income into sources of environmentally sustainable development, not only in relation to the knowledge of the potential within the territory, but also in stimulating the competitiveness of values between territories. [7]

The studies, analyses, measurements and projects on the city of Pompeii carried out by research groups from different subject areas in constant synergy under my supervision, analysing the territory according to multiple perspectives, will shortly be published in the Atlas of Pompeii. In the realization of these volumes, I have interpreted the word Atlas in its broadest sense, as a “complete and orderly collection of information relating to a particular science, bound in one volume”, configuring it as an “Atlas of Knowledge”, which analyzes and integrates knowledge, multidisciplinary research and studies in order to produce a reading of the territory as a whole.

The territory, in the case of Pompeii, is not only the enclosed archaeological site, but rather the whole city, the carrier of critical elements, with an enormous potential to expose and valorise it. It has a huge touristic and cultural value (2.5 million tourists a year visit the archaeological excavations, and 4,000,000 pilgrims a year visit the shrine of Our Lady of Pompeii), but burdened by severe problems arising from the current form of tourism, that in the absence of sustainable planning has damaged the heritage and local identity, without bringing wealth and prosperity to the local inhabitants.

Thus, a vast and diversified territory was analysed, on which even to study only the geometric and morphological aspects, it was necessary to use different methods and technologies, each in the context in which it was more appropriate: from the archaeological area to the monumental buildings, from the urban centres to the suburbs.

The research was carried out as if a test on the integrated use of experimental measuring techniques and equipment, a field laboratory to develop a validated integrated multidimensional and multi-scalar digital methodology that can be used in other contexts .

These investigations were supported by the contribution of the other specific areas: for example, historical research and archives, which have allowed us to formulate novel hypotheses on the evolution of the territory of Pompeii before the first archaeological excavations were carried out, monitoring of the environmental and noise pollution and the designing of soundscapes; structural investigations on different types of building to design environmentally friendly design protocols for the recovery and rehabilitation of historic buildings; investigations on the seismic safety levels; the study of an integrated sustainable transport system and the

generation of electricity (from art greenhouses and solar parks) for a better use of the cultural and tourist area of the excavations.

The studies can be of great use for the protection of the site. The collapses that have repeatedly affected the archaeological area of Pompeii in the last months have sparked much debate on how to protect one of the most important sites in the world, a UNESCO World Heritage Site.

The call for projects for the Great Pompeii Project has finally been published, with the intention of being an integrated regional development project which, apart from the necessary protection and enhancement of the archaeological site, is an attempt to attract a growing tourist demand as well as business initiatives to the area.

Our group has already been working for several years on research in this direction and has carried out an aerial scanning of the area with a Daedalus AA3500 sensor, which has allowed us to detect and map the presence of water on the surface, obtaining an accurate representation of the conditions of the site on the days when the collapse occurred in the House of the Moralist.

Faced with the deterioration of many cultural and natural sites of our country, we should begin to discuss less and do more.

Less or More. Evolution of the concept of measurement and its precision

Manuela PISCITELLI

ARV Architettura Luigi Vanvitelli, Seconda Università di Napoli, Italy
manuela.piscitelli@unina2.it

Abstract

The measurement problem can be considered as exemplary of the evolution of science and thought over the centuries.

If the measuring of space means to assign numbers and symbols to describe its properties, it is evident that the measurement problem cannot be separated from the perception and meaning attributed to the surrounding world. For modern man, space is an accessible reality, homogeneous and measurable; for ancient man, it is a rugged terrain, uneven and symbolic.

Not surprisingly, primitive measuring had a significant nature, expressing something human, symbolic, tied to the anthropomorphic characteristics or conditions of life and work. On the contrary the meter, modern unit of measurement, is connected to the dimensions of the terrestrial sphere and is devoid of further meanings or references in addition to that of a unit of measurement.

The procedures and results of measurements depend on the philosophical, economic, political and cultural context in which the operations are carried out and the conclusions reached. The language adopted from the respective communities to represent the whole of knowledge are valid in a particular historical moment, and change over time in relation to the cultural and social climate, as well as the techniques used to measure and represent reality.

Even the concept of measuring precision depends on the historical period, not only for the obvious evolution of tools and measurement techniques, but also for the evolution of thought and creation of a suitable language to express the results.

Keywords: measurement, anthropomorphic unites, precision, survey, standardization.

Oportet enim rationem mensurae ex mensurato accipere
Tommaso D'Aquino

Introduction

Measuring, in general terms, can be defined as "the assignment of numbers to represent properties". To describe in this way a phenomenon, it is necessary preliminarily identify the unit of measurement required to describe it.

Any measuring operation implies a degree of uncertainty in its result. Knowing how to properly evaluate the uncertainty of a measurement is essential both in science, to fix the limits of validity of the theories describing natural phenomena, as well as in technology, to assert the reliability of products and procedures.

The ISO standard states that is meant by measure the series of operations that produce the determination of the value of the quantity subjected to measurement, and highlights how uncertainty is an integral part of the result.

“The objective of a measurement is to determine the value of the measurand, that is, the value of the particular quantity to be measured. A measurement therefore begins with an appropriate specification of the measurand, the method of measurement, and the measurement procedure. In general, the result of a measurement is only an approximation or estimate of the value of the measurand and thus is complete only when accompanied by a statement of the uncertainty of that estimate”. (ISO, 1993, 4).

The problem, however, is not only of a technical nature, in the sense that the major or minor accuracy of the measurement depends not only by the unit of measure and the instruments available. The measurement problem cannot be separated from the perception and meaning attributed to the surrounding world.

For modern man, space is a reality accessible, homogeneous, measurable; for ancient man, it is a rugged terrain, uneven and symbolic. Not surprisingly, the primitive measures had a significant nature, expressing something human, symbolic, tied to the anthropomorphic characteristics or conditions of life and work.

The Egyptians, for example, first elaborated anthropometrical canons, and the first measurement unit derived from the dimensions of the human. The Egyptian unit of measurement was the cubit, tied to the length of the forearm and probably derived from a cord coiled between the elbow and thumb, used to measure the fields after the flooding of the Nile.

The meter is connected to the size of the terrestrial sphere (in its first definition, it was considered the equivalent of the ten millionth part of the arc of the meridian between the North Pole and the equator). The reason for this choice was to use a unit that had nothing arbitrary or specific to any nation on earth.

Later, the meter was disassociated from the size of the Earth, since 1960 with the definition of the meter as a multiple of the optical wavelength of the light emitted by the krypton 86th isotope. In 1983, it was again redefined as the distance covered by light in vacuum during a defined time interval. The meter is now a derived unit, while the second, as in the pendulum-second, is the real "measure of all things".

This has passed from a plurality of units on the same category of measurement to a unique mathematical language to measure and express the notion of space and time; borrowing the words of the famous essay by Alexandre Koyré, to be passed "from the world of approximately to the universe of precision". [1]

Harakhty the god, lord of heaven, is standing above a cubit.

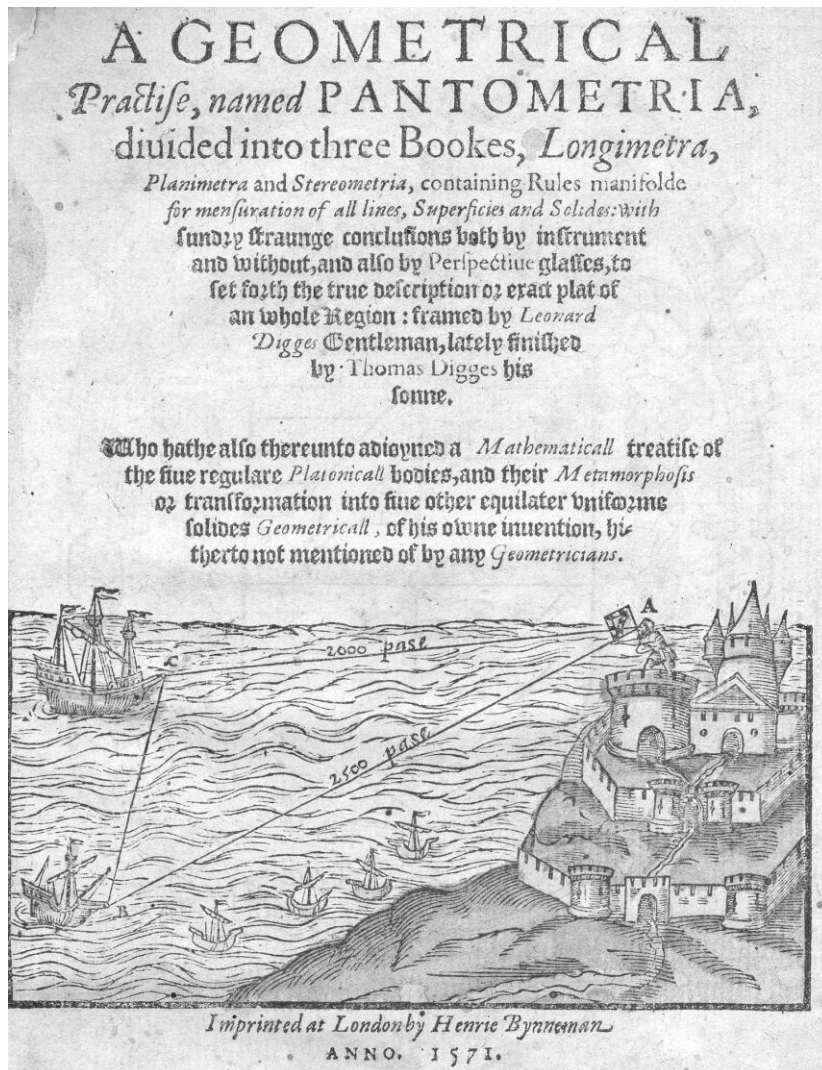

Fig. 2: Pantometria, by Thomas Digges, 1571.

Evolution of the concept of measurement

Measuring is one of the most ancient human social practices, and at the same time, one of the most advanced achievements.

According to the historian of metrology Witold Kula, the process through which concepts are formed on the measures is an essential component of the evolution of human representations of the world, forming classification systems and abstract concepts. [2]

The language adopted from the respective communities to represent the whole of knowledge are valid in a particular historical moment, and change over time in relation to the cultural and social climate, as well as the techniques used to measure and represent reality.

In all societies, to dispose of measures is one of the characteristics of power. This means to confer to measurements, a reason to be law, and manage samples of units, that often in the ancient world had a sacred character. Samples of measurements, which had dedications to the gods, were kept on the Acropolis of Athens and the Capitol in Rome. Moreover, among the public office of the *polis* there was the *verifier*.

The need to preserve samples of weights and measurements to be a national reference, marked with inscriptions in the name of the king and deposited in the main temples, was recognized at least since 2000 B.C. The artifacts found during excavations in Egypt and many other places, confirm how important it was in ancient times, from a practical point of view, to have a standard of weights and measurements of space and time in commercial trades.

Fig. 3: Reel, XVI century.

The first stage of metrology (the science of measurement), which began in the early days of civilization, and was only really concluded with the birth of modern science, has been characterized by highly heterogeneous anthropomorphic units, both in the methods of measurement and in the representation of the measures. Measurements were initially identified by concrete representations, and therefore subjective, and only later passed to abstract concepts. [3]

Next to lines or notches present on isolated bones or objects in stone, we can observe the appearance of signs. These annotations represent the first rudimentary representations of measurements and conceptually precede the invention of writing. Scholars hypothesize that soon there was a link between having an even rudimentary ability to measure and the possession of power.

The knowledge that Western civilization had of the quantification, dating back to Neolithic times, took centuries to become a genuine intellectual passion. Ptolemy, Euclid and other mathematicians of the ancient Mediterranean were devoted to issues related to measurements and mathematics, but few were able to access, in the early Middle Ages, to such works.

In the sixth century B.C., Pythagoras discovered that musical harmony depended on relations between small integer numbers, and concluded that everything in the universe was a Number. However, the birth of mathematics is related more to the solution of practical problems, than the need to measure. If it is obvious to us that the material world is intimately linked to that of mathematics, this was not so for the Ancients. Although it probably had its origin in mathematics from the practical necessities of measurement, they soon diverged. The weight calculation and surveying were considered tangible assets, while mathematics was abstract, mysterious and perfect, enough to become part of religious orders and mystics.

From that point, pure mathematical sciences and metrology became separated sciences. The first belonged, according to Plato, to philosophy, and allows to reach the truth. The second instead was part of transient things such as war or trade, which required mathematical knowledge to perform practical operations.

Plato advised to turn away from the material world, and seek beauty, goodness and absolute virtues, to the triangle, square and circle ideals, abstractions that exist independently from the material world. He was certain that the knowledge of such entities could be reached through the intellect, starting from the study of mathematics. Plato advised the philosopher-kings to study mathematics to arrive, with the help of pure thought, to contemplate the real nature of numbers. [4]

Fig. 4: Cross-staff, XVI century.

The consequence of this separation of a knowledge considered abstract from a practical one, implied the absence of interest in an exact measurement of the physical world (space, time, weight, etc.).

Moreover, the ancients were able to measure, as demonstrated by the precision of the design of the base of a column or a capital, and also possessed measuring instruments based on the same principles of current survey instruments, as proved by a theodolite drawing handed down by Vitruvius.

The Greeks, like other civilizations, also observed and measured the sky with surprising accuracy, using measuring instruments and calculations, and assuming that the motions of the stars were subject to the laws of mathematics and geometry. However, they have not attempted to apply the same geometrical and mathematical rules to the measurement of the terrestrial world, except through art and architecture.

According to the text of Vitruvius, the Greeks already used some instruments to perform accurate measurements on the elements of their temples. The cross-staff was a measuring stick with a movable rod placed at a right angle: taking the measurement of angles and combining it with the prescribed distance between the measuring points, it was possible to calculate the height of something that was not directly accessible.

The birth of the Greek colonial system marked the beginning of a new relationship with the territory. Colonization implied in fact, along with taking possession of a territory, its measurement and distribution in equal batches according to a geometric plan. During the colonial period in the Italy, the Greeks realized an efficient road system, which required a knowledge of the topography of the area. [5]

However, even then the Greeks were not able to describe scientifically the subjected area, mainly because their geography continued to have as a privileged point of view, the vision from the sea, that was materialized in the production of those species of archaic pilot books, the *Periplus*. The Greeks perceived space as one-dimensional, like a series of paths that were developed in a single dimension; hence the production of the *periplus* without indication, that signaled only the succession of points along the path. Not having an understanding of space seen from above, as in a map, resorted to long detailed descriptions of territories. [6]

The political particularism of ancient Greece was reflected faithfully in the particularism of measures and weights. The new *polis* created their own samples as a symbol of their sovereignty, while to captured city the winners imposed its own measures as a symbol of their dominion. The measures standards differed in varying degrees, in relation to the various city-states and the historical period. For example, the length of the foot in the different regions ranged between 27 and 35 cm.

The systems of weights and measurements of the ancient oriental empires, from the valleys of the Tigris and Euphrates, were adopted by the Greeks and, later, passed to the Romans. These, in turn, extended their procedures for measuring to the whole European continent, and consequently many features of the measurement systems used in modern times reflect the Roman system.

The definitive consolidation of metrology is due to the Romans, and in later centuries it was essentially preserved in the various countries of the West, although with large local variations.

One of the reforms intended by the Emperor Augustus (27 BC - 14 AD) was the unification of local measurements in use in all the territories of the empire with those of Rome: this led to the introduction of the foot, corresponding to 29.65 cm about; it became the basis of both surface and volume measures.

Fig. 5: *Graphometre in use*. By Danfrie 1597.

One of the main applications of measurements was in surveying, the measurement and division of the land, according to geometrically regular schemes. These operations were carried out with a special instrument, the groma, only found complete in Pompeii. To measure the miles traveled by vehicles and vessels, there was a rather complex mechanism with paddle wheels, called odometer, known only through literary sources, especially Hero and Vitruvius.

Abstract mathematics and practical metrology, even if joined by some figures of classical civilization such as Ptolemy, remained separate throughout the Roman Empire and even more in the Middle Ages. In the Middle Ages, the time is not seen as changing and evolving. Every reality is perceived as stable and solid. Even medieval space agrees with these purposes: there is not a measurable and equal space, preexisting to human actions. The moral dimension explains and justifies everything. Medieval man cannot imagine space and time devoid of human action, preexisting and autonomous, and therefore does not attribute them the characteristics of homogeneity and measurability that we consider intrinsic. The medieval geography is a moral geography, as exemplified by the representation of Dante's world: centered on the holy city of Jerusalem, excellent place for the concrete signs of God's presence; under the earth's crust, the great chasm created by the fall of Lucifer. [7]

Medieval images, paintings, miniatures, sculptures are striking due to the disproportion between the environment and figures. The figures seem flattened in an environment represented much smaller than reality, without regard to the perspective of vision.

In this context, the master builders of Gothic cathedrals, which raised buildings of beautiful proportions and great strength, represented somehow an exception; however their geometry was purely practical.

Fig. 6: Theodolite. Erasmus Habermel, Praga, XVI century

They did not know of Euclid, but practiced geometry by combining a few basic shapes: triangles, squares, circles. Their patrimony of knowledge was transmitted orally, and measuring was up to the master builder who, pointing to the stone with the stick, symbol of his role, indicated where to cut. [8]

Around 1300, there was a significant change, especially in practical applications. In those years, the first mechanical clock and the first cannon were built in Europe, means that forced the Europeans to think of time and space in quantifiable terms.

The pilot books, pictorial perspective, the double-entry bookkeeping are all indices of change in the way of measuring and representing measurements.

During the late Middle Ages and the Renaissance, a new model of reality emerged in Europe: it was a quantitative model, able to replace the old qualitative model. Copernicus, Galileo, the artisans who became experts in the construction of cannons, the cartographers who mapped the coasts of the earth just known, the bureaucrats and the businessmen who administered the new empires, the bankers who controlled the new cash flows, they all thought of reality in terms of quality. [9]

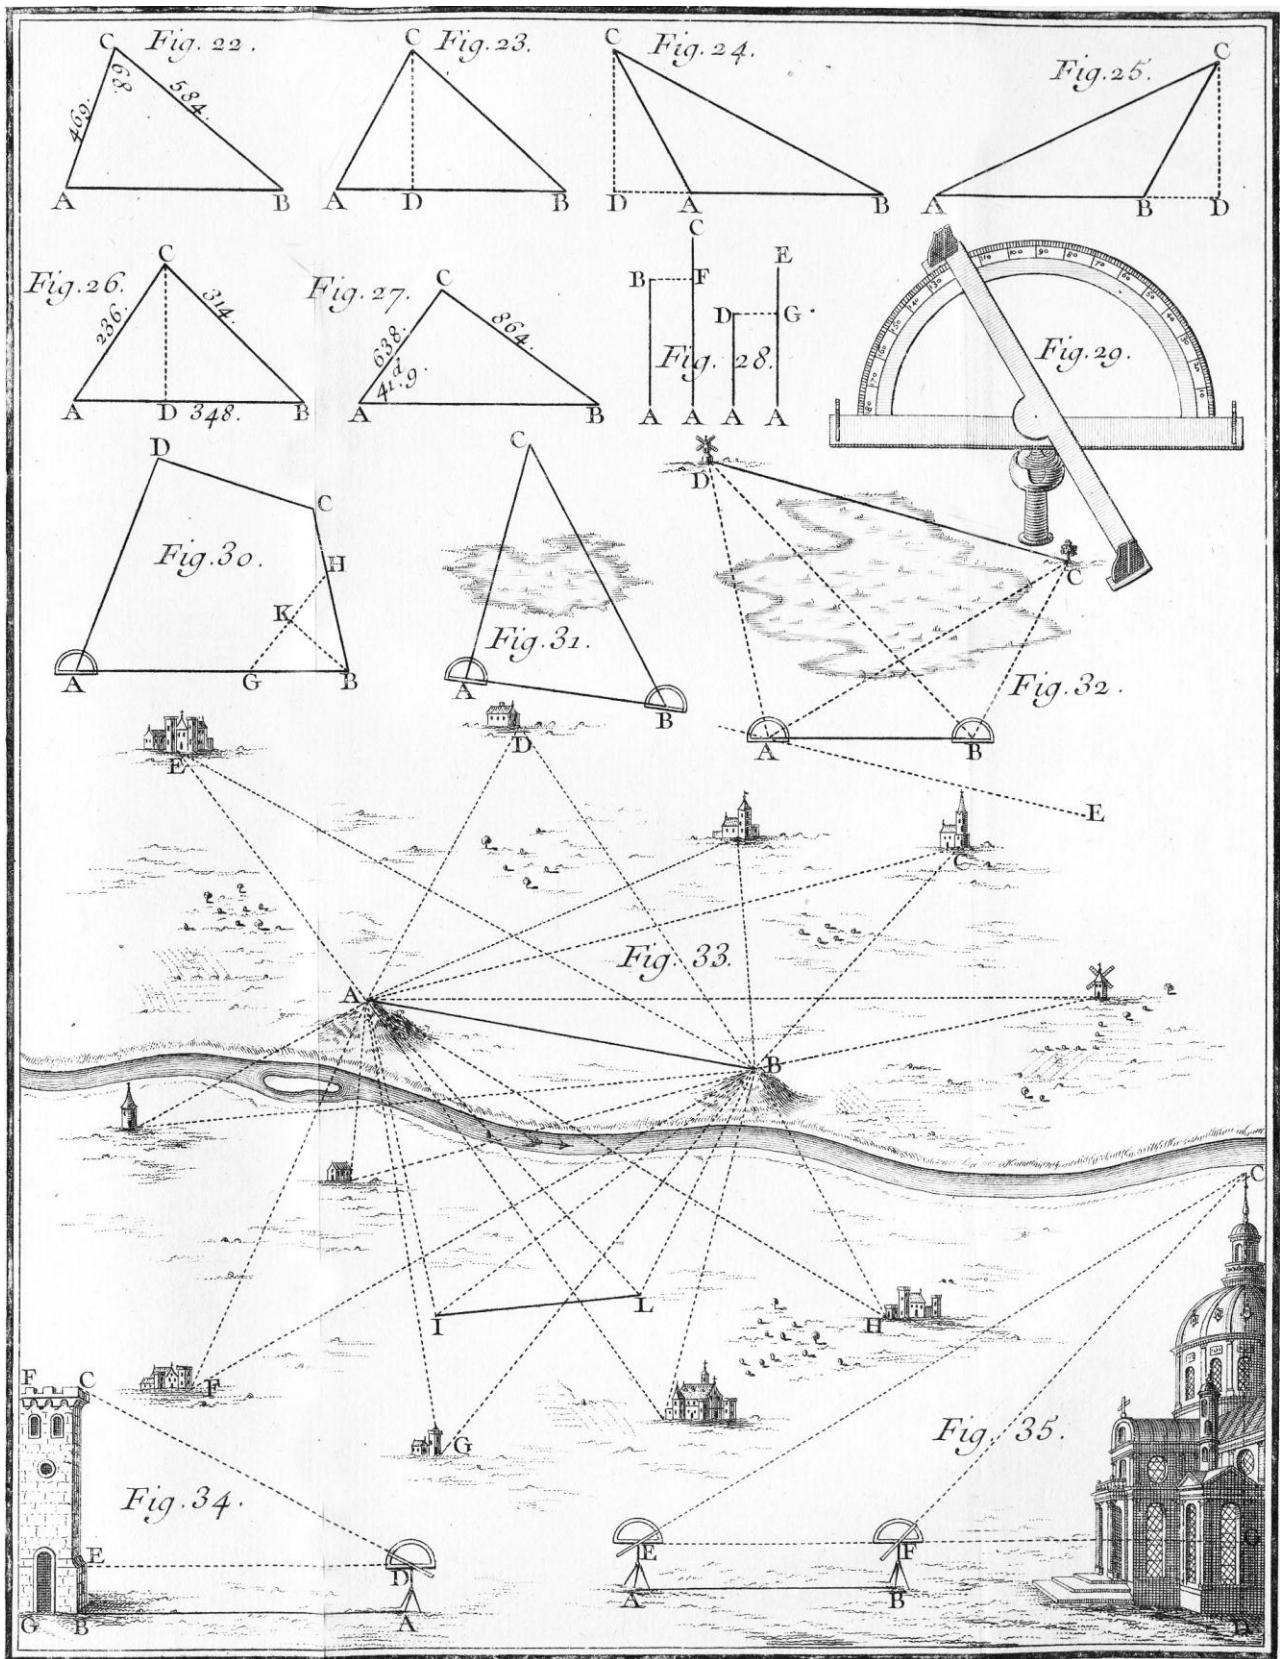

Fig. 7: Surveying. By Deparcieux, *Nouveau traites de trigonometrie*, 1741.

The measurement standardization

The problem of measurement units unification, however, was approached in a serious way only in the time of the French Revolution. In 1790, the National Assembly began the first attempt to build a system of universal measurements, with the declared intention to be "for every people, for every age."

The task of setting the units and samples of the fundamental length and mass was assigned to a committee of eminent scientists.

Even before being adopted in France, the metric system was seen as a future international institution: the committee hoped - and time has confirmed this hope - to get it accepted in all countries of the world.

Condorcet continued to consider as the main objective of the reform its universality: in his view, the reform should not have any particular or national character, so it can be accepted by the whole world. For this reason, the measurements were to be "taken from nature". Nature, in fact, especially for philosophers of the Enlightenment, was common to all peoples and was considered as a unifying element.

The metric system, in contrast to all the measuring units previously used, had as a basis the most reliable and available scientific principles at the time of its invention. It was conceived in order to satisfy the new requirements emerged after the development of commerce and industry. The civil commitment that characterized the Enlightenment was certainly behind this massive effort aimed at resolving in practical ways the problems of daily life.

From a historical and social viewpoint, the metric system marks an important stage for humanity towards the goal of a global common language for understanding, communication and mutual cooperation. The meter, "dehumanizing" measurements, making them independent from man, "objective" to him, morally neutral, becomes a medium that can facilitate understanding and collaboration among people .

Setting the measurement units and the methods for their exact representation, the evolution of the measure has now become a matter of available technology, as meaning that the evolution of the instruments for the survey not only allowed a more exact knowledge of the geometrical and dimensional characteristics, but also to go beyond the visible range in order to investigate inside the structures and highlight failures, degradation, or material not visible from the outside.

The problem of the surveyor is no longer how to obtain data, but is the contrary, how to filter and interpret the enormous amount of data on a single object. The measurement accuracy has become an operator choice, when it sets the tools tolerances for that single survey, or transfers data. The ISO standards, at the same time, have created a coded and global language, shared by all, as they had imagined at the time of the French Revolution.

What perhaps today is lost, is the "poetry" implied imagining that the world can be measured with the human feet, arms, fingers.

Fig. 8: International Prototype Meter standard bar, made of platinum-iridium, used as standard until 1960.

A "laboratory" open air in the urban landscape of Palermo

Francesco DI PAOLA

DARCH Dipartimento di Architettura, Facoltà di Ingegneria, Università degli Studi di Palermo, Palermo, Italia
francesco.dipaola@unipa.it

Abstract

The study intends to make new contributions to knowledge of a interesting "laboratory" in the open air in the urban landscape of Palermo, a cultural and scientific heritage in which architecture, art and decoration coexist in an experiment of collective synergies.

The Botanical Garden Center, with its ten acres of land appears, still, a fervent creative process between artifice and nature, the expression of a specific historical and cultural climate in which expectations converged of a intellectual, scientific and institutional fervor.

The academic institution, founded in 1789 with the intention of cultivating useful plants to the arts, crafts and medicine, contributed to the spread of tropical tree species introduced later, in parks and gardens, public and private, enriching the natural heritage and transforming the landscape of the sicilian coast.

The fifth stage overlooking the garden consists of a unique architectural complex that is articulated in a central amphiprostyle doric building a square plant, the *Gymnasium*, and two lateral buildings, arranged symmetrically, the *Tepidarium* and *Calidarium*, a rectangular plan designed by Dufourny collaboration with local architects such as Pietro Trombetta, Domenico Marabitti and Venazio Marvuglia.

On the basis of a precious monograph of the architect G.B.F. Basile, you will critically revisit all the buildings, full of stylistic features of the greek temples and symbolic codes siceliots of the masonic Enlightenment, the first example of neoclassical architecture in Sicily. In particular, using the latest topographic non-invasive and photogrammetric technologies in acquisition, development and exploration of metric data, we report unedited representations of some devices that characterize the monumental work.

Key words: neoclassical architecture, conservation, 3D modeling

The architectural plant of the Botanical Garden Center of Palermo is well integrated with the adjacent Villa Flora (now commonly called the Villa Giulia). It is established in 1789 in the "Piano di Sant'Erasmus" on part of the lands of "Vigna del Gallo", near the moat of the walled perimeter. The final project designed by french architect Leon Dufourny is realized in collaboration with local architects such as Pietro Trombetta, Domenico Marabitti e Venanzio Marvuglia. Along the Avenue d'Alcala (now Lincoln Street) in front of the Spasimo's bastion the main front consists of a unique architectural complex that is articulated in a central amphiprostyle doric building a square plant, the *Gymnasium*, and two lateral buildings, arranged symmetrically, the *Tepidarium* and *Calidarium*. These last two buildings are equipped for greenhouse crops in temperate and warm temperatures. These three examples can be considered the first project experiences of neoclassical architecture in Sicily, full of stylistic features of the greek temples and symbolic siceliots codes of the masonic Enlightenment, the first example of neoclassical architecture in Sicily.

Inside the garden, in front of the buildings stands the first nucleus of the general layout of the Garden, is also the work of french architect, divided into paths that identify a specific number of beds available for the plants, according to the classification of Linnaeus.

The preliminary study of architectural and typological scheme, the conspicuous photographic documentation of current and the archival documents and historical and iconographic ones directed the steps and criteria of the survey in-depth knowledge.

A precious monograph by architect G.B.F. Basile (published in "New Annals of the Buildings, Arts and Industries" of Sicily, 1872), Dufourny's design drawings and the finding of some previous designs of direct survey, the works of careful experts (Nicolò Puglia, Enrico Naselli, Vincenzo Capitano) was a major point of departure for the revisiting of the buildings, run through the formulation of critical comments and the editing of graphic-geometric analysis [1].

Fig. 1: Entrance to the Botanical Garden (*Dessiné d'après nature par Benoist Lit. Bachelier*), n. 10039, Gab. Stampe Gall. Reg. Sic., Pal. Abatellis, Palermo.

1. The *nec plus ultra* of greek doric and the generating module

The commission directly received by the Vicerè Principe of Caramanico is for the french architect Leon Dufourny a valuable opportunity to test and to summarize his planning theories about the doric order's renewal *des anciens grecs*. He proposes a lexicon greek Revival with functional and formal solutions free from chief concern items handed down from classicality, which he describes in his comment "lexical abuse" and "arbitrary syntactic".

His works in Palermo and in Sicily communicate a new language that follows the European debate (in France: Le Roy, Laugier, Blondel; in England: Stuart, Revett; in Italy: Piranesi; in Germany: Winckelmann, Hittorff, Klenze, Schinke) on the critical study of classical antiquity in Renaissance key, moving away from a neoclassical revival of imitative behavior which shows in its entirety in project drafting the fee proportional language of ancient temples[2].

The Dufourny's theory based on scientific method and on geometric and modular rigor has as its model the reference carrier the doric archaic order "without basis" with the fluted stems of the columns.

The cultural knowledge acquired in the training period at the *Académie Royale d'Architecture*, the review of "royalties" described in the treatises and his careful measurements of the direct survey of ancient ruins in his

long exploratory itineraries combine to provide an unprecedented process of designing and unique in its kind, which he defines as the *nec plus ultra*, which is the "perfect Doric". His arguments on the art of building and on the testing of the ancient personal solutions applied are gathered in his manuscript *Ub 236 4°, t. III*, kept in the *Cabinet des Estampes della Bibliothèque National* in Paris. A precious book, published by researchers Liliane Dufour and Giuseppe Pagnano, shows the translation and a large collection of original project drawings[3].

The morphological characteristics, the linguistic apparatus of the masonry score and compositional organization outside of the three buildings of the Botanical Garden Center makes clear the different design criteria adopted. The most imposing central building, the hub of academic activities and the temple of Botany, of a "richer and more refined Doric," is opposed to the two side pavilions of support, of a "simple and rising Doric".

Fig. 2: Palermo – Orto Botanico, central building (*Gymnasium*). In the foreground the portico of Doric tetrastyle overlooking the garden.

2. A comparison of models

Inside and outside the structures the composition of together, the symmetry and the clear hierarchy of parts harmoniously articulated clearly emphasize the unique characteristics that make the original method of Dufourny. The entire project (the three buildings and linnaean garden) is governed and regulated by a modular system that proportionally divides the space in plan and elevation, in multiples and submultiples. The diameter of the column base of the School measures 5 palms exact corresponding to 60 ounces or inches (1.27 m), the french architect divided into 60 equal parts the module obtaining the reference unit which is, indeed, an ounce (0.0213 m).

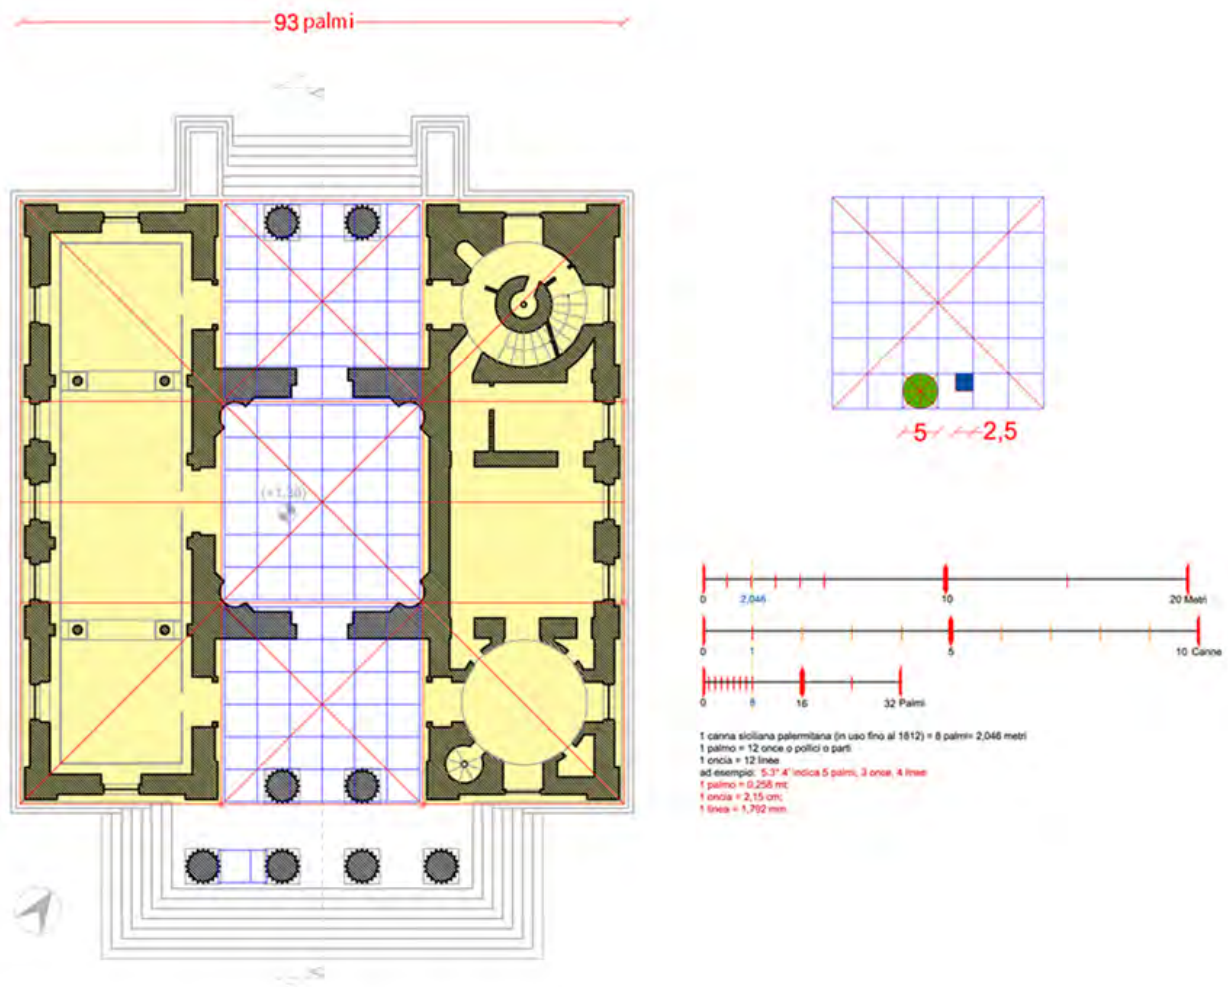

Fig. 3: On the left, the floor plan of representation in the *Gymnasium*. Top right, graphic design of the modular system that regulates the division of space, below, scales, and comparing unit conversion.

The geometric analysis, carried through the creation of modular schemes, have revealed the compositional rigor that governs the articulation of the interior and exterior spaces [4].

From the writings and from some pencil sketch that the architect Dufourny hands down to us, we learn that the original idea of the monument of the first project of the *School* had a compositional structure and location within the Garden radically differ from what appears today. The original choices would give the visitor a completely different view of the whole organism architecture. Initially, he proposes to raise the order of the ground creating a base path vaulted galleries, instead of the current stylobate divided into three tiers that develops without interruption for the entire perimeter of the building. This solution, then abandoned probably for reasons attributable to the excessive cost required for implementation, would create greater visibility of the garden from the the Avenue d'Alcala and, functionally, would be more convenient to isolate the building from humidity of the soil.

The knowledge process undertaken aims to provide useful interpretations for future conservation and for fruition of the site. The creation of digital models of the first idea of the architectural design and of the current state allowed to mature through the overlay layer transparency in plan and in elevation, a greater awareness of the interrelationships between the spatial and volumetric typological systems. The procedure of realization of models has provided key insights into the genesis of the building structure and to highlight the changes that have since characterized the current volume.

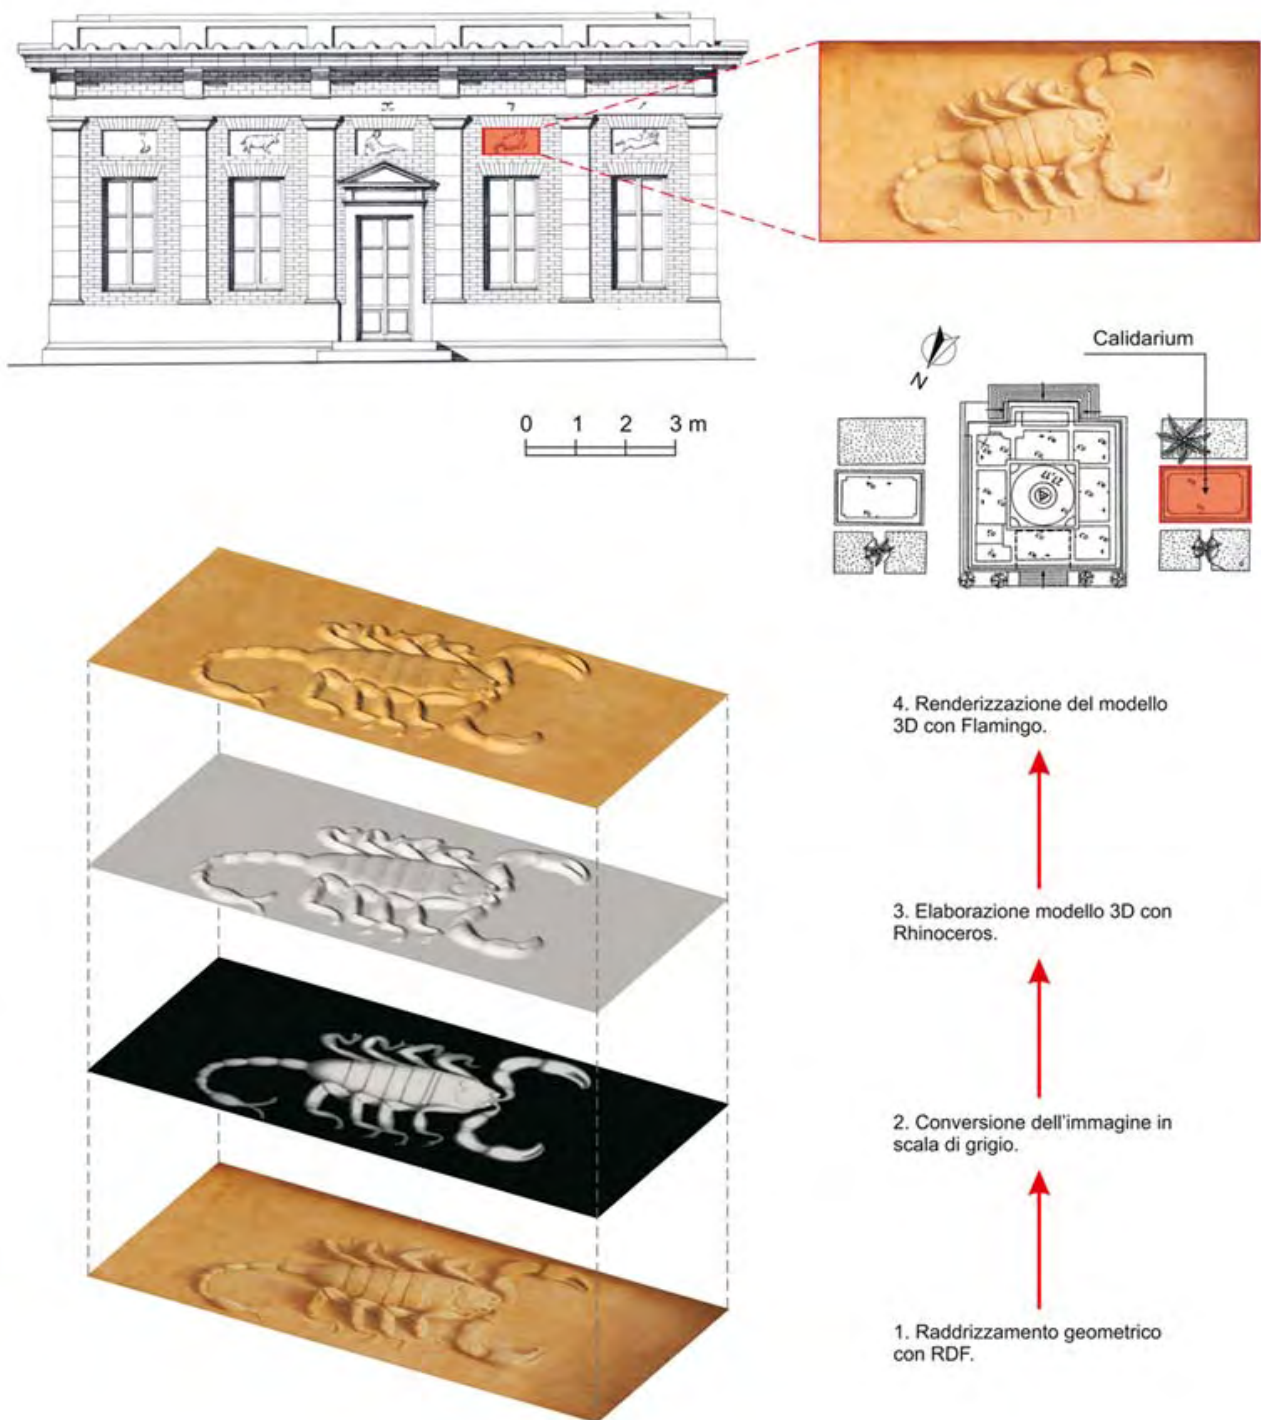

Fig. 4: Phases of one of the twelve zodiacal signs sculptured in relief on the facades of the *Calidarium*.

Fig. 5: Two perspective views of the digital models compared of *Gymnasium*. On the left, the first design hypothesis, that was never built; on the right, the current state.

First results of an experimental campaign to study the influence of cement/sand ratio on strength of cement mortar

Luigi MOLLO

Department of Civil Engineering, Second University of Naples, via Roma 29, Aversa, Italy
E-mail luigi.mollo@unina2.it

Abstract

One of the problems encountered during the design of building restoration is the evaluation of the mechanical strength of the mortar. Mortar is the material responsible for the distribution of stresses in masonry structures. This work aims to evaluate the mechanical behavior of cement mortar for different cement/sand ratios. To do this, in accord with literature, water/cement ratio is fixed. The first results of the experimental campaign allowed to identify, knowing cement/sand ratio, a model to predict the strength of mortar.

Key words: technologies, mortar, mix design, mortar strength

1. Introduction

After the work of Feret, who first recognized the importance of water/cement ratio on the strength of concrete, many studies on different properties of mortar have been made. After about two decades, Abrams formulated his law on the effect of water/cement ratio on concrete strength. According to Abrams' generalization law, Rao [1] confirms that the compressive strength of concrete varies inversely with the water/cement ratio for concrete and so directly with the cement content. However, from time to time, the water/cement ratio law has been criticized as not being a fundamental law. Besides ascribing importance to the water/cement ratio, the influence of cement/sand ratio on strength of cement mortar also should be recognized. Information on the influence of water/cement ratio and cement/sand ratio on the strength of mortar is very limited. From an extensive experimental study by Curie and Sinha [2], it has been observed that the important factor affecting the compressive strength of mortar appeared to be the water/cement ratio. It has also been revealed from the investigations that the relationship between compressive strength and water/cement ratio was unaffected by the use of different sands and sand gradings. It has been observed that the Bolomey expression relating strength of concrete to water/cement ratio can be applicable in normal hardened cement pastes with water/cement ratio > 0.15 [3]. It has been noticed that Bolomey parameters depend on the degree of hydration. Pozzolana cement is one of the most active component between aggregates in mortar and concrete [4]. Generally, it has been observed that the physical properties of cement-based materials are primarily affected by the water/cement ratio, the chemical composition, micro-structure and pore geometry of the cementitious materials, properties of aggregates, cement/sand ratio, and properties of cement/aggregate interfacial zone [1,5,6,7,8, 9,10,11,12,13]. This study has been carried on assuming constant sand weight and constant water/cement ratio hence solely cement/sand ratio has changed, this to understand the influence of cement/sand ratio on strength of cement mortar.

2.0 Materials and methods

Ordinary pozzolana cement CEM IV/BP 32.5 R conforming to EN 197-1 was used for the present experimental investigation.

| Designation | cement [g] | Sand volumes [l] | Sand weight [g] | water [g] (water/cement ratio constant (0,50) + 1% of sand weight as wetting water) | cement/sand [%] | sand/dry total [%] | cement/dry total [%] |

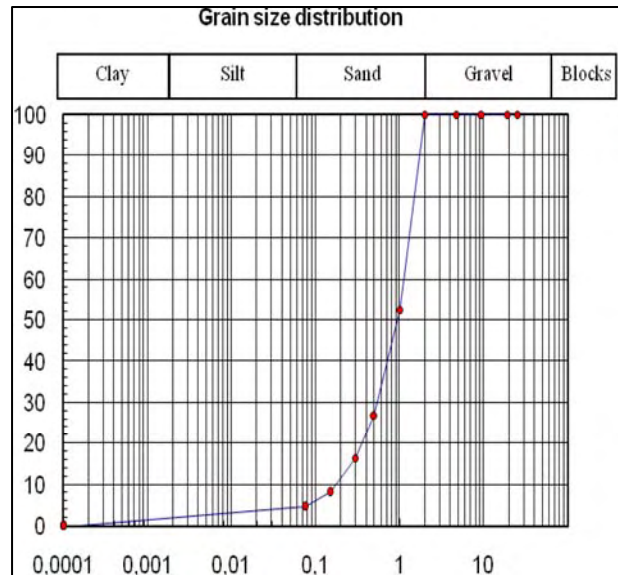

Figure 1. Grain size distribution

Figure 2. Mix proportions of experimental mortar

Natural river sand with sand fraction going through 2 mm sieve and retained on 600 µm sieve was used in this research program. The grain size distribution is shown in fig.1. Care has been taken to avoid the presence of organic and silt particles in the adopted sand fraction. The fineness modulus of sand was 4.92 with a specific gravity of 2.78. The bulk density of the sand was 1530 kg/m³. Tap water available in the laboratory with pH value of 7,9 was used for mixing mortar and curing the mortar specimens as well.

In order to study the influence of sand/cement ratio on strength of mortar, mortar mixtures were designed with a constant water/cement ratio of 0.50 and cement/sand ratio varying from 0 to 1 with an increment varying from 0.031 to 0.125. Fig. 2 shows the mix proportions of experimental mortar.

Figure 2. a) Sample delivery – b) flexural test device

The samples for the present experimental investigation were prepared in accord to the EN 196/1. The samples were prisms of dimensions 40 mm x 40 mm x 160 mm. Standard metallic molds were used for the preparation of the test specimens

The compacted mortar samples were demolded after 24 h and immersed in water till the time of testing (fig.2a). According to the EN 196-1 the samples were subjected, after 28 days, to flexural and compression test. In particular, in the flexural test, the prismatic sample was placed in the flexural test device, with a side face disposed on the support rollers and the longitudinal axis normal to the support. The load roller applied, until rupture, a growing load

with an uniform speed of 50 ± 10 N/s (fig.2b). The flexural strength is determined, for each sample, with the relation $R_f = 0.00234375F_f$ where F_f is the max load [N]. For each mortar composition, the values of flexural strength were determined as the arithmetic mean on a series of nine samples (tot. 171 samples).

Figure 4

Figure 3. Strength parameters of experimental mortar

After the flexural test each sample was divided in two semi-prism of dimension 40 mm x 40 mm x 80 mm. The semi-prisms, resulting from flexural test, were kept in the wet state and thereafter used for the compression test. The compression test was made using a compression test device. The sample (semi-prism) was supported on the test plate so that the long side of the sample (40 x 80) was centered with the plates of the machine (40 x 40). The load plate applied, until rupture, a growing load with an uniform speed of 2400 ± 200 N/s. The compressive strength was determined, for each sample with the relation $R_c = F_c/1600$ where F_c is the max load [N].

3.0 Results and discussion

For each type of mortar the test machine determined the compression and flexural test parameters for each sample.

From the data provided by the test machine, the medium value of flexural strength are calculated, for each type of mortar, using the relation $R_f = (1.5 F_f L)/B^3 = 0.00234375F_f$ where F_f is the max load [N], L = distance between devices = 106.7 mm and $B = 40$ mm. The medium value of compressive strength was determined, for each type of mortar, using the relation $R_c = F_c/A = F_c/1600$ where F_c is the max load [N] and A = area of plate load=1600 mm². The results are shown in the fig 3.

The experimental study shows the influence of sand/cement ratio on the strength of cement mortar. In particular, fig 4 shows the variation of compressive and flexural strengths with respect to the variation of cement weight.

The experiments were carried by assuming constant sand weight and constant water/cement ratio, thus solely cement/sand ratio was changed. Both flexural and compressive strengths increase with increasing cement content, asymptotically reaching the strength of the cement alone.

A first experimental estimate of the optimal cement content is cement/sand ratio around $0.30 \div 0.40$, in agreement with the traditional workmanlike, which suggested a ratio of 1/3. Mortar strength is indeed less sensitive to further increase in cement content and after the ratio $C/S = 0.6 \div 0.7$ is reached, the mortar strength practically assumes the asymptotic value corresponding to cement matrix strength.

Physical explanation of this results is in the mortar structure and behavior. Like all composite materials, mortar consists of a matrix (cement) and of a dispersed phase (sand). The sand, dispersed in the matrix, has the function, in ordinary mixture with water/cement ratio greater than 0.45, to provide rigidity and mechanical strength, taking upon itself the greater part of the external load applied to the material. Instead, the cement matrix has the task to act as a filler. The cement paste, initially, in the state of viscous fluid, fills all the spaces

to adhere fully to particles of sand; afterwards, it undergoes a solidification process which allows to give stability and geometry to the structure. The matrix adhere to the particles of sand to transmit them, with tangential stress, the external loads applied.

The increment of cement improves the mortar strength up to cement/sand ratio = 0.30÷0.40 is reached, because, in this range, the cement fills the pores of the sand, in fact the porosity of the sand assumes normally the value 0.30. After this value of cement/sand ratio and up to cement/sand ratio = 0.60÷0.70, the increment of cement improves slowly the strength of mortar because the cement, dispersing the phases, can wrap up all grains of sand and, so, the friction is eliminated and the external loads applied are transmitted only with tangential stress. When the value of cement/sand ratio is greater than 0.6÷0.7, the phase is so dispersed that does not contribute anymore to the strength, and so the mortar strength tends asymptotically to that of the matrix ($\approx 39 \text{ N/mm}^2$).

The experimental data has been fitted by S-shaped curve with equation:

$$\sigma = Ke^{-e^{\frac{C}{S}-A}} \quad [1]$$

Where C/S is the cement/sand ratio; K is a parameter depended by the max value of strength of cement used, A and B are empirical parameters.

For the mortar used in experiments, the values of K, A and B, for compression strength and flexural strength, are reported in following table.

| | Compression strength | Flexural strength |
|---|----------------------|-------------------|
| A | 0.20 | 0.15 |
| B | 0.10 | 0.07 |
| K | 38.90 | 8.77 |

Really the curve [1] does not pass through the point zero but it is coherent with reality because, in any case, the only mixture of sand and water develops a strength different from zero although it is very close to zero. It is interesting to note that, when cement/sand ratio is smaller than 0.13, the increase of strength is growing much more slowly with increasing of cement probably because up to this point the external loads applied are transmitted predominantly by friction with a minimum component of tangential stress.

The relation [1] can be used as empirical model to predict the compressive and flexural strength using cement/sand ratio when the water/cement is equal to 0.5.

4. Conclusion

The mortar strength seems depending on cement/sand ratio when the cement/water ratio is kept constant. It is important to note that the quantity of cement weight plays, respect to sand, a main role. It is evident that more studies need to be carried on in order to evaluate complete influence of all different contributions to the mortar strength.

MORE OR LESS

Imprecise precision in “regulatory designs” by Galeazzo Alessi

Paolo BELARDI¹

⁽¹⁾ Dipartimento di Ingegneria Civile e Ambientale, Facoltà di Ingegneria, Università degli Studi di Perugia, Perugia, Italia
belardi@unipg.it

Abstract

As Bruno Zevi stated in the early 70s, Perugia does not have a characterizing urban design, at least not in its most common interpretation. It is not by chance that its acropolis has interjected the hyppodamian scheme inherited by the etruscan-roman nucleus which refuted the papal fortress built under Paul III. Nevertheless, the central area between the hills of *Landone* and *Sole* are still today an extraordinary typological example, where an atypical constructive process became real and rose above not only the abstractness of the program-plan but also the concreteness of the building itself. Indeed, Bernard Rudofsky totally agreed with Zevi; in those years, he was celebrating the floating architecture of the ancient *Peroscia*, noticing in its interrupted character and in its pensile houses, the enzymes of an exclusive urban landscape. And he compares the spatial elusiveness of *via Maestà delle Volte* with the volumetric complexity of the Tsukji neighbourhood of Tokyo, establishing a supra link between Kenzo Tange and Galeazzo Alessi. Just as in the case of the japanese neighborhood, also in the perusian acropolis the multi-prospective vocation is not casual; on the contrary, it is the result of a planned “urbatettonico” monitored by Alessi through veritable “regulatory designs”. Its precision lies in its imprecision. By honing the remote control technique defined in Genoa, Alessi does not prescribe dimensional norms nor does he impose constructive choices but rather suggests spatial relations and proposes ornamental models in his basilica of *Santa Maria Assunta in Carignano*, and after in *Varallo*, with the organ plan of *Sacro Monte*. In very few years, he transforms the austere medieval acropolis in a sumptuous Renaissance citadel.

Key words: Perugia, Alessi, regulatory design, urbatettura.

1. Perugia: a multi-prospective city

As Bruno Zevi stated in the early 1970s, Perugia does not possess a characteristic urban design [1]. At least not in its most common interpretation. It is not by chance that its acropolis has interjected the hyppodamian scheme inherited from the etruscan-roman nucleus and refuted the papal fort set up by Paul III. However, the central area between the *Landone* hill and the *Sole* is still today an extraordinary typological sample, where an atypical constructive process became real and rose above not only the abstractness of the program-plan but also the concreteness of the building itself. Bernard Rudofsky totally agreed with Zevi’s statement when in those same years, he celebrates the floating architecture of the ancient *Peroscia*, noticing in its interrupted character and in its pensile houses, the enzymes of an exclusive urban landscape [2]. And he compares the spatial elusiveness of *via Maestà delle Volte* with the volumetric complexity of the Tsukji neighbourhood of Tokyo, establishing a supra link between Kenzo Tange and Galeazzo Alessi. Just as in the case of the japanese neighbourhood, also in the perusian acropolis the multi-prospective vocation is not casual; it is due to the drastic morphological changes induced by the construction of the *rocca paolina* (1540-1543) in the heart of the forma urbis made magnificent by Leon Battista Alberti. Just as widely illustrated by the scientific community and the local scholars [3]. What still remains a mystery (on which scholars disagree) is whether

there is an intelligent design aimed at an urban revolution going on in ancient Peroscia during the pontificate of Paul III (1534 – 1549), in which the fort, although personifying an innovative intervention from a typological point of view (having both a military and a civilian role), and ground-breaking from the environmental point of view (as it engulfs an entire neighbourhood), represents ‘only’ the spectacular seal of a much larger political scheme, aimed at replacing the organic austerity of the Baglioni acropolis with the rational splendour of a Farnese citadel [4]. This was done with a manifest intention to emend the rebellious community with an eternal physical mark. On the other hand, it is obvious that the cartesian plot carried out with plano-altimetric geometry of the road network, along with the regularity of the visual hierarchy established with the capillary dissemination of a scenographical floor and of the panoramic balconies and the strategy of the figurative realization of the impressive facades in brick adorned by minute ornaments in travertine show how an initial urban plan was necessary. Moreover, of obvious pauline matrix, based on the same re-composing techniques already well proven by the Farnese pope in the classicistic transfiguration of medieval Rome, when for example “[...] the principle is introduced whereby new avenues could be built through destruction, in areas where no construction is planned or in area which are unsuitable, for whatever reason, for anything other than *connecting* both physically and optically two poles” [5]. This regards the entire acropolis, from *via Riarra* (today *via Baglioni*) to *via Nuova* (today *via Mazzini*) up to *piazza Grande* (today *corso Vannucci*), where work to widen and repair seem even more pronounced because they have to make do with a very large place to begin with: just as in the specific cases of palace *Baldeschi*, of palace *Graziano* and of the extension of palace *Priori*. In this way, it is not surprising that to carry out a plan which would not be disrespectful to the environment [6], Paul III was forced to terminate an architect who was so incurably old-fashioned such as Antonio da Sangallo il Giovane, and hire an emerging personality such as Galeazzo Alessi for the normative and executive transposition, since he possessed all the necessary prerogatives: he was born in Perugia of a noble lineage, he was raised in Rome in the best craftsmen’s shops and known by the most prestigious people in office in the Vatican.

2. The alessian DNA

Documents showing Paul III’s building policy carried out by Galeazzo Alessi are scarce due to the suppression of the magistrates between 1540 and 1553. This is true up to 1873 when the first list of his works is available; this is when Adamo Rossi reporting “the memoirs of the writers and archivists”, records that “during Cardinal Tiberio Crispo’s legislation, a road was opened which linked the main road to the *Sopramuro* and this is where the *Church of the Madonna del Popolo* was built, then the *piazza della Paglia*, the road which leads to the *Prome* and from the start from where the Perugian Switzerland can be seen, a porch early turned in a little church; the building next to the one of the *Popolo* was shortened for governmental residence use and a balcony was built to crown it; the *Campo di Battaglia* was levelled; the bridge on the *Chiagio* was built which is now known as *Bastiola*. It was customary that the Cardinal would task Alessi as requested by his predecessor – cardinal Ascanio Parisani – and from his own works” [7]. An enviable portfolio for a thirty-six year old architect (this was Alessi’s age when he signed the contract with the Saulis for the design of *Santa Maria Assunta in Carignano*), but still not enough for an infamously untrusting administration such as Genoa to task him with the integral urban renovation of that city. There was probably more to the story. It is not by chance that besides the seemingly occasional acclaimed work by Alessi (the division of the *via Nuova*, the rebuilding of the *Church of Santa Maria del Popolo*, and the *Church of Sant’Angelo della Pace*), the entire blueprint of the Perugian acropolis exudes an elegant design, composed of a mixture of broken lines and sinuous bends which remind us of two opposing tridents (which originated the current *piazza della Repubblica* on one end and *piazza Danti* on the other), yield a scenographic reform pursued in Rome in the early 1500s under the aegis of Raffaello Sanzio and marks a profound divide from the narrow-minded character of the ancient *platea magna communis* as sketched in 1469 by Benedetto Bonfigli in the *Traslazione del Corpo di Sant’Ercolano da San Pietro alla Cattedrale* [4]. This inspired the idea that Alessi after having successfully headed the construction of the *rocca paolina*, may have been tasked to head a project *ante litteram*, which did not (this is the novelty) prescribe dimensional norms and did not impose building choices, but suggested spatial relations and ornamental models. All this was possible through a series of regulatory designs the precision of which laid in its imprecision: quality vs. quantity. This explains the impasse of the critique produced by a long series of architectures which, although stylistically akin, could not be claimed as Alessi’s (also for chronological reasons as well) and clarifies why many of the works of Ignazio Danti’s, Valentino Martelli’s and Bernardo Sozi’s are inspired by Alessi’s way of composing architectures of facades which aimed to support perceptive alterations due to a slanted vision. An example is *via Bontempi*, the urban area of the Perugian acropolis where perhaps the gradual gap imposed by the pauline reform is most evident. Furthermore, this is even more significant due to the figurative collision

between the masked-monumental facades of Alessi's legacy and the moderated pre-existing medieval urban fabric.

3. The *Accademia del Disegno*

In a short missive dated January 1570 sent to cardinal Fulvio della Corgna attached to his design for the façade of the roman *Chiesa del Gesù*, Galeazzo Alessi openly confesses his poetic creed, sadly stating that, in order to surpass the "ordinary form", "new things [...] needed to be done, provided that they did not clash with the rules and terms of Architecture" [8]. This statement summarizes the most original value of Alessi's school of thought, which is known to be both conformist and eccentric thanks, among other aspects, to the mastery of all the representative techniques [9], of organizing designs with rationality typical of Sangallo and to create facades with freedom typical of Serlio. On the other hand, Alessi was not only a great master of drawing experience [10], but also well-versed in remote controlling [11]: that is when geographically distant, he controls through detailed epistolary instructions and when temporally distant, through appropriate graphical instructions. When geographically distant, we can note his prolonged correspondence with the Sauli (creators of the genovese *Basilica of Santa Maria Assunta in Carignano*) which Alessi would gloss with explanatory sketches to compensate for his prolonged absences from the construction site [12]. On the other hand, when temporally distant, two of Alessi's essays written in the last years of his life are worth mentioning: the *Libro dei Misteri* (1569), dealing with the coordinating design of the *Sacro Monte di Varallo* and includes the typological repertoire which introduces the imminent achievement of the "normalizing design" [13], and the *Libro di Fortificazione in modo di Compendio* (1570) in which he is the first to claim that the design "allows the architect to state his opinion effectively as opposed to others" [14]. Above all, it is the birth of the *Accademia del Disegno* in Perugia: an establishment which aimed at conferring a new social status to artists and founded by the painter Orazio Alfani and by the mathematician Raffaello Sozi in the spring of 1573, right after Alessi's death (December 30th 1512). Very little is known about the original organization of the perugian institution since there is no name list of the academic staff nor a statute of its organization; on the other hand, it is true that the *Accademia* along with the entire city, was greatly influenced by Alessi's legacy [15]: in the aegis of a *Disegno* so dedicated to guaranteeing widespread quality. This is proven directly by the rational order of the new *via Nuova* (currently *via Mazzini*) where the regulatory design aiming to organize the several facades in a unitary spread is proven through the organizations of the pavements of the corner buildings carefully aligned with the cornices of the "serliana" of the *Santa Maria del Popolo* church: this is perhaps imprecise from the point of view of construction norms but precise from an architectural point of view since it allows to organize the private buildings and to guarantee continuity of the scenographic backdrop. This is also proven by the portal bosses (more than one hundred each equal to the other) which were aligned in the historical center of Perugia in the second half of the XVI century: this is the legacy of the regulatory design of Alessi which the local craftsmen shops made popular [16].

⁽²⁾E-mail: jetik.doli@hotmail.com

Abstract:

Genius Loci: The tradition acquired through centuries of ancient masters resulted in the creation of certain construction principles for the conception of cities in harmony with the spirit of place, or genius loci.

Ecopolis: The complex natural features like geographical and topographical position of the city, adaptation to the topographic features of the land, the rational orientation - the extension of the city along the south side of Alp Mountains, types of zoning and construction adapted to the climatic conditions, the natural and planned water potential system conditioned and directly influenced the formation of an urban and architectural environment of the old city of Peja which was characterized by the genuine features of an ecopolis. The ancient masters as a result of an over century experience managed to act in harmony with the spirit of nature. Therefore, the spirit of nature with the spirit of physical structures is presented in a synthetic harmony creating an expression of regional architecture with distinct features of high value. Districts and units constructed in accordance with nature and bioclimatic conditions: The districts of Peja respectively the south-oriented yards of the houses were constructed in accordance with bioclimatic conditions. In this context the traditional house design in Peja included all bioclimatic architecture components. Hence, these houses bearing architectural and functional high values can be considered as energetic and ecologic models. Typological and rational features of Peja's traditional house are: Articulated and typified volumetry of the house; proper thermal orientation and zoning; proper house connection with the terrain-greenery and water; orientation corresponding to the view; interlacement of interior and exterior spaces; articulated functional and shaping interlock due to the tradition of ancient Albanian masters; compactness of form - a prerequisite for minimal heat loss. It has been ascertained that many Peja traditional houses achieved the degree of spatial perfection. The principles of architectural configuration of these houses are very similar to those of today. Knowledge of principles and methods of their creation is a criterion for their renovation and revitalization and also for the conception of new types of construction and neighborhoods, as to maintain the specific expressions of a regional architecture.

Keywords: harmony; tradition; city concept; urban environment; typological features; orientation; zoning; volumetry; form compactness.

1. Genius loci

Twenty centuries ago Vitruvius in his treaty for construction mentioned the deeper awareness for respecting the qualities and the spirit of land, respectively the genius loci. The tradition of ancient masters based on the knowledge acquired through centuries resulted in creation of certain construction principles for conception of cities in harmony with the spirit of a building land, or the genius loci.

2. Ecopolis and the old city of Peja

The complex natural features that directly influenced and conditioned the formation of an urban and architectural environment in Peja, the city characterized by the genuine features of an ecopolis, are:

- Geographical and topographical position of the city;
- Adaptation to the topographical features of the land;
- Rational orientation - the extension of the city along the south side of Alp Mountains;
- Zoning and construction types adapted to the climatic conditions;
- Natural and planned water system potential:
 - River (Lumbardhi)
 - Drains
 - Ravines
 - Water flow lines.

The ancient masters as a result of an over century experience accomplished to act in harmony with the spirit of nature. Therefore, the spirit of nature with the spirit of physical structures is presented in a synthetic harmony, reaching an expression of high value regional architecture with distinct features. architecture structure of this part is characterized with an organized spontaneous development, which in its wide concept harmoniously synthesizes all the upper mentioned features and principles.

Fig.1.0. The geodesic survey of a part from the old city core of Peja, dated 1938

The districts of Peja city and their subunits like the south oriented house yards were constructed in accordance with bioclimatic conditions. The design of traditional houses of Peja included all components of the bioclimatic architecture. After the general analysis which is uncovered in detail in the following paragraphs, it will be concluded that these houses share high architectural and functional values and are considered as energetic and ecologic models.

3. Typological and bioclimatic characteristics of Peja traditional houses:

- 3.0 - Typified and articulated volumetry of the house;
- 3.1 - Compactness of form - prerequisite for minimal heat loss;
- 3.2 - Designing different spaces for summer and winter seasons;
- 3.3 - Articulated functional and shaping interlock;
- 3.4 - Proper orientation and thermal zoning;
- 3.5 - Window apertures according to climatic criteria;
- 3.6 - Application of thermal tampon zones;
- 3.7 - Proper house connection with the land- greenness and water;
- 3.8 - Orientation corresponding to the view;
- 3.9 - Interlacement of interior and exterior spaces.

3.0 Typified and articulated volumetry of Peja traditional houses

When analyzing the plan layouts of Peja traditional houses, which are presented in the following figures, we can draw the conclusion that these houses are characterized by a compact volumetry.

3.1 Compactness of form as a prerequisite for minimal heat loss

The compact volumetry or spatial formation of the traditional house is in a direct and organic relationship with its plan layout, the latter being always distinguished by its square or rectangular contour, with a minimal perimeter. The plan layouts of these constructed houses create an architectonic volumetry that determines a minimal ratio between the exterior surfaces and the volume of the house, ensuring minimal heat loss. The volumetric compactness determines a minimal house surface in the direct contact with the outside cold air; hence the heat loss is also minimal. This implies that ancient masters managed to optimize the house surfaces, reducing the heat loss in proportion with the reduction of house exterior surfaces. Again, the plan layout with a contour of a square has a minimal perimeter, while the plan layout with a contour of a rectangle is 10 % larger than the former. All the houses included in this study share square and rectangle contour plan layouts. The plan layout contour of house floors: H1 (fig.2.2); H2 (fig.3.2); H5 (fig.6.2), and especially the house plan layout H6 (fig.7.1 & fig.7.2) are almost in a square form. Meanwhile, the houses: H3 (fig.4.2); H4 (fig.5.2) and H7 (fig.8.1 & fig.8.2) [1] contain a rectangle plan layout. In this respect, a specific feature characterizes the ground-floors of H6 and H7 houses, that is all the ground-floor walls, including the exterior and interior ones, have a higher thickness, which means a higher thermal mass.

3.2 Designing different spaces for summer and winter seasons

The idea of ancient masters was that with a proper architectonic structure of walls, window spaces and cross ventilation to maintain the solar energy as a source of heat during winter, and meanwhile to ensure cooling during summer, as back then they did not have active temperature control systems. In this geographical position, the city has major seasonal temperature differences; therefore ancient masters used the concept of designing different living spaces for winter and summer months. As it is seen in fig. 7.1 (2.) and fig.8.1 (2.), living rooms for winter months are positioned in the ground-floor between the high thermal mass thick walls.

Fig.2.0. Site plane - H1

Fig.2.1. Ground floor

Fig.2.2. Upper floor

These walls are made of high density materials: stone, bricks, or adobe. These high thermal mass materials can conserve energy and when slowly radiating it add a pleasant effect to the living conditions. In accordance with climatic criteria living rooms were positioned among these walls and small dimension windows were opened. The different bioclimatic disposition of living rooms and protuberant parts of corridors suitable for stay in summer offer pleasant living conditions. The east oriented rooms and the parts of corridors for stay offer great commodity during summer afternoons, while the same spaces when south oriented are more suitable for utilization before noon.

Fig.2.3. Perspective view - H1

3.3 Articulated functional and shaping interlock

Regarding Peja urban houses, and in general Kosova urban houses, it must be said that ancient Albanian masters due to their old tradition ensured an organic harmony between spatial, compositional and the functional structure of the house. Peja urban houses in a certain phase of their development gained crystallized stylish features. Hence, there is no coincidence in considering Peja traditional houses to have achieved the degree of a perfect spatial crystal. In these houses, the functional and spatial structure almost always was realized according to an asymmetric shaping concept. Therefore, traditional houses of Peja from the end of 18th century and 19th century are distinguished for the building typology and the crystallized stylish features.

3.4 Proper orientation and thermal zoning

As it is depicted in fig. 7.1 (2.) and fig. 8.1 (2.), the three rooms (2.) of H6 house and the two rooms (2.) of H7 house for winter living are east and south oriented. Their windows are also set in respect to climatic criteria, mainly in south and east parts. Owing to their experience and ingenious dexterity, Albanian ancient masters as far as proper orientation and thermal zoning was concerned, applied the concept of “tampon zones”, which translates in designing helping spaces with compact structure in the north or northwest parts that aim to protect or slow the cooling process of thermal mass walls. As the plan layouts of H1 and H7 houses show, all these houses share high thickness walls in their north or northwest parts, as it is these walls that maximally protect the thermal mass of inner walls from the cold winds, which almost always blow from the north.

Fig.3.0. Site plane - H2

Fig.3.1. Ground floor

Fig.3.2. Upper floor

3.4 Proper orientation and thermal zoning

As it is depicted in fig. 7.1 (2.) and fig. 8.1 (2.), the three rooms (2.) of H6 house and the two rooms (2.) of H7

house for winter living are east and south oriented. Their windows are also set in respect to climatic criteria, mainly in south and east parts. Owing to their experience and ingenious dexterity, Albanian ancient masters as far as proper orientation and thermal zoning was concerned, applied the concept of “tampon zones”, which translates in designing helping spaces with compact structure in the north or northwest parts that aim to protect or slow the cooling process of thermal mass walls. As the plan layouts of H1 and H7 houses show, all these houses share high thickness walls in their north or northwest parts, as it is these walls that maximally protect the thermal mass of inner walls from the cold winds, which almost always blow from the north.

3.5 Window apertures according to climatic criteria

In the fig.2.0; 3.0; 4.0 and 7.0 plan layouts, and in all other house plan layouts presented below, the positions for window apertures for house upper floors are made based on climatic criteria. All window apertures are positioned in the south, east or southeast in the main house upper floors. An exception is at the windows of the upper floor of H2 house (fig.3.2). Here windows are positioned in the south and west side, because of the urbanism disposition of the house parcel. This type of functional and architectonic window structuring allows capturing passive solar energy, as windows are exposed to the sun. It enables a direct gain from the solar energy during the cold seasons of the year. Respecting climatic criteria, windows permit solar radiation to enter directly inside the house. This heat in its largest part is conserved within the house as it is absorbed by thermal mass walls. After the sunset, the same heat starts to radiate back to the house keeping an almost constant temperature even during night temperature drops. In addition, compositional window structuring based on the continual series concept actualized in an organic harmony with the house spatial formation built centuries ago is defined by modern architectural features, which is also inspiring for contemporary designers. The functional structure of Peja traditional houses is distinguished for a high level functionality covering even today's requirements.

3.6 Application of thermal tampon zones

From the plan layouts of H1-H5 house upper floors it is noted that thermal tampon zones are designed in their architectonic and functional structure. Thermal tampon zones in H1-H5 plan layouts are presented with parallel lineament (fig.2.2; fig.3.2; fig.4.2; fig.5.2 & fig.6.2). They function as communicating areas within the house floor, are used for living during summer, and are sun oriented. While, during winter they act as buffer zones between warm living areas and the outside cold climate. Thermal tampon zones prevent living spaces from cooling during cold seasons, and meanwhile prevent living spaces from excessive solar heat during summer. As it is further noted in these plan layouts, tampon zones and all the living spaces along the sun side are enfolded by thin small thermal mass walls that cool during the night. Other architectonic elements that protect the living spaces from excessive solar heat are deep sheds. In summer months, when the sun is up high, these sheds block the sun rays from penetrating the inner living spaces, while in winter when the sun is in a lower level, rays penetrate from the numerous windows into living spaces in ground and upper floors. Thick inner walls with high thermal mass absorb parts from this heat and release it when the sun sets ensuring constant warmth in living spaces. Natural summer cooling of the house was also managed through cross ventilation. In the fig. 3.3; 6.3; 6.7 [2], respectively in the plan layouts of ground floors: fig. 2.1 (1); fig.3.1 (1); fig.4.1 (1); fig.5.1 (1) and fig.6.1 (1), it is noted that houses include porticos in their ground floors, that are under shadow during summers and contain a cooler air than the air above the roofs. The specific weight gradient of cool and warm air forces its circulation. Air circulates from the portico through the stair space to the corridor, open air traditional kitchen and finally makes to the dormer, the roof opening. It is through this vertical cross ventilation that the natural, passive cooling of the house was achieved. Another mean of passive cooling was also horizontal cross ventilation through the openings of south exterior wall windows, and north oriented small windows.

3.7 Proper house connection with the land - greenness and water

The philosophic or urban and architectonic concept of middle age Kosova houses consists in organizing life in harmony with the sun, water and greenery. This principle has naturally conditioned a proper house connection to the land, respectively positioning the house to the side of the sun, greenery and water. Therefore, in many middle age cities of Kosova, the natural water infrastructure is so planned, that in almost every house yard flowing water system is present

Fig.4.0. Site plane - H3

Fig.4.1. Ground floor

Fig.4.2. Upper floor

3.8 Orientation corresponding to the view

Ancient masters in the context of micro urban conception of the houses always sought that the orientation of window openings to be in accordance not only with climatic criteria but also with the best views that could be attained. Hence, windows are sun oriented and in the same time open to the side of yard greenery and grove. Such conception enabled a decent interlacement of exterior and interior spaces.

3.9 Interlacement of interior and exterior spaces

Ancient masters interlaced the interior space with the exterior through many window openings, especially in the main house floor. The system of window openings in series, based on actual principles, enables viewing the entire exterior yard greenery. In this way, even the stay inside the house offered the commodity and the pleasure as like staying outside in the cultivated yard gardens.

Fig.6.5. Perspective view - H5

Fig.6.6. Perspective view - H5

Fig.6.7. Perspective view - H5

Fig.8.1. Ground floor

Fig.8.2. Upper floor

Conclusion

In the conclusion of this study, it must be added that the architectonic formation of traditional houses consists of similar principles as those of today. Knowledge of principles and methods of their creation sets a criterion for their renovation and revitalization and also for the conception of new types of construction and neighborhoods, respectively for establishing a special expression featuring architecture

Promotion of Cultural Heritage. A case of a little village in Apennines

Valentina CINIERI¹

⁽¹⁾ Dipartimento di Ingegneria Civile e Architettura, Facoltà di Ingegneria, Università degli Studi di Pavia, Pavia, Italia
valentina.cinieri01@universitadipavia.it

Abstract

Territory is a non-renewable resource, whose preservation and promotion should help to main and strengthen Local Identities.

Embresi is a place on the Apennines, characterized by high naturalization, without services and easy routes. There are marks of important past events, despite severe abandonment's damages. Its tower rises as a landmark in the middle of stone buildings and the carved faces are peculiar.

Interesting issues were revealed by a multidisciplinary study, developed within a degree thesis of Architecture and Building Engineering.

The Architecture is related to a territorial and economical organization's process, arranged by Lombard sovereigns (VII-VIII century), through the activities of Saint Colombano's and Saint Paul's monasteries, to improve and control a territory bordering on the Byzantine State and necessary step to reach Rome.

The X-ray diffraction revealed the nature of the limestone ashlar, mainly made of calcite, quartz and dolomite. There's a connexion between content, strength and function. The builders had a profound knowledge of materials, in according to the hypotheses.

The strength of Embresi is the position along the ancient roads. The idea is to create temporary housing for visitors, who like History and Landscape, despite obstacles and isolation. Stonework becomes the envelope in which missing features are inserted like boxes.

Key words: Cultural Heritage, Restoration, High-Medieval, Stonework

1. Aim of the work

This work belongs to the group of the researches relating to the conservation of the historical building heritage, developed at the University of Pavia and, in particular, regarding the Interdepartmental Centre of Research on the Conservation of Cultural Heritage.

This research started with the work of a graduation thesis (tutor: prof. Ing. Marco Morandotti, co-tutors: proff. Massimo Setti, Ing. Daniela Besana, University of Pavia) then subject of a publication [1], and develops an approach which should have a real effect in the field of design, because it combines the process innovation with the issues of design quality. This innovation concerns both the diagnostic techniques and the definition of intervention strategies

In particular, the work investigates the connection between the traditional approach to the conservation of Cultural Heritage, which underpins the pair knowledge/design, and the relationship between re-use, observant of conservative needs, and its sustainable promotion.

The importance of conservation is accepted by all of us, because the building heritage is considered harbinger of primary needs which have to be preserved, but there are also evident needs of fruition of a historic building, seen as a trigger valorization processes and cultural developments.

The preservation of building heritage is important for the improvement of the quality of life and for the safeguard of traditions and history, but it is also significant for the economy of a territory, because the cultural and the traditional heritage increases the tourist interest in this territory.

The case of study is a little rural village placed in an interesting territorial background, filled with history and naturalistic beauties. The main reason of interest in it is the fact that this hamlet shows distinctive features, which demonstrate its importance and prove as it is not only the result of a poor rural civilization.

The aim of the work was to consider an ancient hamlet, which had never been a subject of scientific studies, with the goal to plan the recovery of its ancient buildings and an appropriate re-use, which allows for historic features and discoveries, made from cognitive researches.

2. Promotion of Building Heritage: opening notes

The Italian law (*Codice dei Beni Culturali e del Paesaggio*, D.Lgs 22/01/2004, n.42; art. 6) explain that the promotion, which is compatible with the safeguard and doesn't prejudice needs, is the practice of functions and the control of activities designed to promote the knowledge of Cultural Heritage and to provide the best conditions of use and fruition, to the purpose to promote the development of culture.

There is a connection between the safeguard of the Cultural Heritage and the use of it. The safeguard is considered in its meaning of conservation and preservation, because the Cultural building Heritage is seen as a bearer of important messages and history, which have to be safeguarded. The use is the element that spark off the cultural development [2]. This connection between "conservation" and "use" is the element that most of all should be investigated. On this front, the research, which was conducted, attempts to provide a reflection.

The start point is the importance of knowledge, that is the basic condition to actions of restoration, of recovery or valorization. Each historic building can be seen as a text, characterized by several writings, gaps, additions, integrations, which make it specifically a "palimpsest". So, the terms "knowledge" and "interpretation" are at the centre of the study. The quality of the memory is bound up with the authenticity of the fabric of the monument, which, when altered, distorts the memory and therefore diminishes the value of the artifact [3]

In a restoration, it is important to foresee a re-use with the purpose of preventing the conservation comes down to "embalming" and "fetishism" [4]. Re-use is connected with the use value of the architecture, which demands a continuous change of needs, connected with living. Without a re-use, each conservation planning would be meaningless, because it could satisfy the image, but the really goal would lack, that is the comparison with people who will benefit the building.

The building recovery includes different intents [5]. One of these intentions is the simple rehabilitation, without a change of use. Another way is a new use, that has to be compatible with the historic building. Finally, there is the intent to capitalize a resource. Changes of users and needs impose adaptations and that causes problems of conservation.

So, conservation, re-use and development have to be planned unitarily, starting at the knowledge of heritage, without the fear of innovative and bold suggestions, to the aim to preserve buildings of historic values, respecting today's rules of safeguarding and putting in connection the simple building with the economical and territorial background.

3. The promotion and the recovery of Embresi (PC)

3.1 Background and a short historical summary

Embresi is a little hamlet in the territory of Trebbia valley in the Emilia Apennines. It is on a slope at 480 m, in a place quite isolated, without easy communications with other villages, situated in the territory of Mezzano Scotti, a district of the municipality of Bobbio (Piacenza).

The country roads are not easily practicable and, at some previous time, when the near stream *Dorba* was in flood, the passage was interrupted. So, the most ancient buildings of Embresi were in a condition of a fossil-village for many years, showing features of an important past, in spite of rehashes and serious damages, caused by the lack of repairs and the today's neglect.

The buildings are made of facing stone and their roofs are the typical roofs made of stone slabs. A tower emerges in the middle of the hamlet as a landmark. In spite of it was lowered twice, it still has a considerable high (23 m at eaves level). The presence of two graven faces are peculiar, too.

Fig. 1: The landscape near Embresi and, in particular, the relief *Pietra Parcellara* (Piacenza)

Fig. 2: The tower of Embresi in the landscape

Fig. 3: The ancient buildings of Embresi

The territory is a beautiful landscape, filled with natural beauties and history. The near towns Bobbio and Travo (PC) are known for the prestigious cultural past and archaeological discoveries. The valley of Trebbia is famous also for its geology (it is a tectonic window) [6].

The predominant element of the landscape near Embresi is the imposing ophiolitic relief *Pietra Parcellara* (836 m), mainly made of black serpentine, which belongs to a Site of Community Importance (SIC IT4010005) [7] with the near relief *Pietra Perduca* (659 m).

The place has features of mountain territories: the human settlements are small and centred in compact groups and the agriculture takes place on terraces, because fields are on steep hill sides. In the past, these small villages made profit from the territory, in which they grew respecting natural features and ties, but they was also able to supply needs of comfort; the economy was based on agriculture and commerce at the markets down in the valley.

The rocky fields, which are not fit for cultivations were called *zerbide* and the inhabitants used them to pasture the livestock, but the *zerbide* were also source of income: people harvested berries of junipers, which are very common in the territory. This activities are proved by old inhabitants and by documents of *Estimi Rurali Farnesiani*, a census of every properties that dukes Farnese wanted (XVI-XVII century) with the intention to determine the value of taxes for each family.

Important historic findings were made in Trebbia valley. The historical knowledge of this territory permit to set Embresi in a peculiar historical background.

The discoveries go since Neolithic period. The arrival of Ligurian population is proved by many findings; their reign continued for five centuries. Then Celtic populations arrived. The Romans began a war, because they wanted to keep down the expansionism of these populations and the Romans civilization of this territory began in 14 a. C.

The picks of mountains were holy places [8], which were destinations of pilgrimages. In particular, there were some places of worship near Embresi, as *Pietra Perduca*, a sacred pick since the Neolithic, where there is an high-medieval church. The Christian religion replaced the local pagan worships. The ways of this territory were also the communications with Rome. Probably there were garrison houses to control the roads.

A process of severe degradation of the territory and the local economy happened with the fall of Roman Empire. When the Lombard arrived in Italy (VI sec.), reaching the valley of Trebbia, the communications were degraded, because of the lack of maintenance. The news ways favored high ground villages.

The Lombard sovereigns complied with the wish of Irish monk Colombano to build his monastery at Bobbio for political and economical needs. Another important monastery was the Saint Paul monastery at Mezzano [9]. Saint Paul monastery had a task similar to this one of Saint Colombano monastery. In this way, the Lombard put to use a process of territorial and economical organization. The monasteries controlled the communications to Rome near the Byzantine border and monks reorganized the economy and the structure of the territory.

The local commerce was important. This consideration is proved by the findings of an important Lombard settlement along the ways that connected Embresi and Mezzano with the level plain towns (Piana di San Martino, Pianello V. T., PC) [10]. A group of archaeologists discovered a great quantity of coins of different periods and different countries near the roads, mark of a flourishing commerce [11].

The position of Embresi is related to the ancient ways of commerce and pilgrimage. The most known pilgrims way is the Francigena Way, which was going from the plain cities to Rome, through the passage of Cisa in the Apennines; but there was another shorter way called Way of Abbots, that is getting across mountains and the territories of Trebbia valley. The Way of Salt was a very important commercial itinerary, too, and the Caminus Janue, which was the ancient way to join Genova and the sea, was overstepping the territory near Embresi. Close to Embresi, there is a place called "the Boat" on the bank of Trebbia. Historically, here there was a passage to reach the other riverbank by boat.

The stone buildings of Embresi, the morphology of the hamlet and the tower remembers a fortification near the ancient medioeval ways, which was situated in this historical background, near tourist centres, in a territory of great natural potential.

3.2 Construction features along high-medieval ways

The constructions, which were located in territories amministated by Saint Colombano's monastery, present the same construction features [12]. The repetition of serial characteristics seems to be the result of the action of skilled workers, in spite of that buildings have always considered only rural construction without any importance. In particular, this situation is thought in connection with the planning and the process of colonization, that were wanted by Lombard kings (VII-IX centuries).

Stone and wood were easily found in the territory, thanks to the presence of forests and rocks and the villages, in which are shown the construction trademarks described, are quoted in high-medieval documents. In the opinion of researchers, an action like this had to take place in a period of reorganization and social reconstruction after the slump that followed the Roman empire decline and the next barbaric invasions.

The particular way in which are built windows and doors is peculiar and this feature is always found in the high medieval constructions, located along the Lombard communications. Door and windows frames are made of stone blocks (1-7 elements), bigger than other ashlar used for the masonry, and these blocks are, one after the other, in vertical and horizontal position. The same peculiarity was used to built the corners of buildings. In some exemples the windows frames are made of an only big element, which has trapezoidal shape in order to mechanic reasons. The stone blocks are worked only on three faces. The fourth face is only rough-shaped, because it is turned to the interior of the masonry. The pattern of the walls are regular and the mortar between stone element are not visible in the external face. The two door frames stay on a monolithic element, which constitute the doorstep. It was one of the stones that are put at fist during the moment of the construction. In fact a resistant area of support was necessary for the foundation of the frames, which has a considerable height. The frames support the architrave, which can be linear or curved. Sometimes there is not a lintel, but a stone arch made of two or more element. The ashlar of these arches are worked in the same way than the blocks of frames and lintels.

Fig. 4: The position of Embresi in connection with the Lombard ways (VII century). (Satellite picture by Google Earth)

Fig. 5: Graven faces on the wall of a building

Fig. 6: A window with monolithic frames

Fig. 7: the pattern of the masonry of Embresi

Fig. 8: A monolithic doorstep at Embresi

Fig. 9: The west front view of the tower and its longitudinal section

Doors and windows of Embresi have got all these features. In particular, the two doors of the tower has stone arches made of two ashlar and there are some little windows with monolithic frames and architraves, which are much smaller in the external faces than their internal this one. Some windows has the frames that present these feature, but the stone architrave is changed with a wood lintel. Probably, some of these windows suffered rehashes and changes. Doors and windows of Embresi are set in a background that shows the morphology and the characteristics of high-medieval buildings; so it is very probable that Embresi was really a fortification of Lombard age. The masonry is made of two faces of stone blocks and it is at least 50 cm in thickness. The walls of the tower is nearly 1 m at the foundations. The corners are particularly studied. The stonework remembers dry masonry, because the joints between ashlar are very thin and the mortar doesn't appear in facings.

There are different hamlets that shows the features described, in Liguria and in other place connected with the Lombard reign and, in particular, with the monasteries of Saint Colombano. In some examples, the stones used to made the blocks of corners and the frames of doors and windows are different from the stone used to made other ashlar. Sometimes this is clearly visible also in the colour of materials. The stone material used to build ancient building of Embresi has similar features; in fact, mineralogical analyses of some different stone blocks shows differences in composition connected with the position of the element and, so, with its use, too. X-ray powder diffraction (XRD) analysis was made at the Department of Earth Science of the University of Pavia (prof. M. Setti) and it demonstrated that the builders of Embresi had to have an exact knowledge of materials and techniques, as the hypotheses said. The stones used to make Embresi's ashlar are limestone, mainly made of calcite, dolomite and quartz. The findings of the analyses show the limestone used to built corners, doorstep, door frames, steps have more quantity of quartz then the stones of the other ashlar. Quartz is more resistant then calcite or dolomite, so the builder used the most resistant materials to realized elements which are apt to more wear and strain.

Buildings of Saint Colombano's age were built on slopes, along north-south direction and stone stairs rose to the differences in high. The plans were square and they changed according to constant sizes. Buildings has two or three above ground floors and, sometimes, a basement floor. Rooms at the ground floors were services and real houses are placed at the upper floors. Embresi has these features, too.

At Embresi, a second tower was remembered by the old people; it was torn down, because of the construction of the driveway. However, the two towers and some carved stone faces are peculiar features, that are rare in other similar hamlets.

3.3 Planning strategies and hypothesis of re-use

Embresi is a small settlement, that is perfectly included in a territory characterized by landscape values. Its importance is not only given by itself, but it depends on the close connections with the environment: the morphology is connected with the orography and the natural surroundings.

The village is been as an uncomfortable place, because of the costs of interventions and due to the unsuitable living conditions. This situation is common with many unknown historic centres, in spite of people is involved with them. However, this weakness is able to be turned in opportunities to enhance value of the frail territory and to create a new development [13]. The historic villages set in rural landscape are able to answer to many non-material needs, which have surfaced in modern society. Nature, calm, psychophysical regeneration are in contrast to the hectic life in cities. This is the starting point of the planning.

It is significant to set Embresi in the present, respecting its historic and architectonic features. Many villages of the territory were drastically changed and few places preserve the peculiarities of the place. So, the importance of conservation of local identities is obvious. The approach is critical and it wants to argue cultural values, which have to be preserved, now and again at the expense of the design.

Embresi suffered deterioration and rehashes and it has now come to us as a rural settlement with several structural damages. The planning follows on deep investigations about architectonic features, materials, historical stratifications. So it was carried out activities of metric survey, of studies of materials and techniques. At the same time, the research included a study of the local history, essential support to understand the truth. The hypotheses of re-use sprang from the interpretation of the local spirit. Embresi is near some holiday resorts as Bobbio and Travo, known for their cultural history and for their landscape beauties. Therefore it seems natural the choice of temporary houses, thought to play host to tourists, who can be called the today's pilgrims to the discover of ancient ways and local traditions, or who choose a short holiday in peaceable places. The aim is to give a new life to the ancient buildings, preventing they remain *embalmed memories* [14].

The buildings of Embresi are houses and, so, the planning maintains the residential functions, even if they don't keep to comfort rules, needed for living conditions. Ground floors maintain their service functions. They were sheds or cellars and did not communicate with the real houses. The bathrooms didn't exist in buildings. The entrance stairs were outside. Internal rooms are not usually high according to the law and there were wooden ladders to reach possible upper levels.

The idea is to preserve geometric features, masonries, existing windows and doors. The re-use supports the choices, because obstacles and country roads and the isolation from the city represent the potential of Embresi.

The plan divides the hamlet in nine living units and it creates some common rooms. The tower, instead, is suitable to become an exhibition centre, in which photos, rural tools and other documents connected with the history of Embresi can be shown. The creation of residential units and common services has taken account of the possible movement flows that might occur within the hamlet.

It isn't possible create shops or restaurants, in fact this idea would be unsustainable because of the bonds and the distance from cities.

The design approach is the insertion. The existing buildings are the envelopes, or rather the casings in which the missing functions are inserted. It is like to create "rooms in rooms", specifically adapted to the existing spaces, thought as transpositions of the external walls toward the inside of buildings.

The new functions (bathrooms, kitchens) are thought as boxes, inserted in the buildings. These elements are designed as standalone boxes, that are detached from masonry.

The favourite material is wood. The timber has already been used in floors and roofs, this material is suitable to be used in combination with the stone and it is available in the territory. Timber structures seem to be temporary elements and they represent the precariousness and the reversibility of the design in according to the restoration rules. The internal stairs are wooden structures, too.

The floorings of the ground floor were clay court or stone floorings. At the upper floors, floorings were usually made of planks of wood. If the flooring no longer exists, the plan is to make new wood floors.

The plan is to preserve chimneys or insert wood stoves, which can act as boilers. This project proposes to use radiating panels. In summer, the activity of the stoves is replaced with the activity of gas boilers. So, the planning wants to pay attention to the aspect of sustainability. The design wants to favour the dry techniques, too, in agreement with the concept of reversibility.

The restoration of an ancient hamlet and the creation of accommodation facilities, that don't cause the overbuilding of the landscape, are an effective way for the development of the territory.

City and Architecture Marginality and reappropriation The Case of *Cavone* in Naples

Riccardo FLORIO

Department of Architectural and Environmental, Faculty of Architecture, University of Naples Federico II, Naples, Italy

E-mail: riccardo.florio@unina.it

Abstract

Contemporary town calls for a peculiar attention nowadays.

Its text exegesis, written by history through stratified emersion of its becoming, is requiring a critical interpretation in order to understand its final state, which is expressed by the forms of its contemporaneity.

The connected operations of interpretative reading and dynamic representation put us in the privileged condition of catching deeper meanings which are translating terms such as latent information into manifest information.

Those are suggesting possible scenario(s) to define suitable and well-balanced intervention's strategies.

If Survey is not only collecting data and Representation is not only an empiric restitution of information through sign vocabulary, Survey and Representation together are a complex operation to prime a process of stratified knowledge in order to delete hampering parameters to the unveiling identity of a place, of its characterizing components, of interferences (meaning genetic crossing-over), all of which are marking the place's belonging to town and to environment.

It is like looking for a subtle and hidden vein within which the town's genoma is flowing. It means referring to this to be able to imagine and think over that place's identity renewal and the criteria to confirm and consolidate the spirit of its domain.

The experience I would like to propose as a good practice is that concerning the study of "Cavone" area in the city of Naples. This area was at first a river-bed and then a tufa quarry until XVIII century. It was situated outside city walls in front of what was once called Largo Mercatello. Today the area has been totally absorbed by the tumultuous plot of contemporary urbanization.

It is a difficult area, as far as its morphological origin, its urban character, its social and living conditions. This area is pervaded by an atavic imprimatur of degradation and marginality (less) which is imposing at this time the promotion of a total regenerative action (more) in order to bring back town's role of strategic relevance as a whole.

Key words: excavation, porosity, division, regeneration, re-appropriation

1. Introduction

"I dare say that an urban x-ray is far more beautiful than its photograph, it beyond any doubt leads us into pathological areas, showing us deformations we did not see, but always astonishing us because the miracle of urban life is revealed. Among the cities whose x-rays are most extraordinary that of the most amazing of cities cannot but emerge: Naples. What other city could have maintained the meaning of "cave", this shadowy and mysterious, sinister and divine place?... And before we see these grottoes, caverns, caves, quarries, still less

Fig. 1: View of Lafrery, 1566, detail. The Porta di S. Maria di Costantinopoli and Porta Reale are indicated with n. 7 and 8.

Fig. 2: View of Baratta, first edition, 1628, detail. To be noted Colle di San Potito with cliff over the Cavone and the Granaries..

we knew of Naples and of her fascination; beauty of history and construction, and indeed of other things... But we were also beginning to perceive that the city could not be fully known without its sections, and how alternative life in these sections was”[1].

The study proposed regarding the urban area of Naples derives exactly from these considerations: a hidden beauty, disregarded, often vilified, which calls for a motion of emergence which passes through a difficult needle eye of conscious recognition thus, a recovery to a sense of belonging to the city. It is most true, a part of the city discovered through an in depth x-ray exploration, a part of the city that on photograph remains reticent, indifferent and devoid of character. It is still very true that this city needs to be dissected through incisions that evidence its naked beauty often made to shreds distractedly by man, but unavoidably resurfaces in conditions closest to misery. It is necessary to descend into the intimacy of form because “Beauty is a severe and difficult affair and does not allow to be conquered at the first attempt: the moment in which it is ready must be attended, then it must be spied, stalked and tied firmly to force its surrender. Form is a Proteus far more ungraspable and much richer than fairy tales traps: only after endless struggles, it is possible to force it to reveal its true resemblance”[2].

The shape of the numerous figures of the Cavone which crystallizes according perpetual motion never succeeding to embody it, as if belonging to a continuous flow, it deposits itself on the multitude of these buildings disposed in a labyrinth hive-like where life takes place according to ancient rituals and processions, competing daily with outdoor spaces, annexing and consuming them, conferring them always new and various forms. An agglomerate sequence of caves and buildings together where “for urban architectural forms of the past here is no longing. Only allusion to principles that have ‘nourished’ all the past times and still the present. The shape and materials of the constructions become recipients of a living nature - eternal projects depersonalizing buildings and making them timeless -. The man-made visual insults, always acknowledged by the outbreak of Spring”[3].

2. Features of history and urban growth

The furrow of the Cavone along the ancient and steep walls of the tufaceous reefs, was configured within two high grounds in correspondence to two hills: the south-western one around the Pontecorvo ridge and the north-eastern one beneath the *Costigliola* plain, where the “Limpiano boundary was set”[4]. The marked depression was determined by the development of one of two arenas that encircled the *Pendino* slope, upon which the ancient city settled, in particular from the ditch of the *Arenella*[5], which conveyed the torrential waters coming from the upper part of the city, that were in part distributed along the *Infrascata*, presently named via Salvator Rosa, enclosed the entire *Costigliola* high ground, later named of the *Colle di San Potito*. The valley exceeded

in a difference of proportion, today the difference in height between the two extremities of Via Francesco Correrà, the road that occupied the sediment of the riverbed watercourse converging a steep gradient on Salvator Rosa, and on the other side 'flowing' almost at ground level on Via Pessina, is over 40 m.

The area was so densely vegetated between the two tuff banks that it was barely accessible until the Angevin period, when in the late fifteenth century a hunting lodge was built. Celano reported the allocation of the construction to the Fosse del Grano near Largo Mercatello: "There are wonderful and numerous ditches to store grains in the necessary periods, afterwards the conservation resulted lacking for the city had grown in expansion throughout the entire area up to Porta Alva. Opposite this area of storage, on the left, a ditch-like may be seen, and within it a building made all of travertine pipernini, with windows adorned of white marble, which is now possessed by the Prince of Leporano of the noble Muscettola family of piazza di Montagna. This site is said to be the Conigliera (rabbit hatch), because it once was a rabbit hunting ground. Here King Alfonso came often, and, to spend some time on this hill, on which today is located the Monastery of San Potito, he build the present lodge ... In those days these places were rather savage..."[6].

Therefore Celano refers to not only to the initial condition of the area, but also to the growth of the city, particularly the suburban boroughs which involved the whole city of Naples in the second half of the sixteenth century, as a result of population growth and substantial migratory pressures from the countryside. On the one hand, the plan for urban renewal wanted by Don Pedro de Toledo, established with the objective to draw back into the city old and feudal nobles, and on the other the pragmatic Viceregals, who followed one another from 1566 to 1631, in order to prevent construction outside the city walls, they resulted in a combined effect drawing into

the capital a considerable flow of peasants, farm workers and people with very poor financial possibilities who could not afford housing in the city due to the extremely high costs and who did not disdain to build and live on the margins, contrary to the prohibitions established in the vice-regal notices[7].

Complicating the situation even more, which already recorded practiced a continuous and intensive development of boroughs, the so-called "right to the island" contributed even more. It was exerted by many religious orders during the seventeenth century which,

Fig. 3: Giacomo Conforto, *Abbraccio della Platea della Costigliola dell'III.mi sig.ri Carafa sopra li Regi Studi fuori la...*, 1614. The map was updated in 1722.

Fig. 4: View of Baratta, second edition, 1670, detail. To be noted Porta Reale, the Porta d'Alba and the Cavone with a series of houses.

Fig. 5: *Mappa topografica della città di Napoli e de'suoi contorni*, Giovanni Carafa duca di Noja, 1775, detail.

Fig. 6: *Pianta topografica dei Quartieri di Napoli disegnata da Luigi Marchese*, 1804, detail.

with the support of the Spanish Government and the Church, chose Naples to establish and build churches, monasteries and various religious foundations. “The progressive expansion of ecclesiastical property and land contributed to worsen the housing shortage...” to the point that on numerous occasions “the municipality of Naples was obliged to appeal to the king to put a brake on scandalous raiding of land and property accomplished by the most powerful religious Orders”[8].

The creation of major religious complexes on both sides of the Cavone determined, albeit indirectly, the characteristics of its settlement during the '600, features which to some extent still remain today. In fact, along both the Pontecorvo hill and the southwestern edge of the Costagliola important religious buildings succeed one another. “Representative the salita Pontecorvo.... «Coming from the Church of Gesù e Maria you encounter the Conservatory of S. Maria della Maddalena ... built in the early seventeenth century»... further on, the church and cloistered conven of S. Francesco delle Cappuccinelle and lastly the great fanzago-style temple of S. Giuseppe delle Scalze”[9].

On the opposite side the urbanization of *Costigliola* Carafa is regulated by a proper estate development plan assigned to architect Giacomo Conforto, who in 1614 designs a map in which an orthogonal plant of evident ippodamea inspiration can be traced[10]. The new monasteries of S. Potito and S. Giuseppe dei Vecchi rise and reach considerable dimensions on the tufa border overhanging the Cavone, the first initially due to the conversion of the building and garden of Vincenzo Capece in 1614, and for subsequent annexations of lands bordering with the construction of the church starting from 1630[11]; the second was established, also in 1614, through the purchase made through the Chierici Regolari Minori of the Fabrizio Carafa palazzo “which occupied a privileged area on the top of the hill. The palazzo was restored rapidly”[12], but only in 1634 the construction of the church began on a project designed by Cosimo Fanzago. You can see in a 1629 view by Baratta, the small church of S. Maria dell'Olivo, presently S. Giuseppe dei Nudi, while “the monasteries of S. Monica and SS. Sacramento ... founded later are not yet visible”, along the Cavone there are already numerous construc-

Fig. 7a: Orographic section of the Avvocata territory, from the park of Scudillo to via Falcone Beneventano.

tions”[13].

Even Celano when describing the area of Mercatello, following the alley “which ends at Santa Maria dell'Avvocata.... founded by friar Alessandro Mollo of the Carmelite order, where he founded a small convent; in approximately 1580....”, focuses on the shape of cavone and on the urban development which until then, 1692, in this large ditch was recorded: “After this alley, there is another by which you climb to the convent of 'the Capuchin Fathers, called the Cavone, because through it the torrent rain water come down from the above mount; today these waters are diverted, and the area reduced to a road, populated from one side to the other by comfortable housing. Across from this, on the right our famous public Wheat Storage This beautiful machine was made from the design and layout by Giulio Cesare Fontana, beneath the wall...”[14].

Celano describes “comfortable houses that populate” the big ditch, even if, in fact, the systematic urbanization on both sides, on which, as we have seen, constructions merge and expand to accommodate monasteries, convents, churches and new middle-class houses, taking advantage of better, more pleasant, scenic and certainly more attractive positions as the plains that developed above the two tufaceous banks, confining in the lower part, inside the ditch, the population without means and easily adaptable to the particular conditions of promiscuous living which branded the community of the Cavone from the beginning. “The first speculative works are carried out mainly along the cavone, where until the eighteenth century the construction activity was minor, though constituting authentic channels for rainwater collection, thus, very poor living conditions”[15].

However prior to 1775, the date of the plant designed by Giovanni Carafa, Duca di Noja, the urban structure around the two margins of the Cavone was nearly defined: on the side of the Costigliola small buildings succeed one another and at S. Giuseppe dei Vecchi the unwinding of the first ‘*fondaco*’ (trading posts) appear, first S. Joseph and second S. Anna; on the Pontecorvo side the large ‘*fondaco*’ Cafaro warehouse opens and appears already completed “as... seen on O. Tango’s plant, a structure of communication with connecting alleys, in the construction of the ‘Cavone’ and between the monasteries of the Cappuccinelle and Maddalena”[16].

To be considered that urban development within the vast depression did not register the presence of noble palazzos let alone the presence of religious buildings, this confirmed an exclusive residential inclination made possible by settlements obliged to a complete adaptability. If initially the present cavities, including the warehouses, were used mainly for storage of merchandise related to businesses and sale, these activities soon gave way to the increasing need of homes. From the beginning this need was accompanied by a considerable versatility of subservience to terribly prohibitive and unhygienic conditions, which often compromised the health of the entire settlement.

3. Cavone the porous city

Consequently, it would appear, from the considerations reported up till now, that the name *Cavone* derives from the action of burrowing made by the torrential waters over the years restituting after their course, not only a large carved ditch, but also a series of more or less marked cavities, and that these places, rugged and full of asperities, from the beginning of the seventeenth century were inhabited. Indeed, to this etymological indication

Fig. 8: Orographic section of the Avvocata territory, from corso Vittorio Emanuele to vico largo S. Agostino degli Scalzi.

Fig. 7b: Orographic section of the Avvocata territory, from via Falcone Beneventano to piazza Cavour.

Fig. 9: Planimetric reference.

Fig. 10: Section G-G', from via Gesù e Maria to via S. Rosa

should also be added the one that shows the unnatural but real action of the anthropogenic transformation exerted on the rugged and steep ridges of the tufaceous walls. "In fact, because for centuries the waters washed away the loose material overlying the roof of the tufous, creating the engraving, the optimal conditions were determined for the extraction of such material that visually resulted suitable for both open air and underground cultivation. Don Pedro de Toledo's decree came in corroboration of this hypothesis... which forbade extracting tufa within the city walls, and given that for the entire Viceroy period ... the Cavone was external to that circle, and precisely in that period, within those limits, a myriad of cavities and quarries came to exist, which in addition to, giving the area its name, they contributed to its enlargement facilitating settlements"[17].

Moreover, besides those cavities definable superficial and used for the extraction of tufous, other cavities, rain-water cisterns and all empty spaces caused by the erosive flows of water, are present in this area and are called deep cavities, referable to an ancient system of water distribution, which together constitute a network of tunnels and cisterns connected internally among themselves in a sort of resistant underground structure, which from time to time surfaces towards the open air excavation.

The aqueduct which supplied this area was attributed in all probability to "that of the Carmignano, which began in fact in 1629. Assertiveness, in the present case, does not stem from a syllogism or an analogical test, but from the fact, unique in all of Naples that on a wellhead of the area, precisely at num. 16 of Via Tommasi, a marble plaque was found with the inscription 'Acquedotto del Carmignano'"[18].

A collection composed and diversified of cavities and openings, of tufaceous depressions and impossible raised sections, of unexpected gardens and amazing twists, an unexpected *canyon* which opens into the compact city and reveals its gorges and its permeability. A geological and architectural porosity, where "nothing is finite and completed", porosity that eventually becomes human, where every site is used twice, three times, a

Fig. 11a: Section E-E', from salita Pontecorvo to via Salvatore Tommasi.

thousand times, in which matter seems to absorb and enslave human life. This unique blend of men and things, that seems to dissolve everything in a constellation of “dismembered fragments embedded in discontinuous reliefs” of *disiecta membra*, “a mosaic of fragments” [19], reveals the real credible face of this incredible city. “Architecture is as porous as this stone. Construction and action interpenetrate in courtyards, arches and stairways. Everywhere appropriate space is maintained to become the theater of new unforeseen circumstances. This avoids what is definite, formed. No situation appears as it is, forever thought, no form declares its «like this and not otherwise»[20]. In this passage Benjamin manages to grab “a salient character of the city, interpreted as the unity of men and stones, where no form (whether social or architectural) is «conceived forever». There is a perpetual transience, a constant becoming, a passing from one state to another that is exactly the opposite of the «all completed» of Berlin, the barrack-city by antonomasia, compared with the amoeba-Mediterranean cities from Naples to Marseille”[21].

The Cavone is a large, open space, towards which it seems everything agrees then escapes. It is a gash in the city, a gash in its social substrate and in its material sequence, regaining in matter the prime meaning of its genetic affiliation “‘matter’ has the same root as ‘mother’, ‘mater’. Therefore rock is the mother of the building. Matter is mother”[22].

The Cavone is a great chasm in which a portion of the city converges in its tumult and everyday disorder that needs to be investigated by additional divisions, so that it goes beyond the veil of the sudden event manifested on the surface and in which in-depth activities of knowledge are undertaken. The Cavone is moreover a wound which the city evades, wanting to leave its healing in a condition of marginalization which, in the moment of its conversion, produces an urban and social suffocation.

Can we today, in a position of taking on new principles for the setting in motion of actions addressed to the regeneration of historic structure, strongly stratified and, subsequently, crowded of functions, of inhabitants and other activities, imagine that the city expels from its body with obvious violence a part which could be reconsidered in a strategic propensity of renovation and re-appropriation?

This role into contemporary town calls for a peculiar attention nowadays.

Its text exegesis, written by history through stratified emersion of its becoming, is requiring a critical interpretation in order to understand its final state, which is expressed by the forms of its contemporaneity.

The connected operations of interpretative reading and dynamic representation put us in the privileged condition of catching deeper meanings which are translating terms such as *latent information* into *manifest information*. Those are suggesting possible scenario(s) to define suitable and well-balanced intervention’s strategies.

If Survey is not only collecting data and Representation is not only an empiric restitution of information through sign vocabulary, Survey and Representation together are a complex operation to prime a process of stratified knowledge in order to delete hampering parameters to the unveiling identity of a place, of its characterizing components, of interferences (meaning genetic *crossing-over*), all of which are marking the place’s belonging to town and to environment.

It is like looking for a subtle and hidden vein within which the town’s genoma is flowing. It means referring to

Fig. 12: Section B-B', from via Gesù e Maria to via S. Giuseppe dei Nudi.

this to be able to imagine and think over that place's identity renewal and the criteria to confirm and consolidate the spirit of its domain.

It is a difficult area, as far as its morphological origin, its urban character, its social and living conditions. This area is pervaded by an atavic *imprimatur* of degradation and marginality (*less*) which is imposing at this time the promotion of a total regenerative action (*more*) in order to bring back town's role of strategic relevance as a whole.

The present-day targets directed to the proper action of regeneration of historical cities concern the pursuit of quality in the transformations of physical space and environment as well as the convergence, via the implementation of multiple public and private strategies among the citizens' expectations and that of the economic operators and the public institution policies towards a joint project regarding the city's future in terms of urban quality, landscape and environmental sustainability and social cohesion.

In this new system of relationships attention has to be focused on this area of the city of Naples that has over time acquired, above all in the contemporary, the role of "*casting off*" urban area, despite its strategic location in the consolidated historic structure of the city and within the district of the Avvocata, which proposes itself as an essential hinge for the potentials it is capable of expressing and for the inclinations that have characterized it in the urban role.

Fig. 13: Section D-D', from salita Pontecorvo to via Salvatore Tommasi.

Fig. 14: The Cavone from the edge of Pontecorvo.

Fig. 15: The Cavone from the edge of via S. Tommasi.

The network of the *good practice*, founded on the fundamentals of knowledge and on the administration of the existing tangible and intangible resources and pursued through the instruments of cultural importance and representation, wants to establish a regenerative process aimed at attaining high quality standards, recovering restored characterizing components in the matrix of contemporary cities, as the *mixité* (blend), the hybridization of spaces, overlapping of functions, the new "*shape*" of the city and, by this means, the governing of sustainability of intervention and its renewed urban dimension.

It is necessary to regain possession of the awareness that this city, partly dug underground, irregular in form and promiscuity of customs and habits is a confidential part of the other city and "it would be useless and foolish to discover some immediate functionality, infrastructure and tourism whatever it may be. To be part of the city means that it can and should be covered through, perhaps to the square, possibly to the sea... and it is in this idea of covering through that the project will originate and form. The increase of the city's consciousness lies within its strength. In this manner the drawing does not insinuate itself, nor does it retrace the urban topography, but rather... it precipitates it, almost a sudden transition of the physical state of matter. That same matter which by its addition and subtraction indicates the origin and osteological development of the city"[23].

Title: Heritage architecture: a complex design with natural light

Mounjia Abdeltif, Mejda Benchaabane

School of Architecture, Algiers, Algeria

Ecole Supérieure des Beaux-Arts

abmounjia@gmail.com

mejdaben@gmail.com

Abstract

The ancient city of Algiers (the “*Medina*”), “a master piece of human creative genius,” according to United Nations, has been a universal heritage site since 1992. The original codified language of the architectural morphogenesis of the medina is unknown.

Our specific research deals with the language of morphogenesis of “**Dar** El-Djezair” which is more than a house. It is a place where a lot of functions could take place without altering quality and harmony. In order to understand the generative process, we decided to use fractal geometry which helps build efficient models.

Complexity theory is a more appropriate theoretical framework because it could help us understand the underpinnings of complex built. During the twentieth century modernist ideas were about reductionism, separation of fields, and simplification of forms. Today ugliness is a true reality.

In Algeria future sustainable architecture should be rooted in heritage. In our research we have been re-constructing the intelligibility of this “DAR” through a fractal model called “Menger’s sponge”. In this kind of architecture **natural light** is a kind of “designer”. Through a metaphorical approach the immaterial light enters a volume in its center and starts a process of “carving” central spaces connected with fractal rules. In final, we aim to elaborate a pattern language for this “Dar”.

Key words: morphogenesis, Dar, light, language, fractals.

1. Introduction

1.1 Heritage

In Algeria, after the event of colonization (1830), most of valuable heritage architecture became French colonizer’s property. Algerian people had to leave their houses and their city. Thousands of beautiful houses collapsed during nineteenth century. At the starting of twentieth century, French administration began to value that local precious architecture. Algerian society did not have the right to get an education. A very few went to school. At the time of independence (1962), ninety per cent did not know how to write and read. The Algerian society has been discovering the quality of its heritage architecture for about ten years. The old quarter of Algiers (capital) has been world’s heritage since 1992. Despite that it is degrading day after day. Authorities and scholars ignore the urban and architectural **code** of that fabric. It urges to undertake researches because buildings are disappearing. They are the only witnesses of that period (seventieth and eighteenth century). Timeless beauty, complexity, harmony, designs with nature and efficient way of building are the characteristics of El-Djezair (ancient city of Algiers).

1.2 Theoretical framework

El-Djezair is a city composed mainly of houses named “Dar(s)” because they are more than houses. Their design morphology is suitable to numerous functions. Overtime, whatever the use, quality of space did not alter. Spaces inside always fit to inhabitants. Even esthetically, until now, people from all over the world are surprised by such beauty. We became aware of its value and decided to find adequate methodology to elaborate the pattern language (code) of this “Dar”. Our framework has been complexity theory, fractal geometry, analogical and metaphorical approach. Since we could not decompose such a shape, we had to find its mathematical model in order to keep it as a whole while studying its intelligibility.

2. Research

2.1 Morphogenesis and interiority

“The architecture of a shape is the logic of its morphogenesis, during the process the shape is unfolding”, Jean Chrétien Favreau.

Ancient Algiers, as a medieval city is a compact fabric that matches with local land form and river system (network). Very often, streets were rivers or contour lines. Most of the buildings have only one wall facing the street. All, without exception, are courtyard units. Interior living places **had to get natural light** through the courtyard named “West Ed Dar” (centre of the Dar). It is actually the centre of life, the main connector, the well of light and the place where all events keep occurring.

In our metaphorical approach, we consider that at the first stage of design, we start with a cubic block corresponding to the buildable three dimensional piece of land inside a compact fabric. Theoretical generative process is the action of creating void inside the given volume. Through a fractal interior organization (Karl Menger’s sponge), the light coming from the sky, “falls” inside the cube. Then, for the next stages, light is expanding, creating infinite surface and reducing volume to zero. The sponge is a model for natural organisms. These are structured at infinite scales. But manmade organism has limited levels of scale. We aim to describe and explain a number of scales in this **Dar**. Hausdorff’s dimension of the sponge model is 2, 7, between 2 and 3. It is actually a fractal model and the most interesting one for architects. The process of creating void with natural light helped us understand all specificities of the Dar: proportions, special place for each needed space, dimensions, proportions, degree of connectivity, quality of arrangements and the right measure for elements at each level of scale. We could explain the “why” of a lot of specific features.

Fig. 1: Some images for Karl Menger’s sponge

2. 2 Dar as a case study

The morphogenesis of Dar is a complex process inspired of natural organisms such as lungs or sponge. It is a step by step process similar to an algorithm. This shape is made of four parts: a base related to urban landscape, two main inhabited levels and a terrace (“Stah”). The base is convenient for sloping ground as well as flat ground.

Step one:

Fig. 2: Interior process

Inside a solid cube the light coming from the sky vault enters the volume vertically following a nine square grid. This center's proportion is $1/9$. After dilatation in order to get "shin" (gallery around), it becomes $1/5$. This rule is observed in all Dar(s) without exception. According to fractal iteration (Menger's sponge) we start with 9 squares and one void.

Natural light is not static. Changing with sun position in the sky, light generates emotion. It is the main criteria in the design of spaces inside the Dar. We are facing a challenge today: how to save energy? Working with natural light doesn't belong to the past, it is a timeless attitude. Alternating light and shadow provides positive sensations in Mediterranean climate.

Step two:

The empty volume of West Ed Dar (WED=center) is designed with arches and columns and four interior walls which are the actual façades. Specific places are chosen for doors, windows, stairs and ornamental features. Each detail has a fractal relation with others at many scales (auto similarity). For example, rooms around WED are arranged as a helix, columns are twisted, spirals are carved on doors and we can see helix on tiles that decorate walls. Turning shape has been chosen for aesthetical and symbolical reasons since early ages. "Dar" coming from "Daara" in Arabic language means "to turn". We are working on this particular case: "Dar Abdeltif" which was restored in 2008.

Fig. 3: Turning shapes

Step three: Natural light has filled the WED. Then it penetrates laterally to illuminate each Beit. This light goes through large and high doors and two windows. It reaches the center of the Beit: the Kbou which is a niche facing the door (in all cases). Two smaller niches face the two windows, in two sides of the Kbou. These niches are made of three parts. They are built-in closets and can be open or closed par inhabitants. This axis organization is part of specific language of Dar. We could never find a column facing the door of Beit. It always matches with an arch which is also specific in El-Djezair. It is a middle broken arch that can fit all dimensions of WED and number of arches. There are four types of Dar: 4, 8, 12 and 16 columns. Dar Abdeltif is a twelve columns unit.

Step four:

Fig. 4: Axis

Natural light commands the width of Beit and the depth of Kbou. Actually, all spaces are strongly connected. They make this shape a coherent whole. Level of complexity is high because no one could separate parts. Light is obviously participating to build connections. This leads us to establish that the way people, in ancient times, used to organize differently their way of building and constructing. There were teams composed of master builders and workers in different fields as iron, wood, stone, bricks, tiles... They used to coordinate and work together on site. Everyone knows the rules and the specific language and got the process in mind. Measure was not meter but cubit which has always been drawn from human body. The main rules were golden proportion and Fibonacci's series. This means that ancient builders were using natural laws in order to design places at all scales. Christopher Alexander talked about "The Timeless Way of Building" and "Pattern Language". In his last works ("Nature of Order") he made a consistent synthesis to demonstrate that if we want to feel alive in places, we have to work on complex language processes based on Nature.

Of course the process (it looks like an algorithm: simple rules for complex shape) could be made on more steps. Our research is progressing.

Some remarks: In the sponge process, when light "carves" the volume step after step in fractal iterations, the interior volume becomes more **spacious**. This concept is about design not dimensions. A house could be big and non convenient and small but qualitative and full of good places. If the center is full of light we perceive spaciousness. This is a psychological perception. Therefore, we can link spaciousness and interiority.

Fig. 5 : Patterns : WED, Beit, Kbou, Niches, Doors, Columns, Windows.

El-Djezair (today Algiers) as a city, is a large complex system made of two subsystems. One is mineral:

Fig. 6: Mineral city

The other is vegetal:

Fig. 7: Vegetal city

The two systems cannot live separately. Dar Abdeltif is built inside vegetal city. That is why it has exterior windows. Connection with gardens is necessary. Most of people who can afford a second house migrate in summer. These places look like heaven. It is cool, breeze comes from the mediterranean sea through luxurious vegetation.

In summer time, subtle solutions make Dars let the right amount of light in. Different trees provide large shadow and freshness. Inhabitants can migrate inside their Dars. They can sleep on the terrace.

2. 3 About natural light

Working with natural light generates complexity and rich ambiances. Thinking with metaphores connects to philosophy and environmental sciences. We are getting consciousness that all fields should be working as a network for a better world, less ugliness and quality of life. It is of course difficult to use this tool comparing with sun ray which more "scientific" and materialized. Sun ray could be drawn in a triangle. Changing angles depending on latitude, season and day times can be used by anyone easily. But light diffusion is question of place experiment. It is also about intuition. Consequently, it is not really teachable in schools. It is important and urgent to find a way to develop this concept in university because natural light makes projects be more complex, richer and of course they promise to satisfy sustainable development. We should teach how to save energy in looking for efficiency through natural laws. Nature don't waste matter. Everything could be recycled. Our ancestors knew how to save energy. They built with ingenious water systems (Andalusia) and green elements. Organicity made city last until today.

2. 4 Concluding remarks

In Algeria, there is a big gap between schools and practise. Politicians have different values. They decide for urban landscape, they make cities without consulting researchers in urban design and they have been organizing territories by adding disconnected units where housing is outside the urban frabric. Suburban areas are dead places and social diseases are increasing every day.

Buildings don't interact with natural environment. Appartments are so uncomfortable that people spend money in air coolers and heaters without reaching real comfort. This attitude goes against nature, it is impossible to make those places maintain over time. They are not convenient and will break down soon.

Fig.8: Disconnected housing

In such units, people get too much light or not enough. Natural light is certainly not a criteria. There is no complexity, no organic process and no connection with nature neither city. The architectural design is very simplified. Researches must propose new methodologies to politicians. Heritage offers valuable knowledge, interesting concepts and sustainable solutions. It should always be a reference. Things must change before we face an ecological problem. When we look at this ugly landscape, a question comes in our mind: **Do we need architects for producing this?**

Simple tools for complex geometries Genesis and reconstruction of the Philips Pavilion

Alberto SDEGNO¹

⁽¹⁾ Department of Civil Engineering and Architecture, Faculty of Architecture, University of Trieste, Trieste, Italy
sdegno@units.it

Abstract

Two small sticks connected one to the other with some rubber bands define the tool used by Le Corbusier and Iannis Xenakis to visualize the hyperbolic paraboloids that constructed the main morphology of the Philips Pavilion. Realized for the 1958 Expo of Bruxelles and destroyed after the event, it is difficult to think that this sort of children's game – which could be played by hands, changing the position of the two linear elements in the space – was at the origin of such an important and complex structure.

The aim of this research was to study the geometrical genesis of this relevant design of the XX Century, starting from all the sketches, technical reports and textual description of the authors, to finally reconstruct all the single forms in a digital way, using the advanced modeling offered by the CAD procedures.

The *Poème Électronique*, as Le Corbusier called this project – a very effective oxymoron that describes the double finality of the work very well – should have been a presentation of the state of the art of a kind of “human technology” used to exemplify the history of the world in a small path in which the people would experience lights, images and sounds in a very impressive way.

The research ended with the realization of a video that showed in detail the evolution of the morphology from the simplified abstractness of the initial phase to the complexity of the final visualization, using algorithms of realistic rendering, the only way we have to save the memory and visit destroyed buildings.

Parole chiave: Le Corbusier, architecture, representation, model, video.

1. Introduction

Two small sticks connected one to the other with some rubber bands, to be manipulated with hands for generating an infinite series of hyperbolic paraboloids: this is, in brief, the simple and extremely effective mechanism by which Iannis Xenakis explained to Le Corbusier how you could get the complex geometric shapes that would allow the creation of an architecture. Applied to the Philips Pavilion, commissioned in 1956 to the architect by the well-known technologies' firm for the Expo to be held in Brussels two years later, this seemingly simple design procedure would be transformed into a highly elaborate process of composition, which would host the technology event inside, structured in different aspects: sound, video, color. Described by Le Corbusier as the “*Poème électronique*” – an oxymoron of undoubted efficacy, which refers at the same time the natural character of the poem and the artificial component of the technology – is among the most influential and pioneering works of the twentieth century, which now we can find traces only in publications and in a lot of photographs.

Figg. 1, 2: Photographs of the Philips Pavilion.

The research that is presented here, started at the IUAV University of Venice and continued at the Faculty of Architecture of the University of Trieste, was developed from this simple idea, to analyze two levels of study of the work: on one hand the simplicity with which you could derive articulated forms by the geometrical point of view during the concept phase, thanks to the use of easy operative expedients; on the other hand, the complexity of describing in a graphic and technical way, ending to the final realization, the articulated architectural morphology. Starting from these premises we initiated an accurate investigation of all the hyperbolic paraboloids that make up the external surface, until the realization, in digital form, their reproduction, both from the point of view of the configuration, and from that of photorealistic execution, in order to verify the correspondence with the drawings of the authors and the photographic images available.

2. Brief history

We do not analyze all the steps of the designing process, as there are a lot of publications that describe it, but it is necessary to remember that the design was commissioned to Le Corbusier by the Philips, and precisely by Louis Kalff, who is the light engineer of this well-known firm. As Xenakis remembers, Kalff, in one of the previous meeting, required to Le Corbusier some detailed information: "I would like that you design the Philips Pavilion without exhibiting our products. A demonstration among the most ambitious about the effects of sound and light, where the technical progress could lead in the future" [1]. The great freedom given to the functional aspect – the exhibition – and to the definition of the morphology and to the contents, allowed that the proposal was accepted by Le Corbusier, who signed the contract on 13 October 1956, and started studying the possible design solutions, with the help of the musical composer and engineer Iannis Xenakis. Some days after there was the first idea of the project, and in November there were some details on the sketchbook of the architect. In December the second solution at the scale 1:200 is finished, for the final structural verification. At the same time some physical models of the volume for the analysis of the deformation are built. In the meanwhile Le Corbusier thought about the organization of the direction of the sound space, asking Edgar Varèse to find the soundtrack of a video that should be projected on the interior walls of the pavilion. Despite the opposition of Philips, that did not like the music of this composer, in September 1957 Varèse arrived in Netherland to define the musical composition. On 17 April 1958 there was the official inauguration of the Pavilion, but immediately it was closed to be re-opened on 2 May, due to the complexity of the system. After six months of free exhibition during the Expo and about two millions of visitors, on 30 January 1959 this architecture was destroyed, otherwise there was a proposal of Le Corbusier to transform it in a center of scientific research.

Fig. 3, 4, 5: Drawing of the tool used by Le Corbusier and Xenakis for the study of the hyperbolic paraboloids and first planimetric schemes by Xenakis.

3. Geometrical analysis of the design

As we have written in the beginning, the geometrical genesis of the pavilion is based on a very simple compositive mechanism, represented with a small sketch where two metal sticks A and B – signed as “directrice” in the text of the figure – are united with elastic bands, called “génératrices”. The movement of them with hands allows to easily reproduce, such as during a game, a series of spatial morphologies, from the simple to the more complex ones, reproducing forms that the history of geometry has classified as a particular type of ruled surfaces: the “hyperbolic paraboloids”. In reality before reaching this result there were some partial steps, that have been defined only thanks to the use of this technical instrument. The initial idea, in fact, should have been to represent a human stomach, as it was drawn for the plan, where entrance and exit would determine the explorative capabilities of the space, but, in the same time, the concept of the bottle should be the focus of the research, as documented by some sketches and notes signed by the architect himself. As Xenakis said: “In October 1956, Le Corbusier proposed to ‘translate mathematically’ some ideas. He gave me a sketch. Le Corbusier [asked me] to look for a form of a ‘bottle’ containing the ‘nectar of the visual presentation and of the music’ for the building. For the cinematographic show, he wanted to have flat vertical walls. For the spatial effect, I asked a bottleneck tapered up to the roof of the pavilion where the projected images would disappear. As for the bright colors, he wanted concave and convex surfaces [...] to accept requests from architects who were working near the Dutch pavilion: ‘We recommend a simple convex surface for the Philips Pavilion, to not exceed the garden and the foliage surrounding the Dutch buildings’. Because of the darkness within the ‘bottle’, the beauty was not the main concern” [1].

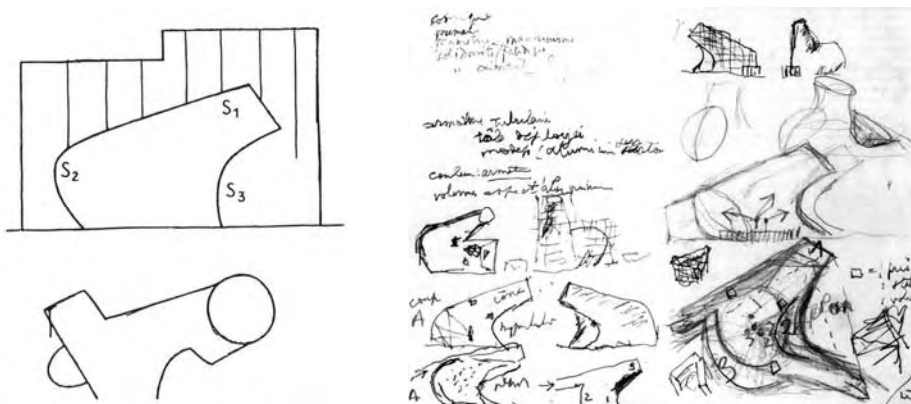

Fig. 6, 7: Drawing in plan and section of the “bottle” configuration and sketches by Le Corbusier.

Fig. 8, 9, 10: Sketches by Xenakis of the volume configuration as a “tent”.

Immediately the idea to transform the morphology in a “tent” volume was presented, in which the inclined walls would have been incurred each other, thus avoiding the need for an internal supporting structure. About this first solution there are some sketches and models, which are made with piano wires bent at the elbow and stuck in a board. The second project was carried out using the methods of descriptive geometry, as exemplified by some technical drawings. The tool of the sticks with elastic bands, subjected to torsion, could be represented as plan and elevation on a drawing paper. Once again Xenakis explains the procedure used: “To choose one of the surfaces of the pavilion we proceeded more or less fixing the selected geometric curve in correspondence of a specific drawing. [...] For this architecture in three dimensions the architect has to think not only in plan: he needs a three-dimensional representation as the elevations aren’t only the result of a parallel movement obtained by the orthogonal projections. The new heights of the three cusps have been chosen and their projections were determined on the horizontal plan, to increase the size of the central cone L. The first cusp was set at 21 meters above the ground, the second at 13 meters and the third at 18. Later, using both the experimental tool and the descriptive geometry, all the paraboloids were modeled, with the conditions that the intersection with the horizontal plan would conform the primitive scheme of the plan itself” [2]. The graphical tool, then, becomes a device essential to understanding the work totally, despite the difficulty of grasping the project in its spatial dimension. Tables and geometric diagrams with orthogonal and axonometric projections, alternate to make explicit the genesis and evolution of form. In particular, the hyperbolic paraboloids are represented in the projective form making use of descriptive geometry, so as to identify the development of each individual surface. From this analysis emerges – as will be confirmed by the digital restitution – that each element takes place also under the floor, and for this reason we decided to evaluate only the upper part of the morphology, leaving out everything that stays under this plane. Although many graphical documents were destroyed in that period, some of them are still available because they were published in the journal called “Philips Technical Review”.

Fig. 11, 12, 13: Drawings by Xenakis, describing the geometrical analysis of the hyperbolic paraboloids.

Fig. 14: Geometrical drawing representing the hyperbolic paraboloids.

We have also to notice that the origin of the morphology is in the attempt to define a strict relation between architecture and music. Xenakis, in fact, attempted to propose a graphical method to describe the sound with the work *Metastasis*, thanks to the theoretical proposal of the *Modulor* created by Le Corbusier. It is not a coincidence that the architect himself, impressed by the hypothesis of the assistant, would include in the book *Modulor 2* a brief text and two images describing the musical score by the composer. In the note Xenakis was very explicit: "In the composition 'Les Metastasis', for classical orchestra of 65 elements, the role of architecture is direct and fundamental thanks to the Modulor. The Modulor found an application in the essence of the musical development. [...] the six algebraic and temperate intervals of the range of twelve sounds are emitted in times that are proportional to frequencies. [...] The sequence of temperate intervals is a geometric progression. The times will be the same. [...] On the other side, time has the additive property. A period can be added to another one and their sum is a period too. [...] Among all the geometric progressions, there is only one in which the terms have this additive property. It is the progression of the golden section. Here is how the idea of the Modulor created a close structure link between the time and the sounds" [3]. And in another text the composer explains the relation between *Metastasis* and the experience of the Philips Pavilion, above all in reference to the raising and lowering of the height of the sound, known to specialists with the term *glissando*: "If the *glissandi* are long and well intertwined, we could obtain some sound spaces in continue evolution. Among the possibilities, then, there is also that one that allows to arrive graphically (drawing the *glissandi* as some straight lines) to project some complex surfaces. I have done experience in *Metastasis*, the composition for orchestra which was executed in 1955 in Donaueschingen. Well, some years after, when the architect Le Corbusier, where I worked, asked me a proposal for the architecture of the Philips Pavilion in Bruxelles, my project was developed by the experience of *Metastasis*. So, I think in that occasion music and architecture found an intimate correspondence" [4].

Fig. 15: Graphical transcription of the composition *Metastasis* by Iannis Xenakis.

Figg. 16, 17, 18: Models of the pavilion at different scales.

After this graphical works, there were a lot of spatial representations. A large quantity of models in different scales, in fact, were realized for the occasion, starting from some simple studio's *maquettes* – realized with wireframe structures – up to models that tried to reply the whole volume of the architectural object. In particular a model in 1:25 scale. Realized in plaster, served for understand the possible deformations of the structure subjected to its weight and to accidental loads, while a further model in 1:10 scale allowed to verify the assemblage of the plates of the walls and the placement of the cables that should put the structure in tension to ensure the stability in time. The study on scale prototypes allowed the subdivision in one meter squared parts all the surfaces, regulated by a grid of straight lines. The same elements was useful also for the construction, as during this phase was realized a temporary framework which reproduced the drawings of the base composition, able to allow the assembly of about two thousand of fragments of paraboloids, which will be united with concrete, using prestressing steel cables, to weld all the elements together.

4. The digital reconstruction of the project

After the analysis of the main documents of the design we started the geometric reconstruction, from the available graphical or textual information. A series of simplified models allowed to understand better the real configuration of every single parts. In particular the use of the color was very important to associate every element to the corresponding shape, so to identify single units in homogeneous way, and operate all the necessary deformations to obtain the final aspect of the model. After having identify the linear structure on which anchor the hyperbolic paraboloids of the walls, we started the spatial geometrical reconstruction of every single paraboloid, drawing it in orthogonal projection. The complex grid allowed us to understand the three-dimensional parts that compose the Pavilion, confirming the extension of all the surfaces under the floor.

Figg. 19, 20, 21, 22: Geometrical schemes describing the operations of model deformation (elab. M. and M.S. Soraperra).

Fig. 23, 24: Wireframe models of the Pavilion with the integral extension of the hyperbolic paraboloids under the ground level (elab. M. and M.S. Soraperra).

After this control phase of the geometry there was the construction of the design at the 1:100 architectural scale, with the insert of all the details regarding the openings (windows, doors, etc.), internal walls and architectural technical spaces, using advanced graphical primitives, such as *spline* and *patches*. The large flexibility of surfaces now allowed in generating digital forms permits us to obtain an equivalent model to the original one, although we did not use a precise quoted drawings as starting document. The geometry, then, was obtained with the interpolation of surfaces from the analysis of the position of cusps and of main inclined elements on which the surfaces should be anchored. As the heights and the plan geometry were known from the technical drawings of the archive, it was possible to define the main volume of the project. To verify the correct execution of the constructive operation we decided to slice the model in progression, both in plan and in elevation, in order to render totally visible the architectural space. As a precise correspondence between the digital model and the graphical information from archives and publications was found, we developed further the representation to realize a photorealistic scene, using some algorithm of light simulation and texture mapping.

Fig. 25, 26, 27, 28, 29, 30: Vertical sections of the digital model (top) and elevations (bottom) (elab. M. and M.S. Soraperra).

Fig. 31, 32: Perspective views of the digital model (elab. M. and M.S. Soraperra).

The final digital model was realized analyzing all the details of the realized project, without omitting the re-drawing of the wireframe structure of the external cables which ensured that all the surfaces were aligned. Then, it was geo-referenced, and integrated with the main pavilions that were built in the same area, near the *Poème Électronique*. One last aspect of the construction phase here described, was the creation of a video animation that could express directly and in an exhaustive way the relevant steps of the research, from the analysis of the geometry, thanks to the use of the flexible bands, to the reconstruction of the surfaces and to the realistic simulation of the scene. We defined a series of key-frames to realize some relevant sequences. In details we reproduced the sticks and the elastic bands of the tool used by Le Corbusier and described before, and their continue movement until the position in which the single surfaces appear. Definitively, it was as Le Corbusier's hands were moving and searching the correct location for every element, but translated in digital form, adding all the parts that characterized the architecture itself (details, furniture, devices, etc.).

5. Conclusions

The research allowed a precise identification of the design geometries, a verification of the procedures to generate the morphology, and a perfect correspondence of the empiric methods (use of the tool composed by sticks and bands) and the realized surfaces in the constructive phase. The experimentation has reached the aims defined in the hypothesis, confirming the great scrupulousness and determination by the designers in determining all the aspects of the complex morphology of this important architecture of the XX century.

Innovative technology and historic heritage: Itali's wealth

Anna MANDIA,

Dipartimento di Cultura del Progetto, Facoltà di Architettura, Seconda Università di Napoli, Italia
email: anna.mandia@fastwebnet.it

Abstract

Innovation often finds obstacles in a country like ours, one that has such a vast historical-artistic heritage to protect, though this wealth should not become an obstacle to the application of new technologies. This is the case for the C Line of the Rome underground, where the mere thought of building a new metropolitan line is already a challenge. It is an all-Italian project: the General Contractor MetroC is a Consortium of exclusively Italian companies. It has been and still is difficult to define a possible route for the C Line, but the spirit of the project remains unchanged, aiming to unite the suburbs with the city centre, from the south-east to the north-west, passing under the Colosseum and the Tiber River. The innovative technological aspect of the C Line is that it will be a driverless underground train and the Western world's first "heavy type", using trains longer than 100 metres in length that are able to transport 24,000 passengers per hour. The project has had to unite the transport needs of a European capital that today has just two underground lines with the historical and archaeological constraints that a city such as Rome presents. It wasn't enough to dig the tunnels 50 metres deep with ultramodern technology; the real challenge is the historical city centre stations, as the hole needed to be dug from the surface to the platform passes through all of the historical layers present.

Keywords : underground, C Line, Rome, driverless

1. The Project of C line

Such a complex and innovative project, in such a monumental city of the world, cannot be undertaken without careful and detailed analysis on the impact that this will have on the monuments, both during and after the work.

As mentioned above, the section of the C Line underground crosses the city from East to West, passing underneath some of the most important historical monuments.

Work is currently in progress on the first section, from Pantano to San Giovanni station, then proceed to the Fori Imperiali, with recent funding and in the future to the station of Farnesina, as shown in Figure 1, for a total length of 28.5 km.

The most delicate sections, where the tunnels pass underneath the heart of the city's historical centre, are the T2 and the T3; the T3 station, in fact, particularly affects some historical monuments of unique architectural and historical-cultural importance for which a monitoring system will be installed in order to guarantee their safety during the work on the new underground line.

The monuments are:

The Aurelian Walls at Porta Asinaria

The Aurelian Walls at Porta Metronia

The Church of Santo Stefano Rotondo The Celimontano Aqueduct

The Flavio Amphitheatre (Colosseum)

The Massenzio Basilica

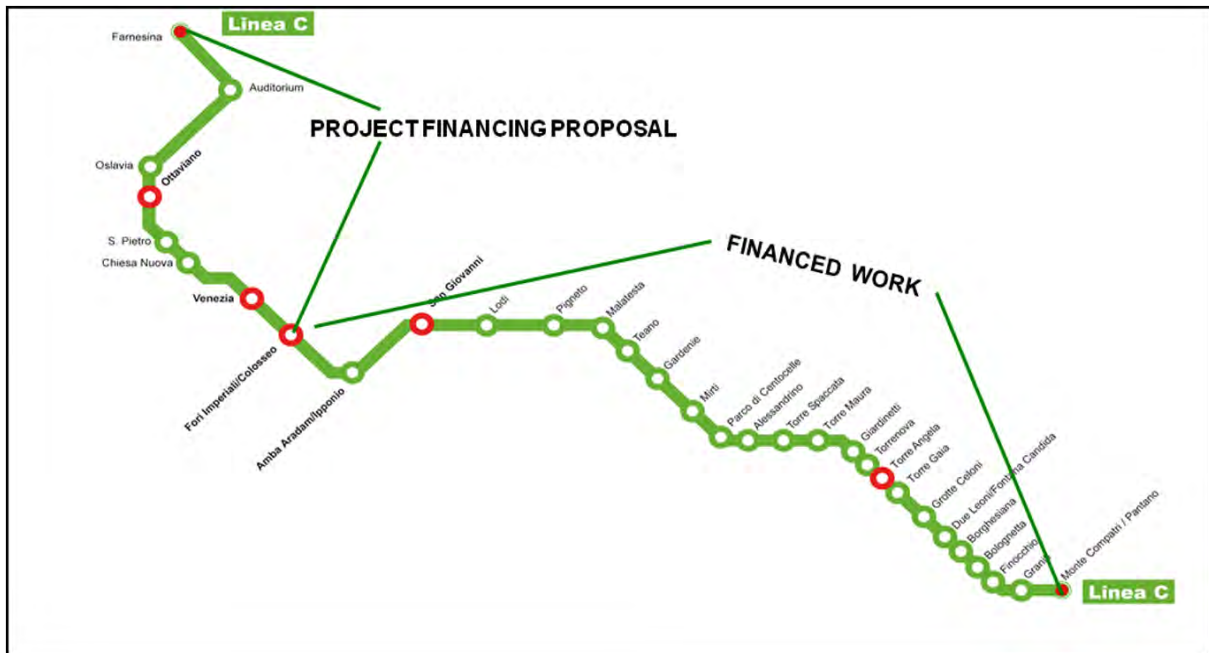

Fig.1 Line C

The Columns of the Nerva Forum
 The Columns of Caesar's Forum
 Monitoring systems have been arranged for these eight places.

2. Interaction tunnels excavation and buildings

The Department of Structural and Geotechnical Engineering at Rome's "La Sapienza" University together with the S.T.A. have carried out well-defined studies on the interaction between the tunnels excavation and the buildings, gathering the information available and in some cases arranging specialist studies. The section T3 route stretches from Via dei Fori Imperiali, jointly with Caesar's Forum, to Piazzale Appio, where the tunnels of the line underneath cross the existing Line A San Giovanni Station for an overall length of approximately 2,900 metres.

In the pipeline are two new stations - Fori Imperiali and Amba Aradam-Ipponio, and a series of shafts and structures serving the underground line. The tunnels will be dug under the Imperial Forum transiting near the long list of historical places mentioned above, till the manufactured station S. Giovanni, where T3 station ends and where is the connection between line C and line A.

3. Safeguarding interventions

Considering the delicate state in which we were to intervene, the project had to respect the regulations drawn up by the Ministry for Cultural Goods and Activities – Archaeological Office of Rome, due to the presence of important pre-existing archaeological sites. Taking this into consideration, it hasn't been possible to carry out geotechnical canonical interventions such as sub-vertical column sectioning in jet grouting or pole and micro pole bulkheads that, being followed by a campaign plan, would have inevitably altered those very pre-existing sites.

The interventions can essentially be retraced to two categories:

Precautionary interventions to be put into act before starting the excavations. Said interventions are basically to reinforce the elevated and foundation structures. In this category are included interventions aimed at rectifying a pronounced degradation and shoddy state of the structures, effectively found following diagnostic investigations and therefore are not directly linked to the effects caused by the T3 section works, but necessary to guarantee the protection and safety of the workers due to the proximity of the section works building yards.

Interventions to be carried out during the digging phase, aimed at contrasting any subsiding caused by the digging in real time and to prevent total subsiding below the pre-set thresholds. This category also includes interventions to compensate subsiding with cement mixtures injected below the depth structures via perforations equipped with valved tubes (compensation grouting). Because of the existing archaeological restrictions, said perforations have been planned for section T3 next to the monument/historical buildings in shafts of suitable sizes created and equipped before the digging starts. Because of this, the sub-horizontal perforations and the injections are carried out at such a depth so as not to interfere with the archaeological substratum.

Just seeing this route on paper shows how delicate this engineering work is. For this reason numerous monitoring systems are planned, both for the elevated structures (structural monitoring) as well as the land and structures in contact with the terrain (geotechnical monitoring), and also some non-invasive geotechnical investigations.

3.1.1 Objectives of the monitoring

This activity aims to monitor the static behaviour of those monuments affected by the work on the T3 section of the new Rome underground C Line and the annual management of the system itself (remote assistance and maintenance). The Monitoring System has the goal of surveying the monuments to see the effects of the digging of the line through physical measurements (shifting, deformations, opening of fissures, strain and stress). Vital information will be supplied by the measurements registered during the various phases of the work, compared with the theoretical values predicted in the design phase, and will be made available to the works management and designers, to evaluate any corrective action to be carried out.

Obviously, for the choice of the tools to be used, the following series of aspects was considered:

- Type of monuments: historical value and relative restrictions;
- Installation methods of the tools (sensor clamping and via cable);
- Dislocation of the measuring equipment (logger data);

and of many other aspects linked to the elasticity of the system, the flexibility and modular structure

3.1.2 The configuration of the monitoring

The monitoring of the monuments has been divided into 4 sectors:

- SAR system monitoring based on the elaboration of a series of historical data from satellites that refer to individual monuments as well as the whole of Rome's historical centre. The data supplied must allow us to purify any interaction phenomena observed during the construction of so-called "background noises" that may be linked to shifting caused by environmental phenomena.
- Geomatic monitoring, aimed at measuring vertical and horizontal shifting, carried out with Total Stations referring to prisms placed in specific points of the monuments and outside of them. These measures, when necessary, will be integrated with conventional geometric surveys.
- Geotechnic monitoring of the monuments' foundations and the surrounding terrain through the positioning of tools that survey vertical and horizontal shifting as well as variations in interstitial pressure.
- Structural monitoring of the monuments through the positioning of automatic reading tools, fissure gauges, strain gauges and electronic pendulums. These tools allow us to measure the entity of the interaction phenomena in terms of variation of the existing fissures, the formation of new fissures and the rotation of elevated monuments. The monitoring results, acquired through the above-mentioned systems, will be acquired by local units and simultaneously sent to the data processing centre that manages a GIS system that will make them available to the CTS on the appropriate website in real time.

4. Description of the system

The diagram in figure 2 shows the general configuration of the monitoring system with the connection to the Data Acquisition Position. The system is based on the use of compact peripheral measurement units (PMU) which, if no network power is available, can be powered by solar panels, and communicated to the Data Acquisition Position via GSM telephone line. The connection of the sensors to the PMU is carried out by cable for Phase I sensors (long-term monitoring) and by wireless systems for Phase II sensors (short-term monitoring). Each PMU will be completely independent, acquiring the data from the various connected sensors; all the measurements acquired will be validated, complete

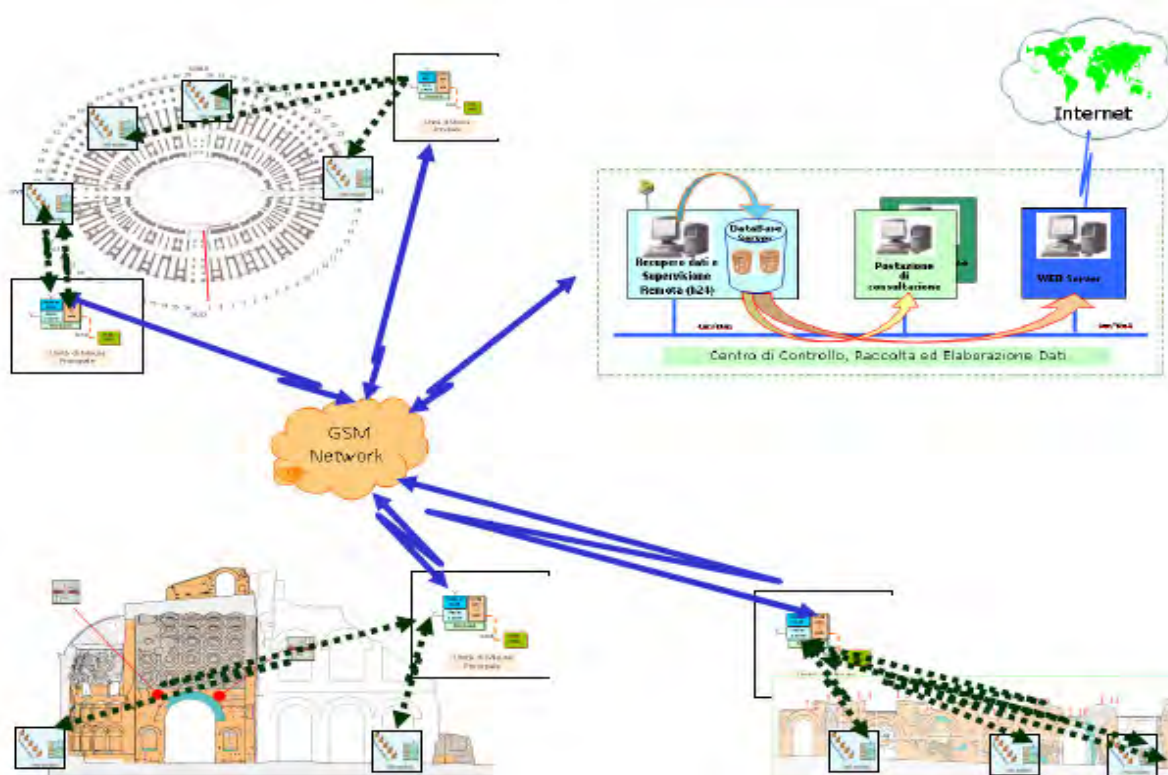

Fig. 2 shows the general configuration of the monitoring system with the Data Acquisition Position connection.

with time reference and validation code, and then archived on local memory devices. In the event of anomaly or measurements carried out outside of the pre-determined thresholds, a text message will be automatically sent to the Data Acquisition Position that will then be activated for the necessary data recuperation operations. As, however, each monument is a case in itself, with its own particular installation layout problems, a unique technical solution has been developed specially for each one. The system is based on the use of compact peripheral measurement units (PMU) which, if no network power is available, can be powered by solar panels, and communicated to the Data Acquisition Position via GSM telephone line. The connection of the sensors to the PMU is carried out by cable for Phase I sensors (long-term monitoring) and by wireless systems for Phase II sensors (short-term monitoring). Each PMU will be completely independent, acquiring the data from the various connected sensors; all the measurements acquired will be validated, complete with time reference and validation code, and then archived on local memory devices. In the event of anomaly or measurements carried out outside of the pre-determined thresholds, a text message will be automatically sent to the Data Acquisition Position that will then be activated for the necessary data recuperation operations. As, however, each monument is a case in itself, with its own particular installation layout problems, a unique technical solution has been developed specially for each one.

5. Purpose of geomatic monitoring

The geomatic monitoring of the buildings is articulated altogether in two distinct phases. The first phase, prior to the digging of the tunnels, intends to supply an outline of the static behaviour of the structures in undisturbed conditions. The second phase, in progress, will serve to control and evaluate the effect of the digging on the stability of the affected structures, in order to be able to survey any acceleration of existing movement or the triggering of new, potentially damaging phenomena.

6. Structural Monitoring

The structures will be monitored figure 3 via the integration of various geomatic sensors (high precision robot total stations figure 4, GPS receptors and bi-axial inclinometers). The motorised total stations will automatically carry out cycles of measurements, suitably programmed and modifiable remotely by the user, of azimuthal directions, zenithal angles and distances to reference retroreflector prisms placed at a distance from the excavated route in places considered stable or which in any case are not affected by phenomena that may cause shifting on the buildings to be monitored. The prisms of reference will be numbered from 10 – 20, so as to strengthen the network and allow, with the highest precision possible, the determination of the total station position. The positions of the total stations will be arranged considering the criticalities resulting from the surveys carried out on the buildings and monuments affected by the C Line construction. The data originating from the motorised total stations, the GPS sensors and the inclinometer sensors converge in a central processing system whose output parameters, based on definite alert threshold, must highlight any phenomena of instability.

The diagram in figure 2 show the Data Base must take on through which all information of engineering interest resulting from the measurements acquired by the sensors installed for geomatic, geotechnical and structural monitoring (including the accessory sensors, such as meteorological sensors), both in undisturbed conditions for monitoring the background noises, as well as in progress during the digging operations, will be archived, managed and consulted and, if necessary, subjected to primary elementary elaborations. The DB, contextually to the data mentioned above, must also archive and manage the relative metadata and its updating and make it available for consultation figure 3.

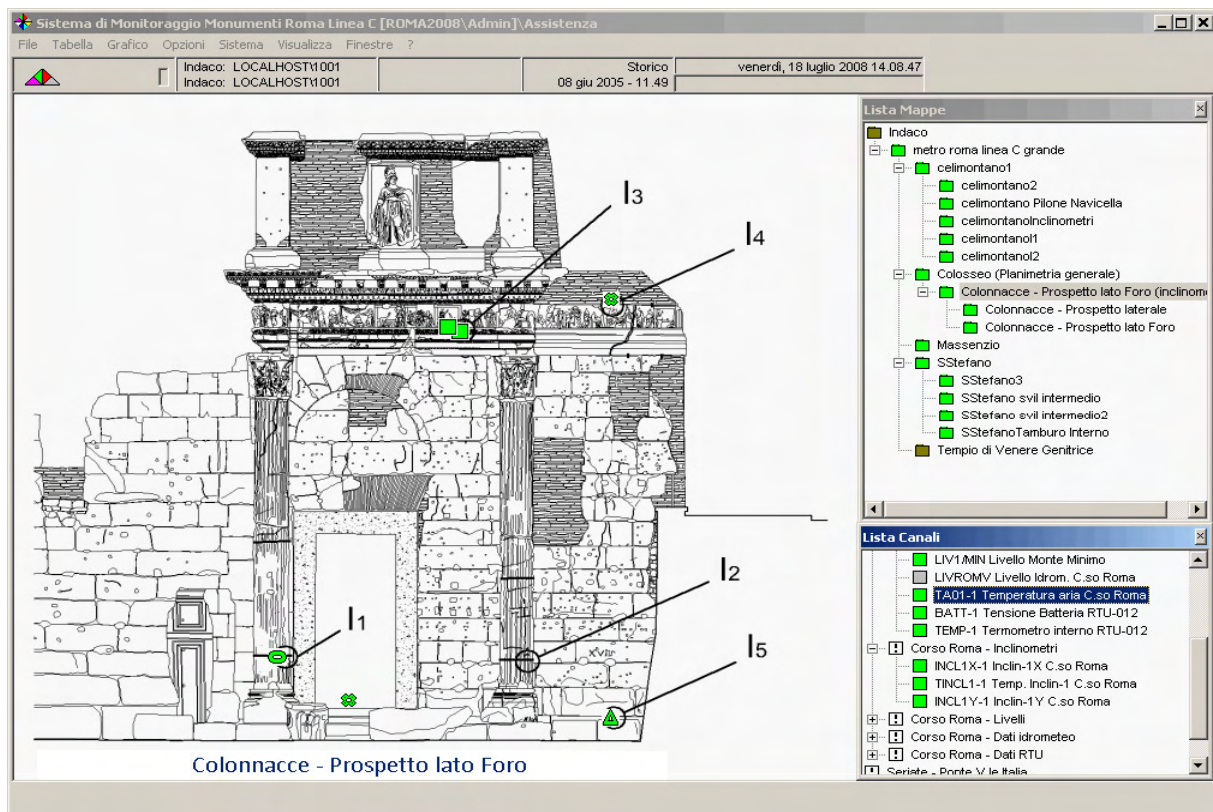

Fig.3 structural monitoring

Fig.4 Total station for monitoring

7. Geotechnic surveys diagnostic investigations

As well as capillary monitoring of the surfaces, detailed analysis and surveys have been carried out in the subsoil; numerous geotechnic surveys have been carried out giving an accurate survey of the various layers of the terrain; sub vertical foundation geotechnic surveys, from 5 to 25 metres in length from the surface, have been carried out to determine the impost depth of the first soil found above the same; continuous logging has been carried out with the withdrawal of an undisturbed sample, carried out in the horizontal masonry, creating holes of diameters of between 65 and 150 mm; videoendoscopic exams have been carried out on the wall structure through reduced-diameter holes made in existing lesions and/or cavities, or holes of approximately 2/3 cm in diameter made in the walls; the testing for strain on the wall face with a single flat jack; numerous trials and tests on soil, walling and plaster samples have been carried out, several laboratory tests have been done in order to obtain a detailed view of the subsoil.

Abstract

The mobile laboratory MOLAB, European infrastructure of the CHARISMA project, avails of numerous portable instruments that exploit the use of non invasive techniques and supply information concerning the elementary and molecular composition of surfaces of historical architecture.

Some case studies carried on monuments of national interest (the portal of Palazzo dei Priori in Perugia) and of international interest (in Spain the portal of the Cathedral of Santiago de Compostela) will be reported to demonstrate the analytical potentiality of the integrated approach of non invasive techniques.

Keywords: non-invasive, analysis, architecture, monitoring, conservation

1. Portal of the Perugia Palazzo dei Priori

In recent years, thanks to increasingly miniaturized and efficient optical and electronic components, portable instrumentations have been developed with a performance comparable to laboratory equipment, opening new possibilities for the non invasive in situ study of cultural heritage materials. The mobile laboratory MOLAB, European infrastructure of the CHARISMA project, avails of numerous portable instruments that exploit the use of non invasive techniques ranging from X-ray fluorescence to the molecular spectroscopies (IR, Raman, UV-Vis absorption and emission etc.) and supply information concerning the elementary and molecular composition of surfaces [1].

The MOLAB portable instrumentations enabled a campaign of non-invasive in situ analyses to be carried out at the different levels of the portal of the Palazzo dei Priori, Perugia during the different phases of the current restoration.

X-ray fluorescence, integrated with the mid-infrared measurements, has provided interesting information on the nature of polychrome residues present on few areas. Mid-FTIR spectroscopy, equipped with fiber optics has permitted the identification and mapping of pollutants, alteration products and restorative materials from previous interventions. It has also been possible to monitor the effectiveness of cleaning by performing measurements before and after the intervention and comparing the information obtained.

The measurements were performed by transporting the equipment directly onto the scaffolding, in Figures 1a and 1b shows the experimental set-up for the two portable techniques.

Fig. 1: experimental set-up for in situ measurements at the Palazzo dei Priori by XRF (a) and mid-FTIR (b)

1.1 Study of polychrome residues

In some panels of the portal residues of polychrome blue, white, black and red are visible. The XRF analysis of the areas of blue showed the presence of significant levels of copper suggesting the presence of a blue pigment characterized by this element. The mid-FTIR with the optical fibers recorded spectra on the blue areas containing copper have shown that the pigment responsible for blue color is a basic carbonate of copper, azurite. It is a natural pigment obtained by grinding the corresponding mineral, widely used in antiquity for paintings on panel, canvas and mural paintings. Its use was common up to the first half of 1700 when it was supplanted by the first synthetic formulations, such as Prussian blue or ultramarine blue. The spectrum obtained on blue decorations are shown in Figure 2, where signals identifying the basic copper carbonate are evidenced, the other visible signals refer to the carbonate matrix and to pollutants present.

Fig. 2: mid-FTIR spectra recorded on an area that presented residues of blue. The diagnostic signals of azurite are labelled.

It was noted that white coating was present in some areas, often found on top of a black color. The XRF measurements in these areas showed an increase of signals of lead indicating the presence of the pigment lead white. The white is a white synthetic pigment with excellent covering power, consisting of a mixture of cerussite, lead carbonate, and hydrocerussite, basic lead carbonate. Produced by different synthetic

processes, white lead was used since Roman times up until the late nineteenth century. In the black patina characteristic elements are not detected by XRF, suggesting the use of a black carbon based pigment such as carbon black or bone black.

With regard to red residues, there were no significant concentrations of elements which are clearly due to the presence of a red pigment such as iron for red clay (Fe_2O_3) or lead for red lead (Pb_3O_4). This may indicate the presence then of a lake, an organic dye based pigment that cannot be detected by XRF.

1.2 Study of the distribution of patinas and incrustations

The surfaces of the portal before the restoration were characterized by the widespread presence of patinas and incrustations whose nature was identified through measurements carried out by the fiber optic mid-FTIR spectrometer.

All the mid-FTIR spectra are characterized by the signals of the matrix, calcium carbonate which constitutes the stone carbonate of which the portal is made. In addition to the signals of the carbonate matrix other bands related to pollution or restoration products are observed. In particular in the incrustation, calcium sulfate (gypsum) is identified by the presence of a band inverted at about 1146 cm^{-1} . There is also a diffuse presence of calcium oxalate patina, identified by the characteristic band at 1320 cm^{-1} . The gypsum and calcium oxalate are typical weathering products of carbonate surfaces exposed outdoors. The first can be derived from dry deposition from the environment or from the transformation of the calcium carbonate of the matrix by the action of acid rain containing sulfuric acid, whilst the second is produced by processes of oxidation of natural organic materials used in ancient maintenance interventions or by metabolic processes. Meanwhile, the gypsum, is a partially soluble salt that following phenomena of solubilization and crystallization may cause damage to the surface structure of the object, it is reported that the calcium oxalate, in virtue of its very low solubility also at acidic pH, plays an important protective action for the externally exposed carbonate surfaces. In addition, the surfaces of the portal are characterized by the widespread presence of organic synthetic materials attributable to recent restorations, and in particular an acrylic resin has been identified as probably used for consolidating surface de-cohesions and a silicon resin with protective water repellent functions.

1.3 Control of cleaning interventions

The portable mid-FTIR system is particularly suitable to follow in-situ cleaning processes, as the technique is very sensitive to the presence of surface organic or inorganic materials, and has already been used in the case of mural paintings and sculptures marble obtaining important results to optimize restoration methods [2,3,4].

In the case of the portal of Palazzo dei Priori, from a comparison of the spectra collected on unclean areas and the spectra obtained in the same areas after cleaning it can be seen how the chosen intervention determines the complete removal of sulfates and acrylic resin. The protective silicon is also removed by the cleaning, although only partially. The cleaning did not act at the level of filler, where the signals of acrylic resin and protective are still visible.

Concerns the calcium oxalate, the measurements clearly show that the cleaning method chosen is respectful for this type of coating, as the signals of calcium oxalate are even more apparent after cleaning as they are no longer covered by the absorption bands of the sulfates and the acrylic resin.

The results obtained by integrating the two investigative techniques of XRF and mid-FTIR allowed the constituent materials of the residues of polychrome blue and white, respectively, as azurite and white lead to be identified. The state of conservation has also been assessed in surface areas by identifying the nature of the incrustations, the patinas and products used in past restorations. Measurements carried out in different phases of the cleaning intervention have verified the efficiency of the actual method that has effectively removed the sulfates and residues of acrylic and silicon resins while respecting the patina of calcium oxalate. In conclusion, the work carried out demonstrates the efficacy of non invasive portable techniques in identifying, the constituent materials, in assessing the state of conservation and in optimizing the restoration interventions all carried out in situ and without the necessity of sampling.

2. Portico de la Gloria of the Santiago de Compostela

The MOLAB laboratory carried out a non-invasive study of the polychromy and alteration phases of the Portico de la Gloria of the Cathedral of Santiago de Compostela (see Fig. 3).

Fig. 3: experimental set-up for in situ measurements at the Portico de la Gloria

The following analytical techniques were utilized: elemental analysis by X-ray fluorescence (XRF), molecular analysis by reflectance in the mid infrared (FTIR), UV-vis fluorescence, colorimetric analysis and image analysis by video microscope.

2.1 Incrustations and superficial deposits

Regarding the conservation state, the Portico is characterized by widespread alterations of gypsum and oxalates that are observed macroscopically as white deposits, dark patinas and respectively. Sulfates and oxalates are always present, although not visible to the eye, in all measurement points, even those relative to deep lacunas in the stone support.

In some points of the pillar, areas of sub-efflorescence of calcium sulfate are highlighted, which are visible in the images recorded by the video microscope precisely in the phase of breakage of the external paint layer due to the pressure of crystallization. It is thought that the problems of loss of color in the areas of the skin tones are due to crystallization under the paint layer of calcium sulfate which cannot migrate externally due to the hydrophobicity of the lipid layer.

On the other hand, the diffuse and concentrated presence of gypsum, demonstrates that the sulfate also comes from seepage of water from the outer surface. Of similar origin, are areas of calcite of new formation, mostly found on the left side of the porch. Finally in all the surface, with accumulations in the Pillar of the Evangelists, chlorides are highly diffused, while in many points the presence of nitrates is observed.

2.2 Organic binders

The outer layer of the faces, due to the intervention of Crispin de Evelino who in 1651 was appointed to act on only parts of the complexion of an unknown number of figures, over painted the faces with white lead, cinnabar, and probably red ochre in lipidic binder. Also observed are signals of proteinaceous material, which can also suggest the use of a temper although subsequent maintenance interventions cannot be ruled out. The paint layer shows the typical cracking of the paint in lipid binder and the formation of lead carboxylates, that result from the saponification reaction between the free fatty acids of the lipid binder and the basic lead carbonate. In all the statues analyzed, the outer layers show, in a more or less clear manner depending on the state of conservation, the features discussed above.

The statues of the central arch and epistle pillar present signals of varying intensity of wax in the flesh tones. The reflectance FTIR spectroscopy does not permit the recognition as to whether it is beeswax or microcrystalline wax due to the presence of the lipid binder.. In many statues of the arch, especially in correspondence to the clothes and black writing of the scrolls, synthetic acrylic resins were identified, attributable to the intervention of consolidation of the 1992-1993 restoration.

2.3 Metallic decorations

The polychrome presents residues of metallic decorations, the most common are those over lapis lazuli paint layers in correspondence to clothing and are characterized by gold and lipid binder residues. Decorations in gold were also detected in hair and beards. In some brown areas of the robe of the statue of the Angel with Crown of Thorns signals of gold and silver are observed by XRF, suggesting the presence of a metallic decoration that is different from the others. At all points silver is always present along with gold. In some statues, the investigations identify the presence of residues of the applied brocade decoration technique. In these areas, the presence of high levels of wax, residues of gold and tin, traces of lapis lazuli and lipidic material are observed.

2.4 Pigment analyses

Reds - All the red areas analyzed by XRF showed the presence of mercury, an indication to the use of cinnabar. The same pigment mixed with wax, was used to realize the blood on the ribcage and in the stigmata of Christ. UV-vis fluorescence measurements permitted the exclusion of the presence of red lakes residues, in all points analyzed.

Yellows- Residues from the repainting intervention performed with yellow ochre are diffusely present which result to be rich in iron oxides and kaolin. Possible evidence of a lead and tin yellow have emerged in the decorations of vegetation type in the Evangelist pillar.

Blue- All the well preserved and vivid blue colors are made of lapis lazuli and lead white. Traces of natural ultramarine are often found in correspondence of the gold decorations. All blues with green hues are based on azurite and lead white, for example in residues in the clothing of Christ. It would be interesting to understand the sequence of interventions of azurite and lapis lazuli, so as to understand which of the two pigments was used in the original Romanesque polychrome. In this regard, the mantle in the Evangelista pillar statue is predominant in azurite in the lighter zones and inside the folds of the mantle, whilst lapis is found in the darkest areas. This occurrence suggests the presence of two distinct operations rather than the use of azurite as a preparatory layer to lapis lazuli.

Blacks- The blacks of the pupils were systematically analyzed, obtaining in most cases indications of the use of carbon black with a prevalence of protein binder.

2.5 Polychrome alterations

Many polychrome areas of the arch present obvious green alterations that are highlighted by the non-invasive analyses to be of diverse origins.

The arch corners are characterized by severe green alterations affecting both green areas that represent the vegetation and the garments of men. The surfaces have strongly altered in morphology to suggest that the green material is largely a result of a process of secondary crystallization. The XRF analyses showed the presence of high levels of copper and chlorine, suggesting that the alteration is made up of green copper chlorides atacamite / paratacamite. The FTIR analysis showed the presence of high quantities of nitrates, oxalates and sulfates, which also may have contributed to the degradation.

Many areas of the portico that show green blue coloration present traces of azurite and show evidence of high levels of copper to indicate that the process of deterioration is even in these cases due to the formation of copper chlorides resulting from the interaction of chloride ions carried by water with azurite.

The integration of analytical data acquired through a multi-technique approach provides a comprehensive and satisfactory framework of constituting materials of architectural surfaces of art-historical interest, that inform of the principal forms of alteration that sustain the basis of functional diagnostics for preventative conservation projects.

RELATIONSHIP BETWEEN FIGURATIVE CODES AND NEW TECHNOLOGIES IN THE 19th CENTURY: KNOWLEDGE OF THE PAST IN ORDER TO DESIGN FUTURE STRATEGIES

FARRONI Laura

DipSA, Facoltà di Architettura, Università degli Studi di Roma Tre, Italia
E-mail: -mail: lfarroni@uniroma3.it

Abstract

At the end of the 19th century the introduction of iron in the construction processes, generates a different way of thinking about architecture; triggering all that industrial production that has led to economic, political and social reversals. Therefore, knowing the ways and strategies adopted in the solution of the contrast between the classical tradition and the new prevailing construction technologies, through the analysis of the production of iron bridges in Europe and beyond (and of some other buildings), is a form of knowledge of the ways, regulated by the humanity, of the use of technology in order to modify the natural environment and then satisfy the needs of an increasingly complex social life. The iron bridges of the 19th century (described in treaties and manuals) become archetypes, whose images are not only a demonstration of the adopted techniques, but, also, of architectural organisms, of spatial and formal values and of their context. In light of such theoretical considerations, developed through an analysis of the treatises, manuals and construction courses, it was felt necessary to verify them in operational terms. The development of a digital model of a pier of the Pio Bridge 1862, made it possible to understand the relationship between geometry, construction and architecture in a given historical period. This strategy provides guidelines for a wide-ranging procedure geared towards selecting the criteria of conservation or reutilisation of buildings classed as examples of industrial archaeology.

Keyword: Architecture, Representation

1. The construction process at the end of the 19th century: realising ideas

At the end of the 19th century, the introduction of iron into the construction process generated a different way of thinking about architecture, triggering all of the industrial production that led to profound economic, political and social upheaval. The conceiving and designing of iron buildings and structures was naturally associated both with the possible production processes of iron as a material and with the development of construction technologies. There was a revising, if not an entirely new arrangement, of the phases of the building process, whereby the construction potential of the initial concept was put to the test through the new static solutions being designed by engineers. The development of architecture made from iron gave architectural design back its essentiality and its construction rationality [1]. New occupations came into being, with very precise remits: designers, educated at the polytechnics; contractors; construction workers; and guilds of master craftsmen. Communication between these various roles was entrusted to technical drawings with a view to reaching the shared objective: the realisation of the building. The technical drawings gradually acquired their own individuality as design drawings, which were deployed in a range of contexts. The necessary search for codification led to the laying down of a universal technical language that was able to ensure unambiguousness in the transmission of information to all those involved in the construction process. For its part, industry – or, rather, the workshops producing the components designed for the construction – also started to take an active part in the construction process. While the workshops had close contacts with the designer and the craftsmen, they also imposed a standardised form of construction onto the market, as

expressed in their component catalogues. The role of the client became fundamental, and the clients put their trust in the contractors. The representation of the design became the main instrument of transmission of the shared intentions of those involved. Structural monitoring, the progress of the steel-working (quantity of the material produced and its quality if cast iron, iron or steel), the features of the manufactured items (profiles or pipes), given that the components of the metal structure were produced in the workshop and then assembled in the yard – all of these elements made it possible to reduce execution and labour times, thereby transforming the construction phasing. In terms of architectural representation, the dimensional control of the object – through the use of the metric system and the identification of the components using the methods of descriptive geometry – allowed for a graphical "narration" of the architecture targeted not only at the formal communication of the object but also at its execution. Factory drawings were produced with indications of the "pieces", their quality and their combinations, alongside drawings for use on site, which showed not only how to assemble the pieces together but also the execution times. In addition, there were the drawings produced by industry, which prior to the realisation of the product had to draft support drawings for the construction of the models and dies. The different methods of casting metal, and the various uses of cast iron and iron, made it possible for the workshop to manage the forms and dimensions of the components. For single die-cast pieces used for interior decoration purposes only, modular elements were produced for assembly as structures.

1.2 Treatises and manuals providing information on 19th-century experimentation

This essay describes the links between figurative codes and new technologies at the end of the 19th century, in a well-defined architectural environment – i.e. that of iron architecture – through the study of the evolution of representation in the context of the construction process. The proclamation during the period of a "new freedom" in the interpretation of traditional culture was linked to the introduction of iron and to the consequent use of architectural components, transforming the process of architecture and, therefore, the process of erecting buildings. The initial re-use of traditional figurative codes was substituted by a careful "re-elaboration" of them, such as for example was the case in the use of the classical order, where the maturation of an architectural language with the capacity to express the sense of space afforded by the use of the new material connoted modifications both of the proportions and of the morphology of the elements, according to the situation. Indeed, the application of the design "invariables" of iron structures came about with modes of representation that presented the object as a machine that could be dismantled, characterised by the relationships between the component systems, and by the modes of processing and of assembly. The presence of different languages in the productions of the period was due to the intentions of the individual designers and to their capacity not only to master the technical data but also to interpret it from the formal perspective. During the 19th century, with the development of the railways and bridges, major industrial production began in earnest; the craftsman was replaced by the worker or the industrialist – a development hastened by the use of the Bessemer process [1], which enabled the industrial-scale production of large quantities of steel. The engineer dealt with verifying the properties of the materials; these checks had become indispensable to guarantee the application of the products being offered by industry. In construction terms, mass production afforded the opportunity for assemblies and combinations of structural elements, which – freed from "historicist" connotations and characterised by new forms – made it possible for different architectural elements to exist side-by-side within a rational, safe system that had been fully designed in advance, in which the design idea found its full feasibility. Architectural drawing in its many guises assumed the primary role in design *per se*: from geometric drawing, which reached its apex in graphic statics, to drawings intended to analyse the types of structural elements and drawings geared towards communicating the assembly methods. In iron architecture, it is clear that the form was linked to the structure and to the technical requirements. On the basis of 19th-century construction courses and manuals whose purpose was, first and foremost, to educate and highlight the "state of industrial progress", it is evident that the theme of the metal bridge underwent a number of evolutionary stages associated with the development of scientific knowledge. This is attested to by the various images featured on the construction courses of Sganzin (1849) and of Demanet (1862), and in the manual entitled the *Appendice all'Arte di Fabbricare* by Curioni (1865), as well as by the works actually constructed. The bridge across the River Severn, constructed in Coalbrookdale in 1779, is the first important structure in which iron was used as the construction material to cover wide spans, and was very much a case in which "the entry of cast iron and iron came about even before the structural possibilities of the materials had been grasped" [2] (Figg.1-6). The cast-iron arched bridge was a solution that still bound the designers to tradition, because the cast iron used was treated as if it were stone. Later on, bridges constructed with wrought iron (which made it possible to exploit the resistance to bending), such as suspension bridges, girder bridges, and trussed bridges, succeeded in deploying new structural forms, decomposing the system into simple elements. The combination of vector graphics and detailed

design drawings in which the formal aspect is reached, represents the expression of that landscape between the concept of “construction as the subconscious of architecture” [3] and the realisation of its expressive image. Within the courses held and manuals produced, it is possible to trace a thread running through the development of the content of 19th-century technical literature that is associated not only with the evolution of the production techniques and the use of new materials such as iron and cast iron but also with the changing attitudes of engineers and architects, who were becoming aware of major changes affecting both the art of building and the communication of technological data. To demonstrate this, the issues dealt with in the treatises and manuals communicate both the technical/scientific aspects of the art of building and the affirmation of a different concept of design drawing, thanks to the appearance, for example, of graphical verifications of the stability of the elements. Treatises analysed in the course of the research include Reynaud's *Traité d'architecture* (1850) and Breymann's *Trattato generale di Costruzioni Civili* (Padova 1884). While substantially different, they represent two successive stages in cultural and technological development: the first displays a still-traditional approach towards new technical possibilities, whereas the second represents the codification of construction systems and architectural languages accompanied by a codification of the “technical drawing”. The treatise entitled *Cours complet des dessins des machines appliqué a la construction par M. Robinet Ingénieur-dessinateur* is strictly mechanical in the way in which it describes architecture and, for example, the classical order is examined as a series of pieces in detail, whose representation consists of a general part of initial schematic drawings and of another part featuring application tables [4] in which the pieces are assembled. Giovanni Curioni's *L'Arte di Fabbricare* (1865-1884) represents a key stage in the development of tools suitable for the transmission of technical and scientific knowledge – not simply at the conceptual level but also in terms of practical application. This stage was hastened by the development of the construction industry following the Unification of Italy [4]. Curioni's teaching, which was delivered at the Scuola di Applicazione in Turin, was intended to make accessible to students the theoretical and practical instruments of the art of building. The approach to planning was a multi-disciplinary one. The tables concerning the iron structures constituted the definitive appropriation of the innovations introduced via the use of iron as a construction material: what was being represented now encompassed a definition that was both technical and formal, so much so that it could be transmitted through teaching. One specific aspect emerges from an analysis of the tables concerning iron constructions: in the volume part, the elements of the construction are represented “in the manner of a real manual” in the sense that, removed from any context, they take on a life of their own, since they are “abacusised”, but this is not the case for the tables in the appendices, where there are construction examples, such as bridges, which by communicating graphically the entire design process of the construction demonstrate the practical application of what has previously been discussed in theoretical terms. What is most striking about the tables of the *Appendice all'Arte di Fabbricare*, and specifically those in Volume II, is their narrative character, which is different from that of the other treatises, because the narration not only bears witness to the level of technological development reached but also analyses all the phases of the construction process that led to the definition of the work: soil analysis with associated study of the profile of the river bed, with information on the distances between the banks, both progressive and partial, accompanied by simple wire frame drawings to indicate the position of the bridge relative to the position of the embankment attachments. The exclusive use of dual orthogonal projections emerges as a common thread within all of the tables, since it ties up the architectural, mechanical, urban planning and environmental themes [5], making the layout simple and clear to read: graphic static diagrams (for the verification of the structures), orthogonal projection drawings of the entire construction (to give an idea of the spaces reached), and details of the piers and main joints to demonstrate the specifics of the design and therefore of the execution. 19th-century technical drawings of metal constructions are interpreted as “algorithms of calculus, explaining a procedural phase with which the project is executed” [6], and so the planning and representation processes are combined in a single conceptual operation; citing Edoardo Benvenuto when he states that “the graphical tool does not have a role of useful application, but rises to a founding principle: it becomes the argument, it becomes the evidence to demonstrate and define static concepts”, acknowledging “statics as an interpretation with respect to the abstract and rigorous theorems of geometry” and the projective relationships among geometrical entities and the similarity between entities and static sizes (correspondence between force and oriented segment), the concept of correspondence between tensile strength testing and design can be affirmed (Fig.7-10).

1.3 Digital modelling as a survey system: an example of a route to knowledge of the geometric, formal and construction characteristics of Ponte Pio in Velletri

The Ponte Pio – also known as the Santa Anatolia bridge and named after Giovanni Maria Mastai Ferretti, Pope Pius IX – represents the application of the theories of forces on iron constructions and also serves as an application of the canonical classical figurative code. It was described as follows in a document issued by the Pontifical Government: “The bridge with iron struts rests on four supports, the edge supports made from brick and those in the centre from iron; the iron supports are divided into three orders, placed one atop the other – Tuscan, Doric, Ionic – rising up from the base of the valley on a walled plinth to a total height of 41 metres”. Interest in the bridge relates not only to the fact that, compared to the four suspension bridges built at the same time in Rome by the Società dei Ponti Sospesi sul Tevere, it has a different structure, but also to the fact that there is “artistic input” in the shape of the piers. To return to Jodice: “the bridge...forces the new technologies of iron and cast iron to retrace the traditional formal and figurative itineraries, deemed necessary to ennoble the cold mechanical nature of the construction. The upshot in any case is a fascinating work, which manifests the signs of a struggle between two heterogeneous, rival ideologies, and in which the separation between “quantity” and “quality”, even if yet to recompose itself into a potential expressive unit, is already dramatically evident in the same peremptory physical and linguistic separation of the horizontal girder and its supporting piers”. Displaying classical figurative codes, which follow the proportions of Vignola, all of the components of the piers were produced in the workshop, meaning that they were subject to a process of mass production – a concept featured in the images within the manuals studied. The order is treated as a mechanical piece, which serves as decoration, but is however also linked to the structural design, so much so that in the project drawings and from an observation of the work it is possible to discern a correspondence between the structural joints and those of the order. The development of the digital model was a form of analysis and study of the understanding of the relationship between planning strategies adopted and construction processes. The geometric model made it possible to retrace the main theoretical and operational principles of a given period in the history of architecture, starting from the design drawings and the archival documents, and comparing the manuals of the period. Composed of individual elements, the model required thought to be given to measurements, highlighting the relationship between formal units and dimensional units of the individual objects. On the basis of a study of the available documents concerning the construction of the various components, a process was implemented whereby geometry, proportional rules, construction techniques and compositional principles were cross-referenced. A second phase saw the production of abacuses of the “pieces” used in the work as built, returning in this way to the methods proposed by the manuals and catalogues. During the development of the model, the choice of the methods of creation to use for the parts had to take due account of the implementation techniques, relating in this instance to metal. All of this has made it possible to monitor the architectural language adopted, with particular reference to the proportions of the order used and to the morphology of the cornices, columns and capitals. In the orthogonal views, the modularity and proportions have been highlighted, comparing them with the geometry of Vignola, before moving on to the creation of the raw model, starting precisely from the drawing of the profiles used as the generatrix. This procedure involved, then, a cataloguing of families of elements to be enriched in future with technical information, thereby constituting the basis for a model of information geared towards interoperability at the moment when the decision is taken either to conserve or re-utilise (Figg.11-16). In this specific case, since the Ponte Pio is considered a historical construction, it may be understood as the manifestation of certain basic concepts of the industrial era and, therefore, building a model of the bridge has made it possible to abstract the rules of reference for the study of similar works. In this way, from a single example it is possible to extrapolate an array of strategies for future interventions on architectural works made from iron or for projects of industrial archaeology.

THE SMART DRAWING FOR THE KNOWLEDGE The historic town of Ruvo di Puglia

Cesare VERDOSCIA,¹ Anna Christiana MAIORANO²
DIAC, Facoltà di Ingegneria, Politecnico di Bari, Italia
E-mail: c.verdoscia@poliba.it¹, arch.acmaiorano@gmail.com²

Abstract

It is to follow a path to research ways of interpretation of urban form, in order to understand and then communicate, that can make visible through the graphical representation, our conscious perception of the shape of the places and its intangible aspects.

A real and scientific chance to understand the complexity, is to proceed by addressing its parts, identified by initiating an structuring operation, which is conscious act that is defined from time to time in relation to a given purpose.

It is necessary to identify in the complexity, a number of solutions arising from simplifying processes, typical of human mind, which take into account past experience and can anticipate future, which is not emptied the complexity of the real, but add variables of vision of the problems from a different point of view.

These processes are used by humans to minimize the energy, improve and speed the transmission of information, achieve smart essentiality, which can define the word "Less" for the drawing.

The object of this experiment is the urban fabric of the historic town of Ruvo di Puglia – built-up of ancient origin, located north of Bari - rich in important human evidence, and more low-value building products, along testimony of human presence of each historical period.

Parole chiave: model, simplicity, visions, town, communication.

1. The model and the drawing¹

The reduction of reality in graphical representations involves the interpretation of what you see through the memory formed of empirical experience and its cultural significance, producing forms and things, images and gestures, communicable and achievable.

The knowledge of places and architectures can be manifested through a drawing that materializes a code of intellectual understanding of the real world, which can consolidate the architectural and urban image, witness the membership to an buildings category or town-planning, confirm its origin and especially, put it in connection with his cultural matrices.

Everything can be usefully represented through the figurative traditional system of the drawing and of the graphic scheme that compose symbolic and analog forms identified by lines and colors.

The drawing is memory, understanding, interpretation. Allows the collection of information and the complete knowledge of the thing observed operand selectively to the extracting of those aspects that most interest, ignoring others.

We can proceed to further phases of study from different points view (structural, distribution, figurative, formal and chromatic), applying a process of synthesis that establishes a hierarchy of signs, making a geometric abstraction of shape for simplify the contour and searching objective references.

But, find a path of knowing the world of architecture and of the city is essentially to define a methodological route made of choices that try to discover the secrets of the complexity of the phenomena of the real world to identify the specifics of their nature.

A concrete and scientific possibility to decipher the complexity of an urban structure - which looks like a mesh, a tissue of relationships materials and intangible - is to proceed addressing the its parts identified through a process structuring. A natural phenomenon seems to the mind following to the interpretation and subsequent transformations of the sensory stimulation of the perception act, which requires the ability to look, in the sense of learning the order in which to examine their surroundings, anticipating and guiding the eye and the cognitive action, constituting a reference that builds a mental representation in a *egocentrato* system, that is from the point of view of the viewer, *allocentrico*, from another point of view, or capable of realizing a simultaneous multiple perspective, or from several points of view simultaneously [1].

The idea of an architecture born by immediate perceptual acts, which express to the eyes of the perceiver, events and simple shapes, and from indirect perceptions that may, for example, provide a feeling of pleasure and contentment, which transmits the symmetry, the balance, the proportionality between the parties. It is the result of an act of knowledge derived from a conscious selection and is consists of a mental framework of relations of analog nature with the real phenomenon which represents [2].

This selective and structuring action is an operation that is defined in relation to a function assigned, realizing an iteration between the components of complex phenomena according to a certain point of view, and in this sense can refer to the definition of constitution or form of something that is perceived in its entirety and qualify his understanding.

We can use the concept of structure to indicate a set of elements interconnected by certain relations, such that it can be considered parts of a functional unit and formal, that in the meaning used in architecture can certainly relate to rules of connection (static, functional and formal) between the parties of a building related to each other in an order determined by a particular purpose.

If the target is knowledge and if this can be understood as the ability of man to discover the degree of simplification of complex phenomena, then to make them understandable we must apply of the principles of simplify shared that they can reveal those components that may give meaning.

Examples of structuring, according to principles of simplification, can also come from observation of the biology of living beings, that for their needs - as identified and defined with the term "simplicity" by physiologist of the perception Alain Berthoz - use a variety of solutions arising from processes of simplification, related also to our minds when we should deal with complex situations, which always resolved on the basis of past experience, anticipating the future [3].

Identify the components "simplicity" of a phenomenon, it means adopting an naturally approach, that help us, without changing the complexity of reality of which they are party, to recognize the processes of simplification, that allow the birth of a real phenomenon, and at the nature to build, from a small number of patterns, a multitude of interaction models capable of generating very complex organisms.

We can imagine structures mental "simplicity" that allow us to form the idea of a phenomenon, a model of understanding, that in the presence of an apparent complexity additional, a deviation, allow the vision of the problems from a different point of view, so control the phenomenon or a complex system.

Alain Berthoz writes that "... contrary to what one might think simplification is not simple, because it involves particularly to inhibit, to select, to connect, to imagine" [4], which are the drawing properties and of all operations mentally conscious.

The man in order to minimize the energy and speed up the transmission of information, uses models of structuring of reality the same or similar in different sectors of knowledge and from our point of view, the application of principles of simplify, is an effective tool to learn more about the built environment.

It's important to try to formulate some principles of simplification, that may help us identify and describe the properties and laws that underlie the mechanisms that regulate the life and the expansion of cities, that help us build a model for understanding the observed phenomena, used and identified for each individual purpose, to collect data, process them and provide new evidence to overcome the many problems posed today by the conservation and regeneration of urban centers and for the their sustainable development.

The definition of a model as already theorized by Structural linguistics [5], should be based on some principles that we believe fundamental: those of the pertinence, of the analogy, of the generalization.

The model, must represent a structure according to a specific purpose (describe the facts under one point of view and take into account, of the complex reality only those features that proposes any disciplinary interest, excluding others), with analogical logic (drawing signs and symbols representing something that resembles, that you may consider iconic because it shows the same properties of its referent with varying degrees of similarity) [6], and generalizing (by starting a confrontation between structures of different phenomena, which

seem to have the same meaning and comparable, to infer another more simplified that contains the essential features, so as to express an hypothesis of knowledge valid for all) [7].

Moreover, we can add those what would seem the natural principles that govern the structure of living beings.

The model must differentiate and separate functions for modular decomposition, to locate quickly using elegant and effective solutions the simplest elements of complex phenomena through specialized modules and then reassemble the whole, making a deviation from the "simplicity" according to the cartesian method. The model must be flexible, or easily modifiable to follow the evolution of the phenomenon and the refinement of the idea, and contain memory of the actions previously performed. By operating an exchange of value as a function of scale reading, it should be possible to identify those elements constituting the model – which in turn, can be structured in the most rapid way - that are detectable even in the schematization of different phenomena.

In short, we must devise models that can accelerate the phase of depth knowledge, the simulation of potential design transformations and improve the transmission of information.

Operationally, this intellectual operation translates into graphic representations (digitals or analogue) which is characterize: for the position relative to a reference; for the form definable by relations between the geometric components; for assignment of color qualities of the surfaces that bounding the bodies that determine the boundaries; for the scale of enlargement or reduction that identifies the appropriate level of detail.

From our point of view, modeling was an effective tool for study of the built environment, object of our interest, an operation intended at a interpretative vision of the appearance, more that the accurate reconstruction of the object, not a simulation that seeks to replicate exactly [8].

The slavish reproduction of the existing, normally does not no present useful meanings for the knowledge and for the project, even if the prefiguration of a possible transformation is certainly important.

The modeling, as a mental operation, is in its very essence a way to explore what we see and the graphics materialization makes visible the results, realizing of a perceived object, both the representation of the real appearance and his fiction.

The representation methods that science has encoded to return the data of the actually built and its design, help us understand the world, for what concerns us, through the reduction of two-dimensional and three-dimensional space and the discretization of continuum, representing its elements for partial images that allow, through mental processes, to restore the original continuous form.

So, the shadows of the statues of animals and things - narrated in the myth of Plato's cave - which make recognizable the forms of nature to a group of men jailed since her birth, once that free they reached the light, or the clever design of the crab, made by Chuang-Tzu, in an instant with a single gesture, but result of years of painstaking study of the animal - described by Italo Calvino [9] - may become appropriate examples of a representation that quickly reaches a smart simplicity that can define the word "Less" for drawing.

2. Visions and reflections²

The design of architecture and its many variations that cross sectors of science, even far from each other, interposes "... between the project and the survey, between the idea that becomes architecture and the constructed architecture that, through analytical routes, goes back to the drawing, between the project leading to the construction and the survey that from the extant, returns to the project, moving in paths space-time, that direct to the future or are modeled on the past, going back to the formative stages. The ideal meeting point for this graphic and creative process, the central hub of the system, is the conceptual moment, from which they have start and are reunited the complex areas of graphic representation"[10].

The experience of research and design of the old town of Ruvo di Puglia (on the occasion of the Convention for the preparation of studies and analysis aimed at drafting the plan of urban and building recovery of the historic center, between the city of Ruvo Puglia (BA) and the DAU of the Polytechnic of Bari, coordinated by prof. Francesco De Mattia), assumes the meaning of the meeting place of ideas, of the expectations about the future of the city, a moment of reflection on the identity of places.

The public spaces, through the interpretation of the data collected, they are tested to verify the ability to accommodate, among the them historical traces and their physical weight consolidated, new forms, new languages, and develop a possible model of urban growth.

In the cultural context on the issues of representation, the research is orientated to know at both the cognitive process, based on reading and processing of scientific data collected in order to suggest possible strategies of transformation, evolution and enhancement of urban environments, at both the communicative aspects of drawing seen as a place of materialization of the idea of the city that has formed in the mind.

In this experience of project and research becomes essential think to the drawing as a very special way to understand and to examine things. The drawing pushes us to think about the essence of the architecture, of the landscape and the world, where the thoughts, reflections and visions are made with visual material. Reflect on the future of the cities, identifying places and unstable situations, through scientific operations, defining methodologies for the analysis of urban events, means to relate different data, construct a system of values and define categories, to get to develop general criteria intervention, to improve the city, and above all the life into the city. Then imagine, prefigure, create an "environment conducive to life" [11].

By interpreting the thought of Aldo Rossi, we can define the complex analytical work on the city historic center like the research, in every direction and with any means of the current image that is the paradigm of everyday life and identity synthesis of places.

The old town of Ruvo di Puglia (a settlement of ancient origin placed on top of a hill at the northern edge of the plateau of the Murgia. Located in a strategic and important location in the geographical area, since Roman times as *Statio on Consular Trajan*), boasts the existence of a physical structure ancient and nineteenth-century old still well preserved arise where buildings of great historical and architectural value. Ruvo has been consolidated over the centuries on two main directions, the axis connecting Piazza Matteotti and Piazza Bovio in which converges Cathedral street. After the demolition of the sixteenth-century city walls, in early nineteenth, Ruvo has developed along the south and west directions where there are the important and representative buildings of the city.

The research and study work has produced interesting results in which the urban spaces and the architecture have undergone figurative experimentations aimed at urban regeneration. The research was developed through three matrices: visual, constructive and interactive/multimedia matrix.

The visual matrix is developed through the search for identity of the place that has passed through every step of the knowledge of the places themselves, has inspired analysis and urban survey and guided its definition and translation in graphic way.

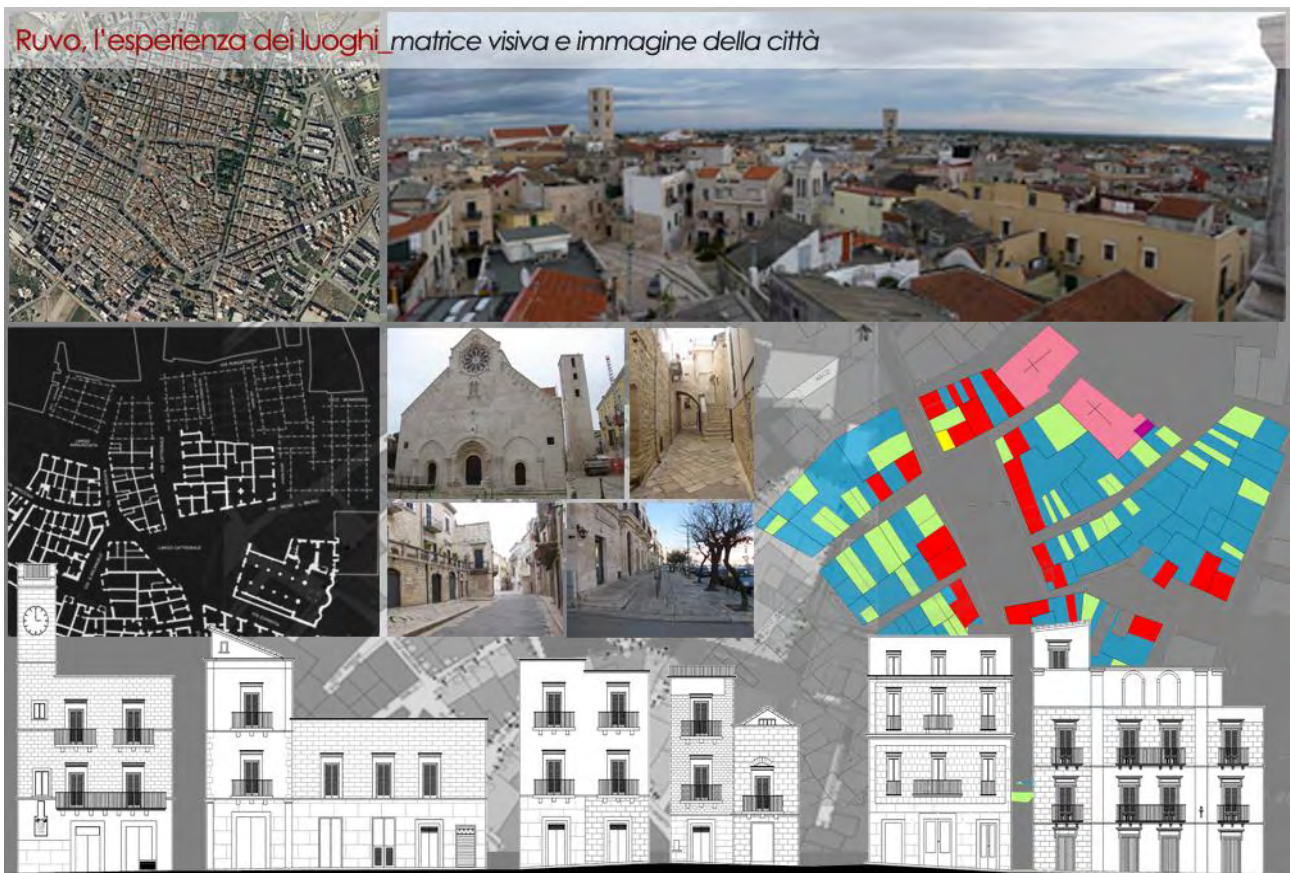

Fig. 1: The matrix and the visual image of the city - Thematic graphs entitled: Ruvo, the experience of places. (Drawings produced by Pietro Lavallo in the degree thesis in Building Engineering at the Polytechnic of Bari - supervisor prof. arch. Verdoscia Cesare).

The process of knowledge, that starts from the urban survey (for example urban fronts, ground attacks and profiles of the isolates, roofs and attics, etc.), from the analysis of the condition of existing buildings (intended use, state of conservation, infrastructure, paving, etc.), passing through the interpretation of the desires and expectations of citizens which are compared in working groups on specific issues, comes to the definition of the elements of disorder, category in which were included unauthorized building, traffic, barriers to the use of common areas, improper use of internal spaces, and all that it was considered an obstacle to safeguard the image of the city.

A story in pictures that begins with the observation and description of the place and then develops through the interpretation and representation of places. The story of the city in its real state / current is entrusted to the digital tools of visual communication and spatial representation, such as photography, digital graphics and video.

The construction of images (constructive matrix), expressed through the composition of the data and testing the relationships between architecture and world of media, which represents the central moment of the search path, where the architecture is the protagonist of a knowledge process aimed at the redevelopment and enhancement of the rich and complex architectural and urban heritage, implements existing documentation and provides new data and elements to communicate and suggesting new design strategies. Starting from real situations, from the complex and unresolved areas of the town of Ruvo was possible to realize structured models of cities that can become conceptual forms, within which to test their skills and creative expression, looking for a new image of the city and was possible to process graphic and visual material and going over the threshold of recognition between real and virtual.

In the constructive matrix is addressed the relationship between architecture and digital environments where the drawing is the "place of learning a new system of cognitive values and creative" [12] and represents the main tool to understand and describe reality, designing the transformation and communicate the ideas underlying it.

Fig. 2: The matrix construction and the digital model of the town of Ruvo - Thematic graphs entitled: Ruvo, architecture, city, visions. (Drawings produced by Pietro Lavalle in the degree thesis in Building Engineering at the Polytechnic of Bari - supervisor prof. arch. Verdoscia Cesare).

The story of the city has established a process of building and texturing of the environment modeling which has generated new visions, reconstructing that space with buildings, surfaces, objects, etc. through photomontage and solid modeling operations.

And it is here that the representation is equivalent to the thought, to the idea. In this radical form of graphic processing the idea of transformation is contaminated by the medium of communication, in which digital images hide disturbing elements and show new events in a continuous movement that reproduces virtually the action and simulates the perception.

In this contest are born the "Urban Visions", telling the city not only through plants elevations and sections, but are aimed at mending interruptions, interrupting serial elements, reconstruct missing parts, replace with other objects, fill voids, free space, insert new objects, to shape light and color where there is not, and suggest activities.

Some of these operations are extreme acts, but all aimed to suggest possible strategies of composition and design and encourage debate. We operates on the surfaces, spaces, shapes that allude only to the content and whose vision is postponed to a possible, future execution phase of the project.

The process of transformation of some urban areas studied, ends in the interactive and multimedia matrix in which the designer, after some considerations relating to the specifics of the project and compared to the communicate ideas, takes on the role of director of complex system of data, result of the previous stages. The choice of medium of communication shall submit the draft to the verification and delivery it into the hands of those who will move into that space.

New visions of the city are told through the development of communication projects that see video as an expressive tool of great potential and that fit well with the objectives of the project, as it allows the viewing of a work in its context and in its possibilities of use.

Ruvo, architetture città visioni_ matrice costruttiva, fotomontaggio e costruzione dell'immagine

Fig. 3: The matrix construction: the new image of the city through the operations of photomontage - Thematic graphs entitled: Ruvo, architecture, city, visions. (Drawings produced by Pietro Lavalle in the degree thesis in Building Engineering at the Polytechnic of Bari - supervisor prof. arch. Verdoscia Cesare).

It includes, summarizes and updates the traditional methods of describing the architecture in a format better suited to the media immediately understandable. The video tells a plot, an urban plot, where the plot term is not random because it is intended both as a narrative of one or more events as well as texture of the built.

Telling a story yet to be discovered is define, perhaps, among the many possible, to suggest other stories by visual stimuli.

Measure yourself with the video and the language of film applied to the theme of the city and the representation of architecture suggests new questions and opens up new themes.

The merger between the different languages of graphic communication and the representation of architecture, of the urban space and landscape, generates an additional language, an space between real and virtual full of content, capable of exteriorize the messages of the project you want to communicate and at the same time tell a story, an event, a past situation or futuristic.

The design of the city as it was described collects all the stresses and inputs dictated by the analysis of the built, added to the predictions of the project and opening the new spatial configurations. The result is a superposition of complex images computer-generated, a concise and intelligent composition of elements ranging from preliminary sketches of the project, to the virtual model, from photographs to technical drawings, from rendering to the photomontage.

This drawing aims to reach all the recipients of the project, offering an immediate approach to content, to the message and the realization of the project. Makes the architecture more understandable not only because virtually reproduced in the figurative sense, but also because it reinterprets it in terms of a story in which the power of visual communication submitted the projects to the attention of the people in visual form.

The research, ultimately, attempts to answer the need for improved communication among engineers and between them and the future users of the project: consider, for example, to participatory planning and the enormous difficulties that the people involved in the process once given the go-to forums, roundtables and debate on the issues. The question is to facilitate the transfer of information from one category to the other without that the process is depleting or risks not to be considered in all its aspects.

On the connotation of the word “ksour” in the Mediterranean

Marinella ARENA,

Università degli Studi *Mediterranea* di Reggio Calabria

e-mail: marinella.arena@unirc.it

Abstract

The Arab word “Ksour” is widely diffused throughout the “Limes arabicus” and the “Limes africanus” amid the coasts of the Mediterranean Sea. “Ksour” indicate different kinds of earth constructions. Leading academics have studied the etymology of the word “ksar” and its variants: qasr, gsar, qsar and qsayr.

“Ksour”, for some, is perhaps borrowed from the Latin word “castrum” or from the Greek/Byzantine word “κάστρου”; for others, it derived from the verb “qasara” (singular) or “qusur” (plural).

This research tries to verify, through objective data, the true meaning of the word “ksar” and their common elements.

The employed methodology includes an analysis of some cross-cutting issues related to land management and landscape:

1. Location of Limes during the Roman occupation: Finding “ksour” inside the “Limes Africanus” and the “qsar” within the “Limes Arabicus”.
2. Identifying the natural characteristics of the territory: the topographic and hydrographic conditions.
3. Analysis of the typological system and construction techniques.
4. The cultivation of wheat in the Mediterranean

This study aims to produce a reference system where previous findings and future studies can be combined, in order to pass on tangible and intangible evidence within these areas, establishing a comprehensive circle where knowledge could lead to architectural recovery and the revitalization of territories that we were once thought to be abandoned.

Keywords: Mediterranean, ksour, Berber, Limes, the cultivation of wheat in the Mediterranean

Figure 1: The topography and position of water resources within “Ksour” territories. From left to right: Ksar, Tamegroute in Morocco, Qsar, Tamemitit in Algeria, Ksar, Boujlida in Tunisia, Qsar, Kabau in Libya, Qsar, el-Labeka in Egypt and Azraq in Jordan.

1. Introduction

The Social and Economic condition of North Africa is in great turmoil. European governments have mostly dealt with the transition of these states from colonies to sovereign states. The economic crisis that has recently hit Europe has plagued many already fragile economies, including Egypt and Tunisia. The new air that one breathes in the Maghreb leads, on the one hand, to the vindication of Islamic values, not always recognized cultural identity and on the other, mocks at countries and cultures often disgraced by corrupt governments and patronage practices. All countries in North Africa are represented in Europe, and in particular Italy, a cultural and economic shore. Historically, Maghreb was a place of cultural and religious exchange, with a history interwoven with that of the southern Mediterranean, where traces of a common past resurface in many aspects of daily life: language, place names and architecture.

The policies that new governments are preparing to re-introduce in these areas should not ignore an in depth analysis of available resources.

This study aims to systematically analyze an aspect that, for different reasons, has often been overlooked: spontaneous architecture interrelated to exploitation of the soil. The census and analysis of indigenous architecture, popular in rural areas far from the coast and often made of clay, should be a priority for sustainable development in economically depressed areas. In fact, some government organizations on the Southern shore (the Southern Developmental Board "ODS" in Tunisia, or the Moroccan Ministry of Agriculture with the Marc Vert "Green Morocco plan") have made the development and promotion of these areas their primary objective. On the north shore, The European Union, frequently promotes initiatives to support economic and cultural cooperation between countries facing each other on the shores of the Mediterranean.

In this context it seems useful to provide government organizations, who work in this field, with an objective documentation on the condition of the places and some details on spontaneous architecture which together give a measure of the material and immaterial components of these locations.

2. Roman Limes

In the Maghreb, Egypt and Jordan, examples of "ksour" architecture are commonly found. The Arabic word has many variations due to transliteration or Arabic dialect: qasr gsar, qsar, qsayr. The term could be a derivation of castrum originally from Latin. In actual fact, Roman limes have been documented in the areas of interest and in its fortified buildings, castrum or castles.

This research attempts to verify, using unbiased data, surveys and time analysis, the connotation of "ksar" and the differing common elements. In some regions examples of "ksour" are fortified granaries (Libya and Tunisia), in others they are real citadels (Algeria and Egypt) and in other cases they are still private residences (Jordan). (Fig. 2)

The adopted methodology includes an analysis of some cross-cutting issues related to land management and landscape:

1. Location of Limes during the Roman occupation: Finding "ksour" inside the "Limes Africanus" and the "qsar" within the "Limes Arabicus".
2. Identifying the natural characteristics of the territory: the topographic and hydrographic conditions.
3. Analysis of the typological system and construction techniques.
4. The cultivation of wheat in the Mediterranean

This study aims to produce a reference system where previous findings and future studies can be combined, in order to pass on tangible and intangible evidence within these areas, establishing a comprehensive circle where knowledge could lead to architectural recovery and the revitalization of territories that we were once thought to be abandoned.

Figure 2: Location of the "ksour" in relation to Roman territories and Limes.

Figure 3: The principal exigency mountains and the placement of "ksour".

Figure 4: The main water resources of the region.

3. Identifying natural characteristics of the territory: the orographic and hydrographic conditions

3.1. Orography

The Atlas Mountain range characterizes the entire North African orography. The mountain range is divided into small Atlas, Telliano, and the great Atlas, or Saharan Atlas. The first runs along the Moroccan and Algerian coast and merges into the Medjerda mountains in Tunisia. The second, Saharan, is separated from the small Atlas, Telliano by a regular succession of folds grouped into clusters which include the "Ksour", Amour, Zab and finally Aures mountains.

The Atlas mountains spread from the west to the east and create a barrier between the African coast and the Sahara desert. The orographic structure of this mountain range, climatic conditions and anthropological environment have made it the ideal location for the Berber population to build their fortified villages. The Berbers, or more accurately, the "Amazigh" meaning "Free people", are indigenous, semi-nomadic or sedentary, and speak Tamazight. Despite repeated Arab invasions, the Berbers managed to maintain a certain degree of cultural and social autonomy which they have now lost, due to Colonial influences and regimes.

The geographical location of "ksour" does not always coincide with the Atlas Mountains. In actual fact, "ksour" in Morocco are located in the deep valleys of the rivers, such as the Draa. In Algeria, "Ksour" follow the contour of the Atlas Mountains but they are also present further south in the vast desert areas of the M'Zab Valley. In Tunisia and Libya, "ksour" occupy the slopes of the Djebel Demer whereas in Egypt, "ksour" are present in low depressions parallel to the Nile.

By means of aerial photographs it is possible to evaluate the orography of each area: in some cases desert plateaus clearly separate one area from another, in other cases, the measurements have a complex morphology such as Morocco, Tunisia and Libya. (Fig.1-3)

3.2. Hydrography

The aerial photographs also illustrate the river system. On the plateaus of Jordan it is possible to locate the course of water channels that are now dry. In Algeria, it is possible to follow the path of the ganat (underground aqueducts) that carry water from the slopes of the mountains to the valleys or directly to "ksour". It is only under rare circumstances in the Moroccan valleys that water flows to the surface. The quantity and quality of water supply is determined by certain geological factors such as altitude. Moroccan "Ksour" are typically found between 1200 and 600 meters above sea level, while the Egyptian "Ksour" vary from between 50m to 200m. It is important to note that "ksour" are located between 25 and 32 degrees parallel and therefore belong to a very specific climate. (Fig.1- 4).

4. Analysis of the typological systems and construction techniques.

The material culture of the indigenous people of Maghreb, has been the subject of numerous studies which have examined the aspects of anthropological and sociological neglect and in many cases, the relief and representation of artifacts.

The research group I belong to has completed several major campaigns over the last ten years and intends to do further analysis in the Draa Valley in Morocco.

Typological analysis as an approach only hinted at here, can show the relief of around seventy "ksour" situated between Jordan, Tunisia and Morocco. The analyzed "Ksour" belong to different regions and have very different dates for example, some go back directly to the Roman period and others have been made within the last 200 years. Despite this, they are still all classified as "ksour".

The research objective is to single out any common elements that the "ksour" may share. In other words, try to figure out whether the common name hides a cultural and typological continuity between Roman defensive architecture, the spontaneous architecture of the people of Maghreb and the castles of the Umayyad in Jordan. The comparison aims to evaluate these complex elements in order to verify the influence of geographical context and socio-economic and anthropological aspects.

4.1. Typological System

From a typological view point, the planimetric area is very simple: a rectangular perimeter defined by four corner towers. The smaller structures are square while the larger may have a more irregular pattern with rectangular or square towers. Exceptions to this are Tunisian and Libyan "ksour" which often have an irregular form dictated by uneven terrain. The more modern Tunisian "Ksour" are built on plains but resume a square shape that recurs throughout the homes and mosques of Maghreb. It is worth mentioning that even a very old barn like "Ksar", Gattoufa has an original square core.

One of the most obvious variants is the morphology of the turrets.

In Moroccan "Ksour", the tower has a standard dimension, 3 m by 3 m, with a pass of 25-30 m. In Algerian "Ksour", the area between the side of the tower and the perimeter wall is usually larger: the turret is around 2-3 meters while the wall can reach up to 50 meters. The more established "ksour" have a smaller overall size. Each "ksour" is 25 metres and the ratio between the wall and the tower is similar to that of Morocco, for example the "ksar" Adar. Other established "ksour" are not square because they have adapted to the conformation of the ground. This is the case of the "ksar" Irhzer, where there are also cave dwellings.

In Egypt the "ksour" are small or isolated outposts in the desert or citadels in the oases that develop parallel to the Nile. In typology, they are very similar to Moroccan "Ksour", although in some cases, the turrets are rounded.

In Jordan, as well as Syria, there is a return to the square form. Some "Ksour" were Roman forts, as is the case of Azraq or Hallabah, while others like Mushatta and Balqa are palaces. The size and treatment of the turrets illustrate the difference between a fort and a palace. In the fort, the towers are square while in the palace, the size of the turrets are reduced to become decorative counterforts, 2 metres in dimension and with a semicircular plan.

From the research carried out so far, we can draw upon the conclusion that the following factors are common typological elements: closed structure; defense position; protected access by a door and the presence of towers or bastions.

4.2. Construction Techniques

The construction techniques of spontaneous architecture are strongly linked to local resources. In the Draa region and that of Dudes and Ziz the quality of the soil and the presence of water led the local people to use clay. The Moroccan "Ksour" of the Middle Atlas are mostly made using the pise technique, this makes them particularly vulnerable to diverse weather conditions and lack of maintenance. In this region vast palm groves are present which allows the inhabitants to utilize palm trunks for their interior ceilings. In more arid regions, such as Libya and Tunisia, where the desert is made of stone and the presence of wood for the construction of framework is rare, the ceilings of the buildings are made with architectural coverage "Vaults". In Jordan, the construction technique makes ceilings using stone slabs while the supporting walls are constructed with rubble masonry. In some cases, for example Mushatta and Al Tuba, the Persian influence led to the construction of vaults in adobe building materials, using an inclined substructure.

Figure 5: A typological plan and section of various examples of "ksour": From left to right, a Moroccan "Ksour", an Algerian "gsar", a Tunisian "ksar", a Libyan "gsar", an Egyptian "qsar" and a Jordanian "qsayr".

5. The cultivation of wheat in the Mediterranean

There are basically two types of Roman settlements in the Maghreb created to protect the “Limes africanus”: “castrum” and castles. The former are large, fortified settlements which reflect the structure of the Roman city. The latter are small and isolated fortified structures designed to protect the Limes and the encampment. Often “castrum” were transformed from temporary housing made of tents into real towns with secure housing, markets and spas. Inside the “castrum” was the granary, whose structure, from a typological point of view, was very similar to the Moroccan.

The theme of wheat and its cultivation and preservation is strongly linked to “ksour”, if we consider the term “ksour” to stand for the first buildings created to protect the Berber population and their crops.

6. Conclusion

From initial investigations we can draw some conclusions in relation to the term “ksour “ and the quality of architecture of the Berber population in Maghreb. The cases analyzed throughout this study show continuity in their typological composition: “ksours” are closed, defensive, quadrangular structures often with towers. Moreover, “ksours” are mainly fortified farms and so the term can certainly be attributed to Roman domination and the presence of the Limes.

In fact, in other areas, such as the Moroccan Anti-Atlas range, the fortified granaries take the name igouar or agadir in the singular form.

“Ksours” are however, predominantly defensive structures commonly made by the Berber population in the

Figure 6: pattern of land on which they insist ksours: From left to rightksar Tamegroute Morocco, Algeria Tamemtit Qasr, ksar Boujlida Tunisia, Libya Qsar Kabau, ksar Labeka, qsayr Egypt and Jordan Azraq.

Atlas mountains. Nevertheless, local governments have only recently begun to recognize the cultural and social importance of the Amazi. The process of systematically cataloging “ksour” could facilitate the monitoring of these territories and be the driving force behind the recovery and conservation of architectural heritage and landscape.

Jordan's Umayyad Qasr: variation of invariant features

Paola RAFFA

Dipartimento di Architettura e Analisi della Città Mediterranea, Facoltà di Architettura,
Università degli Studi *Mediterranea*, Reggio Calabria, Italia

paola.raffa@unirc.it

Abstract

The Umayyad Palaces are the first example of civic muslim architecture. In the geographical area that includes Syria, Jordan and Palestine, sources report more than fifty examples of monuments. These monuments have similar typological and functional features. Known as "desert palaces", in Arabic, Qasr, these monuments testify of a typological system based on principles of rational organization of the space, geometric structure of the form, repetition of modular elements, frescoes and stucco decorations. They are an example of innovation, technical and functional, as they represent the synthesis of expressions and combinations of all architectural forms inherited from a pre-Islamic past. The Mediterranean influence is recognizable in the "Roman villa" layout style. Techniques and functional subdivision come from the Byzantine features. Ornamental and decorative art was adopted by Sassanid style. Qasr are one of the elements that compose larger settlement complexes, of which they are the residential built of the aristocratic power. The other elements are crushers, mills, granaries, dams, canals and elaborate irrigation systems, evidence of a flourishing agricultural activity. Other elements are baths and mosques index of the practice of the new religious cult, and in some cases sporadic residences subordinate. Each element structural, functional or formal is repeated in each monument; the different combination of elements constitutes the single variant. The architectural survey of Qasr Hallabat, Qasr Kharranah, Qasr Mushatta and Qasr Qatrana, compared to other examples in Syria and Jordan, compared with other palaces of Jordan and Syria shows that all monuments were designed and constructed by reference to accurate rules of layout and facade scheme. Along with a common type of plan: a square plan with a central courtyard surrounded by rooms; the exterior walls have circular or square corner towers.

Parole chiave: mediterranean heritage, architecture, qasr.

1. Architectural Heritage

The Umayyads palaces represent the first example of civic Muslim architecture. In the geographical area that includes Syria, Jordan and Palestine, sources report more than fifty examples of monuments. These monuments have similar typological and functional characters. Known as "desert palaces", in Arabic, Qasr, these monuments put evidence on a typological system based on principles of rational organization of the space, geometric structure of the form, repetition of modular elements, frescoes and stucco decorations. They are an example of technical and functional innovation, as they represent the synthesis of expressions and combinations of all architectural forms inherited from a pre-Islamic past. These are combined and tailored to the needs of life of an rising society that changes its own way of life according to religious practices. The influence of Mediterranean style is recognizable in the Roman villa layout style. Building techniques and functional subdivision come from Byzantine characteristics. Ornamental and decorative art was adopted by Sassanid style: geometric patterns alternate in rhythmic harmonies, interweaving and swastikas, round and octagonal rosettes and moldings in a zig zag. On the current hypothesis that the extra-urban Umayyad's palaces were "luxuries seasonal residences of the aristocracy" Paolo Cuneo opposes the assertion that these settlements were fortified agricultural farms, of the Byzantine and Roman characteristics. "Of these they adopt the axial and symmetrical floor plan, and the compactness of the enclosures wall reinforced by cylindrical towers [...] while the layout and construction of the towers and the

decorations are taken from Sassanid models". According to Cuneo the contribution of the Umayyad inventive lies in the union of "these different elements". Oleg Grabar mentions about fifty buildings scattered throughout the suburban area of the Umayyad Empire, built by Sultan Al Walid I (705-715 AD) and his successors. Some of these "buildings were erected outside the main urban centers", others were in semi-desert areas, but most were distributed in "areas permanently cultivated and were all part of large agricultural establishments" (Oleg Grabar).

2. Type and function

Qasr are one of the elements that compose larger settlement complexes, and they represent the residential center of the aristocratic power. Other elements are crushers, mills, granaries, dams, canals and elaborate irrigation systems, evidence of a flourishing agricultural activity. Other elements are thermal baths, mosques and house. The typology of Umayyad Qasr is structurally defined and unambiguous: a square plan with a central courtyard surrounded by rooms or more structured spaces; wall fence reinforced by square or circular, corner towers. The primary function is residential, and as mentioned, they are part of an agricultural type of settlement complexes of which they are the house of aristocratic and government power. Each element, structural functional or formal, is repeated in each monument; the different combination of elements set up the different variant. It is possible to identify two categories of palaces. If the palace is a single unit, the type is a central courtyard surrounded by a portico which distributes more or less extensive local, whose functions are independent on the size and shape. "The main residential unit was a square building, usually of about seventy meters in length. From the outside it seemed a fortress with massive corner towers, a variable number of semitorri on each side and a single entrance. But fortified appearances was only an appearance and unlikely corresponded to some military function" (Oleg Grabar).

Qasr Hallabat, Qasr Hair al-Khaf, Qasr Al Azraq and Qasr Bshir present system of fortified walls and square corner towers. In Qasr Khirbat Al Mynia, Qasr Kharannah, Qasr Al Hair Al-Gharbi the angular towers are cylindrical, and there is the presence of semi-towers leaned to the side walls also when the development in length of the tape wall has small size. The plan layout is always the same: a monumental entrance, a reception room, a mosque, thermal bath, residential area. The monumental entrance is placed on the median axis of the plan square, it is always announced by a large doorway surrounded by the double colonnaded. It is a hall composed by one or more rooms that are disposed in succession up to enter the central courtyard.

Fig. 1: Umayyad Qasr.

Fig. 2: Qasr Mushatta: plan. (drawings by: G. Luccisano, G. Granieri, E. Morano, M.C. Laurora, M. Fallica)

Fig. 3: Qasr Mushatta: sections. (Drawings by: G. Luccisano, G. Granieri, E. Morano, M.C. Laurora, M. Fallica).

Fig. 4: Qasr Mushatta: facade. (Drawings by: G. Luccisano, G. Granieri, E. Morano, M.C. Laurora, M. Fallica).

Entrance to the palace has the specific function of waiting room; for the subjects asking audience to the prince, or traders who traveled the caravan routes, etc. afterwards these were officially received admitted in the "throne room". The courtyard is a distributive area, it organized the access to different rooms. The presence of the mosque in the building confirms the new religion of the Ummayyad's dynasty. In small palaces, the mosque is usually an external building, located near the palace, or in the case of Qasr Al-Azraq, it is located inside the courtyard. In Khirbat Al Qasr Mynia the mosque is inside the palace, it is a room on the left of the entrance; here is obvious the derivation of the Byzantine chapel inside the palace. Another element always present is the thermal bath. These units, of Roman origin, can be internal or external to the buildings. In the case where the palatium is a large settlement, a real citadel, it is composed of several units side by side but independent of each other, all enclosed just one fortified wall system. It repeats the central courtyard type, which contains smaller units: housing, independent of each other, they do not ever look directly into the central courtyard, but through chicane entrances that reach secondary courtyards around which are distributed small rooms.

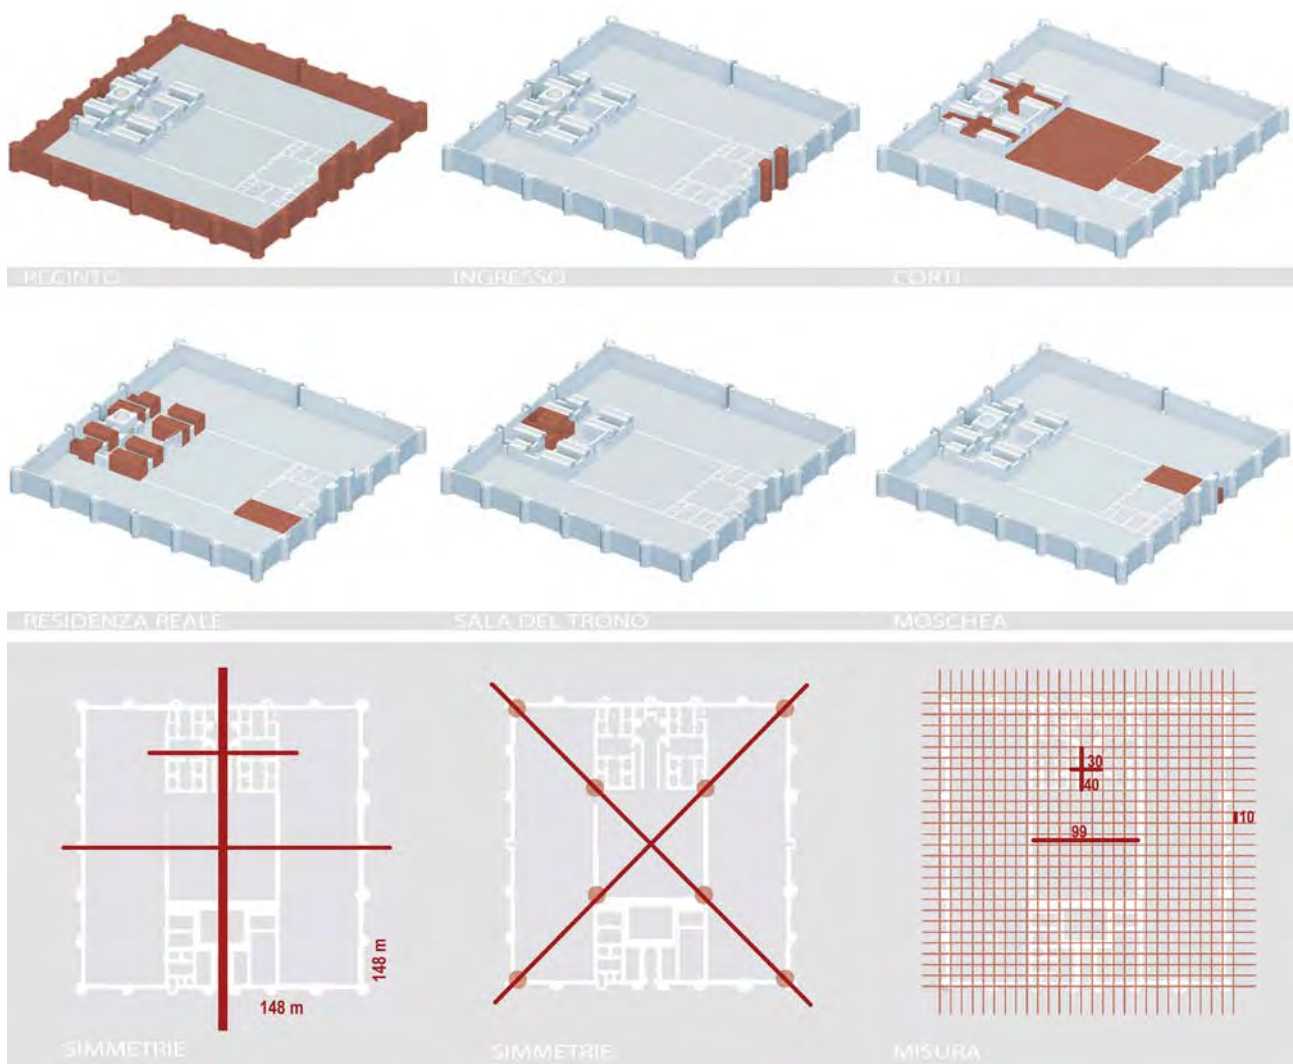

Fig. 5: Qasr Mushatta: plan proportions. (Drawings by: G. Luccisano, G. Granieri, E. Morano, M.C. Laurora, M. Fallica).

In the case of Qasr Hair Al Sharqi there is four symmetrical entrances, placed on the median axes of the square plan, that reach the central courtyard; they are placed side by side to the entrance tunnels and facing to them there are eight square blocks with central courtyards. The tripartite scheme of Qasr Mushatta expresses the same composition. While in the case of Al Qasr Mafjar two courtyards split residential rooms from semi-public spaces, the thermal bath, the piscina, the mosque. If these buildings are cases of adaptation of a new lifestyle to a "vocabulary of preexisting forms " as claimed by Oleg Grabar, we can think that the Umayyad palaces are accurate architectural compositions that accept architectural standards derived by a detailed knowledge of Roman, Byzantine and Iranian architectural code.

3. Geometry, rule and proportion

The careful graphic drawing of surveys of Qasr Hallabat, Qasr Kharranah, Qasr Mushatta and Qasr Qatrana executed in the month March 2011 shows the state of conservation of these monuments; some of which recently have been restored. The architecture analysis performed on schematic models, compared with other palaces of Jordan and Syria, shows that all monuments were designed and constructed by reference to

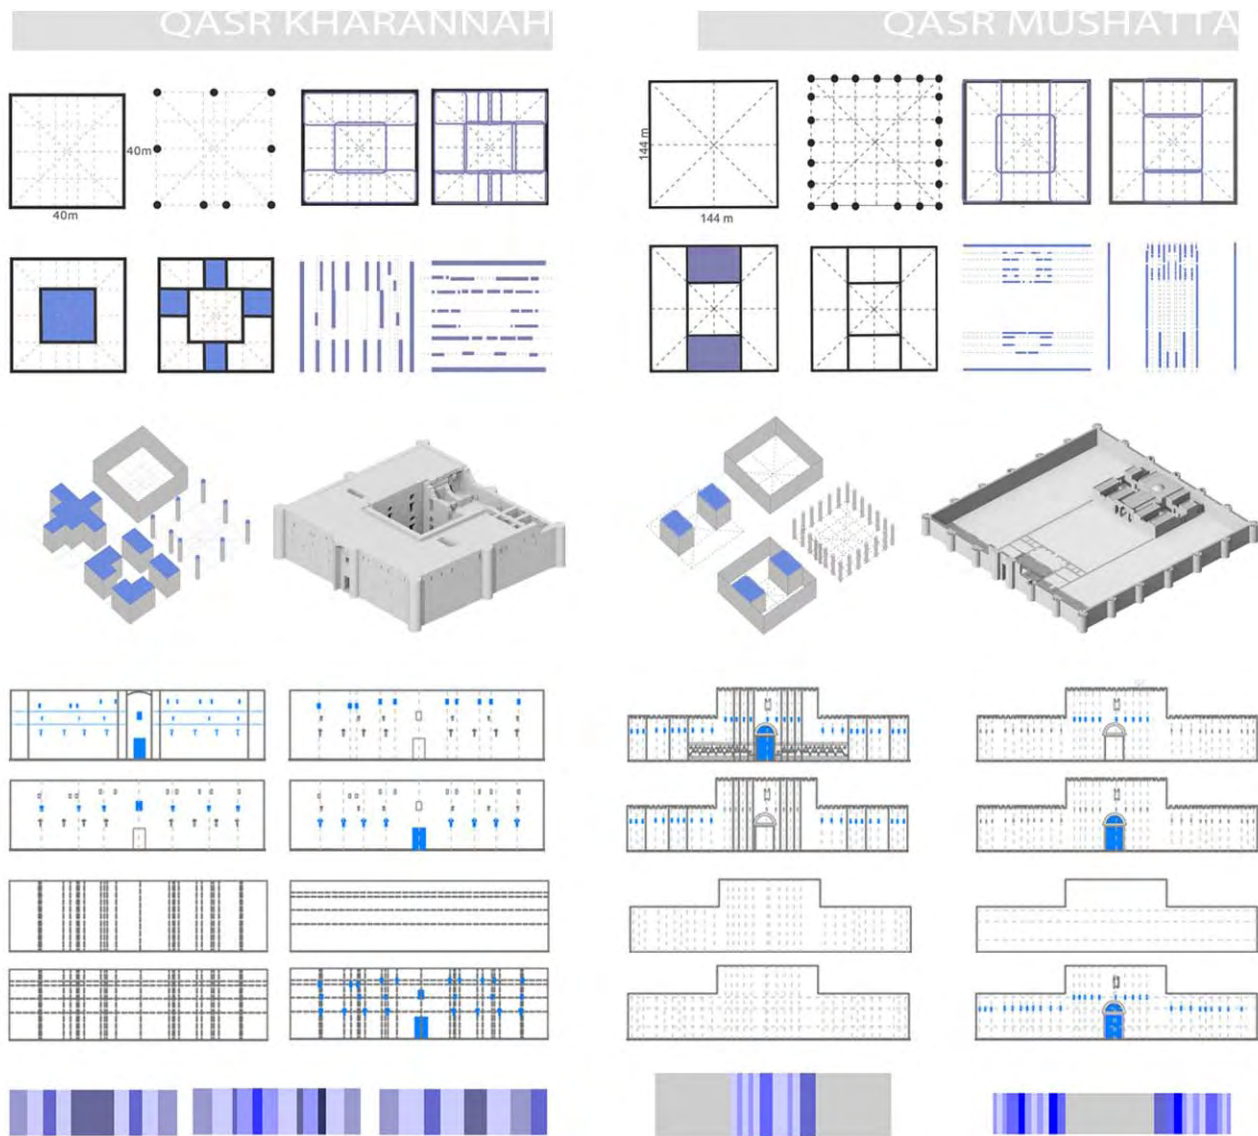

Fig. 6: Geometry, Rule and Function: Qasr Kharranah and Qasr Mushatta (Drawings by: G. Giaino, S. Firrito)

specific rules of layout and facade scheme. Regular geometric patterns of squares organized symmetrically without any preferential direction or orientation. Rigorous observance of geometric rules, intersections of median and diagonal axes of the shape-generating: the square. Subdivision in modules, submodules and double-modules; repetitive basic architectural unit cadences; symmetric axes accentuated by size, shape and position of the part. The measure is organized on the cubit (57.66 cm), plans are 35, 70 or 140 meters long. Qasr Mushatta is divided in three equal section. This section is further divided into thirds part. A colonnaded hallway conduced into a triple iwan. The facade consists of a zigzag pattern creating a panel of triangular forms. The plan of Qasr Karranah (36.50x36, 50 m.) is a tripartite square: two modules of 9 cubits external include 4 modules of 5.60 cubits of the central courtyard. 4 cylindrical corner towers locked the basic square while a semicircular tower on each side marks the median axis of symmetry, that, however does not correspond to anything important inside element. The same pattern is present in Qasr Khirbat Al Minya (73x73 m.) and in Qasr Al Hair Al Gharbi (70x70 m.); in these two cases the size of the court in larger than the built part. "Beyond elementary measurement and the establishment of the most basic modular principle of designing [...] There is a combination of a set of buildings from a restricted period of time, in a relatively limited space, and with a more or less same patronage "

Abstract

The Church of St. Mary Immaculate of Longuelo is one of the most interesting and representative works of the Lombard architect Pino Pizzigoni. This project, which construction began in 1961, was founded on technological innovation assumptions and characterized by a space covered by reinforced concrete thin-shells supported by inclined pillars. The formal configuration of the Church was set in close connection with its religious significance; New Testaments words and meanings were translated by the architect into a building design. From a formal point of view based on a hyperbolic paraboloid, the interior is characterized by an enveloping space emphasized by the light penetrating only from tall windows and inspiring visitors with a deep sense of the sacred. Today, more than forty years after its construction, the geometry of this prestigious example of modern architecture remains almost unknown, understood and/or full accepted by the users. Its forms, sometimes sinuous and winding, sometimes edgy and essential, are affected by many degradation phenomena and lowered by several posthumous interventions (due to new liturgical requirements) not always fully respectful of the architect's intentions. Observed through the eye of laser scanner, in a conscious manner directed by the operators (surveyor-restorer), this paper aims at illustrating the spatial complexity of a place that, more than others, links the materiality of architecture to the spirituality of the Christian faith.

Keywords: Restoration of modern architecture, Pino Pizzigoni, 3D Survey, Longuelo.

1. Introduction: the Church of Longuelo and its architect.

A Christian Church is not a physical space in which believers gather to worship. The Church is the community itself that becomes the place where to meet in prayer (in front of the altar of the Eucharist) and listen the Word of God. The ecclesiastic edifice is then built around the faithful, by using forms and shapes that are the expression of theology of the time of its construction. The churches are not for the Christians new temples replacing the Pagan ones, because Christianity is, for the believer, the mankind's wish to come into contact with the divinity, and the figure of Christ represents the encounter between God and the men. Jesus Christ is for the Christians the temple where to profess their faith and the practicing can thus be considered as the "living stone" of this new building. The Second Vatican Council (also known as Vatican II), addressing the Church's relationship with the modern world, has given back to the believer the role of owner of the liturgical action. The Office of the "priesthood" now belongs to the whole community, and it is no longer strictly reserved to the celebrant, so that "all the faithful should be led to that fully conscious and active participation in liturgical celebrations which is demanded by the very nature of the liturgy and is in their right and duty by reason of their baptism". To this end, the "New Liturgy Constitution" of 4 December 1963 has

therefore created a revolutionary model of church buildings, opening the presbytery towards the faithful congregation.

The strong economic growth and urban expansion experienced by Italy in the years after World War II, as well as the need to rebuild what destroyed during the conflict, has produced from the mid-50s and the late 60s of the last century, an impressive number of religious structures, often characterized by the expression of the free creativity of their designers. Drawing a church was the dream of every architect, not for the economic interest which might be connected, but for the professionalism required for dealing with a topic having at its core the spatial materialization of the spirituality. The decision to build new parish edifices was taken by the bishop that, in agreement with the Curia, had free power to entrust the project to an architect enjoying his esteem and confidence. This is the context in which the architect Giuseppe (Pino) Pizzigoni was commissioned to design the church of *Santa Maria Immacolata* in the new quarter of Longuelo in Bergamo (fig. 1). Pino Pizzigoni, closely linked to cultural and artistic world of Lombardy, was a figure having in mind a mature idea of space as well as an important interpreter of expressive languages of his time. The chronicles describe him as a complete artist who used to quote the phrase "without abstracting, we cannot speak or even think." A multifaceted personality, who loved to experiment, both in sculptural and painting fields, through disassembly, deformation, perspective and geometric distortion procedures. The design of this church was for him a *chance* to find the point of synthesis between sculpture and architecture; a challenge in which sacred space could be melt and sublimed in an enveloping structure with a strong plastic value. This in the aim of translating into constructive materiality the Gospel passage - today written on the ambon: "the Word became flesh and made his dwelling among us" (Gv 1,14). The so-called "hut of the Catholic community" has been the last work of Pizzigoni and can be considered the witness of a complex personality, "certainly not *routinier*" and "a way to understand the practice of architecture as a continuous research for a constant overcoming of acquired positions" [1].

2. The Church yesterday and today: history, geometry and desired contradictions.

The construction of the church was initiated in 1961 and in June 29, 1966 it was consecrated by Archbishop Clemente Gaddi to the Blessed Virgin Mary Immaculate (fig. 2). This has been a work characterized by a great structural commitment and desired contradictions, realized through tensor integral structures and tiny vaults, in order to assign it an innovative look having a high impact. The first studies on the reinforced concrete membranes carried out by Pino Pizzigoni date back to 1955, with the construction of the roof of some industrial buildings and of a kindergarten in the town of Monterosso. The tests undertaken on buildings based on simple systems allowed the architect to acquire the knowledge and experience necessary for the design of the church and its structures, which lasted over two years.

The essentiality of the geometric matrix founded on a quadripartite square along its median axis is not clearly expressed; the spatial complexity of the elevations which varies in size and sections depending on the altitude, hides the simplicity of the central plan, albeit slightly modified during the building phase (fig. 3).

Fig. 1: The Church of Longuelo, today.

The understanding of structural system, easily legible in the plan and in design drawings, is not immediate in the spatial perception of an observer who enters the church for the first time. To the planimetric regular division into four parts correspond many reticular trusses separated by joints that hold vaults and tiny frameworks differently oriented, that constitute the coverage and the vertical closures of the church. The complexity of the outer space that shows the articulated geometry of the structures and that imposes itself with "brutality" on the city, is strongly contradicted inside (fig. 4). The intimate space of the church is, on the contrary rather "romantic", rich in rhythmic relationships and free from decorative constraints. Its proportions are marked by changes in the inclination of the reinforced concrete large areas.

Rods and nodes are in the church interior transformed into surfaces in *béton brut*, along which runs the light coming from small white glasses. The atmosphere of understated simplicity has been researched by Pino Pizzigoni through a coherent use of the materials: this is particularly evident in the chancel where the great Madonna stands out from the grey walls thanks to its light color. The huge work of art realized by geometric elements engraved in relief, with the exception of the faces of the Madonna and the child figuratively made (attributed to the former student of Pino Pizzigoni, Dietelmo Pievani, but that recent studies endorse to the same architect) rises to 11 meters in the pyramidal space of the apse's sail, "abusing" of the sacral space. The church design project was born from the drawing, considered by the architect as a tool to understand and communicate - to-himself and to the others – the thoughts on his mind. For Pino Pizzigoni, the design was the place on which to elaborate the idea and test the project: "by drawing, I'm getting used to think about what I want to say and not to the elegance and the drafting style of the design". The drawings made for the church of Longuelo are quick sketches, made on common/casual sheets of paper just to halt by the line, any impromptu inspiration; each new design was the evolution of the precedent on which new ideas were refined.

The preparatory drawings of the church project came one after the other and run wildly after each other because when the sign appeared on the paper, the mind of Pizzigoni had already gone further, creating in him the need to steal a blank space to stop new thoughts before they flew away. The architect was used to date and initial any sketch, even the most insignificant ones, not in the aim of documenting the history of the work but to draw a map of its changes, to assess its evolution step by step and even to go back and take other paths (fig: 5). Even the use of perspective, who he taught for more than thirty years at the *Accademia Carrara* in Bergamo, was functional to the understanding of the spatiality of the project, to think about the unresolved issues and then to solve them. The design idea was investigated both with quick doodles made by pencil and with fine collage taken from the redesign of the maquettes' pictures joined with touches of color (fig: 6). The drawing combined with the use of scale models was used by the architect for the control of the project as well as to test the spatial construction and to verify its structure. The models, made of wood, cardboard or nylon, and brass for the countercheck of the curvature of surfaces in the space, was a means of control not only volumetric, but also aesthetics (fig. 7).

The construction site did not follow an easy process because of the geometric complexity of the project and the difficult construction of formworks. In particular, it was difficult to recreate in the reality the exact surfaces and curves of the model, forcing the designer and the building company to make continuous changes in order to place the containment structures of the shells [2]. The real geometry and the true size of the church are nowadays still not known both for the lack of documentation and transcription of changes that were made and for the difficulties in the correct spatial positioning of the nodes that were placed and adapted to the capacity of the workers; in certain cases the real curvatures of the vaults are completely unknown as well as the true distance between nodes.

The today's church is very different from Pizzigoni's original design due to the many changes that have been made over the years. The walls are much darker and a faint light of a thousand colors now invades the nave, originally imagined painted white by the architect. Colored light penetrates even from the new framed glass portal made in the 90s by the artist Mimmo Marra [3, 4], replacing the previous gate. The altar has been substantially modified in order to hide the image of the Madonna, considered as a "theological horror" because of its size, larger than that of Christ. Among the last works undertaken there are the confessional and the baptismal font designed by the architect Attilio Pizzigoni, son of Pino who in his interventions, like everyone else, has been able to comply with the architecture of the father. In particular Attilio Pizzigoni has well seized the intentional contradictions in the church design and interpreted them in a modern way. In this sense, he has created a difference between the confessional wall made outside by dark stone to adapt to the concrete walls of the church and inside in light marble to create a reassuring place for receiving and forgive the sins of the faithful. An equal sought contradiction appears in the baptismal font where the pink marble basin harmoniously interacts with the copper sheathing, without screeching in spite of the difference between stone and metal [5].

In the past years, maintenance works have been undertaken on the church but unfortunately they concerned only limited parts of it. Many outdoor areas exposed to the rain are today in an advanced state of deterioration that requires urgent restoration work (fig. 8). The most common problems are related to reinforced concrete structures exposed to the action of rainfall, where the oxidation of the metal bars has caused internal failings of the mortar. However, to establish a conservation project, it is first of all necessary to carry out a complete and accurate survey of the structures that has never been realized. This is what the authors of this work have done through the most innovative methods and technologies.

3. 3D survey for the geometrical knowledge

Today, the use of structured light 3-D measurement system in the architectural framework allows approaching the work of art to be investigated without requiring its prior knowledge. It is actually possible to perceive the architectural space and its environment even in the absence of previous surveys (normally carried out through sketches, pictures and direct measurements) to later really understand them, in the restitution phase. The laser scanning survey is a tool that allows the architect-operator to rejoice with naive wonder of spaces seen for the first time, as a child who is enthusiastic and delighted when something unexpected happens in front of him. It is so that, while the traditional technique forced to the realization of numerous eidotypes to record, from time to time, metric data as well as to annotate the peculiarities of the buildings themselves (i.e. the masonry walls, the characteristics of the materials and their state of conservation), today with the laser scanner is no longer necessary. This instrument gives us the possibility to enjoy the place during the time in which, in an autonomous and automatic way, the instrument makes the job. Laser scanning technology has actually completely revolutionized the practice of surveying for restoration purposes; following the data processing, the point cloud, in addition to ensuring the rapid and complete measurability of architecture (distances, surfaces and volumes) through the definition of plans and cross-sections, allows us to obtain important information related to the structural stability of the building and of its state of decay, providing a reliable and accurate support for the development of the restoration project. Rather than the preparation of the eidotype, it now appears important to plan the survey: the location of bases and support networks, the definition of scanning steps and their resolution, the correct choice of the station points. This in order to obtain a global cloud that could completely cover the building, limiting as much as possible hidden areas.

In the case of architectural elements of highly complex shape, such as the church of Longuelo, the survey project has considered the problems of matching (in jargon, registration) of the individual scans and the need to contain the error within a tolerance of the same order of the instrument uncertainty (e.g. the scanning of a masonry wall must to overlap at the end of recording, without giving rise to two different surfaces located in planes staggered between them). The structural complexity of knots and kinks of the surfaces have also made it very difficult survey operations because of the many shadows and hidden areas visible from any station. The restitution of data measured *in situ* has been made by software based on an advanced form control algorithm that has allowed the overlapping of each scan with a range of tolerance range less than 1 cm. For the purpose of a better use of the algorithm, one of the point clouds has been chosen as reference scan, to keep fixed in the space, and all the others have been roto-translated over it. Several orthophotos related to the cross-sections and elevations have been extracted from point cloud in order to highlight the true geometry of the church so far never redrawn, as well as the possibility of returning the exact plant, complete of all the projected elements. (fig. 9). The continuous model, made up by millions of points, is a source of knowledge only when properly questioned. Excessive information, if not structured and correctly organized, causes the same inconvenience of the lack of information. We need then further elaboration to make use of the acquired metric data: the points cloud has actually to be transformed from a nearly continuous model into a discrete numerical model. This latter can then be considered as a reduced and simplified version of the continuous model, obtained by discretizing only some of the available data, chosen by the operator in an intelligent but arbitrary way. A further simplification arises from the choice of the cross section planes, orthogonal to each other, from which measures are needed. The discretization of the points cloud is then made by cross-sections cut at regular intervals (30×30×30cm): a good compromise in view of the subsequent structural applications necessary to define significant parts of the geometry. The point cloud, so simplified to a grid of spatial curves perpendicular to each others can be used to evaluate the stress state by the F.E.M. (Finite Element Analysis) on the basis of the true geometry for the purpose of a possible monitoring of the structure and the formulation of seismic behavioral hypothesis.

4. Conclusioni

The community of Longuelo has with regard to the church an attitude at times critical. They are frightened and perplexed by the bold geometries that very much deviate from the imaginary typology of sacred space.

Fig. 08: The church, today (outside and inside).

Fig. 09: 3D Survey (plants, cross-sections and front-elevations obtained from point-cloud).

Its position in the urban fabric, the lack of a square in front of the church (it only exists a small *parvis* limited in its dimensions by the presence of the street and trees with large leaves surrounding the lot in the hide), the absence of a bell tower largely considered as a symbolic and representative icon, transform it in an anonymous presence limiting its role of urban catalyst for the communities. The church even today, 50 years after its construction has a certain dignity coming out from its design and construction techniques that continues to arouse attention and interest. Visitors are fascinated more by its forms and architecture than by its sacred importance. The church is a must for scholars of arts and architecture, as well as an attractively destination for the numerous tourists that, intrigued by the information written on the guide-books of Bergamo, decide to visit it (Fig. 9). The church itself is experienced and used as a place for public meetings and conferences that are not strictly related to the sacredness of the liturgical celebrations (Fig. 10). The originality of the relationship between structure and form, "fundamental in architecture, otherwise the issue of languages is evanescent", reflects the true *raison d'être* of the Longuelo church that is more based on the mathematical model of the structural frame that underlies the project, rather than in the external appearance that of it can be considered a simple consequence [6].

Today, the Curia is very critical towards the project and the architect's inexperience in liturgical setting – the rearward altar, the centrality of the tabernacle, the double ambon- not in keeping with the indication of the 1964 Council, which now make the church unsuitable to liturgical celebrations according to the modern rite. The work of Pino Pizzigoni is instead a significant mark of his genius as he has been able in this work to combine tradition and modernity. The architect has deeply rooted in the project for the church a special sensitivity to "beauty" and a thorough knowledge of the history of art of past centuries. The already mentioned contradictions in the relationship between the inside and the outside of the building are the response of his idea to combine the role of tradition with the main concepts of avant-garde architecture. It has accepted the challenge with the great architectural models of the past in creating, in a contemporary way, a complete and coherent synthesis between a classical structure and an experimental spatial construction.

The final judgment on the work of Pino Pizzigoni is entrusted to the local population. The same architect was wondering whether Longuelo was "really art and then architecture, or rather only a construction machine". The same question is addressed to people that one day will give an answer. Will they recognize in this work an innovative value? Will the spatial intuition be recognized by the others and not only by the author? "So if this judgment will be positive, this will certainly say that it is art ... if on the contrary it will be negative, it will mean that the church is only five thousand cubic meters of covered space, useful but not *speaking*. It will thus not to be considered *architecture* nor sacred" [6].

The perfect proportion

Eugenio MAGNANO DI SAN LIO, DARC “Dipartimento di Architettura”, facoltà di Architettura, Università degli Studi di Catania, Catania, Italy.

magnano.e@unict.it

Abstract

The pursuit of perfect proportion has been one of the most dominant themes in the history of Architecture up to our times and, until to day, also if in a less explicit way, it is a dominant theme in contemporary Architecture. We can also state that Architecture itself (which for many architects would be entirely included in the art of architectural composition) is just the research of the perfect relations between different elements, the correct proportion between full and empty –in volumes ad surfaces-, between horizontal and vertical elements, between parallel and orthogonal. The vitruvian *commensuratio* and *simmetria* which obviously had an absolute value, especially in classical Architecture, are willy-nilly, part of our cultural heritage.

Because graphic analysis, that we can make correctly only on original drawings or on careful surveys of the existing buildings, is competence of “Science of Representation”, we must define better is cultural role and re-hook this praxis to the age it has been used. It may happen in fact that, pleased for having found a graphic reason of a project, we run the risk to attribute generative way of architectural forms to the author whereas they are only ours and not the author’s. The risk is similar to the case of a person that becomes with a greatest case an astrologer after studying old treatises of Astrology, forgetting that Astronomy is the only science which studies stars.

Key words: Proportion, ratio, armonic, rectangle, architecture.

The perfect proportion

The pursuit of perfect proportion has been one of the most dominant themes in the history of Architecture up to our times and, until today, also if in a less explicit way, it is a dominant theme in contemporary Architecture. We can also state that Architecture itself (which for many architects would be entirely included in the art of architectural composition) is just the research of the perfect relations between different elements, the correct proportion between full and empty –in volumes ad surfaces-, between horizontal and vertical elements, between parallel and orthogonal. The vitruvian *commensuratio* and *simmetria* which obviously had an absolute value, especially in classical Architecture, are willy-nilly, part of our cultural heritage.

Because graphic analysis, that we can make correctly only on original drawings or on careful surveys of the existing buildings, is competence of “Science of Representation”, we must define better is cultural role and re-hook this praxis to the age it has been used. It may happen in fact that, pleased for having found a graphic reason of a project, we run the risk to attribute generative way of architectural forms to the author whereas they are only ours and not the author’s. In order to deal with this theme we shall first consider the

proportional relationship of the simplest and most usual geometrical shape in Architecture, that is the relationship between the sides of a rectangle.

If we consider the remarkable ratio among the sides of a rectangle between the form of a square and the *diapason*, we obtain a thick succession of lines as in figure 1 shows.

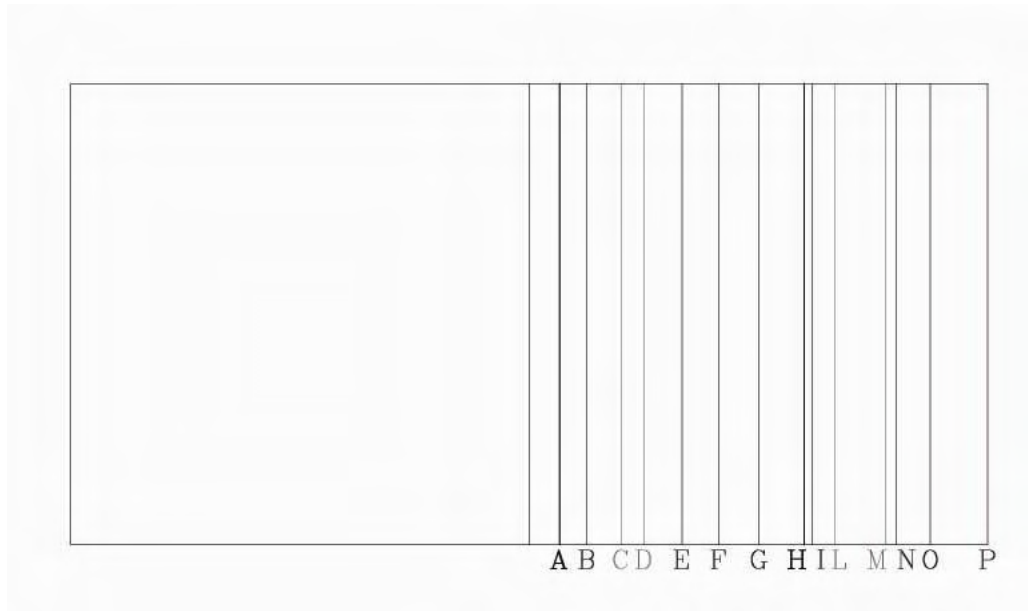

Fig. 1: A – 15:16, second minor; B – 8:9, second major; C – 5:6, third minor; D – 4:5, third major, *sesquiquarta*; E – 3:4, fourth, *sesquitercia, diatessaron*; F – $1:\sqrt{2}$, “diagonea”; G – 2:3, fifth, *sesquialtera, diapente*; H – 5:8, sixth minor; I – divine proportion; L – 3:5, sixth major, *superbipartiens tertia*; M – 9:16, *sesquitercia* double, double *diatessaron*; N – 5:9, seventh minor; O – 8:15, seventh major; P - 1:2, Diapason.

If we consider the divine proportion graphically obtained we also take into account the possible proportional relation of a rectangle including those obtained overturning the diagonal on the short side and on the long side.

The resulting graphic shows a thicker succession of segments similar to the barcode of supermarket goods (fig. 2).

Fig. 2

Perhaps we can obtain any sort of rectangle adding one of that rectangles to one or more square, as in figure 3 shows, for a rectangle obtained adding a rectangle of golden section to a square.

Fig. 3

The analysis of the proportions of rectangular figures in rationalist architecture, characterized by simple surfaces perfectly defined by coplanar lines, requires a clear proceeding, but things change in the case of conformation to classic architectural orders. The geometrical complexity of moulds makes the reasoning on the perfect proportion not so rigorous as it should be. For instance no-one can establish "a priori" if the thin line of the rectangle used for the proportion must run above the centre-line or above the right or the left edge of the pilaster strips, if the sides of the rectangle must exclude or include the trabeation, only the architrave, also the frieze or the attic, if the base of the stylobate must be included, if the proportion of a facade on a sloping road must be considered in the highest or lowest point of the road or in the centre-line, etc. Besides it must be taken into account the amount of corrections brought by architects and builders to avoid optical effects and other expressive faults which alter the proportional relations utilized in the project.

Fig. 4

We must also take into account the uncertainty margin resulting from the analyses done with modern instruments or at the computer and the approximations due to the use of old

instruments and tools, the building site, the corrections brought during the works and the reutilization of pre-existing structures.

The arbitrary use of geometrical analysis is clear in the drawing of a medieval building showed in figure 4.

Under the perceptive point of view the perfect proportion, which is after all just a convention, does not exist and a simple experiment may turn useful to demonstrate it. If we show to unknowing people two rectangles, the former in rapport of seventh major (A in fig. 5) and on the contrary the latter obtained lengthening the rectangle of the diapason by the same quantity (B in fig. 5), asking them to choose which is the perfect rectangle of diapason, they would choose inevitably the rectangle A without noticing that one side is not exactly twice as long as the other.

Fig. 5

Even in those historical periods when projecting involved proportional relations, their use did not hinder a more immediate and less rigorous approach.

This is the case of a door for the small church of Mercy Friars in Catania (1730); as established in the contract, the dimensions of the door were fourteen and a half spans high and seven and a half spans wide: no notable relation were used.

These reflections don not deny the value of geometrical analysis but suggest a more attentive and aware use of it, since it is to architecture as astrology is to astronomy.

Abstract

Before the Normans came to the conquest of western Sicily, they spent several years between the two sides of the Strait of Messina. Messina was the first Norman settlement in Sicily, and for years remained the real center of the power of domination over Trinacria, until the recurring and devastating earthquakes over the centuries (1693, 1783, 1908) have zeroed each track. In the green valley of Mili San Pietro, in the suburb of Messina, we still have a beautiful example of Norman Architecture, the Basilian church of St. Maria, (XI century). The church is in an obvious state of neglect, this place preserves the original structure of the ancient monastery of monks, but needs a restoration, through the rehabilitation of existing materials, bringing to light the techniques of the time, and arrangement of space in front. The church has one nave and the transept. There are three apses as they appear inside, outside only the central one is visible, the other two are included in the thickness of the wall. There are three domes of the transept, the central one, placed on a octagonal drum with internal corner joints; first structural experiments of Byzantine-Norman architecture, like the decorations, the use of red brick, the pointed arches with splayed rings, sometimes intertwined, as in external facing.

1. Architecture

The convent of Santa Maria in Mili San Pietro, was built in the last decades of the eleventh century, it was entrusted to the monks of the Eastern rite, in 1092, with a donation of Count Roger the Norman. The presence of the Abbey, that was the center not only religious but also economic and, for a certain period of time, even political of Mili Valley and surrounding areas, it stimulated activities such as silk production, the cultivation of land belonging to it and grain milling, resulting in the formation of the first places inhabited in the area. The Abbey, between the '300 and '400, went through a period of decline, above all, because of the usurpation of land by some unscrupulous nobles of Messina, whose names appear even in the series of the Abbots of that period. The recovery, based on the few documents discovered to date, had to begin with the sixteenth century, when the church was enlarged, (1511). Then the Abbey had a period of decline, but the end of the religious institution not arrived until 1866, when the newborn Italian State has seized property of religious corporations, putting them on sale to the highest bidder: thus throughout the abbey, with the annexed lands, was divided into several parcels to be used as barns, houses, storages of equipment and agricultural products. Activities that are performed yet today. The convent is now in a precarious stability, the most of it has already collapsed, while the church, had an interim restoration in the early 80s, but the precarious condition of the entrance has determined, in December of 2002, the closing of the Abbey. The architectural complex was also the subject of an intervention project, promoted by Agenda 2000, that had as its objective the creation of a cultural center for conferences and master's students. But the Regional Department for Cultural Heritage, in 2002 stated that the restoration project for the Mili's Abbey, inserted in the second list of priority ranking for funding of Agenda 2000, it will not be funded with these funds. Sicilian Region has virtually ruled out, once again, the chance to put, Mili's Abbey, inside of tourist-cultural circuit of Basilian monasteries, together with the churches of St. Philip Fragala of Nebrodi, St. Peter and Paul at

Itala, and that of Saints Peter and Paul in Forza d'Agro.¹ This possibility would fall in a plan for the use and enjoyment of the architectural and landscape, making them also an economic resource. Today, youth associations begin to pursue awareness campaigns for the preservation of places so important, that are part of our cultural and architectural heritage. Thus, such an architectural gem, gradually gives way to the blows that the time to gradually settles down, taking it away from the enjoyment of citizens and tourists who flock here from abroad. The convent, in degradation from decades, is prior to 1092, excavations there have uncovered important remains of a Byzantine monastery prior of that one Norman. So it was reconstructed on the previous, demolished or destroyed for reasons unknown to us. The building, which dates from the eleventh century presents architectonic characteristics of the Basilian churches built at that time this area of Messina. Despite the modest size of the original church (initially measured 7 meters in length), it can be defined the first in a series of churches built under Norman rule in eastern Sicily. The church has one nave, the crypt probably used as a burial crypt has a series of rectangular opening on the walls, of the niches, and a small apse to below the main apse. From reading the plan, one can imagine that the system architecture was a church in Cuba, then stretched in the church hall. The three apses, of which only the central emerges to exterior with its semicircular profile, while the other two lateral remain included within the thickness of the wall. Each one is covered by a dome, of which the central one of larger size, that is supported by an octagonal tambour, not very high, with references to Byzantine and Norman art. In the side facades, the party decorative of the lower part consists in a reason of crisscross arches, typical of Norman architecture. the upper part presents an orderly succession of compartments alternately blind and open. The church is surrounded by the remains of the ancient monastery of the monks of St. Basil, the custodians of the church. In the sixteenth century, during the renovations of 1511, the wooden ceiling was redone, and the church was extended by about a third: the trace is clearly visible in the exteriors walls, where the party's decorative stops, had to finish the original length the church. A Renaissance portal in marble and stone, characterizes the facade, the wooden door dates back to 500, while it surely dates from the Baroque period the apparatus of pinnacles adorning the completion of the facade². In some parts it is possible to recognize the buildings surrounding the remains of the convent, the other buildings surrounding the temple, are the result of a stratified building activity over the centuries, in close relationship with the changes that the monastery has suffered during his history. To the west there is a long building, which develops in a direction perpendicular to the church and had to be probably the old refectory of the convent. This block about 30 meters long, stands on two levels, one side bordered by the wall of the road and the other one with the surrounding countryside, but one time, it was joint with the parallel corps of the convent church, probably the dormitory of monks. This corps exposed to the north is more complicated and compromised by a structural point of view. The ground floor rooms, probably used for processing of agricultural products, and their conservation were accessible by two arches, which in turn are the support of two flights of stairs which lead at the upper floor, which could be, instead, the guest quarters or dormitories monks. These scales are now completely covered by vegetation. Across the corps which joins the church to the convent, we find the structure of the monastery that today is the most degraded, of which there are only ruins, and fragments of walls. The monastery is situated in a surreal dimension, lost between the old and degradation, it is as if the "Patina of time" had not taken root here. The place where the monastery stands is a very complex place, between the river and the town road, the path that leads to entrance of the monastery is located in the river bed and one part is paved and one part is covered by pebbles, carefully arranged to facilitate the passage of cars, that cross frequently to go no one knows where, maybe in barns, chicken coops and vegetable gardens, a place where the only attraction, the monastery, remains beyond the path, beyond the bed of the river, in a space deliberately forgotten, a mirage only visible from the road but almost completely inaccessible. Recent buildings of brick and reinforced concrete have been matched and superimposed to the ruins of the monastery, only to be abandoned to the actions of the time. Today everything is equally shrouded in vegetation that hides and confuses what is old and what is not, clinging with arrogance until to make disappear all it completely under a carpet of brambles. The side exposed to the South is now completely inaccessible, a wall of vegetation and thorns prevents the passage, just from the street level, it is possible to see the upper part of this prospectus, with the Its arched windows with brick, but is not visible the decorative party of the lower part. John Ruskin, believed that a piece of architecture can be seen in its full bloom no earlier than 4-5 centuries. After more than 900 years this architectural gem can not yet be considered at the height of its splendor, probably because there was not the most basic intervention of restoration, the only admitted by Ruskin, daily maintenance, prevention of damage, without violate the laws of nature to which even the building is subject, no action excessive and artificial has to

¹ <http://www.iccd.beniculturali.it/medioevosiciliano/index.php?it/112/catalogo-generale/41/>

² <http://web.tiscali/normannamili>

oppose the slow processes of natural aging. In this optical must to be made interventions for conservation and maintenance, extensive and detailed cleanup, and liberation from vegetation are therefore the necessary first step towards making this place livable. The part of monastery, exposed to the east, the ancient refectory, requires a structural consolidation and repair of part of the roof where the tiles are been moved by the wind. There where however the coverage is totally compromised as in the corps that once linked the church to the monastery, and in the part of ruins you should think about a project to rebuild all completely with an appropriate design intervention. Regarding the arrangement of the garden around, instead you might think to realize a garden of aromatic and medicinal plants, to remember the ancient peasant habits of the monks of old.

Analysis of the masonry coursing pattern in Casale Castello: representation of the urban development

Ingrid TITOMANLIO

Design Knowledge Department, Faculty of Architecture, Second University of Naples, Aversa (CE), Italy
ingrid.titomanlio@unina2.it

Abstract

The empirical experience shows that cities cannot be considered a whole of streets and squares or a space balance, but are the outcome of historical, economic, religious and social determinants. The planimetric drawing is not always the result of classifiable and detectable historical events, but is often due to dynamic stratification and sequence of town planning and building. This is the case of the "Casale Castello" village which is examined in this paper through the representation of its urban development. Under this perspective, analysis and representation of the city building logic and the wall remains assume a noteworthy interest for investigating the guiding principle of the town planning evolution. Before, activities as site location, roads drawing and ancient bibliography reading are performed; afterward, it is carried out the analysis and cataloguing of masonry walls types testifying the increasing in workmanship and reflecting the time in which the techniques appeared. For Casale Castello were not the notarial acts or historical documents but rather the painstaking study and representation of coursing pattern of walls and masonry veneer to suggest a critical review of the settlement. In fact, they advise a date or a manufactured period. Klaiber, Lavedan and Piccinato several times stated the difficulty to chronologically establish the various types of medieval settlement. However, the period of the decline of the Roman Empire, related to the dissolution of the feudal society, is characterized by the construction of towns in defensible positions, around castles and monasteries. In eleventh century only, the revival of the economy allowed the urban and building activity to show itself as unprompted development of new cities.

Parole chiave: masonry, representation, urban development, dynamic stratification

1. Historical stratification of Casale Castello

Currently in Casale Castle village, you can see only few houses dating back at the beginning of the nineteenth century and survived to the earthquake in 1805. Nevertheless, there are visible signs of the Aragonese domination of the fifteenth century (Figure 1). Living testimony of this domination are the portals on which is carved a flower, symbol of the patriarchal organization of the family [1]. Briefly tracing the history that has characterized the village, it appears that, after the famous battle of Forino (667), the Lombard domination replaced the Byzantine one. In this era, began the building of a castle in visual communication with the Mercato San Severino and Montoro castles that was inserted into the path of the defense system of Roccapiemonte and Serino castles. The original manor position was undoubtedly dominant, but still now you cannot have a precise planimetric reading of the fortress. It is completely covered by vegetation and visible only some pieces are visible (there are the perimeter curtain walls and the base of the square tower in shapeless stones) [2]. The rediscovery of a rich heritage of stories, events, culture has been the research focus, which took place through the careful analysis of archival documents, original texts, reliable historical sources, and above all of the classification and cataloguing of the different coursing patterns of the place.

Fig. 1: Casale Castello: Analysis and classification of masonry coursing pattern

It was possible to retrace and experience in their concreteness, although according to a personal idea of proposed development, the economic, legal, manufacturing and cohabitation relationships, in which the difficult and harsh existence of this place moved and burned up. All this in order to "recover" an artistic and cultural heritage that, in the long historical process, showed the rise in wealth and culture of the new bourgeoisie, as an alternative to the structures of the feudal nobility, but which is, apart from rare exceptions, in poor storage conditions. However, the place have an original and not denatured identity (Figure 2). The work done on it was particularly difficult due to lack of "material" evidences destroyed and rebuilt after the harmful environmental events. It is certain that this Casale, built for military and social life needs, reveals the evolution of the human spirit of its dominating people [3]. All the urban traces of this place reflect the serenity of the Greeks pure beauty, the Romans architectural expertise, the mysticism of the Gothic art tending to God, as well as the memory of the civil and political struggles of that period. The shape of the town faced significant changes throughout history, from a central core, densely built, up to a continuous expansion in the nineteenth century. Figure 3 represents the summation of the various surveys carried out that lead us to a representation of the urban development of Casale Castello. With the first comparing analysis, we detected the location of the old travel routes, with the second survey we identified the access roads to the village. The third survey wants to identify common coursing patterns, symptomatic of an era and a contemporary building technique. The fourth survey aims at finding defensive items like towers, square walls (Figure 4), subways, steep walls. The height of the buildings complete the survey allowing to achieve the analysis and cataloguing of worship places, portals and balconies (Figure 5). The study of different historical eras and peoples that dominated Forino, is necessarily linked to the history of Roman Abellinum [4].

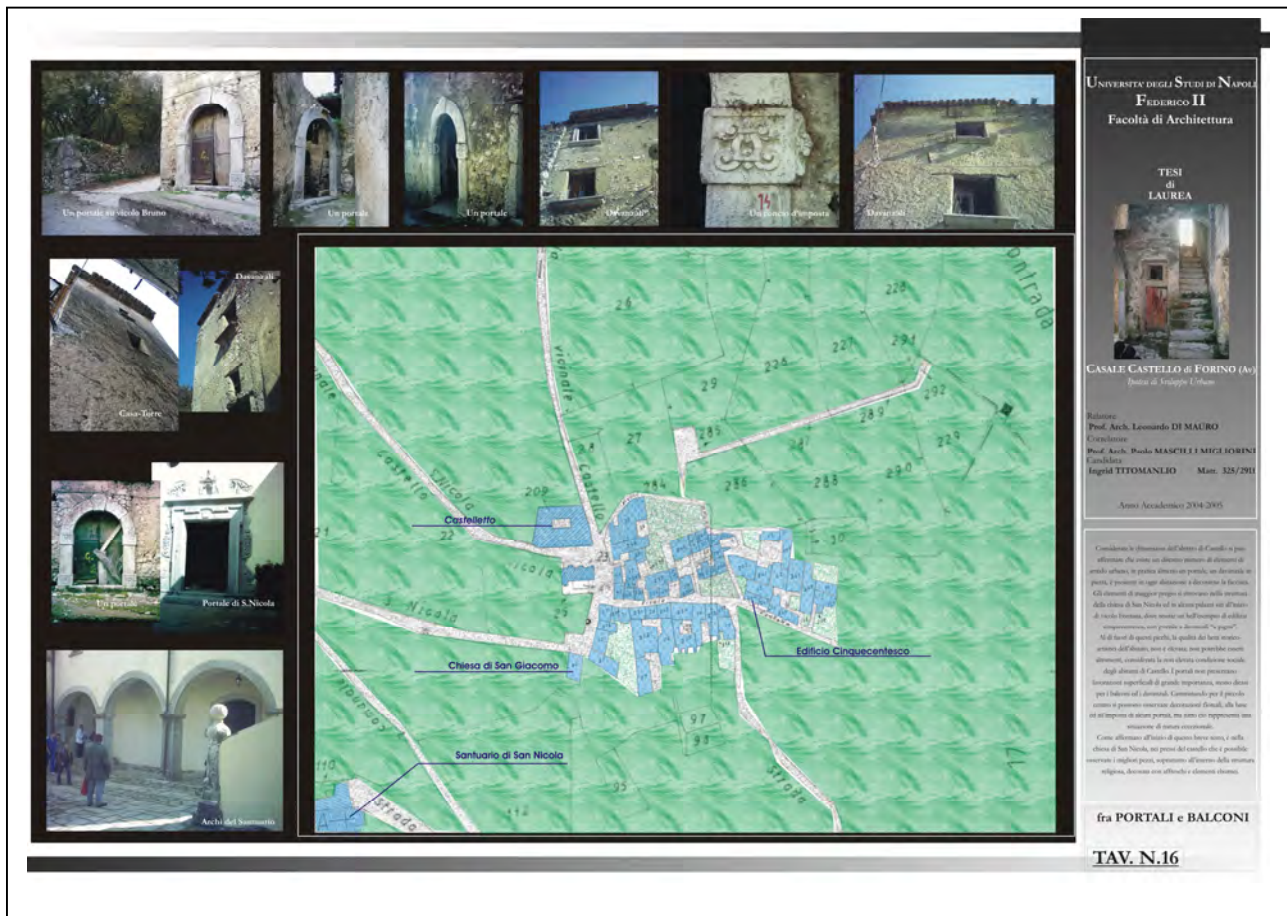

Fig. 2: Casale Castello : Analysis and classification of decorative elements

The Roman Empire implemented a complex defensive system, based on the "castra" (fortified camps of the army) and on "limes", placed at the ends of the territory subject to Rome. The local defense was, however, carried out by the locals and for this reason arose various types of "castella". The capital city (oppidum) together with the territory in which were included the minor towns fortified (castella) or open (vici or pages) formed a single politic unit called civitas. With the barbarian rulers, especially Lombards, the term civitas (political union between town and country) meant an administrative, judicial and military district which included city, villages and countryside [5,6,7]. Among the assets of the colony "Veneria Abellinatum Livia" (Avellino), it is believable that there was a large wood in which arose the towns and castles of Forino (Casale Castello). During the Lombards domination it was born a particular type of habitat, which lasted for centuries, defined by the French historians "fortification". In fact, near the Forino castle, were born the first houses of the peasants built in stone and with only a single floor; only around 1000 d.c. began to build a second floor. These houses had the thatched roof, were made of narrow rooms without balconies, had no toilet, and took air and light from small windows without panes, which were closed with pieces of wood to defend from the elements. The houses were built on a narrow winding path, leaning against each other. Only after the advent of the Normans, among them Roberto il Guiscardo and his brother Ruggiero of the Hauteville (Altavilla) family, the Lombards were expelled from Italy and it was created a strong centralized state with an efficient and widespread bureaucracy, characterized by a perfect financial organization and especially by the great tolerance of different religions and cultures [8,9,10]. The territorial structure was established by the class of "knights" holders of feuds held directly by the King "in capite de domino Rege" which became part of the Royal army with the "professional" Knights, providing the soldiers in proportion to the size of their feuds and feudal organization.

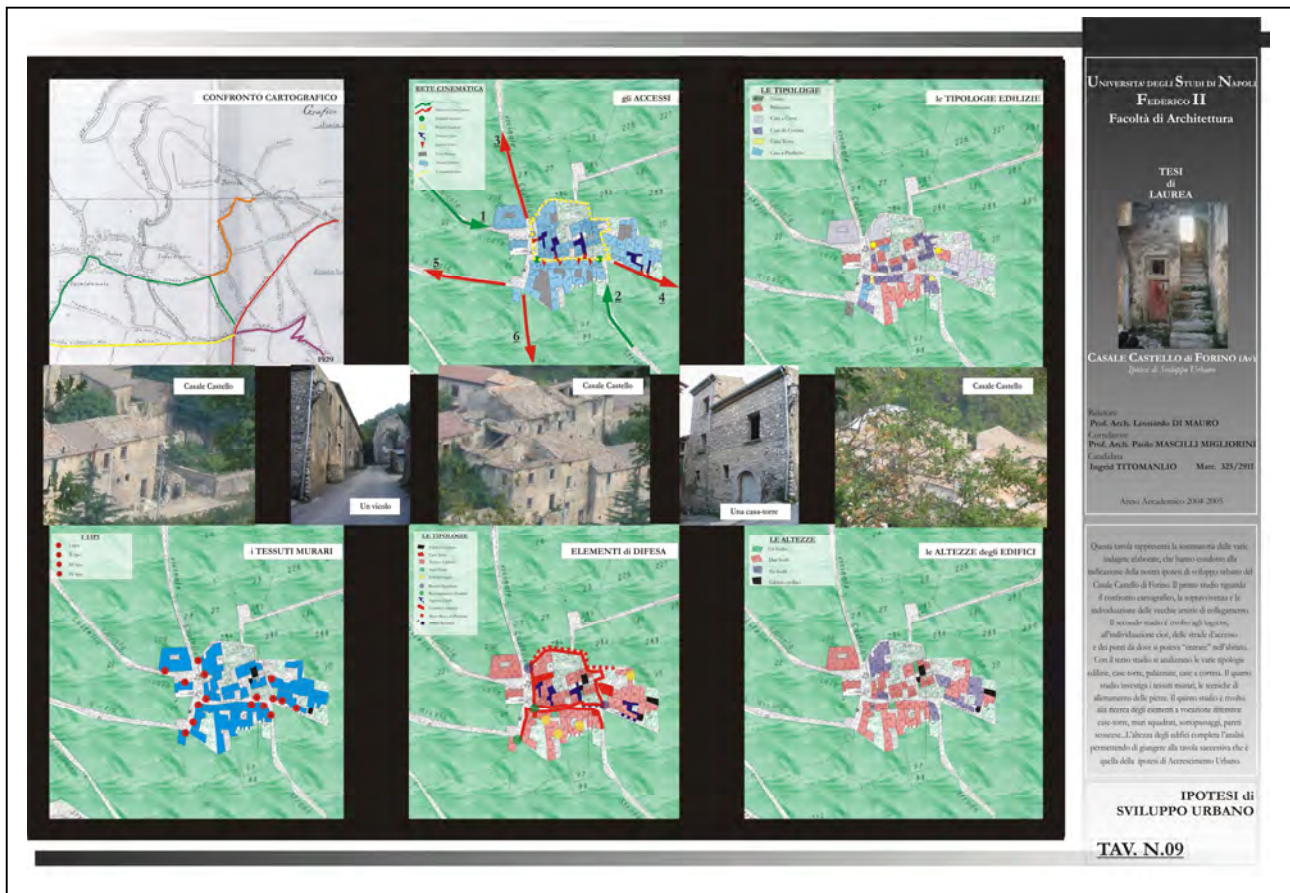

Fig. 3: Casale Castello: Analysis of masonry coursing pattern and hypothesis on urban development

The distribution of conquered lands by the "Connestabilia" and "Contea" which were, however, fundamental categories for Norman military and followed the feudal vassal model [11]. The Norman settlement was characterized by the spread of a new type of fortified castle. However, Norman castles were not good examples of military fortifications, because the Normans, assaulting Lombards fortified villages, which existed before their conquest, adapted and conformed them to the new defensive needs. They were built on an artificial hill called "motta", built with the ground coming from the excavation of a moat that surrounded the hill itself. On the castles appeared the squared or rectangular tower "donjon", with variable height and the thickness of the walls decreasing gradually upwards. The extension of Casale Castello and its reinforcement were made during the Norman rule, and this is as certain, as in 1162 the lord of this castle was Giacomo Francisio, which were entrusted by the Emperor Frederick II of Swabia, the Lombard prisoners Moro Speciale and Egidio Marcellino, so they were kept in a dungeon obtained in the basement of the fortress [12]. As the area was also a worship place, with the first works to the fort, was built the chapel (nowadays on the left of the building), which soon developed becoming a three-aisled building with a bell tower. The portal in travertine is dated around the tenth or eleventh century. The dynasty of the Normans did not last long, because, as the sole heir remained Costanza d'Altavilla, that, as wife of Henry VI, son of Frederick Barbarossa, meant that the Norman crown passed to Swabians, making significant changes to the military order and pre-existing fortifications [13]. The Swabians of Manfredi, with the battle of Benevento, which occurred February 26th, 1266, were defeated by Carlo I d'Angiò, that occupied the kingdom of Naples. After that the Angevin dynasty ruled for more than a century and a half in southern Italy. By transferring the capital of the kingdom from Palermo to Naples, in 1282, Irpinia became an important transit area essential to the expansion in the Balkan Peninsula [14].

Fig. 4: Casale Castello: Analysis of defensive elements

During Angevin dynasty the feud of Forino often changed lord and social life was very turbulent. Among the houses, Castello was already defined and this conformation was retained even in subsequent periods. After, the Aragonese domination left significant traces in the arts. The entrance gates of the houses of Casale Castello and of the oldest houses in the center of Forino had carved flowers which indicated the formation of a new family; every tribe was indicated by the addition of a leaf that was carved on the stem of the flower. This custom meant that from year 1500 to 1700 in some public acts, Forino was referred to as "Floreni", and when the University, in 1500, wanted to use an emblem, a bunch of flowers in the hand of a warrior was chosen [15.16]. Angevin road system was used and maintained by the Aragonese, that resumed the most ancient of the Roman era. With the Viceroyalty advent, the feud system did not change continuing to move from a feudal lord to another. During the Caracciolo principality, two tragic events, which were the earthquake in 30th July 1627 and the terrible Vesuvius eruption, aggravated by several strong earthquakes occurred in 1631, ravaged the inhabitants lives [17]. Despite the obvious importance of the strategic military post, having lost the conditions for its existence, the castle was completely abandoned in the seventeenth century by Caracciolo and suffered devastations by transferring part of its stones to build the Bourbon prison of Avellino [18]. The urbanistic reading of the village is difficult, but we can start analyzing the types of buildings that are assembled in a clear way. They were, in fact, built terraced houses with associated enclosure or compound in blocks of modest size. At the crossroads, around the city walls, near the edges of the paths that departed from the ports, developed a modular housing with continue rhythms, largely due to the conformation of the streets and the territory [19].

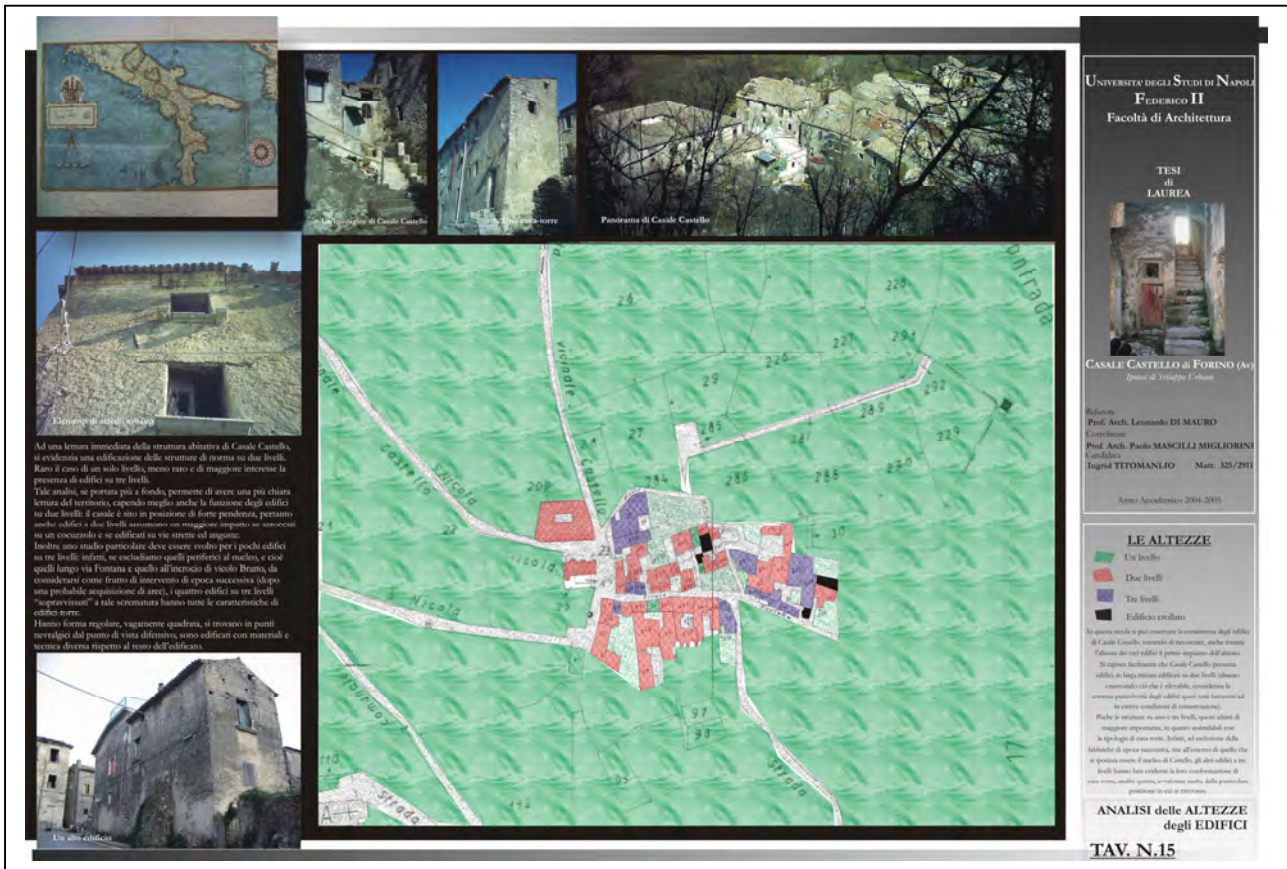

Fig. 5: Casale Castello: Analysis and classification of height of buildings

2.The masonry coursing pattern

In sixteenth and seventeenth centuries the roads of the kingdom were devastated and almost nonexistent. The people and goods transport was carried out with the use of beasts of burden which followed trails and short stretches of ancient tracks, the remnants of short stretches of Roman roads. Due to impassable roads and also for safety reasons, the connections began to decrease. Therefore, was created a complex housing that gradually weaved to the existing buildings [15]. The structural variety that was created, both planimetrically and typologically, made the abandoned village of Casale Castello interesting and characteristic. The limestone rubble masonry, the arrangement of rocks and blocks of different size and the characteristic thickness of the joints, distinguishes the house units of Casale. The constituent elements of the masonry, while being of the same origin, have variable physical and mechanical characteristics. Their implementation can give rise to different patterns of masonry. The first type of coursing pattern detected is composed of squared stone in large angular blocks (Figure 4 Type 1). Two of these types are present in the corners of a ring that rotates around the village and the third along a steep wall of Vico Fontana with a strong defense system. The buildings that employ this type of construction are close at the time of the original settlement. The second design (Figure 4 Type 2) has limestone of different sizes, placed in a disorderly manner and mixed with pieces of pottery. This wall is present in the princely building of the sixteenth century near Vico Fontana. The third type of coursing pattern (Figure 4 Type 3) is made, as above, from stone material of different size, but has rows of tiles in clay, characteristic of most of the buildings of Casale Castello and not of high quality, belonging to the eighteenth-nineteenth-century and located in areas outside the core of the original settlement. The fourth type found shows stones all similar in size and placed more or less orderly, characteristic of only 4 houses placed at strategic points in the housing and having significant height as the tower-houses. The use of limestone depended on the fact that it was easy to find them locally (in the hills)

and easy to cut to build blocks for buildings. They have different physical-mechanical characteristics and according to their resistance, are defined: hold; semi-hard (such as sandstones whose indicative values of resistance range from 4 to 200 N/mm²) and hard as granite and marble (whose indicative values of resistance range from 40 to 500 N/mm²). The relationship between compressive strength and tensile strength of the latter is normally between 15 and 40, with thickening of values around 30. However, we have to consider that, even if their specific weight is fairly constant for the limestone the compressive strength may vary up to 60% depending on the presence of inclusions.

3. Conclusion

Benedetto Croce said: "Tanto più energicamente si conosce un passato e tanto più energico sorge l'impeto di andare oltre di esso, progredendo ... E' sulla tradizione dei nostri antenati che noi costruiamo il nostro presente; senza passato non ci può essere presente né coscienza di se stessi". It is important not to forget in the "new " things, the beauty of the past, custodian of the high classical ideal, and progress fusing in fruitful synthesis "the ancient and the modern sensibility. " In these words we find the importance of analyzing and working on the concept of memory that should be shared by scholars capable of covering the different aspects of reality, different skills, and able to rework it to better meet the needs of modern life. A wide - ranging historical research, based on mixing of different intelligent professionalism, respecting of others' positions, without ideological prejudice. Where you can not find paperworks due to the succession of catastrophic events like earthquake, you should start, as we have worked for the Casale Castello, with the analysis of the remains of coursing patterns, and any tests on site with appropriate equipment in order to obtain information on the historical stratification of the settlement. Only through the knowledge of the techniques used by the laborers of the past and the study of the structural characteristics of buildings you can get a good urban analysis of areas, representative of cultures that follow each other and overlap, and implement a proper process for restoration and conservation. Casale Castello is a small laboratory, unfortunately abandoned to not cure of the time, that needs to be re-evaluated, detailed, excited to run for a small cultural quarter. A work of territorial marketing can create a smart tourist flow, which aims to consolidate a cultural and historical heritage of great importance. Entirely reconstructing the story is the basis of objective cultural honesty and is the basis for formulating proposals for the future. The multi-disciplinary approach to local knowledge ensures that every corner of the district, each building, each portal can tell about himself, as tangible evidence of Mediterranean history.

Department of Design, History of Architecture, and Restoration, Faculty of Architecture, "Sapienza"
University of Rome, Italy.
maria.vitiello@uniroma1.it

Abstract

The time has now arrived to start interrogating oneself on the possibility of also applying the ecological principles within the discipline of restoration.

The need for energy requalification of pre-industrial buildings is now a compulsory regulatory requirement that, before a technological definition of the practical activities required, needs new concepts that can be integrated with the theoretical thoughts behind conservation. Thinking about restoration from an ecological perspective means reaffirming the complex nature of the cultural heritage. During the years this has undergone a double mutation: that of its gradual expansion, and a mutation connected with the recognition of its value, the preservation of which is a moral and social requirement, with the conservation being a subsequent and due action, but not within the inactivity of the binding system.

Buildings, landscape, nature, environment, demographic and ethnographic anthropology objects, and immaterial objects, are the heterogeneous components of the heritage, which main properties are the result of space-time relations made stable by a dynamic and fragile balance, which is subjected to continuous perturbations of natural and anthropic origin. In the same way as other disciplines, like the historic, technical, and chemical ones, ecology can direct its basis towards restoration, contributing to set the methods and the means for the conservation of the existing, within the wider framework of environmental compatibility. This means investigating restoration as a set of objects and processes, with the assessment involving not only the manufactures, but also the relationships between objects and subjects.

Keywords: ecology – restoration – environment – cultural heritage – sustainable development

1. Introduction. The challenges of sustainable development: a little history

Today we live in a situation of "environmental crisis". A situation that we have reached through the indiscriminate use of the territory and its resources, acting as if they are unlimited, and pushing until their regenerative capacity is no longer intact.

This is a phenomenon which started with the industrial revolution, when the harmonic balance between man and nature started to break, but has become particularly strong during the last century, and particularly in the last few years, when the quick demographic expansion brought an increasing demand in resources, to meet the needs of mankind, with important repercussions on the environment.

The environmental crisis is, after all, also a human crisis. By breaking that ancestral attitude, and entering in tune with nature, mankind has started believing in his almightiness, and somehow lost himself; he has in fact lost the good sense of thinking and acting, of looking for that environmental quality that for centuries, and as a necessity, he has lived by, in the realisation of a local and vernacular architecture.

Mankind has lost himself also because although already at the very beginning of the nineteenth century, and even more in the nineteen twenties and nineteen thirties, the understanding was already well established that the growing city, with all its technological architecture, would have brought to the dehumanization of life, he really did nothing to invert that trend.

Fig. 1 – Chicago, Fransworth House, Ludwig Mies van der Rohe, 1945. Transparency and lightness are the expression objective of the removal of the side wall, inborn in the modernist myth of Glasarchitektur. It's the emancipation of the functions of the enclosure, which deviates from its traditional static and massive role, to become the fleeting filter between the various space qualities of the outside and the inside of the building.

Fig. 2 – Alberobello, Trulli. The local architectures of the building tradition are an example of harmonisation of the building with the surrounding nature and its characteristics, and has indeed resulted in the formal differentiation of the building enclosure, the formal differentiation between full and empty, between transparent and massive parts, in relation to height, light, and position.

The changes of the XX^o century are today clearer and clearer, and also clearer is that man has been unable to manage its activities on the planet with farsightedness, and has specifically failed in building good structures. Architecture is the oldest human profession, its the first shelter man builds to protect himself, his activities, and to improve his stay on earth.

Bringing together construction, town planning and environment, following an ecological approach of the building practice, is one of the answers to the climate changes indicated by the international summits.

The principles of the Rio Declaration of 1992, collected together under the more popular name of "Agenda 21", recommend in fact an integrated and creative approach for ensuring a sustainable development within the framework of environmental and building policies.

These principles, which are also actual commitments undertaken by the United Nations, have a dimension that goes well beyond the architectural practice, and involve the economic and social fields, proposing a change of the consumption models and the promotion of new kinds of towns. These principles are also tools for fighting against poverty, for improvement in terms of healthcare, and demographic control.

If the Rio Paper has a social type cultural setup, rather based on theory and principles, the Kyoto conference of 1996 offers a more operating approach to the environmental problem, and the implications for the building sector concern mainly the management of territory, town planning, and architecture.

In effect, it is in the sector of new constructions and public works that a higher degree of effort is required in terms of savings in energy and raw materials. Almost two million enterprises, with approximately 11 million collaborators, organise the habitat of 380 million Europeans. The construction and the use of buildings have a very important effect on the environment.

In the same year, during the "Habitat !!" conference in Istanbul, the commitments were set for the application of the concept of sustainable development to the construction sector, giving way, in the various European countries, to sustainability processes in the building sector, with a sharp increase in commitment in the real estate sector, and in the professional associations.

It was only starting from 2002 that the discipline of restoration started to confront itself with the issue of energy, through par. 3 of art. 4 of the 2002/91/EC Directive dated 16 December 2002, which stated that the member States can decide not to apply performance requirements to "buildings and monuments officially protected as designated heritage in view of their special architectural or historic value, if compliance with the requirements would entail an unacceptable alteration of their character or aspect." It becomes clear from the beginning that the adaptation to energy performance issues is significantly less important for protected architectural works pursuant L. Decree 24/2004, as they are subjected to preventive authorisation by the competent bodies.

On the other hand, this is not applicable to basic pre-industrial building, which only in some cases is subjected to direct safeguard, and fall, on the other side, within the operating rules of all other existing buildings.

However, one not only recognises to pre-industrial building its value of representation of human activity, but also its unbreakable connection with the monument, which identifies the uniqueness of the historic-artistic representation that must be protected.

In spite of the clarifications made through L. Decree 192 of 2005 and 311 of 2006, the Italian legislation has been unable to resolve this conflicting aspect (the unnatural separation between text and contest, the monument and the settlement framework of which the building is part) that emerges from the directive.

Besides, it has given way to a process of extreme simplification of the procedures, creating guidelines solely centred on an assessment based on energy balance, or in the exchange of heat between the inside and the outside of a building, as if the problems connected with energy requalification of pre-existing constructions only related to thermal exchange between the building and the environment.

From here, the reductive and obstructive approach by restorers in relation to a regulatory compliance almost always considered against the preservation requirements.

The fact that a building may not be considered only by itself, neither in terms of history, nor in terms of design, but rather as part of an articulated system of connections that mankind has been able to establish between his artefacts and the territory in its orographic and environmental definition, seems to be the required starting point.

The energy problem and the issues connected with the use of renewable sources in pre-industrial architecture must therefore be considered as a tool for reflection, so that energy sustainability will not bring a conflict between tradition and innovation that should solely be solved in technical terms, of "adaptive" technologies, but that it will rather contribute to an expansion of the references between conservation strategies and the values recognised to the cultural heritage that one intends to preserve within a historical, aesthetic, but also ethical and social framework.

2. Ecology, environment, and landscape

The ecologist movement, born in the nineteen-sixties, was supported by a generation that refuted the excesses of the consumer society. It had the merit of bringing to the limelight a term that up to then appeared relegated to a narrow field of academics and biologists, although this did not happen without misunderstandings and improper uses of the word, which was at times intended as the study of pollution, and at times as the conservation of nature, or other similar definitions.

In reality, the definition of ecology is rather different from the one that is normally attributed to the word. It is in fact not only a discipline capable of providing an indication for man on how to behave to ensure respect for nature, but rather a science, or a complex framework of knowledge aimed at studying the relationships between living bodies and the environment.

In the same years, the notion of environment also started spreading within the regulatory sector. The investigation Commission, the so called Franceschini Commission, for the safeguard and enhancement of the historic, archaeological, artistic, and landscape heritage, was instituted in 1964. And it is indeed after these activities that there is the consolidation of the term "cultural object". In particular, talks began of "environmental cultural objects" as an independent category, separate from artistic, archaeological, archival, and book related ones. It's a definition that is still too close to that of landscape as defined in art. 9 of the Italian Constitution, as highlighted by Salvatore Settis, because it does not take into account the necessary and own connotations of the terms that in those years came to light in Italy and in Europe. It is therefore probable that the juridical definition of environment was at the time meant as the picklock to "[...] force open the magic doors beyond which "territory" and "town planning", after becoming one, may in fact swallow the "landscape", providing the lawmakers with the possibility of implicitly also offering the environment as part of the regional competencies. [1] Whether this really happened or not, is not very important in our discussion, as we are still in the middle of having to search for specifications, and of defining the terms.

"Landscape", "territory", and "environments" are not synonyms, but rather disclose, from different perspectives, the peculiar characteristics of the space where life occurs.

The space where we live is a space of nature, consisting of the continuity of mountains, crests, large flatlands, of the diverse vegetation that grows in it, and the fauna that inhabits it. We could say that this is the territory, an element that is not inert, but rather subjected to man and to production mechanisms. The space where we live is in fact also the space of mankind, or a cultural space, because it is reflected in the history of men and women that experienced it, and of the societies that today, and also tomorrow, shall continue to mould it. Using the famous formula of Henry Lefebvre, we can talk of "social space", which limits and transforms both territory and nature following rites, knowledge, and power, turning its initial naturalistic value into something artificial, although not for this reason only marked by architecture, but also by the manipulation of nature and the adaptation of constructions to the same. [2]

Looking carefully at the productive and the manipulation process, the slow modelling of the territory by man, and the opposite one of the environment that impacts on such social activity, are indissolubly interlinked. The words of William Morris come to mind, which define architecture as: "the set of the alterations made to the surface of the earth in view of human activities", [3] and which, therefore, includes all the products resulting from the many actions of mankind, "spurred from the relationship between nature and society, and which occur in that field that belongs to everyone that is the territory," as pointed out by Gaetano Miarelli [4]. Therefore, it is indeed the landscape, that superior entity that collects in a synthetic unit both the "raw material" of the territory, and the vital functions of the environment, as well as the cultural manipulations, which are in the same amount both temporal and spatial at the same time, attributed to the relationship between man and nature.

May be, as suggested a few years ago by Giovanni Urbani, one should really create one single ministry dealing with the environment and the historic and artistic heritage, which is strictly connected with the territory, in order to safeguard its "environmental" nature. [5]

Following this perspective, it becomes much more simple to talk of sustainable restoration as an activity that is not contrary to the conservation of architectural manufactures, which being nothing more than fundamental components of the environment, perishable, unrepeatable due to their authenticity, and which can suffer deteriorations during the times, may be positively considered resources, and as such safeguarded for themselves, and for their strict relationship with the territory they are part of.

3. Deterioration, restoration, ecology: definitions, examples, and ambitions

Restoration is a complex discipline based on a set of varied actions aimed at the care for the individual manufactures or objects making up the cultural heritage in its diverse composition. Such actions have the objective of initiating new virtuous processes aimed at preserving the things that over the times the generations have left to us, and which it is our duty to deliver to the future generations, through the maximisation of persistence, and the reduction of the modifications introduced in the material and figurative structure by degrading exogenous and endogenous movements.

The actions that are introduced in organising the restoration operate on the current conformations of the existing heritage. Such conformations are always detected from precise and detailed observations, which are then turned into graphic representations and compared, both through historic-documentary analysis -

aimed at the recreation of a chronological series of the various events objects have been subjected to during the times -, and direct investigations aimed at acquiring a chemical and physical knowledge of the material elements making up the objects. We are talking about a multiform set of studies that give the possibility of defining all those pathological processes that mix together and show themselves through the different shapes of the many components making up the objects; pathologies that require timely and incisive behaviours, to ensure that the conservation of pre-existing objects is conscientiously completed.

In general terms, deterioration may in fact be interpreted as a process of modification of matter that shows itself through more or less deep and significant condition changes, linked to the chemical-physical, mechanical, and formal composition of the manufacture itself. Therefore, the degree of deterioration that may be detected through objective observation may be considered the result of a set of causes, which effects often add together, and operate in synergy with each other.

The speed at which the manifestations of decay occur, and the aspects through which this shows itself, are many and depend on the interaction of several factors: the characteristics of the material, the processing, and the environmental conditions this is subjected to during the years.

In most cases, the degenerative process is initiated by disturbing actions that are external to the structure considered: architectural, artistic, sculptural, landscape, irrespective of its articulation; but it may also be the result of a natural ageing process of the material, or of differences in the matter, if the manufacture is the result of an articulated assembly of materials.

For example, a lesion may constitute the manifestation of several kinds of degenerative actions, both exogenous and endogenous. It may be the expression of a matter discontinuity internal to the masonry structure, caused by a disconnection among the components; but it may also represent the visible part of an underground movement subjected to unidentified collapse mechanisms. Or it may even be the residual element of intense perturbation of the building-soil system, such as telluric perturbation, which leaves the walls with lesions that are typical of horizontal cutting actions. A correct interpretation of what in effect constitutes an interruption of the continuous wall system can only be formulated as part of an overall study of the building and of its relationship with the context, as well as through a diagram of synthesis normally called "map cracking", which gives the possibility of bringing together and linking the individual expression to the overall.

Therefore, in general terms the degenerating phenomena that can be detected on cultural goods may be compared to genetic variations as, not unlike what observed by Darwin in 1859 for the evolution of living organisms, these can show themselves in three separate types of mutations: favourable, detrimental, and neutral mutations. While the first ones increase the heritage of living organisms and spread through the lineage, the second ones must be eliminated to ensure the continuation of the species; however, the third ones may pursue one or the other route, depending on the case.

In this way, continuing with the examples, a black crust may also be defined as a detrimental mutation, because although being part of the material, it is always caused by external occurrences, and it is always harmful, as it leads to a gradual loss of the manufacture.

On the other hand, being a surface alteration caused by a natural process that is part of the matter interacting with the atmosphere and the gases it contains, "patina" may itself be considered phylogenetic, and therefore does not need to be removed, but on the contrary stimulates the emphatic feeling that flows in the attribution of the "antique value".

A variation of destination of use could, on the other hand, be compared to a third species deterioration, because the modifications introduced for the changed functional requirements, which must be preserved as testimony of the demonstration of the mutations the work has been subjected to during the times, a chronological time consisting of unrepeatable moments, of irreversible stories that only historiography can present in contemporary terms; however they could also be removed if the actual conservation and overwriting needs of the monument require it.

The classification of deteriorations suggested here would contribute to an interpretation of the same in relation to the mutations that they cause in the matter.

However, it may be possible to add to this interpretation another different one, aimed at breaking them down depending on the processes involved in their manifestation. And for these, it may be possible to identify the hierarchical levels derived from ecology, which would help to retrace, starting from the conformation of the sign manifestation of the pathologies, the processuality of the codifications denoted by the manufacture.

Starting back from the example of the black crust already proposed, one may attempt to recompose the active series of players and effects making up the degenerating processes.

Crusts are defined by Nor/Mal 1/88 as a "surface layer of alteration of the stone material" and appear at sight as compact and pellicular. They tend to cover the whole material affected by the pathology and, due to the dark colour, cause internal tensions promoted by differentiated thermal dilatations (between the surface and

its substrate); while, in addition to physical deterioration, when together with sulphur dioxide, carbon particulate also causes chemical breakdown phenomena. Sulphur dioxide (the anthropogenic source of which can be traced back to the combustion processes of solids and fossils, and to the melting of non-ferrous metals) constitutes the main cause of sulphation processes (the formation of gypsum = bi-hydrated calcium sulphate easily washed out by rain), and brings to deterioration and the partial loss of the surface material of the manufacture.

For these reasons, in terms of restoration process the removal of black crusts is a conservation requirement, and therefore always promoted. In view of this, different intervention techniques have been identified, which aim at cleaning the surface and removing the deteriorating film. These are timely actions implemented with the objective of limiting a pathological sign in a certain manufacture, and it is only on the manufacture itself that can occur the positive effects of the restoration action, which must however be repeated several times.

Fig. 5 - 6 – Rome, Obelisc Piazza della Minerva, Gian Lorenzo Bernini, 1667. The interventions planned by the Istituto Superiore per la Conservazione e il Restauro (Higher Institute for Conservation and Restoration -formerly ICR) costed on the overall € 70,000.00. The different forms of deterioration encountered on the monument, with different degree of importance, constitute vulnerability factors. The works concerned: biocidal treatments; the cleaning of loose deposits and black crusts; the removal of unsuitable plaster and its ripristination; the reconstruction of the “cover” at the top of the base of the pachyderm for correct flow of meteoric waters; the treatment of discontinuities; the final chromatic balance and the protection of surfaces.

In particular, a study of the Istituto Centrale per il Restauro (Central Institute for Restoration) based on the analysis of stratigraphic samples, has highlighted how in the city of Rome surface restorations are performed at "jubilee" intervals, approximately every 25-30 years. It is a very expensive approach to the issues related with the conservation of the architectural heritage: it entails many interventions in short period, resulting in a decrease in quality and an increase in costs. [6]

It may be possible to identify the key objectives to pursue in the protection and the conservation of artworks, such as the planning of maintenance times for the reduction of intervention costs, and the improvement of the state of conservation of the manufacture.

These targets may bring benefits that it may not be possible to quantify in economic terms, but in relation to the state of conservation of the manufacture, and therefore to the slowing down of the deterioration process, with a consequent decrease in the loss of original material and a better possibility of enjoying the monument, or the recovery and the conservation of the aesthetic content of the monument, always with reference to the single manufacture, rather than to the heritage considered in its totality and complexity. Although very ambitious, these are nevertheless minimal objectives when compared with the extension of the problem and the amount of cultural heritage that must be safeguarded.

Sulphur dioxide in fact reaches the surface of objects, either walls or sculptures, through acid rains caused by atmospheric pollution mixed with atmospheric particulate (carbon particles, mostly caused by the emissions of fuel oil domestic heating system). Nothing has been tried up to now to reduce this deterioration, with the exception of limited provisional measures, such as the protection of sensitive parts from meteoric waters using roofs and rainshields, which however cannot be considered universally valid.

The reduction of the deterioration process in a tangible and radical way may be obtained only through an action aimed at decreasing the concentrations of acids in the atmosphere, and lowering the levels of pollution. But this would entail the implementation of behaviours that are not only directly aimed at the individual manufacture being taken care of, but rather at extremely distant aspects, which almost appear

estranged to the restoration process: social, economical balance, and cultural sensitivity aspects, which represent in fact the real driving forces.

Fig. 7 – Statistics on the conservation/vulnerability status and seismic risks for objects split by region. Source, ICR Risk Map. Serie 1 as: earthquake risk. Serie 2 as: vulnerable architecture. Serie 3 as: vulnerable archeological

Besides, it is not easy to trace back all the modifications and dynamic forces that generate the deteriorations shown by the alterations that may be detected in a manufacture, in a painting, or sculpture, in a territory, or garden. It would be a difficult, or even impossible, speculation, and it would bring to the definition of an indetermination principle.

It could, however, be possible to attempt a simplification through a schematisation of evolutions. In this way, it would be possible to place the external energies disturbing the system at the first level. These are nothing more than vectors that cause the motion, and which instigate a process of “new coding of the genome”. To say it with the words of Rita Levi Montalcini: such are the earthquakes, volcanic eruptions, pandemics, gas and particulate introductions in the atmosphere produced by the activity of a new industry, the planning of a demolition, the designing of an infrastructure with high impact, the modification of use of a building manufacture. [7]

The semeiotic exchanges could on the other hand be identified as the second level of the variation process. To this, it is possible to refer all the internal mechanisms that belong to the reorganisation of the matter, and on the basis of which the same tries to find a new configuration, a new asset.

In ecology this is referred to as “coalescence”. The matter disturbed by the external energy tries to establish a new internal balance; a balancing motion that is still strongly dynamic.

Lastly, during the third level, the configuration level, an exchange of energy occurs between units and between systems, following a mechanism that enables the structuration of new assets; a condition that in ecology, like in the field of the restoration of cultural manufactures, brings results that are not always predictable. Deteriorations, therefore, with their many manifestations – lesions, black crusts, biological patinas, and more -, would represent the visible form of this stage, where the mutated matter defines itself in new morphologies.

Mankind, and with him the restoration activity of his competence, can place himself in different moments and perspectives in relation to the deterioration process affecting the heritage. And in fact he must not necessarily arrive at the final moment, promoting conservative interventions in relation to glaring mutations shown by the cultural heritage, following perturbations that have caused variations and disturbance, according to different forms and methods connected with the matter that makes up each manufacture; but he

can be present from the beginning, impacting on the actions originating the unbalance, and which constitute the first level of what may be called the genetic ontology of the heritage.

The mutation process can in fact occur due to different players, such as light, wind, water, heat, but also due to living organisms, either bacteria, algae, or human societies.

The use of the term “player” indicates the repetitive nature of the action, the function carried out by the entity, which repeats its role using a sort of script dictated by chemical or physical laws, or by mechanisms imposed by its organic nature, or again by replicated behaviours that are typical of human society.

The expression of each player is manifested through a motion that initiates a modification process, which causes deteriorations, conditioning, variations in the environment, and in all the objects it contains.

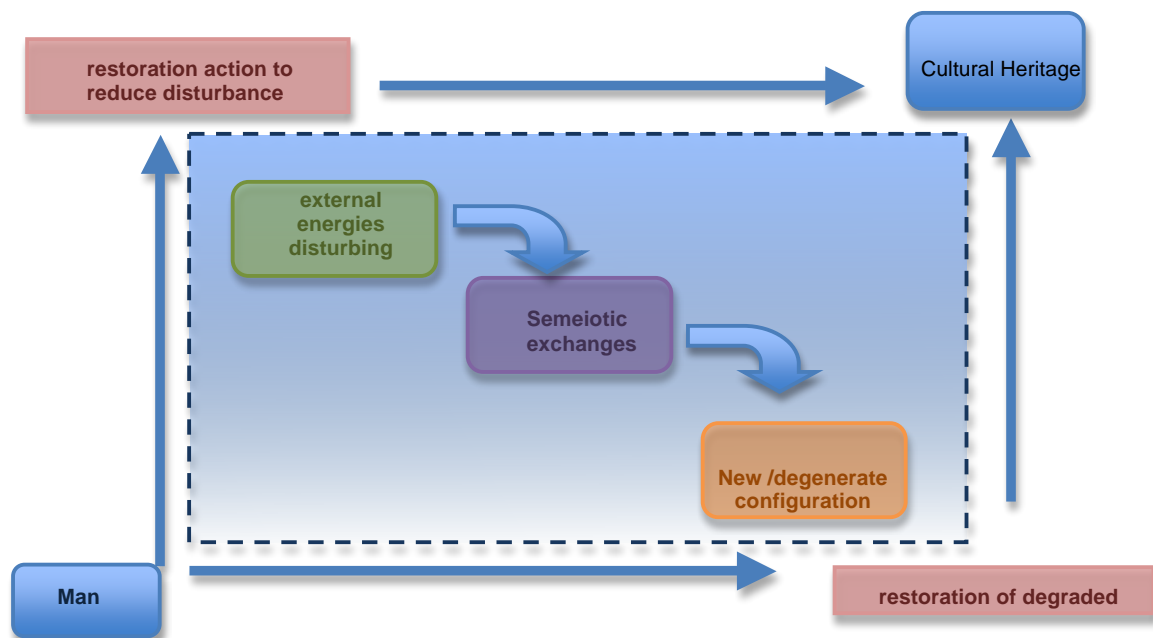

Fig. 8 – Synthesis diagram between: players, processes, and ontology in the conservation of the cultural heritage.

Observing the restoration with an ecologic perspective is therefore very beneficial.

First of all because it brings mankind back to the centre of the restoration activities, identifying him not only as the one who, with his apperceptive activity, recognises in his mind the works of art, imprinting to his conservation activities the desire that they are indeed restoration, but also because it considers the human activity as a whole: the conservational, innovative, and economic activity, and in more general terms the cultural activity, within the framework of the circuit of the ontogenetic dynamics of the conservation of the cultural heritage.

In this way, restoration is not just an action aimed at “preserving and transmitting into the future, making it easier to read, without removing the traces of the passage of time, the works of historic, artistic, and environmental interest” [8] releasing the same, and the care actions implemented, from the environmental framework they are in and live as part of, but becomes a collective movement with a social value.

Already in its famous Theory of restoration, Cesare Brandi defines the “recognition” as an individual’s own experience; however, he points out that at the same time that this individual perception occurs, this recognition “belongs to the universal conscience, and the individual experiencing such immediate revelation immediately sets itself the categorical imperative, as well as the moral imperative, of conservation.” [9]

The recall to the collective nature of conscience, and to the morality of the restoration activity, brings restoration once again back within the framework of ecological questions. And for this reason, it should not only be configured as a selfish action for the maximisation of the conservational interest of one single manufacture, but it should aim at assessing choices, also on the basis of the overall heritage, considered in its complexity, as well as of mankind as a whole, because acting entirely for the advantage of one, either person or object, cannot be justified.

4. Conclusions

If, in the way of Socrates, we were to ask the question: how must one restore? Ecology may offer a new answer, although this would not be univocal. Like the economic discipline, which shares with ecology the same root in *oikos* (*oikos* - *casa*), and which answered the question of how must one live with a double solution, also in terms of restoration one could envisage two solutions.

There is in fact in economy an engineering branch that follows the doctrine of Smith, according to which each individual only pursues rationally his or her own "personal interest". And then, there is the one that, starting from the origin of the economy concept itself, leans on moral philosophy and the concept of welfare. Expressing Smith's rationality of the maximisation of personal interest in the own terms of the preservation of the cultural heritage, may mean having to search for the reasons behind restoration only within the screening of those actions that simply tend to consider the advantages for the individual object of interest, taken by itself, without the action bringing some benefits to the historic, cultural, or environmental framework of which the object is a part. In order to describe the conservative action aimed at welfare, it may on the other hand be more beneficial to indeed lean towards the ecology way of thinking.

Mankind, brought back at the centre of the decisional framework, can identify the reasons for his actions following functions that are of direct and unique interest for the architectural, sculptural, painting work or landscape, object of the repair of the degenerative processes detected on the matter; or he may choose other routes that will bring his activities back towards the overall and collective improvement of cultural manufactures.

It is certain that the solution best suited to the objectives of restoration, also on the basis of how this has been interpreted up to now, is to carry out targeted actions aimed at the full conservation of objects in their historic and aesthetic aspects, because the cultural heritage has been considered as the bearer of these needs, and because there is not a direct control on any other objectives, and therefore basing one's own options on non-exemplary actions may appear rather unconvincing.

However, it is also desirable to make choices based on general objectives, so that the possibility of each object running the risk of not being preserved in its integrity may also be considered, if the non total action on one may be beneficial to the overall group the objects making up our heritage, and in which our identity resides.

In any case, restorers must define their own strategies on the basis of the recognition of the exogenous and endogenous modifications shown by the manufacture subjected to the care. To then consider the totality of the systems and the motions that give way to the degenerative processes is a second option. In any case, tangible choices are necessary: one or the other thing must be done, or even nothing, which is also an option; we are talking about preferences identified on the basis of the recognition of values, and which are connected to all the risks that this kind of condition brings: "...in its relapses and selections, which inevitably, and more or less consciously [the restoration activity] entails: [10] because it is not always possible to operate in the confidence of irreprehensible conducts.

It is clear that there must be a suitable reason in order to identify a way of action rather than another, and not always the completeness of the overall judgement on the positivity of the action can be the actual reason. However, an action must be performed, even if only based on a partial judgement.

With this, one does not want to diminish the importance of the "integral conservation" act, but it is believed that this term may not be necessarily capable of affirming the extremization of preservation. In fact, although one may want to consider everything as deserving of attention, and potentially object of conservation, in reality it may not always be possible to operate in such a way, and the decision would nevertheless fall within the framework of one option, even if just as far as procedures, techniques, and tools are concerned. So much so, that it sometimes becomes technically impossible to preserve, and sometimes "...permanence contradicts vital needs". [11]

In this way, although desirable, the predisposition to total historic and aesthetic conservation of the cultural heritage, would present technical, and possibly also ethical, limitations; it would certainly encounter some collective, political, or may be even economical obstacles.

A community, and therefore also a culture, is rich in artistic resources (architectural, sculptural, paintings, landscape, and natural) when it is capable of wisely managing the heritage received from history; by demonstrating full awareness of the identity value that this brings with itself, respecting it, conserving it, enriching it with the addition of new contributions generated by new functional utilisation requirements, but most of all when together with the historic and aesthetic values, it is also capable of recognising the social ones, which entail cultural choices, defined not only in terms of authenticity and respect of the actuality of the action, but also in terms of interdependence of the options and their aesthetic correctness, and on the collective advantage that may result.

The function, the enhancement, the introduction of elements aimed at facilitating the use of renewable energies in aesthetically and historically defined structures, meant as innovative process, cannot in such case be indicated beforehand as anything separate from restoration, as activities that go beyond it, but are also an integral part. Indeed, restoration can be seen as a privileged tool for the overall assessment of systems, functions, and degenerative motions, from which one must obtain the rebalancing actions for the different environmental components occurring in the landscape, in nature, in architecture, in sculpture, and in painting. And in those cases when options are not supported by an immediate intuitive possibility, one should nevertheless favour those which, even if at the detriment of the single one, will ensure an improvement of the overall conditions of the heritage..

Abstract

To comprehend the complexity of Ortigia's architecture, a place rich in history, means creating an interconnection with the foundations of knowledge, which can grasp the context, the site of interest, by investigating its fragmentary stratification.

The systemic recognition of such architectures, strongly articulated in their structural and formal skeleton, involves recourse to methods and approaches of cognitive interventions that may pinpoint regenerative models, which rekindle the human sensory faculty.

The systemic complex of understanding the heritage of Ortigia, intended as an integral part of "contemporaneity in the making", must furnish the raw materials for the Knowledge Factory and constitute an effective driving force that can spark, in the user of that facility, a full sense of responsibility.

This concerns gearing the research for the comprehension of Ortigia towards the creation of a model of cultured knowledge, capable of educating in everyone the respect for the environment in which we live, which in turn is able to change the needs of people and their lifestyle.

In brief, the aim is to create a virtuous circle in which knowledge determines a conscious and therefore responsible use. This in turn steers the necessary transformations that are bound to the needs of contemporary living and also to the respect for the identity of place, which thus does not lose out in vitality, but gains in intrinsic and economic value at the same time.

Keywords: Knowledge, Quality, Innovation, Survey, Modeling.

1. A Charter of Quality for the documentation of the complexity of architecture (G. Taibi)

For a long time, the survey, considered in its comprehensive and complex formulation, correlated to the implicit and articulate issues connected to it, has continually filled our scientific and temporal spaces.

We recall well this multiplicity of cultural encounters, promoted over the years and on various occasions, to give real substance to intuitions and conjectures in the making, directed toward scientific contents that focus on the theory of the survey, rigorously framed with objectivity.

From the outset, the survey has played a procedural role of profound and meticulous understanding of contexts and architectonic and environmental heritage, interpreted in their historical framework.

The survey that, upon the rigorous fact-finding process and the correct critical appraisal of events that characterize its every transformation, unquestionably needs a cross-referenced control between the data deriving from the current status of the urban composition and those deriving from historical documentation, undertaken by an accurate confirmation of the single events and a systematic comparison of heterogeneous data.

Furthermore, the need is also felt today to devise computer graphic systems that can both acquire, implement and modify heterogeneous data, with scientific rigor but also keep pace with the transformations

of a reality in continuous evolution, both to generate clear, interactive and increasingly divulgative communicative elaborations that are technically codified at the same time.

“The premise of any intervention on cultural heritage is the understanding of the architectonic and environmental asset considered in its entirety, in its overall articulation; it is an awareness of its being the result of a stratification over time, of successive interventions (very often realized with different criteria and constructive techniques).

Moreover, in markedly historicised buildings, each part is always tied - in its structural, aesthetic and functional rationale - to the whole. In other words, this means reconstructing, through a complex activity of surveying (mensoria, historical-critical, archive, bibliographical, technical, technological), the criteria, procedures and rationale with which the organism has come about over time.

Safeguarding the cultural patrimony represents one of the objectives and equally one of the most important challenges of our time, because only this can ensure the conservation of the documented historical memory of our civilizations; this safeguarding - that we consider here from a scientific, technical and technological viewpoint - is first and foremost a moral, social and educational problem. Indeed, it presents not only working and technical problematic aspects, but also those of a programming and managerial, social and educational kind.

Clearly, the first level of safeguarding is knowledge; to know means, in some ways and in any case, to document. Indeed, documentation constitutes an indispensable support for the protection of the cultural patrimony. In recent times, the evolution of concepts and the progress of technologies have meant that the cultural and scientific debate should evolve in the examination of which type of documentation is the most suitable.

In architecture, this problem has been conceptually surmounted in the survey; a composite operation to which a precise meaning is attributed.” [1]

In this work, our attention focuses on understanding the morphological complexity of a historicised site, giving broad room to the fertile growth of the cognitive process on the buildings of Ortigia.

In this systemic picture of the knowledge of the urban situation – realising that the urban form means an inhabited density within a territory, defined by the intimate connotations of the typical essence of that city – it becomes above all important to focus attention on a wider spatiality, in which the features of the urban presence are still manifest and effective in an environment that transfers the existential conditions of the culture of the place and expressive modes, also in cohabitation with a fragmented present situation.

Such a complex issue as this (like the one undertaken at the Laboratory of Representation), namely the fact-finding investigation of a historicised site, culturally engages and involves an immense body of working units, with diverse expertise and competence, able to respond fully with results to different urban fringes, typologically diversified, of the site of Ortigia.

Fig. 1: Aerial view of Ortigia. Stratified materiality of *Palazzo Lanza Buccheri* and of *Palazzo Migliaccio*.

Today, the need to observe city sites by entering their meanders and penetrating their reality with the aim of being able to interpret, understand and appreciate the values of the more recondite intimacies of the places, is increasingly felt.

In many cases, the current urban configuration is the outcome of articulated stratifications and transformations occurring over the course of centuries; in this case, the conceptual operation of interpreting its complexity may happen, only and exclusively, as already mentioned, through the meaningful and appropriate integrated reading of archival, cartographic and calligraphic data of the physical structure.

Tangible testimony is given by those urban centres, recognizable for being, in truth, cities reconstructed in situ, that bring into play and show coherent peculiarities and features, even deriving from natural or intentional stratifications.

In these cases, it is easy to recognize a precise character of the place, defined by the persistence of latent or manifest signs that remain in the fragments of the architecture of the past and are kept over time.

In truth, we are marking the image of that place by understanding it, in a metaphorical sense, as a veil by which to filter and observe the historical, cultural and material contents of the investigated situation.

It is clear that, in any case, the addends of the system, made up by the fascinating enthusiasm of surveying and revealing and by the ensemble of latent or manifest signs, expressed also in cryptic form, confer keen cultural interests and strong emotions to the careful operators in the field.

In all this, the interest and the anxious impulse aimed at achieving an improvement of the procedural course that may give life to a system, above all conceptual, that has the verifiability of the reliability of the survey carried out as its primary objective.

This need arises from the reflection that all the commitments spent at any level to be able to define the rules of the survey never entirely satisfy us.

It is almost like saying that we are affected by a beneficial greed, tending to produce in us a kind of adrenalin tension toward attaining ever more noble objectives.

It is fully shared that it is necessary to obligatorily differentiate the typological sections of the survey in relation to the objectives of future intervention on the study case.

And it is equally fundamental to bring into play the construction of parametric elements, or rather pointers, to support the problematic of interrelation of the data acquired from the investigations with the reality of the context.

“For the purposes of a partial indication of the possible interpretations of the built environment, considered in its architectonic, urban and environmental complexity, we note (...) some indications (...) related to the cognitive surveys that are possible to carry out on the ground, outlined in relation to the forma urbis, to the forma architecturae and to the modus habitandi. The ensemble of this fact-finding data, if constructed in a coherent methodological structure, potentially allows creating pointers as useful tools for the progressive interrelation of every survey on the constituent elements of the city.” [2]

In this sense, with regard to the **forma urbis** and the **forma architecturae**, the historical-evolutionary analysis, the morphologic analysis of the aggregative systems, the typological analysis of the building type, the architectonic/diagnostic/structural analysis and the analysis of infrastructures and services are to be considered determining, while concerning the **modus habitandi**, the building analysis, the settlement analysis, the analysis of the property and economic/productive analysis, are to be considered determining.

But in any case representation is the “*outcome of an intellectual and applicative work*”, [2]; indeed, as Roberto de Rubertis states “*it is the very model of the reality that man constructs in every action of knowledge; ... it is the logical scheme by which (he gives) meaning to the complex entirety of appearances with which reality presents itself; ... it is an extraordinary process of simulation for the exercise of the mind; ... it is the model... of a system of observed, assumed or planned relations ; ... it is never reality that is being represented, but only its model, namely only the ensemble of the characteristics that intuitively or deliberately are selected and destined to become sign*”. [3]

In this sense, the model, assuming great responsibility, unequivocally becomes the strategic tool of historical-critical knowledge.

“Such representations, in the unavoidable fluctuation between iconography and symbology (...) constitute (...) one of the many possible images of the surveyed city and at the same time a interpretative document, it itself interpretable as such. The ensemble of images forms the representative model of the historicised urban reality, as the end and current product of the historical process of formation and transformation”. [4]

In a research work curated by Mario Centofanti and Stefano Brusaporci for the city of L'Aquila, the Santa Maria Paganica Quarter, an interpretation oriented toward pinpointing the typological features cross-referenced with the historical-architectonic value, the historical-artistic value and the historical-environmental value, is proposed. In this context they conclude: “*The two-dimensional representative model (...) is*

constituted by a Charter of historical-architectonic values, a register of analysis charts for each single building, by a Charter of the environmental values and by historical-synchronic cross-sections". [4]

In the light of the legacy of research carried out and of the already acquired experience, it is legitimate to hope for the construction of an outline document, namely a *Charter of the Quality of the Survey*, understood as a territorial system of quality aimed at raising awareness toward protecting the landscape, that has its forerunner in the Charter of the Survey of 2000, and that can gather together the results of all the experiments undertaken in the field in the various research centres.

This entails conceiving of a *Handbook of maintenance and safeguarding of the landscape*, an instrument of suitable intervention to read and interpret the constituent elements of the intrinsic structure of the landscape features and that investigates the history and nature of places, analyzing their evolution, stratification, settlement structure and the environmental and landscape configuration, following a disciplined path and with precise scientific rigour.

2. The Knowledge Factory, summary of the survey of Ortigia (R. Valenti)

The continuous improvement in digital instrumentation, a support for the survey at various scales, involves a dynamic process of adapting in the field of applied research.

Undoubtedly, what the operators in the sector demand of technique and the tools that it produces has changed profoundly; but the skill in comprehending the cause-effect relationship that the use of the instrument entails has also changed. The quality of the results of an instrumental survey may be valued, certainly, through a judgment of efficiency and performance of the machine, but this, for the purposes of research, is only one aspect, without doubt important, especially when the laboratory in which one is working is a highly articulated place both in quantitative and qualitative contents, as is the site of Ortigia.

Indeed, the peculiarity of the three thousand year old island consists precisely in having safeguarded the hallmarks of its history in an integral way, in having conserved the traces of successive ages not according to precise episodes, but through a co-existence of elements belonging to different ages in the same building, through a contextualised re-use. In Ortigia, the generations preceding us behaved with a genuine idea of re-using the existing material and its rational insertion in successive usages, directed toward modifying the aspect of the city, adapting it to the styles and functions of the time.

The need for a reasoned order of the parts of the pre-existent historical-architectonic elements, authentic fragments of a compositional language in continuous evolution, which may be found widely at all levels in the urban fabric, from the underground to the visible city, from the elevations to the plans, from the corner joints to the stringcourses, was already sensed when the renewal construction sites brought to light details of a building language of one of the periods of greatest splendour of the city, taken up again with contaminations in ages closer to ours, almost to highlight the nature of the distinguishing signs of a place with a profound history.

Fig. 2: *Palazzo Montalto*. The signs of the identity of a place and the details of a compositional language.

In the variety of observable elements, it is as if one may find again a coherence of language, the expression of a way of doing and intending architecture, even in the apparent range and diversification of forms and typologies.

Ortigia, therefore, has a particular potential, during a fact-finding approach, namely to reveal itself through fragments; by these it is possible to carry out a detailed interpretation that may provide an explanation of the original architectonic nuclei, of the transformations, consequences of political, social, economic, cultural and natural processes which the city has undergone.

If Siracusa, during its territorial expansion, has experienced changeable vicissitudes over its centuries of history, the island of Ortigia may be thought of as the vital nucleus of the city, able to convert and adapt its layout and architectonic fabric to the events to which socio-political and natural destinies have subjected it. Its prominent role as a cultural and economic centre is well known, above all in Greek Antiquity and the Middle Ages, a role that from an architectonic profile has lent it an expressive faculty and a lexicon that makes the island a unique monumental complex.

“Every urban system always has a highly complex and changing configuration, and it is often difficult to understand its evolutionary logic of transformation. The instrument that perhaps more than others is concerned with seeking to understand such logic and, therefore, control it, is represented by the urban survey.” [5]

The survey, in implementing the complex fact-finding process, in order to achieve the objective of penetrating the context, must base its articulation on a system of investigation that can focus on the signs and languages making up the substrate of a collective memory that, unconsciously, recognizes in these the very identity of the place.

It should not be forgotten that it is precisely memory that is the measure of the importance and need to safeguard, to restore to a usable condition and intervene in a place in order to ensure its vitality is never forgotten. Moreover, so that the social system in place is durable, it is necessary that it has the capacity to self-reproduce and, therefore, to reformulate the functional requirements according to the expectations and behavioural motivations of citizens.

The opportunely organized understanding, according to ordered schemes, can attribute to the amount of information, ever more abundant, a narrative and evolutionary sequence, able to connect apparently decontextualised signs and substantially linked by the history that unites Ortigia with a broader territory to investigate, including other municipalities of the Val di Noto.

The task of understanding of the city, therefore, follows a fundamental critical course in devising an investigative method that, starting from the profound knowledge of the morphogenetic complexity of the historical built environment, takes into consideration not only the metric aspects, but all those fragmentary elements whose recognition depends on the cultural expertise of the research team. No instrumentation, however sophisticated and precise, can determine the quality of a survey alone ; it is supported by a working technique that makes experience an added, inevitably connected value.

Fig. 3: *Palazzo della Camera Reginale*. Memory as a measure of protection and intervention.

The systemic complex of the knowledge of the heritage of Ortigia is therefore integral to “evolving contemporaneity”, in the sense of understanding the architectonic fragments that, in their continuous integration with the whole, contribute to the characterization of the evolution of the *facies*.

In order to do this, what is necessary, as Paolo Marconi affirms, is the “*recognition of the built structures. Such recognition takes place thanks to a profound practical and cultural preparation, in which not only the identification of the histories and images composing them is applied, but also the examination of the stylistic features, as well as that of the working techniques and modes of production*”. [6]

The detailed location and highlighting of elements in a global mapping of the site establish a network of easy visualisable thematic connections, whose purpose is to coherently compose what appears fragmentary, so that from the multiplicity of data one can move on to a unique picture, determining for the Knowledge Factory.

This is of fundamental importance in order to start up a process of raising awareness at several levels (administrations, inhabitants, visitors and students) so that the unitary perception according to a thematic nature recalls the memory of a context, endowed with similar qualities extending also beyond its boundary.

It follows that the widespread consent towards conserving historical non-monumental assets, emerges from the usefulness value universally attributed to these by an aware community, since well-informed, and that the safeguarding and valorisation entail a “balanced or sustainable development” [7] tied to the concept of overall social worth, tackled by researchers such as Milan Zeleny, Peter Njikamp, Henk Voogd, Luigi Fusco Girard, which when referring to resources of common interest, represents a paradigm that counters the one of total economic value.

“*The correct knowledge, understood as a whole, can trigger that symbiosis between cultural and economic development that, in the era of globalization, is fundamental in order to insert a territory, however much known and emblematic, into a vital circuit that must be self-maintained and that cannot yield, in order to survive in a qualitatively acceptable way, to fragmentary policies of intervention*”. [8]

Following this perspective, the detailed knowledge, by fragments, of the monumental context of Ortigia, organized in synthesis according to thematic qualitative relationships, becomes a tool with which to unravel the signs of an obvious, though not easy intelligible, stratification. Therefore, by structuring knowledge according to a summation of the individual thematic traces it is possible to reconstruct the memory of the place and start an organic process of characterising in the territory. To this end, the use of multimedia technologies also enables sharing the categories of information collected with other situations that, in this case, may have similarities and would in turn help to implement the network.

“*Further investigations in this direction arise from the will to render the virtual medium an instrument, in addition to being fascinating and stimulating from a cultural point of view, are also useful, above all if shared with the bodies in charge of developing the territory*”. [9]

Raising awareness of those working in the various administrative sectors and stimulating the sharing of joint policies of intervention, aimed at tourist-cultural routes, may induce benefits of an economic kind in territories with a strong cultural value.

Fig. 4: *Palazzo Chiaramonte*. The signs of the stratified history of Ortigia.

3. Evolutionary systems for the representation and transmission of knowledge (M. Liuzzo)

The research activity undertaken for many years on a rich and complex site such as Ortigia, with the aim of building interpretative models that can recognize and communicate, in a structured way, its multiple stratifications and changing aspects, cannot overlook the implementing and gradual development over time of some underlying principles on the methodological choices and purposes of this study approach.

Those concerned with the knowledge, safeguarding and transformation of the environment in which we live have always raised important questions on the “why”, “for whom” and “how” to tackle cognitive processes that are new and different each time.

Undeniably, modern computer technologies, by now widespread and consolidated, are able to offer an immense range of alternatives including choosing to give an answer to the question of “how”.

It remains, perhaps, to enquire further into the way in which the indisputable potential of such tools and software can be shaped and, therefore, fully taken advantage of in relation to the cultural and technical-practical requirements of man, on the basis of the “whys” and of the “for whom”.

“In this sense, researchers in the field of Representation, of whom it is demanded to keep ‘apace’ with the fast progress of information technology systems - that has strikingly increased the potential of the interpretative-representative system – must duly approach the aspects of extreme research into expressive effects with a critical sense, sifting, according to culturally and scientifically oriented foundations, the fascinating range of alternative proposals and promoting the gainful embedding of new relationships of interaction between the administrators and users of a city.” [9]

The general economic conditions, the difficulties in implementing effective actions in terms of conserving and revitalizing the vast historical-cultural heritage of which the national territory is so abundant, are so onerous as to vehemently motivate the scientific community that – far from being able to remain entrenched in a position of the learned observer, indignant but unheeded regarding the actions of agencies operating in practice and deciding the fate of our territories - cannot absolve itself from dedicating its expertise and specific study areas to the service of the collective, opportunely orienting its own research lines and very own “wherefores”.

“The damage to the landscape hits us all, as individuals and as a collective. It kills historical memory, wounds our physical and mental health, offends the rights of future generations. The environment is devastated with impunity every day, the public interest trodden on for the profit of the few. The laws that should protect us are dominated by a paralyzing “friendly fire” between public powers, by conflicts of competence between State and Region. But in this maze it is necessary to find the way out: because the apathy of citizens is the best ally of predators lacking scruples. [...] The quality of the landscape and environment is not a luxury, it is a necessity, it is the best investment for our future. [...] a strong popular action that again raises the issue of the common good as the foundation of democracy, freedom, legality and equality, is necessary.” [10]

If “apathy” towards of our heritage, our cities, the multiple weave of memory of our past and our identity, arises from a general lack of knowledge and awareness, the prime cause of the total absence of a sense of responsibility concerning the common good, it then becomes a priority to implement democratic strategies of transmitting the very process that may create a virtuous circuit in which understanding determines a conscious and hence responsible use. This in turn should be oriented towards the necessary transformations linked to the needs of contemporary living and also to respecting the identity of place, so that it does not lose its vitality, but rather gains in intrinsic and economic value at the same time.

With this responsibility in mind, a suite of digital instruments, online and offline, called “Crabnebula”, has been conceived - and applied, in the first instance, to a significant portion of Ortigia [11] - with the aim of uniting and integrating various useful information towards a critical interpretation of the places: from the integrated environmental, urban and architectonic survey, to the three-dimensional rendered model, for an interactive and culturally oriented use of the investigated sites.

A database, that can always be expanded and updated in content and categories of information, accompanies the virtual model. It enables collecting much more information that, suitably catalogued and dated, by superimposing and cross-referencing, constitutes a matrix articulation, useful for an overall understanding based on discernment and reassembly of the parts.

The desire to render knowledge communicable, coherent and accurate at the same time, of the spatiality of the investigated site, has been decisive in choosing a three-dimensional representation of synthesis that, thanks to today’s tools of computer modelling, allows a controlled transposition, through mesh and nurbs, of the data of the survey and, therefore, an accurate representation of any architectonic form, ascribable to simple assemblages and rough three-dimensional transformations or the most complex solids and surfaces of free or organic form.

Fig. 5: Simulation and Virtuality. The modeling of the “ronchi” aimed at understanding the urban grid of Ortigia.

The intrinsic potential of virtual reality, the ability to express by mimetic representations of phenomenal reality that may be transmitted, without overlooking those aspects of precision and reliability demanded of coded graphic representations, means that the same medium can be imagined to aid the sharing of information with various kinds of users, the foundation in order to favour new and beneficial relationships of cooperation between operators and users of the common patrimony.

On one hand, it has been decided to not abandon encoded two-dimensional graphic representations, to be set alongside the three-dimensional representation of synthesis, not as self-standing designs, but as correlated data, above all in anticipation of accurate transformations of the real scenario to be transferred, in rapid time and coherently, into all the representations, through an interface of dynamic data updating, so that by *“modifying the data of the 2D model in a suitably created file, an updating of the database, the 3D model and of all the information in which the record is present, can be achieved. In this procedure a report of the operations undertaken is generated (log)”*. [11]

The in-depth exploration in this direction arises from the aspiration to start up, thanks to the sharing of “Crabnebula”, an effective collaboration with the administrative bodies in charge of organising the development of the territory, providing them a useful monitoring tool and control of the changes, able to point out sensitive areas and critical zones, and receiving from these same bodies information in real time on ongoing phenomena, facilitating accurate updating of the linked model and database.

On the other hand, believing the chance to exploit the multimedia technologies on the market today a priority, not only to promote tourism but also for a culturally oriented daily use, the “Crabnebula” suite has envisaged associating to the virtual model of Ortigia a *Qrcode*, the code for interactive reading, through suitable devices already in common use such as the smartphone or tablet, with a series of alphanumeric information, that acts as an on-line guide for consultation, by the city community, for a dynamic utilization of the virtual reality.

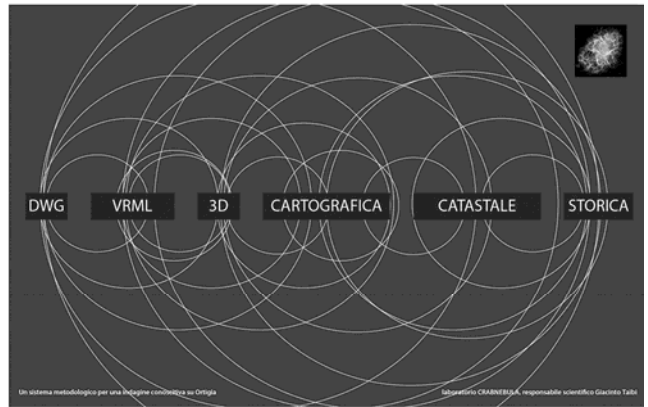

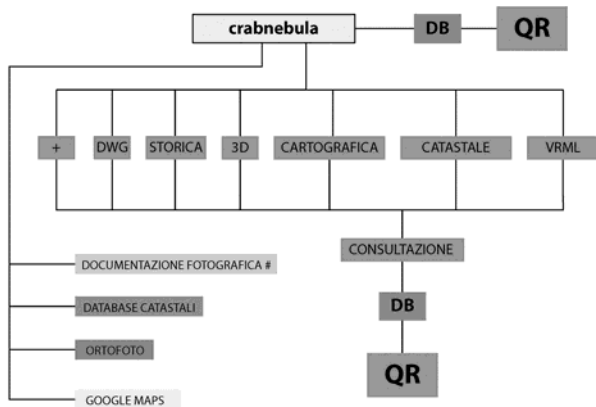

Fig. 6: The Theorem of the Knowledge Factory: Analyze, Explore, Share, Know, Communicate.

What has been achieved is only a first step. However, it appears entirely in line with the current directives of support to research and sustainable development, both international and national, that hope to see the implementation of project ideas aimed at realizing *smart cities and communities*, characterized by applying new technologies of information and communication with the aim of improving the governance, management and enjoyment of the heritage and services to the public.

Such a directive cannot fail to have a particular significance when applied to a country that has one of the greatest resources, and hence responsibilities, in its historical cultural heritage. *“If Europe has singled out the priorities in energy and sustainable mobility as applied to the great city contexts, in Italy we have the duty to be the hallmark of this vision, in the first place by applying it to the city and widespread communities; in the second place, by valorising distinct assets of the country like the historical and cultural patrimony and finally, by valorising models of social cohesion.”* [12]

Abstract

The productive activities of the cerebral hemispheres, the moment they manifest themselves, whether they involve a path of material construction of the idea, a reading process of the thought that supports the form, or a procedure of environmental and architectural survey, need adequate systems for an appropriate and targeted graphic representation.

Cartography, useful means by which is possible to record the changes of the city or of a single urban area, is the heart of planning or conservative interventions. The structured supporting systems, related to the computer logics of GIS, make possible the decoding of complexity whether urban or architectural.

All these elements allow an orthodox survey that meets the condition of scientific rigor in the phase of acquisition of geo-referenced data through the use of topographic techniques.

Today the available hardware is underutilized and the software is often closed and not post implementable, whereby various applications must be used for simple operations. The new frontier lies in the ability to write targeted plug-ins using visual editors, thanks to open-source technologies that allow to manage the graphic representation in a more simple and rational way, following the example of Grasshopper, visual editor of generative algorithms, that doesn't require the know-how of a computer programmer.

Keywords: creativity, freedom, place, hardware, software

1. Freedom of expression in heuristic manifestations of cerebral hemispheres (G. Taibi)

Today, by far, the concept of freedom is the most evolved form of inner well-being of human beings.

There is and there can be no progress, broadly speaking, without freedom, even tacit or overt.

Freedom to exercise decision making powers with the aim of achieving a goal. Freedom to act independently, with the support of the baggage of past experiences.

Freedom to fly through the mind on an ethereal plane, full of insights and imagination.

Freedom to change preconceived reality, according to new scenarios and more articulated structure of requirements.

Freedom to shape, with their own hands and cultural insight, new products and new forms of everyday life.

It is evident that the deeper meaning of free will and freedom of expression, within the productive activities of making architecture, lives, obviously, in close connection with creative skills and conception, intended as potential production of human race.

Creativity, actually, is a very broad and sophisticated concept which, in very simple words, can be condensed into a multifaceted and eclectic activity, aimed at thinking and producing in the direction of progress and innovation.

"Creativity consists in the ability to produce new, original, appropriate ideas and objects to which is attributed a value that can be social, spiritual, aesthetic, scientific, technological." [1]

A propulsive activity, whatever may be its incipit, intention and purpose, is inevitably a prelude to a process of introspective ability, also referred to the temporal dimension, that is essential to focus on all issues related to it.

Procedures inherent in the fertile proliferation of artistic production, the peculiarity of creative process is identified in succeeding in highlighting and tackling, simultaneously, a plurality of needs and requirements that are an integral part of desiderata, evident expression of daily life outcomes.

All this, however, must satisfy the need to consider, in the same time, all parties and their differences as well as to be able to define typological aspects of spaces and determine their dynamics, seen in a possible time sequence.

The support provided by computer systems turns out decisive, because they can develop simulation models of reality, regardless of graphic process, and, sometimes, even of the Euclidean geometry, which can represent, reductively, only a small variety of shapes and that, therefore, could contract and reduce the knowledge of those space reality defined by a specifically complex morphology.

By acting in this way and arranging special rendering typologies, thinking in terms of totality of a complexity and addenda of a composite whole is no longer an utopia. They, in their value of quantitative and comparative assessment tools, satisfy the need to reconstruct, in a general framework, parts and fragments into a sort of representative forms, capable of simulating sensations and visual perceptions.

It is important to reconstruct sequences so as to be able to combine, into a single graphics performance, the requirement of accuracy, completeness and adequacy in the simulation of reality as well as the possibility to include into the type of representation, the time function.

This function, which can normally be understood as a continuous succession of identical empty, or a series of containers to be filled of activities, can be considered as a discrete or indeterminate set of smaller parts, consisting of fractals of the time continuum.

These are *fractus* elements that find reason for being, at first, in moments, very short space of time, and then in seconds, in what is going to happen, in what is going to be created, in what can cause new blood and new propulsion.

But all this takes place, constantly, every moment, where *momentum* is to be considered a contraction of *movimentum*. And every moment is to be understood as an impulse in its meaning of *impellere*, or to push forward.

But then we are in the presence of a continuous movement, a continuous process.

It is, in other words, that fraction of time in which we expect something to happen.

It's that time *fractus* in which our creative process can have an intense activity and all our requests have one or more solutions, in accordance with the apparatus of needs within the context.

The mass of ideas' production should be set just there. Getting inspired from the baggage of the imaginary of signs, it aims to produce a range of possible solutions, which must be compatible with parametric setting concerning basic binding issues.

Ideas, formulated in the cerebral hemisphere, originate from external stimuli, experiences, pre-existences find within places. Ideas that, in their formulation, are clear manifestations of mental productions, free from constraints, facts and feelings of limiting closures.

Unfortunately, the specific human behavior, related to behavior pattern of daily routine, inevitably leads to a reduction of vitality that materializes when daily life dulls and paralyzes ideas' production.

In other words, ideas are creative processes that lead to a process of representation and a full freedom of expression and movement.

"Albert Einstein gave particular importance to the intuitive mode of thought, understood as a sympathetic understanding of experience, well differentiated by cold and logical observational attitudes. Compared to Poincaré, he gives us a deeper examination by allowing us to describe the succession of mental operations that precede and prepare the intuition: moving from first perception, up to visual memorization and till the formation of a reservoir of images that can be recalled and used repeatedly and in various forms, up to the opportunity to freely play with concepts and see intuitively functional relationships between concepts and new sensory experiences." [1]

Generally, when we speak about representation, we make reference to known situations and also to inner facts of our psychology that, although articulated in a complex form, of course, even with difficulty, can be part of our representative ability.

"Design is treated in pedagogical terms, mostly in reference to J. Dewey's and W.H. Kilpatrick's theories and also to planning, understood as the tendency or inclination to design, ideas' production, programming etc., as referred in psychology.

In philosophical terms, we can even say, in general, that the design is primarily aimed toward an anticipation of possibilities: any prevision, prediction, planning, ordering, predetermination.

In this sense the design - not necessarily related to data or events - becomes a way of being of the human condition and precede, or should precede, any action, whether individual or collective:

Martin Heidegger, in Sein und Zeit, introduced the notion, pointing out what he calls the ontological-existential constitution of the project: planning his life the man realizes its real possibility, its potential to exist". [2]

"It is unanimously thought that paths of knowledge, interpretation, ideation and representation will materialize into a cultural and artistic moment, in which converge the whole wealth of knowledge and also that the full awareness of the goodness' philosophical content of what it was thought, understood as primeval but mature idea, takes determination on the basis of the relationship with the phenomenal apparatus of the real and events'panorama".[3]

The concrete, in some way, oriented towards the formulation of ideas, suggests that we must think in terms of more sophisticated products, able to take into account the structure of needs and therefore a production aimed at the development of appropriate expressive systems and flexible and implementable custom software.

On the other hand, it should be expedient to activate processes of recognition and identification of logical deductive procedures, capable of making explicit cultural experiences that have supported the project. These procedures, conducted in the opposite direction to the generative process of ideas, are very important to trace the reasons of the project, the whole collection of conceptual reasoning that, on the basis of analyses conducted on dynamics of territorial expansion, on the evolution of aggregate forms, on parametric aspects they have in common and on those that determine a differentiation and even on the basis of the attention paid to the cultural, economic, political and social setting, that was its background, allow to highlight issues relating to the reconstruction of the ideative process, which have always been the object of deep reflections.

It has to understand, chiefly, relationships and connectives that are established among the parties, rebuilding and reactivating the tangle of relationships between nature, man and building, to find a sense of belonging in places' identity and also understand, finally, what signs can define its image.

1: Simulation of Complexity. Herzog & de Meuron, *Epicentro Prada*, Tokio, Giappone.

Fig. 2: Gianfranco Pugliese, *Snapshots of the complexity*, result obtained with software Ultrafractal.

2. Composite Software to investigate the geometry of place (G. Maniscalco)

One of the fundamental problems, so typical of our inner drive, is linked to our impulsive temperament to succeed in exploring in depth, with plenty of information, the cognitive process of what constitutes our specialist field, the object of the study.

The survey, a specific field for knowledge, with its performances, implies the acquisition of a wealth of data on the situation of architecture and also a faithful schematization of the place, to be able to understand and analyze it.

“Undertaking the survey of an object, of a territory, whose geometry is particularly complex, means knowing its dimensions, its forms and the relationships between them; this allows analysing it quantitatively and qualitatively, starting from objective data, and to build a graphic document that, projected on a particular plane, is its image reduced to a certain scale”. [4]

In a territorial context, the cartographic support is decisive. It may be considered a kind of measurement of the landscape, a very complex element that cannot merely be broken down into a reality of addends, but must be seen and framed in a puzzle of interrelations between parts.

The territory is a sovereign field, it is the inspiring force of our design-concept abilities, it is the spur to define the guidelines of the project.

“The problem of knowledge on a built territorial context (...) can be faced, regarding some historical periods that are closer to us, making use of a valid aid, namely that of ancient cartography.” [5]

It is well known that there can be no project without an understanding of the territory, of the place. By the same yardstick, the preliminary operations for the use of the territory must focus on all the problematics of the knowledge factory of the complexity of the environmental system that is made up of fields ranging from geomorphology, the protection of natural resources to the safeguarding of water resources and agro-forestry problems.

Interpreting the physical-territorial, historical-cultural, settlement components and the transformation of the landscape, constitutes the process of regeneration that is useful toward elaborating a coherent description of the identity of the place.

In this sense, analyses of the nature of the *topos* are useful tools for targeted projects, examining the natural conditions of the territory, deriving from the study of the elements of geology, topography and climatic aspects.

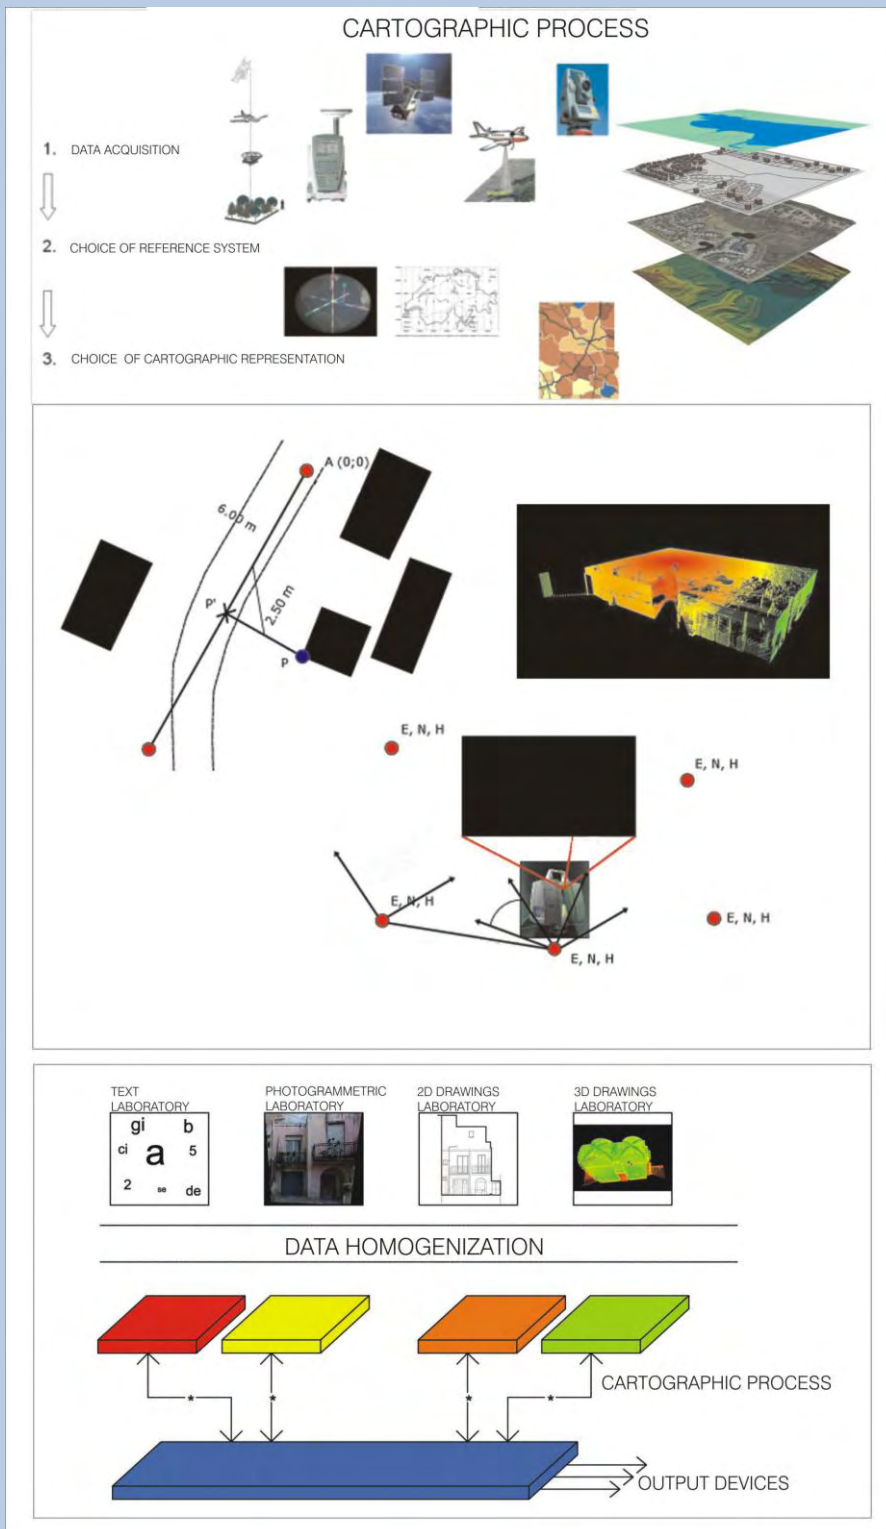

Fig. 3: Procedures and elaborations of the complexity of the cartographic process.

All this induces a full awareness of the need to set up an organization of the information, able to implement a series of interactive procedures between phenomena and requirements, making recourse to an information system of data. Interpreting modern cartography as the locus responsible for the analytical description of the territory, we must strive toward giving emphasis to some interpretative elements, in an attempt to render them above all communicative, through a representation system that we may call critical-analytical.

It is appropriate to start up an entire operating system that has the faculty to fully appropriate, memorise, analyze and manage all the kinds of geographic information of reference and that, through suitable IT aids, may speed up the recording, cataloguing and management of data through software, able to organize and combine remarkable amounts of information, whether acquired in graphic or alphanumeric form, establishing, sometimes, relationships referring to images of spatial or photographic origin, making recourse to symbology and characteristic data of the language of computer graphics.

We are referring to the GIS that, clearly as a computerized information system, allows acquiring, recording, analysing, visualizing and restituting information deriving from geographic data (geo-referenced).

The GIS, which should not solely be considered a container and visual display of data, but chiefly a dynamic centre of elaboration and verification of historical hypotheses, aims at supplying new information, which cannot be acquired with other means. Indeed, the new techniques, based on the use of technologies and information technology procedures, prove useful in the structured systemic sets on the cognitive documentation of complex architectonic organisms.

In the first instance, in the context of a survey, we may pinpoint and recognize the fundamental kinds of computer science treatment of acquiring and elaborating texts, images and graphic-numerical data.

The ensemble of these applications leads to the formation of an information model, usable under various profiles, as a store of raster or vectorial images, as a container of written texts in relation to images and graphics, as databanks and calculation tools for the most complex problems of topography and structural analysis and as a tool to be connected to peripheral devices of various kinds for written or graphic document production. The scientific research and all the activities carried out in the Laboratory of Representation of the Faculty of Architecture of Siracusa use some experiments of digital photogrammetry, treatment of three-dimensional data and elaborations of virtual reality, both to elaborate synthesis images, as well as construct information systems for the management of the architectonic heritage.

The acquisition and elaboration of data, analysed in the Laboratory, take into consideration the characteristics of every technique related to the single extrinsic capacities, such as precision, accuracy and format of data, inserting them into a database that is useful for multiple applications, among which documentation, diffusion and in-depth analytical-geometric studies.

3. An evolutionary process of software and hardware (M. D'Aiello)

"The historical centers, monuments, even the degraded landscapes are the raw material of our investigation, the hardware, on which the thinking and the integration of skills act as a software to define a repertoire of appropriate solutions to return those area to the community through an action to regenerative protection". [6]

Although, we have today large resources of processing, we use software that, not always, are able to exploit these resources in the best way as happens in issues related to the activity of the "knowledge factory", understood in its broadest sense.

We use powerful computers, with several giga of ram and SSD, just to surf to the web, when the same operations were carried out for some time, with the first "home computer".

In fact, the software, although reliable quality, understood as a refinement of detail and backward compatibility to the bitter end, it's not unable to stand the overflowing development of hardware while the system requirements are primarily for trivial frylls.

Indeed, today, is establishing a new type of software "distributed", which comes from small "software houses", where a part generalist, you can add independent sub-services that implement the ability through specially designed modules and scripts.

Today, 75% of transactions conducted through the classic cad tools are the same as you were making 10 years ago, and implementations, 3d, modern layout, etc., have not undergone the same development of the related hardware.

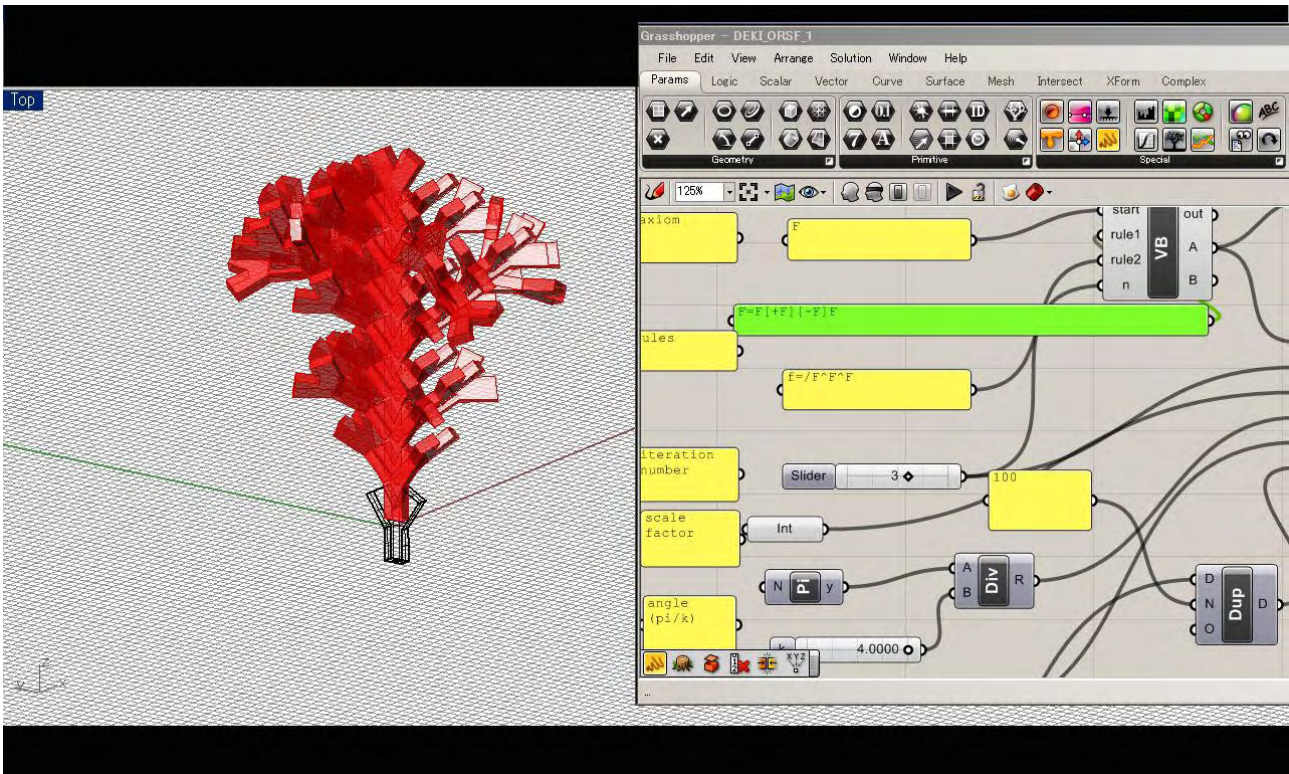

Fig. 4: A processing system of complex shapes.

To meet the growing need, today, we prefer to resort to more advanced programs, which rely on open source plug-in. In fact, these design software do not require knowledge of programming languages, but allow you to build forms using a graphical interface, with nodes and links, to keep the concept open to future changes. Which is of considerable importance and full support for those research that address issues directed to the definition of images in the specific field of ideational manifestation, of the complex and varied activity of the composing and the intense deepening oriented to the factory of knowledge and the finding of the matrices of reading.

But other events in the field of the digital evolution have made the resounding success of the tools "easy" who were born on the internet and making use of large support community. This 3d programs, developed for the web and that have their strength in the simplicity, the learning curve, and the sharp reduction in costs. All this, explains the significant windward taken by tools "easy" compared to traditional software, taking account of their great simplicity, according to a revolution that comes from below, by performing the effect mp3, where a limit, becomes a resource.

Erroneously, at first, were not taken into account the benefits arising from size, much smaller, in relation to digitalization, web resources and relative connection speed and the diffusion on Internet. Later this system, as well as in the case of disruptive technologies, managed to establish itself resolutely reaching levels of power and sophistication such as to overshadow the old systems.

Christensen explains, often enter at the bottom of the market, where they are ignored by established players. These technologies then grow in power and sophistication to the point where they eclipse the old systems.

In fact, going out from seeded and moving within in music, with the format mp3 we have given a new meaning of quality, which is not a quality in an absolute sense, but the quality in terms of response to specific needs.

The computing landscape today is moving toward "cloud computing", that set of technologies that, through a "web based" system, "provider-client", allowing you to store, store and process data (via CPU or software) under utilization of resources hardware / software distributed and virtualized on network.

And this becomes advantageous in that, using the technology of this new computer system, users, connected to a "cloud providers", can perform all operations, including through a simple browser, and use applications even if not physically reside on their hard drives. It follows, therefore, that, at a distance, can be

used in remote systems for processing or for storage, creating, in the latter case, suitably, an automatic and multiple backup.

The innovation and success of "cloud computing" is that, beyond the advantageous reduction of the financial commitments, determined by the contraction of investment and support costs, for effect of intelligence of the technologies, which form the basis, are easily configurable and accessible via the network. For more you can have access to services at all times and in each spacial scope, being able to view and work on documents via the web, from any place and on any device.

All this portends that the near future could take place in software development of "web-based" on "cloud", that is platform independent, allowing the management of a project distributed easily scalable, open-source and possibly with a support community, which promotes growth and making changes, on the examples already cited, so as to be always available, is not subject to cross-licensing and is free from the hardware, at least as regards consultation.

All our problems, including that associated with the virtual modeling, lead us to reflect on the hardware and software necessary and appropriate to meet the needs related to the complexity of the issues addressed. In this sense it seems appropriate to turn our attention to the systemic potentiality, in permitting the complete management of the process, related to the complexity of the issues facing to the knowledge factory, viewed in its entirety, until it comes to virtual representation, are released from platforms and allow a different data management.

Abstract

Normally end users are passive users who do not participate in managing their energy consumption. International literature is demonstrating that involvement and awareness in facility management can help energy saving. For this reason, it is necessary that the subject becomes active and able to fit inside the energy management information.

From this point of view, the Smart Energy Efficient Middleware for Public Spaces (SEEMPubS), a Seventh Framework Programme project, aims to reduce energy consumption in historic and modern public buildings through low economic impact construction works and an efficient ICT network for monitoring, detecting and managing consumption.

At the end of this project, consumption data, which were collected within a number of the test rooms, will be available to end users through a Facility Management application (Archibus) that will allow users to see energy consumption data visible in real time, and to perform a different kind of medium and long term analysis and consequently to plan construction works, when necessary.

At the same time, collected data, are used to study the methodology through interoperability among parametric software, both architectural (Revit Architecture), energetic (Daysim, Radiance and TRNSYS) and Facility Management (Archibus FM).

Therefore, SEEMPubS will be able to transform “users” into “informed-user” involving them in the global energy process.

Key-words: Archibus, SEEMPubS, Revit, Facility Management, Interoperability.

1. Introduction

When we talk about end users we refer to subjects at the end of the process. Generally, this process ends when users performs their actions and tasks and receive a benefit. As just described these subjects are known as Passive Users as do not interact directly with the process, but are limited to suffer the consequences. On the contrary, Active Users are defined as subjects, that in response of a proper information, interact with the system productively synergistically; when operating in this way the subject plays a major rather than a secondary role.

Distinction between Active and Passive Users becomes of basic importance when we talk about energy efficiency and saving.

Since 2000, with the introduction of the European Climate Change Programme (ECCP), and subsequent amendments and additions, the European Union (EU) has pushed and encouraged the introduction of national policies for energy saving and reduction of greenhouse gases.

Alongside with the actions that National Governments have enacted with the aim of pursuing the objectives of the Program 20/20/20 (Directive 2009/28/EC), one of the indirect goals is just to increase information, about energy saving, and transform users in active users able to act in practical ways to reduce consumption.

The advent of Building Automation or rather the concept of Smart Buildings, in which different types of systems are managed in an integrated way, has allowed the involved users to increase their awareness and control about energy saving and energy management. However, this type of building management system was limited to commercial buildings.

The extension of this concept to the majority of people came with the introduction of Home Automation, which is the science that deals with the study of technologies to improve and optimize the use of home places.

Dissemination of these two applications is, in both cases, strongly connected with a strong diffusion of the concept of energy saving and user interaction. The awareness of a single person, who understands that his role, however small, can lead to significant savings in energy terms, is the basis of current policies that are implemented with increasing force, at all organizational levels. It is in fact understood that the monitoring of the role played by rooms occupants is essential to control the total consumption of a building.

The Politecnico di Torino is an institution more sensitive to the energy saving and for several years has been engaged in initiatives and projects related to this topic.

All these projects always consider the active presence of end users and their interaction with the process; for example, it is possible to mention the initiative called “M’illumino di meno” which took place on February 17th, 2012: all Politecnico’s employees were asked to do energy-saving actions paying particular attention to power consumption and to switch off all energy consuming equipments (e.g. printers, computers, etc.) when they are not used, as well as to close windows and lower thermostats.

The monitoring of consumption, combined with user information campaign and to the implementation of the suggested actions, resulted in a saving of over 6.000 kWh (around 15% of total). Although about half of this was due to antifreeze pumps switching off, the remaining part may actually be attributed to individual energy savings measures.

Fig. 1: Representation of the ordinary and effective consumption on February 17th, 2012, for the Main Campus of Politecnico di Torino [taken from web site: <http://smartgreenbuilding.polito.it/>]

This is just one initiative where users are involved directly, there are also research projects developed with national and international contributions, involving the study and analysis of scientific methodologies for monitoring and reducing consumption, such as the European project SEEMPubS.

2. SEEMPubS

The European project SEEMPubS (Smart Energy Efficient Middleware for Public Spaces) is a project of the 7th Framework Programme; it specifically addresses reduction in energy usage and CO₂ footprint in existing Public buildings and Spaces without significant construction works, by an intelligent ICT-based service monitoring and managing the energy consumption. The project bestows special attention to historical building in order to avoid damage by extensive retrofitting.

The project focus start considering that in most public buildings the system management is performed in independent and not integrated way, as a result it is difficult to obtain an optimal management of different type of consumption.

Specifically, the project includes use and implementation of a system based on "LinkSmart" (also called Hydra), a middleware service, developed in other European project (Jahn et al., 2009) (Lardies et al., 2009). The "LinkSmart" is designed to support the development of embedded systems networks, simplifying the interconnection between devices, which are often heterogeneous, and principally communicate with different protocols for data exchange. Therefore, SEEMPubS platform allow to monitor and control, in an integrated way, different type of system (such as lighting and HVAC) and its consumption.

All collected data will be constantly compared with the external climatic condition in order to crate the best interior comfort.

The middleware implementation provides development of an ICT network able to detect consumption data resulting from different type of wireless sensors connected to the system and subsystem and consequently allow to analyse them.

Additionally, all data about energy consumption and energy saving will be made available in a web-site being implemented in order to increase awareness of energy saving and efficiency in public buildings by the users.

The project goals can be summarized as follow:

- Developing an integrated electronic system to monitor different building models, technical building services, electronic devices and operations in order to optimize and integrate all maintenance functions.
- Implementing an interoperable web-based software solution for real-time energy performance monitoring and control of lighting, heating, ventilation and air conditioning services through wireless sensor networks in existing buildings and open public spaces.
- Raising people's awareness for energy efficiency in public spaces.
- Providing multi-dimensional visualization of parameters of building operations and data sharing from technical systems.
- Validating the developed monitoring system through an iterative methodology.
- Translating the most significant research results achieved within the project into a model for existing buildings and public spaces in Europe.
- Disseminating and exploiting the project results according to a strategy based on several awareness-creation means and to the specific business and market targets of the individual partners.

3. Case Studies

The first activity, necessary for data acquisition, was the selection of the rooms. Particularly, 6 pairs of rooms were selected, each one is formed by a test room and a reference room (where Building Management System (BMS) will be implemented for lighting, heating/cooling and electric appliances control and monitoring). The 6 pairs of rooms have a lot of different features between them while the differences within the pair are almost nil.

In this way, we can work with rooms for which it will be possible to make not significant construction works and evaluate energy savings (test rooms), at the same time we are being able to compare these values with the state of the similar environment (reference rooms). The selected rooms are located in the Valentino's Castle, in the Main Campus of Corso Duca degli Abruzzi and in the Cittadella Politecnica. The choice of these three different types of buildings is connected, as mentioned, to the desire of having buildings with different constructive characteristics and different periods of construction.

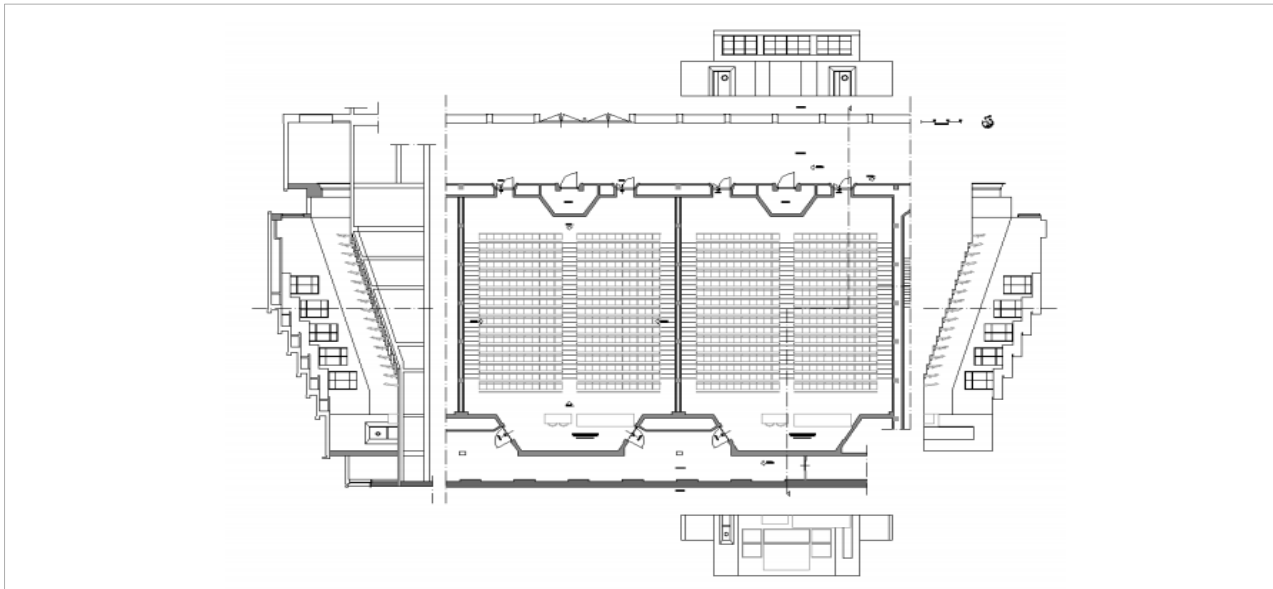

Fig. 2: Classrooms used as case study: test room (on the right) and reference room (on the left).

4. Interoperability to assess performances for different control strategies

A detailed relief of architectural features of each case-study (geometry, furniture and equipment, surface reflection/transmission properties, lighting/HVAC systems etc.) was carried out so as to create accurate 3D models of the selected rooms. The models were used to run energy simulations (TRNSYS for thermal analyses and Radiance and Daysim for lighting analyses), which were validated through monitored data and then used to estimate the building energy demand for different control strategies. As far as lighting simulations is concerned, Radiance was used to validate the models, comparing the simulated illuminance distribution to the illuminance values measured in the corresponding rooms, while Daysim was used to estimate the lighting energy demand and the savings obtained with the specific control strategies proposed for each case-study. Daysim in fact allows running annual simulation for a site, accounting for the specific dynamic climate conditions.

Before starting the simulations, the use of BIM for architectural, HVAC and lighting systems modeling, as methodology to test the interoperability for energy efficiency simulations, was investigated. The BIM approach started with the creation of 3D models of each case-study, including their external environments, through Autodesk applications. In particular Revit Architecture was used for architectural modeling and Revit MEP for the modeling of heating and lighting systems.

In order to run the lighting simulations, it was not possible to import the parametric model from Revit into Radiance/Daysim directly. The software Ecotect was hence used as interface to launch Radiance/Daysim. As a result, the import from Revit into Ecotect was addressed: the first trial adopted the traditional approach based on the exportation in IFC (Industry Foundation Classes) format, but it did not succeed because some elements were not exported or were displaced. The second trial was based on the exportation from Revit by a gbXML file, but some geometrical discrepancies in the surfaces generated from the solid elements made the model unsuitable for the lighting simulation. The third procedure eventually succeeded: using 3D Studio Max as an intermediate software (to convert the .fbx file exported from Revit in a .3ds file to imported into Ecotect) good results in terms of geometrical consistency of the exported model were obtained.

At the end of the interoperability process, lighting simulations were run to validate the models and to use them to evaluate the potential energy savings concerned with the proposed control strategies.

The validation phase with Radiance showed a difference between measured and simulated illuminances ranging from -12% to +30%, depending on the considered sky conditions (clear or overcast sky) and on the position of the verification point within the room. This discrepancy might be attributed to the interaction of the different aspects which are involved in the simulation process: 1) the correspondence of the sky model generated by Radiance starting from the measured outdoor illuminances (direct and diffuse horizontal illuminances) with the real sky condition; 2) the optical characterization of room opaque and transparent surfaces; 3) the accuracy of the instruments which were used; 4) the accuracy of the geometrical model, with particular attention to the modeling of the glass surfaces.

According to the characteristics of the selected rooms, a first series of monitoring and control strategies was proposed. In particular as for lighting new control strategies were proposed (IESNA 2000) (Acquaviva et al. 2011): for spaces with high daylight availability and medium/high users absence probability, a combination of daylight harvesting and occupancy control was proposed; for spaces with low daylight availability, a lighting control based on occupancy sensors was proposed, while a peculiar solution was defined for large classrooms with no daylight: students absence probability during the day is very low, but the classroom area could be only partly occupied when a small number of students attend the lectures. In this case, it was planned to use several occupancy sensors to dim to a minimum the lights corresponding to the unoccupied classroom areas. Anyway, in all cases users were provided with the possibility to override the automatic control via manual command. Based on these assumptions, some recurrent combinations of lighting control strategies were initially proposed for the selected rooms:

- time switching, occupancy detection for personal light and manual control: this mix of control strategies was proposed for the Student Offices where daylight availability is very low and the general lighting is provided by means of High Pressure Metal Halide lamps, which cannot be switched on and off instantaneously and cannot be dimmed
- daylight harvesting, occupancy detection and manual control: this combination of control strategies was proposed for DIST offices, Administrative offices and DAUIN private offices. In these cases the automatic dimming of lights based on a daylight harvesting control strategy could be applied successfully thanks to the high daylight availability and it could be useful to control lights on the basis of room's occupancy too, as a medium absence probability could be truthfully assumed for these offices
- occupancy detection and manual control: these control strategies were proposed for classrooms 1&3 and for the DAUIN open-plan offices as daylight is not allowed to enter the rooms (in classrooms) or is quite low due to the glazing characteristics and the external obstructions produced by the structure of the double façade in the DAUIN offices
- shading device control based on outdoor illuminance or solar radiation: this control strategy was proposed for DIST offices, where motorized blinds are installed on the roof lights, to control overheating and glare due to solar radiation.

For each room, the initially defined control strategies were simulated in Daysim and the corresponding energy demand for lighting and the potential savings were estimated, comparing the energy demand for the new strategy to the demand for the currently installed control system.

The obtained results outlined that, in most cases, the initially proposed control strategies would not provide the expected energy savings (from 5% to 30%). This might be due to the fact that the automatic on and off implies the switching on of lights whenever someone enters the room, independently of the indoor lighting conditions that might be determined based on daylight. Once switched on, lights are kept on, in standby mode, even if daylight is sufficient to fulfill the lighting requirement. Based on this, it seemed fairly probable that energy savings could be increased by using the occupancy sensors only to switch the light off when users leave the rooms, while leaving the occupant the task to switch them on if the lighting level is perceived too low. Increasing user information and awareness is one of the key goals of the SEEMPubS project. This should reduce the number of hours the lights are on, or in standby mode. Based on this, new improved strategies ('updated strategies) were defined and analyzed through new sets of simulations: it was then found that the most effective control solution for some of the analyzed case studies was a mix of manual and automatic control instead of a fully automatic control as initially proposed. The best results were obtained assuming that users have an active behavior in controlling blinds and lights, thus increasing the potential energy savings (range 13% ÷ 39% for an equal mixed passive/active behavior and between 14% ÷ 71% for the active behavior, where passive and active users are based on two different stochastic models implemented in Daysim) (Reinhart 2004).

5. Intelligent Control System

The strategy for smart building management and control leverages upon an ICT infrastructure made of heterogeneous monitoring and actuation devices, such as Wireless Sensor Network (WSN). An innovative web service oriented software infrastructure has been developed to manage heterogeneous and commercial wireless sensor nodes belonging to different WSN. The LinkSmart middleware (Jahn M. et al. 2009), (Lardies F.M. et al. 2009) has been adopted to provide interoperability between heterogeneous devices and networks, both existing and to be deployed. Moreover, the proposed infrastructure allows easy extension to third-party software, such as Archibus, and to other networks, thus representing a contribution to the opening of a market for ICT-based customized solutions integrating numerous products from different vendors. The system manages energy efficiency through the WSN, which is preferred in order to simplify the integration of

new sensors into the system and to avoid the overload of cabling in old buildings. The software infrastructure provides the following main functionalities:

- It enables the interfacing to the application layer by means of web services, through which sensor data can be read and used for visualization or to feed energy management policies;
- It collects sensor data in a local database, in such a way they can be accessed in an asynchronous way and preserved from network failures;
- It allows the remote reconfiguration of sensor node parameters such the sampling rate of physical quantities to be monitored;
- It enables interoperability among heterogeneous networks, characterized by different microcontrollers and sensors.

Fig. 3 Software infrastructure scheme to handle heterogeneous Wireless Sensor Networks.

As shown in Figure 3, our software runs in a PC-Gateway (GW) and communicates directly with the heterogeneous networks. The dedicated *Interface* represents the lowest layer of our proposed stack, and receives all the information coming from the WSNs, regardless of the adopted communication protocols, hardware or the network topology. Hence, each WSN needs a specific software *Interface*, which interprets the data and stores them in an integrated database (DB), in order to make the whole infrastructure flexible and reliable with respect to back-bone network problems, since data are locally stored.

The web-service layer, implemented using LinkSmart, interfaces the WSNs to the web, making easy a remote management and control. Moreover it exports to the application client layer, the last in our stack, all the environmental data stored in the DB and collected by the wireless sensor nodes. At this layer, the information is available to the end-user and ready to be shown via computers or smartphones or to be integrated with the data coming from Archibus.

Particular emphasis was given to the possibility to reconfigure each node, changing, for instance, some parameters about power management. In this scenario, the end-user sends the new configuration via web-services to the GW and stores it in the DB. Then, the new settings will be automatically sent to the receiver mote, when it will wake up from the sleeping period, through the specific WSN software *Interface*. The configurable parameters change depending on the hardware and the Operating System running on the end-node. However, using this software infrastructure, the user can choose only the right settings ignoring the real physical hardware related to the virtual device.

In a nutshell, the proposed web-based infrastructure is a software that makes transparent to the end-user the underlying WSNs, abstracting all the information about hardware, protocol stack and embedded operating system. Furthermore, by the use of web-services, it makes easy the interoperability with third-party software.

6. Data management using CAFM application

The best way for manage a large number of data is to use one or more databases, implemented and customized so as to receive, contain and store data that is decided to manage. Very often the database's structures are the basis of more complex applications whose task is to provide an IT support for the management.

Among the numerous families of applications available today, there is one called CAFM abbreviation of Computer Aided Facility Management. This family of applications has been developed to provide appropriate tools for managing facilities. Therefore the Computer Aided Facility Management are a computer products that are able to give access to a range of information related to capital assets of a company through an integrated alphanumeric and graphic database. Many of the aspects, to be managed inside a business organization, have strong ties with the space in which they are held, such as the management of the rooms,

management of employees or management of equipment and energy data connected to it; accordingly management software, as well as operate through tables and graphs must be able to interact with aided or parametric design software. Politecnico di Torino has adopted one year ago a CAFM application called Archibus FM, and is currently using for space management, maintenance on demand management and fire asset management.

This software, like many other similar products, consists of modules, each of which is responsible to contain and manage data on a particular aspect of business such as management and inventory of assets, employees or space management. Each module exists as an autonomous entity and contains within it all the features and all the tables, related to the database, that allow at facility managers to do their job.

One such instrument remain the professional responsibility of having to make choices about the content, but it is only a tool to infer information and perform analysis about a particular aspect of a organization business, after having examined data concerning it.

This product is currently on the point to be open at all users of the Politecnico, in this way the management of spaces, employees, or equipment, is not achieved in a centralized way but instead are the individual Departments, the individual Division, and in some cases the individual users to edit data and manage them. The idea of collecting data about energy consumption of the rooms and make them available to users is one of the final stages of the project SEEMPubS and thus, a natural tool through which to make available these data, will be Archibus.

Archibus application, adopted by the Politecnico, has developed with client-server structure, a client side where it is possible to manage graphics tools and a server side that containing the alphanumeric information, then through a web interface, users can see graphical information and alphanumeric information linked together.

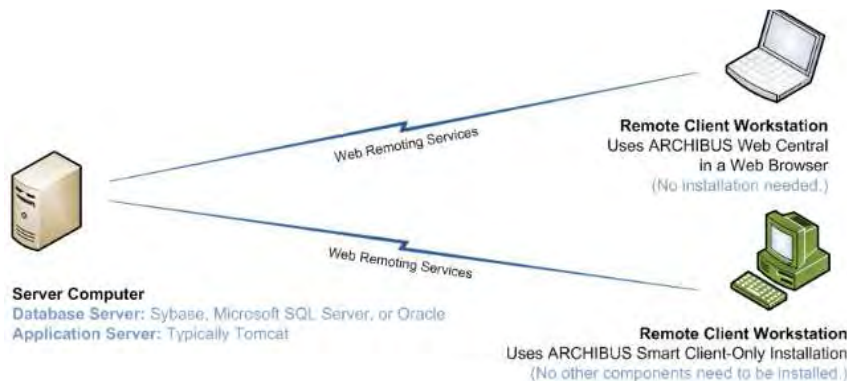

Fig. 4: Client-Server structure of Archibus FM application

Archibus, as described above, bases its operation on the link between graphic information and alphanumeric information; in particular the management of the spaces represent the support on which will be developed subsequent management actions, for example the placement of an object or a employee or rentals management is strongly connected with spaces identified and catalogued.

As just described, the graphical basis for the development and customization of Archibus is made using CAD maps, however, were performed tests in order to use BIM models realized using Revit Architecture.

Omitting the way whereby it is possible to connect graphical data with alphanumeric information using CAD file (.dwg) we can explain how to connect that information using Revit Architecture (.rvt).

First of all, it is absolutely essential that the parametric model has executed in a correct and complete way, at least as regards the architectural part, while it will be possible, at any time, add new information.

Another essential feature, in order to connect the graphical data (contained in Revit) with the numerical data (contained in Archibus), is the fact that each room created in Revit, and therefore enclosed by walls and floors, is also been catalogued using an appropriate Revit's entities called "Room".

This entity allows to catalogue every single space assigning it a identifier name and entering information, related to the room, on the local schedule in Revit.

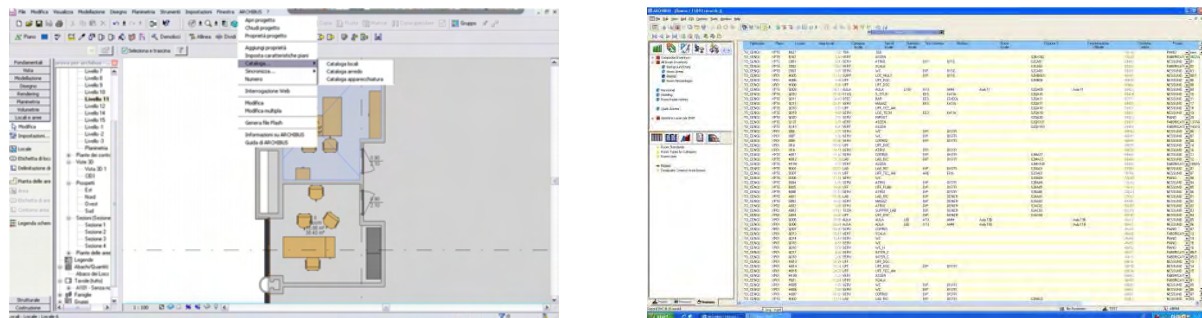

Fig. 5: Revit's interface with "Room" entity and Archibus menu, used to connect graphical data with numeric data.

When the previous operation is done it is possible to proceed connecting Revit data with Archibus data. About this operation it is possible follow two paths, the first is to load in a massive way all identifiers of local (this is the official codes adopted by Politecnico di Torino to identify rooms, for example a single room may be identified by the following code TO_CEN03_XP01_B005 where it is possible to recognize site, building, floor and room), if we work in this way, when we decide to connect the room graphic data with the numeric data contained in the Archibus database, will be possible to speed up the connection operations.

The second way allow to work step by step; each time we link a room we have to populate Archibus table with the correct information about the room such as structure, type of room, capacity, etc.: however any additional information about room can be loaded into the database in following steps.

Regarding energy data management collected for the different rooms it is possible to carry out the management and the subsequent visualization, by a procedure similar to that described above.

Regarding data in Revit Architecture model, connected with the indications of SEEMPubS project, the following features are been implemented:

- vertical walls (insulation, orientation, inertia, performance (value of U, disorders),
- low floors (insulation, orientation, inertia, performance (value of U, disorders),
- roofs (insulation, orientation, inertia, performance (value of U, disorders),
- windows (frame, glass, orientation and mask, performance (value of U_w , surfaces).

Fig. 6: Revit's model concerning the offices and laboratories case studies of the Cittadella Politecnica

Regarding systems modelling, it is possible insert in Revit MEP model information about heating, cooling, ventilation and lighting system.

Fig. 7: Detail of the Revit's MEP model, concerning a piece of the HVAC system of the Cittadella Politecnica

This information can be displayed and managed inside Revit Architecture or Revit MEP, in the schedules that are created during the creation of the elements.

As regards data that we can insert in Archibus we can manage:

Characteristics of sites:

- geographical location,
- year of construction,
- constraints / assets of the site,
- orientation of the construction,
- definition of surfaces and heated volumes.

Characteristics of system:

- Lighting system (type of lighting: direct/indirect; type of lamp: fluorescent etc.; presence of emergency lighting lamp, type of control system)
- Shading system (type with shading system and type of shading control system)
- Heating, cooling, ventilation system (type of heating and cooling system, type of ventilation system, air temperature value, CO₂ concentration, type of control system).

Regarding monitored parameters it will be possible insert the following:

- Environmental and occupancy parameters (indoor air temperature and relative humidity, illuminances, presence/absence detection),
- Outdoor parameters (outdoor air temperature and global radiation),
- Energy parameters (fan velocity and supply air temperature of fancoils to calculate thermal energy consumption, electric power for lighting and appliances' loads.)

Regarding management of these features and dissemination of information to users will be developed a procedure characterized by the following operations. The data recorded by sensor, placed in various rooms, are organized into a database specifically created and that will keep the data as they are collected; then, through the interchange and alignment procedures, these data will be caught and dumped into specific tables inside Archibus database.

Through the Archibus's interface customization, that will be special views where, for each local, users can take vision, in real time, of the data mentioned above such as the internal temperature of the room, CO₂ concentration, etc., furthermore it is possible get an overview of the historical data for rooms and consequently have a vision for the medium or long period.

Users will be able to see their consumption data and consequently may make changes to control systems such as lowering the temperature or increase the air exchanges.

Another advantage will be to make available an additional tool for the Politecnico to undertake energy saving actions.

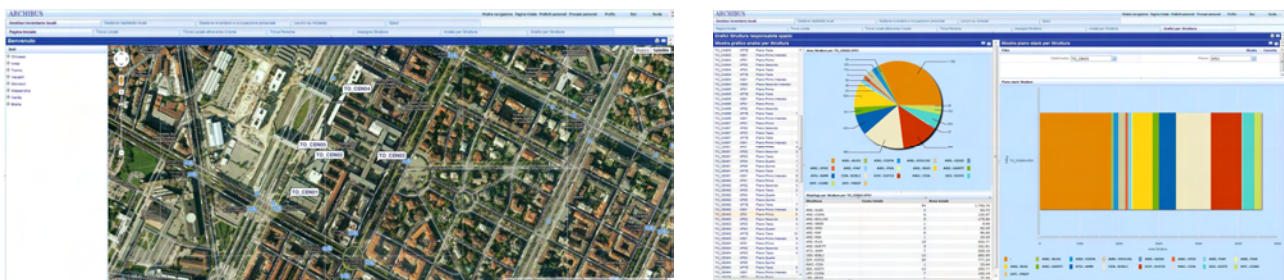

Fig. 8: Archibus's graphical user interface of Archibus for the Politecnico di Torino

7. Conclusion

Through research projects and initiatives involving energy efficiency will be possible to involve end users doing so that they become an active part in the process of energy saving. The SEEMPubS project has already seen active participation of the concerned users since its departure. One of the most interesting activity is about the study of the interoperability between software in particular before starting the simulations to assess energy savings, the use of BIM for architectural, HVAC and lighting systems modeling, as methodology to test the interoperability for energy efficiency simulations, was investigated.

BIM technology for buildings modeling has proved to be very useful as far as transmission of information and editing items are concerned. The model must still be implemented in a balanced way or rather must contain

exactly the information necessary to those who use it. This is useful to avoid having models that are too heavy and unmanageable. However there is also the possibility to implement the model with other type of information. In this case, though, some aspects remain to be investigated especially with regard to some interoperability errors that are still being analyzed and studied.

With regard to lighting simulations, the results outlined that the initially proposed control strategies would not provide the expected energy savings. For this reason, new improved strategies ('updated strategies) were defined and analyzed through new sets of simulations: it was then found that the most effective control solution for the presented case studies was a mix of manual and automatic control instead of a fully automatic control as initially proposed. The best results were obtained assuming that users have an active behavior in controlling blinds and lights, thus increasing the potential energy savings. Raising people awareness is one of the key goals of the SEEMPubS project.

Next steps will involve the implementation of procedures for entering energy collected data within Archibus through the personalization of the graphical interface; at the present Archibus is used by Politecnico di Torino's users regarding display of the spaces and the related features and for on demand maintenance, consequently the possibility to make available energy data collected can only make users more aware.

Abstract

In this paper, the authors shed light on *roshān* [Figure 1] and *jāli*: [Figure 2] two traditional architectural spatial devices that served essentially as *hijab* (veil) in Islamic dwellings of Saudi Arabia and India. The authors will discuss its concept, etymology, historic background, construction materials and techniques and provide comparative analysis of how these forms were utilized in dwellings of Saudi Arabia and India as a spatial device for: 1) separation of spaces; 2) to provide privacy and security; 3) to control and filter light; and 4) to control micro climate of the dwellings. The authors thus show how these two architectural forms are not just decorative elements for aesthetic beauty, but serve various spatial, social, cultural, religious and climatic functions. In conclusion; the authors will provide suggestions as to how these traditional architectural forms can be useful in developing sustainable design solutions for the 21st century architecture. The authors utilized two qualitative research methods, including literature review and case studies to collect the data for this research. Grounded theory was utilized to analyze the data. Conclusions were drawn based on authors' findings.

Keywords: *roshān*, *jāli*, Islamic architecture, screens, Muslim houses

1. Introduction

Roshān is the projected wooden window in large cities in the Hijaz region of Saudi Arabia, Sudan and Egypt. It is an old term for this kind of projected windows being used in most of the Muslim traditional architecture. It was also documented as "*roshān*" in planning and building regulation documents of the Islamic cities at the Mamluk era (1248-1516). This is the era in Cairo when the *roshān* was flourishing in Islamic architecture. The Mamluk controlled the trade between India and Venice for more than 200 years [23: p.101]. The trade route was the domain between these two civilizations, Egypt and the Indian subcontinent, where experiences between artisans may have been exchanged as well.

Jāli is an Indian term for a perforated stone screen, usually with an ornamental pattern [25: p.131]. *Jālis* have been used to cover verandas, balconies and separate interiors in Indian architecture since they were introduced by the Mughals [4: p.113]. Tillotson claims that *jāli* appear in the *zenana* (women's quarters) where the condition of *pardah* or *hijab* (*vail*) dictated the presence of *jāli* or screens across the windows [4: p. 207]. The need for privacy in the Muslim house is crucial, especially in the *harim* (women's quarters). As the *roshān* with its extra lattices envelops windows in such interiors, the *jāli* does the same in the Muslim Indian house.

The *roshāns* and *jālis* have been extensively used in religious to residential buildings in the Middle East and India. However; the construction materials, techniques, its treatment and applications differ. In this paper the authors will focus on the use of these two forms in residential environments and discuss the similarities and

differences between the two to show that both serve larger purpose than just providing aesthetic beauty. Through a comparative analysis between these two forms, the author will highlight its importance in conserving energy, providing privacy, controlling light and micro climate of the buildings. The authors hope that this information will assist the 21st century architects and designers in understanding the concept behind these architectural forms and inspire them to utilize it in providing aesthetically pleasing, sustainable building solutions.

1.1 The Architectural Concept of *Roshān* and *Jāli*

The *hijab* (veil) [Figure 3] is the inspiration behind the concept of the *roshān*, and this is the main reason for the existence of this architectural feature wherever and whenever Islam has existed. These screens work as an architectural veil, where it controls the intrusion of an outsider in a transparent setting like a women's *hijab*. Moreover, both the *hijab* and the *roshān* fulfill the notion of intimacy and seclusion, where curious male viewers have little chance to see what happens behind the screen [4: p. 27]. The privacy and the security for women are the two significant factors responsible for the development of the *hijab* (veil) and the *roshān* as well as the *jāli*. The *hijab* as a concept governs the daily-life of women in Islam; whereas the *roshān* and *jāli* as the enclosures serve as a screen, masking the openings of the house. These screened windows are like the eyes of the house; having the windows screened protects the interiors and thereby respects the residents' privacy. Nevertheless, the veiling of women is just one form of a broader range of understanding of its implications. The word *hijab*, as a noun, comes from the Arabic verb *hajaba*, which means 'to hide from view or conceal'. It can also mean "to screen" or "draw a curtain" or a barrier of any kind. It is essential to have the windows open during the daytime in the hot climate of Saudi Arabia and India, but it is also essential not to jeopardize the privacy of the inhabitants, especially in the Muslim households. Thus these screens not only fulfill the demands of the *hijab* concept wholly, but also provide other benefits such as opportunities for observation of the exterior environment from within and for cross-ventilation. In Muslim households in India, these pierced walls or openings were treated more as an enclosure, offering privacy and security to fulfil Islamic religious dicta, but Hindu homes also adapted this device for the same purpose. However; in India, the use of *jāli* is not restricted to covering windows, it also covers doors, verandas, balconies and are utilized to separate interiors in Indian architecture since they were introduced by the Mughals. Besides the windows and room dividers, these pierced screens are used extensively in Indian architecture around the thrones, platforms, terraces and balconies.

1.2 Etymology: *Roshān* and *Jāli*

In majority of the references; the term *roshan* is used, whereas the term *roshān* is found in some Arabic dictionaries and used locally in Makkah and the Hijāz region of Saudi Arabia until today. Sources vary in their explanation of the origin of the term and its root meaning. A Farsi (Persian) origin is supported by the Farsi dictionary, which includes the word *roshan* under *roshandān*. *Roshan* means 'illuminating', 'shining', 'clear', 'evident', 'vivid', 'a place that shines with light' and *roshān* has similar meanings. It is also suggested that *roshan* derives from *rauzana* and means a small window in the sense of 'light', or a shelf or balcony [6: p. 54]. The translation of the Hindi term is written as *raushan*, *roshan*, *adj*, whereas *roshan-dān* is a hole for admitting light or a skylight. However, the reference also highlights two other interesting aspects: the first is that of the Persian term *roshanā*, means light, splendor. The second is that of *raushnī* or *roshnī* and it means light, brightness, splendor; illumination or clearness (of vision), sight (of the eye); a lamp kept burning at a Moḥammadan tomb or shrine [24, p. 0606].

Arabic dictionaries suggest that *roshan* or *rashan*, under the root *r-sh-n* 'ر-ش-ن' or *r-w-sh* 'ر-و-ش', has the sense of a small window, *roshan* the sense of a shelf, and also *roshan* or *roshān* is a Persian word [3: 228, 6: 315]. Furthermore, in a comment on the root *r-sh-n* or the term *roshan*, Arabic dictionaries maintain that the Arabic verb *rashan* has the sense of stretching out the neck, as in 'the dog *rashan*', that is to say, it puts its head into something, the action of extending the neck, or craning the neck. Also from the root *r-sh-n* comes the adjective '*rāshin*-راشن' that is described as 'established man' but can also be applied to an intrusive person. The linguist Muhammad Labib Al-Batnūnī mentions that the people of Makkah used many Turkish and Persian words, such as *roshan* for 'window' [2, p. 43]. In fact, the word *roshan* or *roshān* was absorbed into Arabic long ago [4: p. 55].

The term *roshān* is still in use in Sawākin in Sudan and Rashīd and Quseir in Egypt. These cities are on the Red Sea and on the route of the Hajj. Trading plays a significant role in the movement of the *rawāshin* across the Islamic world. The popularity of the term among craftsmen goes back to this area, as the makers of these *rawāshīns* were from Bukhara who lived and settled in Jeddah for several generations [27, 132]. Persian

trade with Jeddah as a significant harbour in the region is so old, where some wealthy Persian merchant families abandoned Siraf, on the Gulf, and migrated to Jeddah in the tenth century. It happened when Fatimid-ruled Cairo eclipsed Abbasid Baghdad, and the Indian traders followed the shift in regional power from the Gulf to the Red Sea [14: 13]. Thus it is clear that most of the sources support the Farsi (Persian) origin of the word, though they differ over its root meaning. This is the most convincing opinion, and is supported by the fact that Persian culture is strong and ancient and had a linguistic influence on neighbouring cultures. In fact, the presence of the Persian word was even earlier than Islam [21: 34–41], especially in the area of the Hijāz – and Makkah in particular – because of the two Pre-Islamic trade journeys in the winter and summer [27: 273–283]. These trade journeys were to Yemen in the winter and the region of *Al-Shām* (Syria and the north of Arabia) in the summer to exchange trade with the silk route.

A *jāli* is an architectural device, a perforated screen of stone, wood, brick or other material that protects the interior of a building from direct sunlight while allowing an essential cooling breeze to enter. *Jāli* confers a measure of security; to deter thieves, as the openings are never larger than the size of a fist [13: 470]. McGregor defines the term *Jālī* (*jālikā*) is defined as network, netting, crisscross; a net muzzle. A material of open weave: muslin, gauze; lace, a lattice, trellis, grating; or a screen. [p. 370]. *Jāl* (*Jāal*) is a Hindi term that means a net, a lattice grating; lattice window, and a network, mesh or a web. Whereas *Jāla-dār* (Persian adj.), means consisting of mesh, network; a cloth or garment having network embroidery. Another dictionary defines *jālī* as a Hindi term for network; a net (for holding grass, straw); an ox-muzzle; a lattice; a grating; trelliswork, lace, bobbinet; the integument in which a foetus is enveloped; a coil; the pellicle or coating of a fruit-seed as that of mango. [24: 0372]. The first dictionary highlights the link between the netting, lattice and the embroidery of the garment in the Persian adjective '*Jāla-dār*' that could be linked to the analysis of the *roshān* and the *hijāb*. In other sense, enveloping and protection is tangible, such as the coat of the fruit seed and the ox-muzzle device to prevent the animal from opening its mouth. The description of lace and trelliswork is another dimension that gives an exact definition of the nature of this device in the notion of concealment and protection. However, the link, of the *jāli* as a screen in architecture and the notion of protection and the cover as a garment is not direct in this sense. Dictionary of Islamic Architecture defines *jālī* as an Indian term for a perforated stone screen, usually with an ornamental pattern [25: 131]. According to Gunther, *jālī* is also a stone lattice or pierced screen or a perforated marble screen with an ornamental design [11, 220]. One reference claims that *jālī* is a Sanskrit term for lattice work or netting.

The exchanging of vocabularies between Arabic and Hindi is old and interwoven, due to the trade between Middle East and India through the Indian Ocean since the Pre-Islamic time. The Indian ports were often visited by Arab ships, and the Arabs reported to have established colonies in Ceylon (Sri Lanka), Malabar and the Karomandal coast of India as early as the mid-seventh century [22: 32].

1.3 Historical Background of The *Roshān* and *Jālī*

The word *roshan* or *roshān* in Arabic was used in the context of building and construction and was known to mean a wooden structure that projected from the wall of a house into the street without touching any other opposite wall. If it was supported from the street side by pillars, it was known as *jīnāh* and, if not, as *roshan*. It is also referred to by religious scholars in the 1500s in building and planning when it comes to how to define the *roshan*. The four *madhāhib* [1] came into existence in the period between the Umayyads [2] and the Abbasids [3]. (Murahhem, 60). This precision in the legal definitions by the traditionalists of the 'Four Schools of Law' enable us to deduce that the *roshan* or *roshān* has been used for a long time in construction and building across the Islamic World. This is evidenced from the term's universal use, insofar as all four schools of law had a clear understanding of the definition and meaning of *roshan* and, even if it acquired a variety of forms and descriptions from one area to another, its origin and definition are basically one. Similarly, each of the well-known law schools had their own area of influence in the Islamic world. The fact is that some areas continued to use the term until recent times, which may indicate that it was a well-known and well used term in the Islamic world.

Jālī became a significant feature in Indian architecture after the impact of the *Mughal* Empire so it is beneficial to highlight the historical background of this feature in this part of the Islamic world. Baker [4] points out, that *jālī* is one of the very early features of Indian structural design. These screens were familiar to the master-builders of the 'Mohammedan's India' says Bunt who notes that it latter developed notably at Ahmedabad into an art as exquisite, as it was wonderful [p.14 – 15]. Finely carved examples of *jālī* appear in the houses among specific Muslim families, mosques, tombs and other building types of Gujarat and in the South, in the curved wood balconies of the houses and Hindu temples. [13: 470]. In fact, there is no evidence that proves

that *jāli* is not an Islamic feature introduced to Indian architecture. The development of Indo-Islamic culture began with the arrival of Arab armies in Sind in the years 711–712. The first phase of conquest absorbed the area roughly corresponding to Pakistan, where Arabic was the court language and Baghdad and Damascus were the mine-springs of culture and commercial life. Arab communities settled at important centres along the major trade routes to China and in the principal ports along the coast as far as the Bay of Bengal. [16: 454].

Over the course of several centuries, Islamic architecture transformed North Indian architecture. Islamic decorative traditions in carved and pierced stone—often inlaid with mirrors or coloured glass – and delicate miniature paintings were not only embraced by Indian craftsmen but developed into even more elaborate and detailed design. [30: 42]. The principle of transferring textile designs into the techniques of architectural ornamentation was a regular feature of the Mughal architecture, as it is more or less universal in the Islamic world. Certain sculpted stone grills decorating the windows of Lahore Fort resemble embroidered veil [11: 209]. Screens are customarily used in tombs to give shade while admitting air. In fact, the relation to *hūrma*, a concept that implies holiness, sacredness and respect in tombs is high in Islam. Therefore *jāli*; as a feature being used in tombs, was introduced by the Mughal's to the architecture of the Indian subcontinent to preserve *hūrma*. It was also used widely in houses or mausoleums alike in Muslims and non-Muslim buildings. Muslim architecture in the North-Western regions of the subcontinent: Sind, Multan, Punjab and the North West Frontier, had developed it as an extension of the Turko-Persian cultures to the West [22: 32, 38]. Dhameja also claimed that the technique of applying timber-bonding to brickwork or stone, as in Gujarat, was widely prevalent in ancient Syria and Anatolia as far back as 2300 BC. (P. 101).

1.4 The Construction Materials and Techniques of the *Roshān* and *Jāli*

In Saudi Arabia, the *rawāshīns* are placed in the protruding sides of the ground-floor door posts and form a kind of enclosed balcony, projecting out about 71 cm and screened by rows of woven shutters that can be raised and lowered. The *roshān* is made up of a group of large wooden apertures, projecting out of the sides of the buildings and are made of teak. It is built upon a wooden frame projecting out from the wall which is fitted onto the openings after being assembled and decorated as required. The wood may be left in its natural color, or it may be painted or sometimes dyed. In this, it resembles the *rawāshīn* of the region of Hījāz, such as Al-Tā'if, Al-Madina, Yanbu and some cities in the northern stretch of the Hījāz coastline.

The traditional *roshān* is assembled from identical parts and units known locally, so that the side panels of the *roshān* have one standard height, which also applies to the front panel with slight variations, not in the construction, but in small details. The variation may occur as a result of the joints between one panel and another and in order to achieve a satisfactory general appearance of the *roshān* as a whole, 'with the proviso that generally the width of the side panel should be equal to the distance between the uprights that divide the panels of the *roshān*'. The interior division of the upright panel also has to be appropriately coordinated. The *roshān* is divided into a number of upright sections so that the horizontal aspect of the *roshān* should be symmetrical, while its vertical aspect need not be symmetrical because of the variations in the component parts and their use. Thus, if the *roshāns* were made up of a vertical unit (X) which is repeated, we would find that the unit (X) would be a unit of, 50–70 cm and the *roshān* would then be made up of several **units [Figure 4]**.

The internal divisions of the unit can be considered as horizontal units connected in sequence from bottom to top. If the standard upright unit is 'X', on the inside it would be bottom X, upper X and middle X considered as separate parts. Consequently, the inside of the standard upright unit would be a unit with a horizontal measurement repeated for each of the (X) sections. There are also additional trimmings and extras to join the parts of the traditional *roshān* as a whole into one fixture. Then the various decorative and imaginative items appear inside each unit and its parts, in the plain and empty areas and the hollowed out and projecting parts

In India, the construction techniques of *jāli* varied from region to region depending on the availability of construction materials. In the northern and north-western part of India, stone *jālis* dominated [Figure 5]; however, Ganapathy notes that the stone lattices were later replaced by iron rods and thick timber lattices [p. 470]. Wood prevailed in the Southern part of the country. Surprisingly; despite the shortage of wood in Gujarat, majority of the residential *jāli* work utilized wood, as the wealthy merchants preferred it. [Figure 6]. Wooden interlocked screens and iron interlocked *jālis* as grills were specific innovations using the materials and technology available during the medieval period in Gujarat. [10: 34]. Brick and Bamboo was also used, however, the use of Bamboo was limited to tribal areas and in the North-East region of the country.

The motifs and patterns used in *jālis* differed between communities and disclosed religious identities of the residents: figural carvings were absent in Muslim residences as Islam discourages it, while Hindu households celebrated it. Parrots, peacocks and many other motifs were common occurrences in Hindu *jālis*. Chauhan and Bose also note that there was lesser affinity towards geometric patterns even in the Muslim residences (in Ahmedabad), possibly because the craftsmen and their skills preferences did not vary between communities. [p. 34]. The *jāli* materials also indicated the social status of the occupants: in palaces; stone was extensively used, while the population of the upper and middle class of the society utilized wood. Material selection also depended on the urban vs rural areas: urban residential dwellings utilized wood, stone, brick and iron whereas mud and bamboo were the two main materials used in rural areas of India.

Like the *roshāns in Makkah*, Saudi Arabia, the wooden *jālis* in the state of Gujarat in India, were carved from Teak or Sisam wood. But the similarity of these two forms stops there. Their proportion, scale and construction techniques depended on the function and location of these *jālis* within the doors, windows or balconies. For example, the *jālis* were predominantly used on the first and second floor windows, doors and balconies in Gujarati homes and utilized wood and iron grills as a combination at times. In *poles* (inner city neighbourhoods) of Ahmedabad, the first floor window size sometimes matched the size of the doors. The window frames were made of wood, while the full-length iron grills served as the perforated screens to provide protection, and ventilation. The wooden shutters were attached on the exterior side of the *frame*, giving the residents an ability to completely shun the sun and keep the heat at bay in the afternoon.

Chauhan & Bose observe that along the facade, the windows began from the floor level while the outwardly inclined balustrade was often in solid wood and (were) richly carved externally but plain towards the interior.....Windows were also divided into three parts, with the upper portion functionally serving as a ventilator whereas the lower two parts were operable depending on the seating height of the user. (P. 34). The upper floor windows were sometimes divided in two parts, the bottom part of the window may repeat the same iron grill work as the first floor *jāli*, while the upper half of the window did not have any incision, and was left open to allow air-circulation in the room. Again, the exterior window shutters provided much needed respite from the harsh sun. Chauhan & Bose indicated that the brick walls on the upper floors gave way to thin partitions of half-timbering while the carvings became sparse. (P. 32). The *raveshis* or *zharookhas* (balconies) seen in many *havelis* (mansions) of Gujarat can be compared with the *rawāshīns* of Saudi Arabia, as they too protrude in the street from the first floor, and use wooden *jālis* as carved infill panels and bands along the sill and lintel levels. *Jālis* were also used for the railing of the staircases and parapet walls and utilized the same construction techniques.

Unlike Saudi Arabian *roshān*, the stone *jālis* of northern and north-western India were finely carved either from a large sheet of fine marble or other stones; or made of various small stone blocks. Generally small, square stone blocks of the same size was carved first, and these blocks were assembled together using stone ties on site. The number of the blocks utilized in the *jāli* depended on the desired length and width of the *device* [Figure 7]. *Havelis* (mansions) of Rajasthan located in the North-West part of India are famous, world over for their stone carved *zharookhas* (balconies) Like the *rawāshīns* of Saudi Arabia, the *zharookhas* protrude out in the streets; but utilize stone carved *jālis* to provide privacy and protection for the residents. Jain & Jain observe that stone *zharookhas* are pre-carved with a very sophisticated and predetermined assembly system. It is structured on the facade with the use of geometric articulation along with the other elements. The whole external facade of the *zharookha* is articulated and decorated using finely carved stone *jālis*. The size is beautifully related to the human scale. This can be well appreciated by the fact that the size of a *zharookha* does not change much as the size of a house changes from a small one to a large *haveli*. (P.165) This space gets integrated with the interior space and becomes an extension of it - serving as furniture, for seating or in some cases, sleeping.

In some parts of Gujarat and Rajasthan even mud structures imitated the *jāli* by introducing small perforated enclosures. Because of the characteristic structural weakness, the openings in the mud dwellings remain small, but the exterior facades are adorned with painted decorations. However, it should be noted that despite the impact of neighbouring Islamic regions, such as Iran, Afghanistan and Turkistan (Asia minor), on the Mughal architecture, some materials cannot be found in India, this shows that there are limitations when attempting to imitate a neighbour's architecture. For instance, neighbours' architecture rely on bricks and mud bricks, with plenty of glazed tiles and faience mosaic for ornamentation, while India at the time used stone as a main building material. What is possible in stone may not suit bricks and mud-bricks: as a result, the Islamic architecture in India is similar to the far regions of the Islamic world, such as Syria, Egypt and Anatolia. They

rely more on stone, plaster and marble as materials and on piercing and inlaying as techniques, but Indian examples are more elaborate. This is why various materials apart from wood that is commonly known in the Arab world were used in India for *jali* construction.

1.5 The Roshān and Jāli Within the Interiors

Since ancient times, the traditional *roshāns* and *jālis* fulfilled various desirable aims and purposes because of its strength (of construction) and its continuity over many centuries with its wooden and stone tracery. From a practical point of view, the *roshān* is a window that looks out on the outside world with a screen veiling the light of the strongly blazing sun. While *jāli* is a perforated screen that can be inserted in windows [Figure 8], doors [Figure 9], railings, parapet wall [Figure 10], or can be used as screen walls/partitions to divided spaces and provide privacy. Both serve as a basic part of the building's air conditioning and ventilation system and can serve as the furnishing of the home. In some cases it is even an extension to some of the upper level rooms as seen in *rawāshīns* of Saudi Arabia [Figure 11] or *raveshis and zahrookhas* of Gujarat and Rajasthan. The *roshāns and jālis* benefit the interiors in achieving: 1) Islamic rules and social norms; 2) Flexibility of air-flow and circulation within the interior, 3) Control of a desirable temperature and light, 4) Providing more room within the interior.

1.5.1. How the Roshān and Jāli Assist in Achieving Islamic Rules and Social Norms:

A comparative study of *roshāns and rawāshīns* of Saudi Arabia and *zahrookhas* of Rajasthan here will provide clear understanding of how these devices facilitate the above mentioned benefits. Both provide a privacy feature that protects the residents from the gaze of passers-by in the street while giving them the opportunity to follow what is happening outside without allowing passers-by to see inside the house, either via small openings between the units of turned wood *rawāshīn*, or through the narrow gaps and the openings in the geometrical designs of the *roshāns and jālis*. The fact that it is darker inside than outside also helps to achieve this aim. It also gives a woman in her private apartment inside the house ability to see life going on in the street outside without being seen, so that both these *devices* provide an advantage to her. If she wants to look outside through the shutters or *rawāshīn* or through the perforated stone panels of *jāli*, she can see without being seen. This is achieved by controlling the field of vision through the louvers when the screens are closed is about 90 degrees. By moving the louvers up or down, this device provides great flexibility to the field of vision. The louvers at the same time break the line of vision and prevent whoever is inside from being seen. The *roshān and jāli* allows the residents of the house to use their senses (hearing, sight and smell) to find out which activities and interactions and local events are taking place around the house simply and easily and without impediment. Tillotson states that *jāli* appears in *the zenana* (women's quarters), where the condition of *pardah / hijāb (vail)* dictated the presence of *jāli* or screens across the windows. These are finely-carved stone lattices through which the residents of the *zenana* could glimpse into the outside world or events in the courtyard of the palace without being seen. [31: 5]. Such analysis reflects an association between these screens and women's quarters in the Islamic house. In brief, the existence of the *jāli* alongside with women's section demonstrates the impact of Islam on the architecture of the region through the impact of the *Mughal* Empire. Thus, both these devices protect the inhabitants of the house from outside intrusion and adheres to the religious requirement of modesty, privacy and protection for the women dictated by Islam and also meets the societal needs for gender segregation in these parts of the world.

1.5.2 How Roshān and Jāli Provide Flexibility of Air-Circulation and Flow Within the Interior

The *rawāshīns* are spread out as box-like units projecting into spaces outside, staggered both horizontally and vertically so that they cast their shadows on the façade of the building. These extensions increase with height, so they act as shades for the spaces outside and the lanes around the building. The airflow in the interior spaces is governed by the openings and apertures in the various kinds of *rawāshīn*, as well as the *shīsh* – where it exists – in such a way that these parts act as layers of filters for both the air and the dust. The openings in the *roshān and jāli* also allow the air to enter and be sucked into the interior, thereby reaching the various parts of the house. The broad exposed area of the *roshān and jāli*, with the shade in the upper end, makes the air move very slowly as it enters so that it carries little dust. In openings where sliding panels with louvers are used, the flow and amount of air is controlled because the variations in the way the louvers can be moved makes it easy to govern the direction in which the air flows downwards into the room or upwards, as the resident wishes. Similarly, the amount of air can be controlled by opening the appropriate number of louvers in the sliding shutter; and each shutter can be considered a separate unit that can be controlled independently. This is not possible with *jāli*, as the construction of it is very different. However, the finely carved stone or wooden panels in fully covered *zahrookhas* fulfil the need for air and dust control. When the air enters the inner space, the alcove of the *roshān and zahrookha* creates an area where air can

be transferred or distributed. That is, taking the air in from the outside to distribute it inside across the adjacent area in which one sits. Therefore the air, after being purified and filtered through the previous layers, reaches this area, which is the coolest area in the inner space because it is hollowed out in the wall, the surrounding walls are very thick and the breeze comes in through the openings in the *roshān* or *zahrookha*. This constant entry of the outside air currents and their speed forces a quantity of air inwards and into the inner space as a whole. The direction of the flow makes it easy for the air to enter but difficult for it to get out, which keeps the inner space cool. This is a special benefit because the air circulates round this area and may collide if there are internal currents caused, for example, by a door which helps to cool the area further. Also, the force of the air current coming from outside is not matched by any internal current, and so the airflow is concentrated within.

1.5.3 How the *Roshāns* and *Jālis* Assist in Controlling Temperature and Light:

Wood as a natural insulator prevents the burning rays of the sun reaching the building, except via the walls or through the openings and apertures. The staggered or regular projection of the *rawāshīns* and *zahrookhas* throw shadow onto the façade of the building and thereby limit the penetration of direct sunlight and the rays of the sun reflected from the surfaces facing it. This helps the building to withstand heat from the outside, especially if the surfaces of the buildings facing each other are similar so that the two façades absorb the heat and insulate the area from the heat. The bases of the *rawāshīn* and *zahrookhas* with *jāli panels* are designed to attract shade onto the building to keep the temperature down within the interiors. The other parts of the *roshān* and *zahrookhas* and its decorative extensions and trimmings also contribute to creating shadows and breaking the concentration of the direct rays of the sun, which are dispersed by striking these angles, cavities and irregular surfaces. At night, the interior temperature remain comfortable because the cool air penetrates side from the *roshāns* and perforated panels of the *zahrookhas*, but the thick walls of the traditional houses that retained heat during the daytime, release it slowly. This phenomena can also be observed in the lower areas of the buildings that manage to retain their coolness through their proximity to the lower empty spaces which are comparatively cool because they are not greatly exposed to the sun's rays relative to the spaces on the upper floors.

The *rawāshīn* and *jālis* act not only as air filters but also as light filters since they regulate the entry of light and brightness into the interior spaces and solve the problem of glare. This is even more controlled within the interior space if there are supplementary lattice screens and *shīsh* in front of the shutter. In spite of the great quantity of woodwork in the *rawāshīn* or stone or wood work in *zahrookhas* that extends outside, the amount of light that penetrates into the interior may be considered to be under control because the various parts of these *devices* are sufficient to limit the strong natural light penetrating into the interior and so protect the residents from the problem of glare. If the shutters have louvers, the strong summer sun can create glare when the *roshān* is fully open. Therefore, the louvers are used to limit the glare so that the contrast between light and shade is acceptable and not a strain on the naked eye. During the day, the reflection of *jāli* patterns moving across the floor would double the pleasure because of their intricate geometry. [6]. Such a scene reflects the same benefits of the *rawāshīn* and the beauty of the interiors which demonstrates the dramatic view of the game of light and shadow from within.

1.5.4 How the *Roshān* and *Jāli* Provide More Room within the Interior and Change the Environment

It seems that the purpose in building *rawāshīn* and *ravashi* and *zahrookhas* is also to increase the floor area of the upper storeys and thereby expanding the size of the room. This affects the general size and form of the interior space. The extension outwards may be of balanced proportions, or it may be more one side than the other and this has an effect, both inside and outside. From inside, this extra area has a liberating effect as it makes it possible to accommodate many domestic activities, such as eating, sitting and even sleeping. . [Figure 12].

1.6 How 21st Century Architects and Designers can adapt the Concept of *Roshān* and *Jāli*?

“Less is more” is not just a slogan, but a necessity today because of the environmental, economical and social challenges we face today, these includes the energy conservation to sustainability of the planet. Besides these major environmental challenges, we also have to deal with form and function of the buildings, and social, cultural, religious and climatic needs of our clients. The proper understanding and adaption of the concept of the *roshān* and *jāli* can assist the 21st century architects and designers in fulfilling all of the above needs. The authors do not promote the blind imitation of these architectural devices, nor expect the designers to adapt the traditional decorative motifs and patterns in their design. But a new interpretation and articulation strategy may prove to be the most effective sustainable solution for some of the issues outlined above. For

example, the buildings in the hot climatic zone in the Western hemisphere can benefit from introduction of these devices. In the past Architects like Hasan Fathi and Laurie Baker . [Figure 13], and the contemporary architects like B. V. Doshi [Figer 14] and Charles Correa have successfully adapted these devices in their design. Mr. Baker actually adapted the concept of *jāli* in his brick buildings, where his beautifully designed perforated brick walls served the same function of the *jāli*. Mr. Correa and Doshi have mastered the play of light, shade and shadow in their buildings through the interpretation of this age old concept. For the artistically inclined, the new technology can provide a furtive ground for exploration and experimentation: may that be through the software calculations for heat loss and gain, air conditioning and light control and design of a new system based on this model, or make their dreams come true of achieving artistry of the past in their new fenestration design through CNC fabrication. CNC also provides the ability to customization achieve precision. A careful understanding of this concept and execution of it in the planning and design process from the beginning can truly be beneficial in developing 21st century sustainable solutions.

1.7 Conclusions

It is clear that the appearance of the *roshān* and *jāli* do matter, but this beauty is not just skin deep: these devices have a number of qualities: 1). it provides unifying character that gives an aesthetic touch and a particular beauty to exterior and interior facades of the houses and thereby provide distinctive character to the particular neighbourhood. 2) Although the design of the *rawāshīn* and *jāli panels of the zahrookhas* differ from building to building; they all exude the same spirit and concept giving the urban environment its unity and identical character. 3). The materials used in making these *devices* aid in the creation of a particular kind of beauty, unity and harmony. The strength and durability of wood, stone or iron grills and its adaptability to decoration plays a decisive part in the external character of the *roshān*, and *jāli*. The use of any material over large surfaces creates unity and harmony despite wide variations in measurements and details and decorations. 4). The general distribution of the *rawāshīn* or *jāli panels* and the artistry of their component parts naturally vary in kind and extent according to the means and taste of the owner. The amount of decoration, the richness of the patterns together with the exotic style of *these devices* their size, the kind of carving and embellishment used – the general appearance of the house, including doors, windows and façades – reflect the economic and social class of the owners. 5). Besides the embellishments, these devices are designed to provide: privacy and protection for the residents *and thereby* reflect the main point of the Islamic architecture, where the unity is reflected in the function and the role of screening and a means of *hijab* in achieving privacy. 6). Serve as a great example for the 21st century sustainable solutions for passive cooling as well as light control.

Architecture, Ruins and the Landscape

Anelinda DI MUZIO¹

⁽¹⁾ Facoltà di Architettura, Sapienza Università di Roma, Italy
dimuzio.arc@libero.it

Abstract

Due to its inherent articulation of space architecture develops a tie with the landscape in which it is inserted. Particularly delicate is the construction of a new work of architecture within an archaeological context, within which it is called upon to resolve a twofold connection: with ruins that, in general, have lost their original form, and with the surrounding environment. Often these ruins are also inseparably tied to the environment, producing an 'aesthetic of return', considered to possess a value of its own to be conserved and conveyed. It is thus inevitable that those called upon to design in such a context must consider this tie and seek to maintain the aura of the ruin and the surrounding landscape. Is it then perhaps best to build less and leave more space to that which already exists? Or is it possible to create new works of architecture that dialogue with ruins, egregiously inserted within the landscape through accurate formal choices, the selection of materials, the use of colour, through the search for architectural quality? A quality that is now measured also based on the use of materials and systems according to criteria of sustainability and renewability. The text will critically analyse both national and international realisations within which an informed design, based on the understanding of the specific values of a given site, ensures the conservation of archaeological structures in addition to respecting and safeguarding the landscape.

Keywords: ruins, architecture, landscape, eco-sustainability

1. Premise

The insertion of a new work of architecture within an archaeological context is a highly delicate and difficult operation. In fact, excavated archaeological sites are located in diverse contexts that, to varying degrees, may constitute the elements of an aesthetic 'of return' resulting from the relationship between a ruin and its surroundings.

At the level of perception, the structures revealed through archaeological excavation can be considered mutilated elements that we are able to mentally reconfigure as complete forms only with difficulty. The mutilated work exists to a greater degree in symbiosis with its context, a symbiosis both perceived and appreciated by observers. In the context of a natural landscape, where natural forms develop in turn around the ruin, but also in the urban environment, where the excavation naturally assumes its own identity in relation to its built surroundings. Hence the value of the concept that nothing is more fascinating than the ruin that remains untouched [Carmassi 2006, p. 69], though new architecture, which may often be required for reasons of conservation and/or to proceed with the musealisation of a site, must be correctly verified in relation to the twofold presence of the ruin, and the context in which it exists.

This is often not the case, and there are many examples of self-referential works of architecture, entirely detached from the existing ruin and the context of its surroundings. They are mere architectural exercises that, however, more or less consciously cause significant damage to the archaeological site, irremediably violating the aura that connotes it and renders it unique and unrepeatable.

2. Relationships between Architecture and Ruins

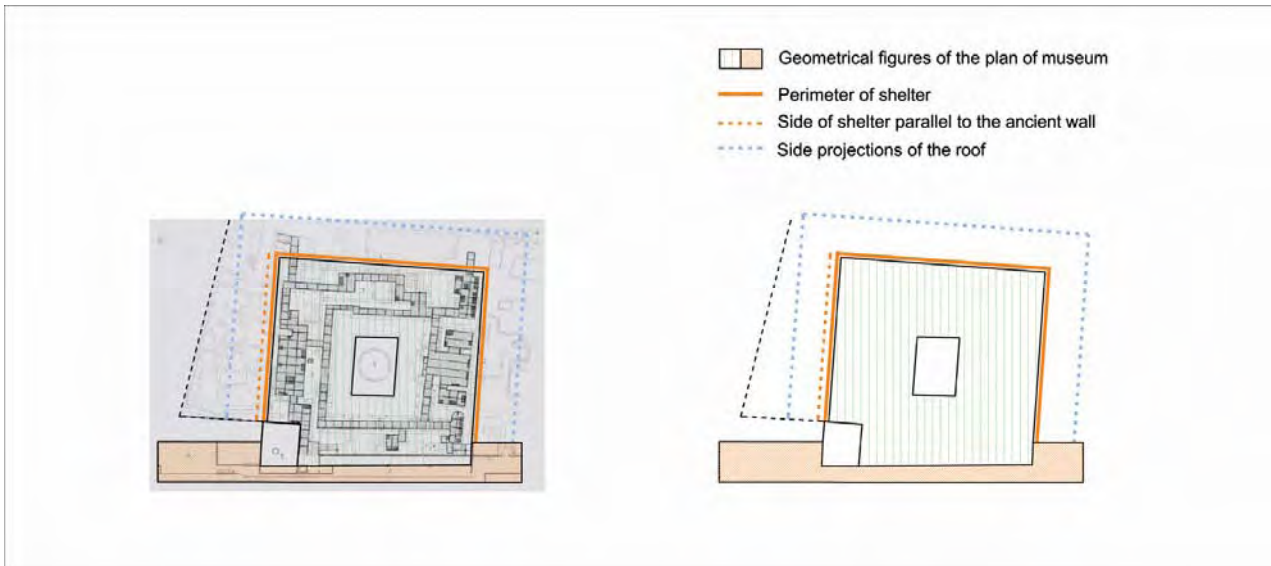

Fig. 1: Périgueux, *domus* de Vésone, diagrams relative to the articulation of the new architectural elements in plan.

New architecture realised in an archaeological context, when configured as a protective structure, constitutes a sort of preventive restoration designed to conserve and transmit the ruins of the past to the future, but also to valorise and render them accessible. The primarily conservative aspects that the covering structure must ensure thus become fundamental, though we must not under evaluate the role played by architecture in the relationship between 'old and new', inevitably created by the new addition.

This new element may relate in a variety of ways with the pre-existing elements, presenting itself in assonance or in sharp dissonance or opposition. These relationships may involve the articulation in plan or in elevation, the structure, the presence, or lack thereof, of paths providing access: all elements and parts of a new work of architecture that inevitably dialogue with the pre-existing elements, placed alongside or atop them.

One example is to be found in the *domus* de Vésone (Périgueux, France) (constructed some time in the mid-first century AD, as proven by the wall paintings discovered here; in the mid-second century the house was buried beneath a meter of earth and reworked to a consistent degree. Thus, the excavations allow for the identification of the first and second *domus*, and the various phases of its history) protected by a structure designed by the architect Jean Nouvel. Throughout the various phases of its construction the *domus* is characterised by the presence of a central garden, around which the spaces of the home are articulated. The centre of the structure features a circular artificial pool, with two peristyles to the north (Fig. 2) (the discovery of the wall paintings led to the site being classified a historic monument in 1963; an architectural competition was held to design a project to protect the ruins, manage public access and create a museum dedicated to the ancient city). The plan of the new construction is defined by an irregular parallelogram, almost a rectangle, at whose centre lies the architectural element of the peristyle (Fig. 1).

Of the four sides of the new geometric figure, seen in plan, only one runs parallel to the ancient wall of the *domus*, while the other three, orthogonal to one another, are rotated by a few degrees: the result is a geometric figure that orderly embraces a consistent portion of the ruins of the *domus*, while another portion of the excavations lies outside the internal space, though adjacent to it and sheltered by the projections of the new roof (Fig. 1).

The functional spaces of the museum are located along one side of this figure, inside a more regular geometric element: the reception hall, the patio and the *lapidarium*.

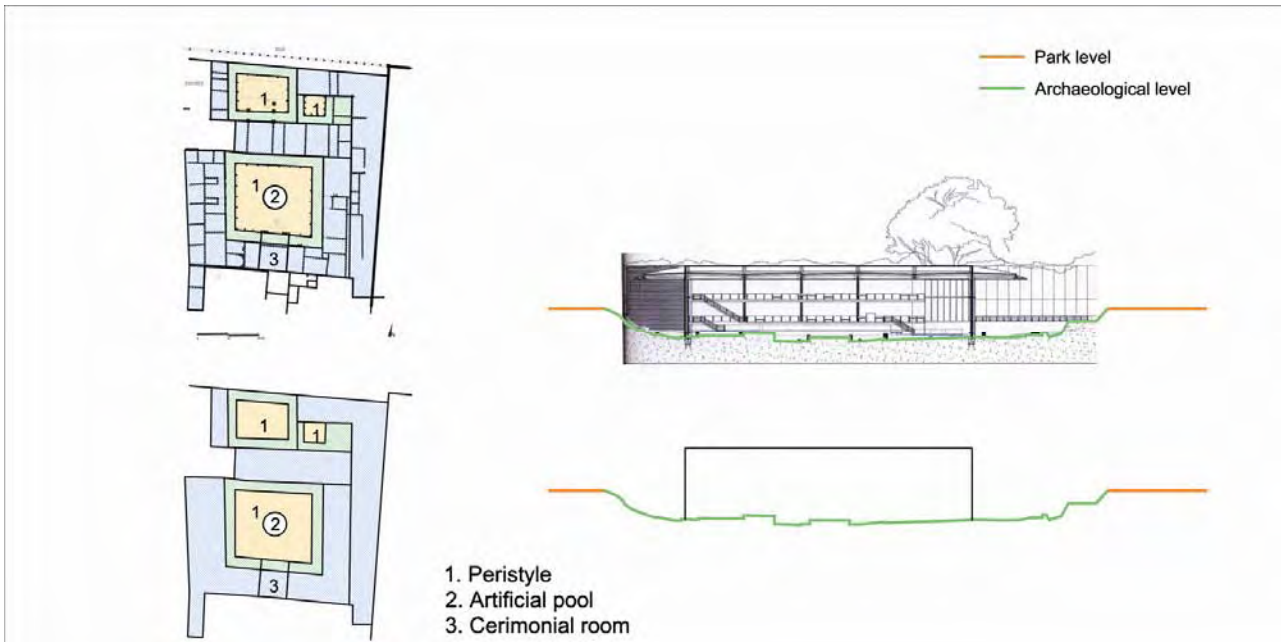

Fig. 2: Périgueux, *domus* de Vésone, diagrams for a reading the ancient structure and the elevation of the new museum.

The three-dimensionality of the new construction, while not conditioned by nearby buildings, tends to privilege the horizontality of the plan, which tracks that of the *domus*, over the vertical of the elevation: this is partially due to the position of the archaeological site, set lower than the park surrounding it (Fig. 2).

The design of the structures of these new work of architecture can also be considered in relation to the existing; for example, precisely for the *domus* de Vésone the decision was made to ensure that the ruins remained the unique protagonists of the covered space; an objective achieved by placing the vertical steel elements of the structure along the perimeter, in correspondance with the mullions of the glass curtain wall, while the large beams of the roof are concealed in a false ceiling on the interior, visible only on the exterior as components of the underside of the roof structure. The structure of the Gallo-Roman Museum is realised in exposed reinforced concrete columns and beams; it houses the *lapidarium*, directly linked to the archaeological area (Fig. 3).

Fig. 3: Périgueux, *domus* de Vésone, diagrams of the structure and the paths inside the new protective structure.

This work of architecture features transparent perimeter walls wrapping the *domus* and creating a visual permeability between interior and exterior. It is often the case that works of architecture constructed atop

existing ruins, created not only to conserve these ancient structures, but also to favour their fruition, require the insertion of walkways. In the case of the *domus* de Vésone they surround the court-garden of the *domus*, allowing for a reading of this ancient architectural space in its correct configuration and function. Other walkways branch off from this central route in rings, allowing the public to visit the spaces surrounding the court. In the majority of cases these platforms assume the geometric plan of the space into which they are inserted (Fig. 3).

A very different example is that of the roof structure constructed atop the *domus* of *Fregellae* (Ceprano-Frosinone) (the ancient city of *Fregellae* was founded by the Romans in 328 BC and the various *domus* are from diverse phases that can be dated from the end of the 4th century to the early 2nd century BC). These structures are rectangular in plan and, while sharing a party wall, are set orthogonally to the *Decumanus Maximus*; in this manner the *domus* and the baths are perceived as a single entity (Fig. 4). The new structure not only re-proposes the rectangular plan of the *domus*, but also the parallelism with the edge of the excavations; the orthogonal relationships with the *Decumanus* are programmatically maintained by the new structure, which represents a co-extension of the ancient architecture (Fig. 4). With regards, instead, to the three-dimensional nature of the composition, the pavilions were designed to evoke the ancient urban structure by suggesting the heights of the original volumes, as a consequence also re-creating the principal element they overlooked: the street. This is a portion of the *Decumanus I* reconfigured as the main route when visiting the site and providing access to the spaces of the Museum. The proportions between the development in plan and the third dimension are the result of a study of the ancient building 'type'. In those cases where the elements necessary to define the heights of the ancient constructions are lacking, as in the baths, the architects opted for a sinuous roofline that constitutes an element of distinction, once again aligned with the axis of the street (Fig. 5).

The structure is comprised of a system of steel columns, with a spacing that appears constant though it is in reality modulated to match the widths of the ancient spaces, set along the longitudinal walls in correspondence with 'void' elements, such as spaces without paving and gardens, in some cases aligned with walls protruding from the excavations. These columns support laminated wood beams that cross the excavations from side to side, in one single bay. It must also be noted that the columns are positioned along the external perimeter of the excavation and at no point do they invade the spaces of the ancient structure (Fig. 6).

Vertical enclosures are present only along the long sides of the *domus*, with the intention of re-evoking the solid nature of the walls that were once shared between two *domus* (Fig. 4).

To ensure the cultural fruition and valorisation of the site, the project also includes proposals for didactic reconstructions, developed in collaboration with the archaeologist, and with the intent of explaining the construction system (from foundations to finishes) by realising a 1:1 scale model of a section through a corner of the one of the spaces.

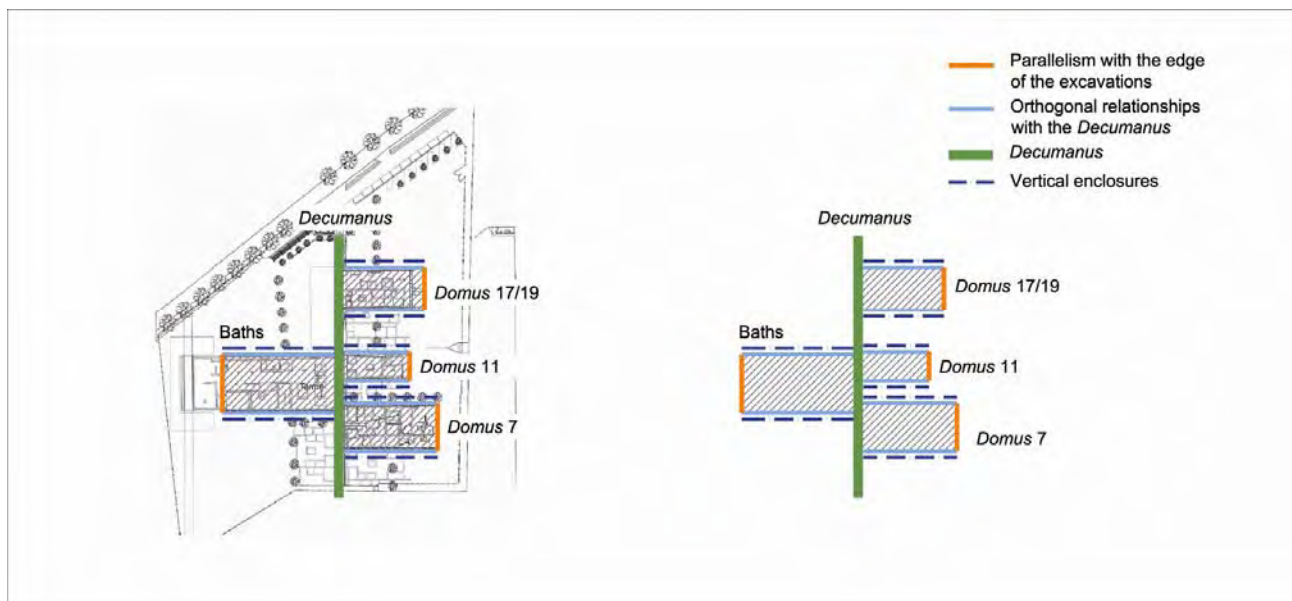

Fig. 4: *Fregellae*, *domus* and baths, plan diagrams of the new structures in relation to the excavated areas.

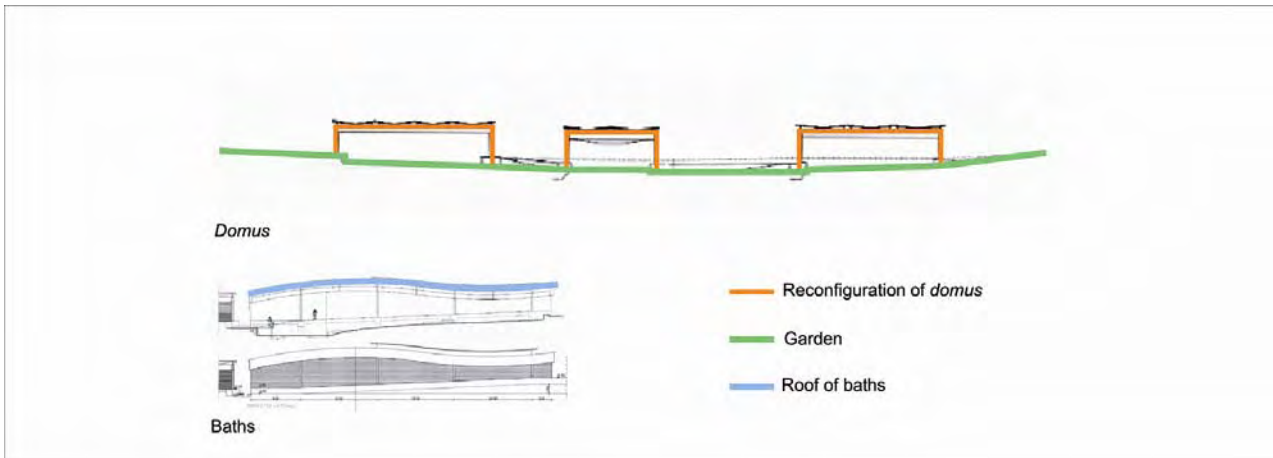

Fig. 5: *Fregellae*, *domus* and baths, elevation diagrams of the new protective structures.

The fruition of this site is also favoured by the creation of paths that develop along the perimeter, together with a central route, realised in steel grating, set parallel, where possible, with the ancient walls, thus consenting a correct vision of the spaces being crossed and offering bearing points in the existing voids between the walls protruding from the excavation (Fig. 6). The architects, furthermore, re-proposed a number of elements of the ancient architecture to recreate an atmosphere otherwise lost: in the *domus* n.11 the atrium was reconstructed together with its roof system, the *compluvium*, with applied pairs of terracotta elements realised based on a study of elements found in situ.

There are other examples in which the articulation of the protecting structure may fulfil a didactic and evocative function. For example, the roof of the *domus* of the *Coiedii* in Suasa (Ancona) is used to suggest the original spatial conditions of the site through the use of different materials: open spaces are covered with transparent skylights while opaque roofing is used above spaces that were once enclosed. There is also the example of Cosenza, where the architectural composition of the roof over the Piazza Toscano site, independent of the archaeology below, communicates the anxiety and drama of the explosion that struck this area.

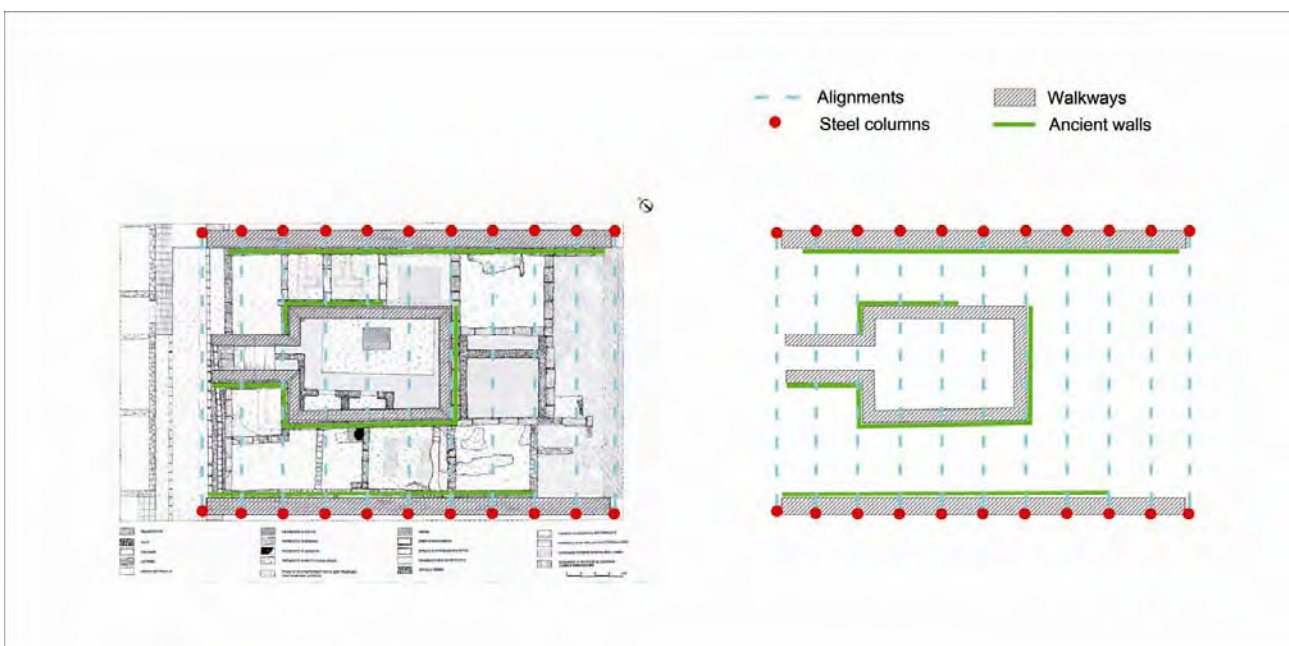

Fig. 6: *Fregellae*, *domus* and baths, diagrams of the structure and the paths of the new work of architecture.

3. Relationships between Architecture and Landscape

Fig. 7, 8: Périgueux, *domus* de Vésone, partial internal and external view of the protective structure.

As mentioned, new works of architecture inevitably create relations with the surrounding landscape. In the case of the *domus* De Vésone a significant level of respect marks the relationship between the protective structure and its surroundings. This new work is egregiously integrated within the park, assisted by the reflections of the landscape in the glass walls wrapping its perimeter (Figs. 7 & 8).

Also in the case of the *domus* and baths in *Fregellae*, the architects chose to pursue a condition of permeability with the landscape, obtained by opening up the short sides of the roof structure (Fig. 9). Furthermore, the materials utilised, wood for the structures and enclosures on the long sides and composite steel roofing panels for the roof, together with the forms, in particular the sinuous structure above the baths, refer to materials present on the site and the conformations of the hills of the surrounding landscape (Fig. 10).

Also in the case of the roof of the *domus* of the Cryptoporticus in Vulci, the form, reminiscent of a sail filled by the wind, recalls the lines of the slightly undulating landscape. Vice versa the roof of the *domus* of the *Coiedii* in Suasa, inserted at the bottom of a sparsely inhabited valley, was designed with a primarily horizontal appearance, in order to ensure the most discrete interference with the surrounding landscape. What is more, the choice to clad the roof in copper, which will oxidise over time, contributes to creating a colouration that adapts to its green natural setting.

In the case of underground discoveries, for example the Tombs at Vergina (Macedonia), the relationship with context is much easier to resolve, given that the level of intervention is far below that of grade. Nonetheless, in this specific case it is interesting to note how the creation of a tumulus above grade, smaller than the original, marks and re-proposes an element of the situation prior to the excavations, laterally absorbing the ramps down to the underground level and resolving the relationship with the surrounding environment in an exemplary manner.

Fig. 9, 10: *Fregellae*, *domus* and baths, the short sides are left open, and the roof of the baths features a sinuous form.

Fig. 11, 12: Brescia, *domus* dell'Ortaglia, view of the main elevation and aerial view of the protective structure connected with the Museum of Santa Giulia [Castagnara Codeluppi 2005, p. 118].

Even the architecture that contains the *domus* of Ortaglia at the Museum of Santa Giulia in Brescia, at least the portion above grade, is largely closed, rendered in some way lighter by the use of colour: the uniform and light grey of Sarnico stone (Fig. 11). Furthermore, seen from above the realisation of the roof garden, whose grass covering melds with the plantings at grade (while the plan of the *domus* traced in stone slabs permits a reading, once again from above, of the relationship with the *viridaria*), resolves the relationship with its surroundings (Fig. 12). The height of the new volume permits an uninterrupted reading of the convent behind, to which the new work of architecture is connected, as an important and emerging element within the urban context.

Also of interest is the protective structure over Piazza Ferrari in Rimini, covering the spaces of the *Domus of the Surgeon*, in the heart of the city. In this case the assonance of the new work of architecture with its context is determined the choice of materials: masonry and glass for the walls (Fig. 13). In particular, the masonry recalls the brick façades of the church of S. Francesco Saverio behind, or the Suffragio, while the glass consents a condition of permeability between interior and exterior. It is interesting to note the method adopted to resolve the relationship with the surrounding gardens in the realisation of a roof, partially covered with a garden; the protective structure becomes an integral part of the square and the plantings that connote it (Fig. 14). Also in the urban environment, as is the case of the roof structure covering the baths of Treviri, the relations with the surrounding constructions are resolved through the creation of a glass cube, an essential geometry that recalls the parallelepipeds present in the immediate surroundings, in both plan and elevation. Its glazed walls, subdivided by mullions into modular elements, re-evolve the 'rationalist' quality of the adjacent façades. What is more, seen from above, it is possible to note how the glass cube becomes an integral part of the square to the point that the paving pattern is re-proposed atop the opaque roof of the cube itself.

Fig. 13, 14: Rimini, *domus* of the surgeon, partial view of the protective structure and general view of the planted roof garden.

4. Criteria of Sustainability and Renewability for New Works of Architecture in the Field of Archaeology

Fig. 15, 16: Stabia, Villa di Arianna, general view of the roof covering the spaces of the H-O-R-S-T-U and detail of the system of fins wrapping the space.

A new challenge in the field of restoration may be represented by the realisation of works of architecture in the field of archaeology, designed in accordance with criteria of eco-sustainability and renewability. Realisations in Italy include the protective structure over the Villa di Arianna in Stabia (H-O-R-S-T-U space) (Fig. 16), which employs a modern reworking of a traditional material: laminated wood. The structure can thus be considered biocompatible, non-toxic to humans and the natural world and eco-sustainable, that is, it does not cause an impoverishment of the environment, given that nature is capable of reproducing at least the same quantity consumed. Furthermore, the roof structure also employs natural systems and 'bioarchitecture' to naturally ventilate the covered area, creating an ideal and controlled microclimate, avoiding sudden shifts in temperature between summer and winter, and ensuring a proper level of natural illumination in the space beneath the roof structure.

Also of interest is the project to cover the Minoan site of Akrotiri in Santorini (Fig. 17). This roof structure is an example of sustainable architecture: it protects against the sun's rays, reduces thermal excursions, and offers protection against the atmospheric agents, in particular rainwater; collected and channelled into cisterns located at the sides of the complex it is utilised for the sanitary services in the small visitors centre at the entrance to the site. These are choices of materials and systems that are non-polluting and can be configured as renewable energies, ensuring the total respect of the existing structures by creating a microclimate suitable to its conservation, and that of the surrounding environment.

Fig. 17: Santorini, Akrotiri, sections through the protective structure, highlighting the systems of natural ventilation and illumination [De Matteis 2002, p. 92].

5. Conclusions

In light of the cases described above, it is possible to ask the following questions: is it perhaps better to build less and leave more space to pre-existing elements? Or is it possible to create works of architecture that dialogue with the ruins and are egregiously inserted within the landscape in the wake of accurate formal decisions, the careful selection of materials and colours and the pursuit of architectural quality? This presentation of works of architecture in the field of archaeology generates a reflection on the relationships between conservation, restoration and architectural design, which must be substantially integrated in order to ensure the achievement of an admissible and suitable result in response to the needs of safeguarding and valorisation. What is more, it is necessary to ensure that these realizations are not configured as autonomous entities. In fact, the conservation of ancient materials represents the primary objective; restoration intended as a methodology for the study and knowledge of the past, assists with its 'revealing' through a recovery of meaning; the design of architecture represents, in the end, an attempt to capture the supreme synthesis of an act of interpretation that respects the ancient evidence and the archaeological context. With this awareness it is possible to build in archaeological contexts, what is more considering the new acquisitions made in the fields of renewable energies and eco-sustainability.

Abstract

In the final years of the 13th century and throughout the 14th and 15th centuries, Gothic architecture became increasingly present in southern Europe, including northern regions of Valencia. This type of architecture is known as Mediterranean Gothic, where buildings show the heritage of Romanesque architecture and a profound interest in developing new plans based on complex geometries. An example dating back to this period in Spanish architecture is located in Morella, where the Church of San Francisco was built attached to the convent of the same name. Historical figures such as Benedict XIII stayed there in the early 15th century, when the Western Schism was resolved. Thanks to modern data collection methodologies, such as laser scanning or photogrammetry, it is possible to produce a highly accurate and faithful three-dimensional model, which can be used to carry out geometric analyses on these constructions, as well as on the development of the construction processes employed in this type of Gothic architecture. Complete graphic documentation of each of the elements that make up the church discussed are developed throughout this comprehensive study along with similar examples, which form part of a virtual archive of architectural heritage built in Mediterranean areas in the Gothic period.

Keywords: 3D scanner, Point cloud, Architectural survey, Gothic.

1. Introduction

The privileged location of Morella, situated between the river Ebro valley and the Mediterranean sea and linking Catalonia, Aragon and Valencia, has made the town a witness to major historical events. Its importance as a strategic position is illustrated by the fact that from the years of the *Reconquista*, in the mid-13th century, it was held as royal property. This was not the case of the neighbouring territories, which were conceded to the different military orders: of the Temple, of the Hospital and of Montesa. [1]

As a result, its defensive walls surround some of the finest examples of medieval architecture, the Royal Convent of San Francisco. Founded on 17th May 1272, with the permission of Jaime I [2], its chambers provided shelter in 1414 to Pope Benedict XIII, during the talks with King Fernando I of Aragon and San Vicente Ferrer, when they attempted to end the Western Schism.

Located on the castle grounds, close to the historic Archiprestal Church of Santa María la Mayor, this convent was initially just composed of the church and cloister. A century later, the capitular chamber, designed by Andreu Tarrasco was added between 1427 and 1442 [3].

The church of the convent is the largest Valencian single-nave church, with diaphragm arches, a wooden roof, five bays and is 13m wide. It includes side chapels with buttresses on either side; the rib vaulting of the impressive polygonal apse finishes off the church head (fig 1). The master builder was possibly

Domingo Pruñonosa, who worked on the Cathedral of Tortosa between 1346 and 1347, on the church of Santa Maria de Morella in 1353 and on the Archiprestal Church of Sant Mateu from 1379 to 1385[4]. Construction on the present building began in 1300 and was consecrated by Don Hugo, Bishop of Tortosa, on the second Sunday in July 1390 [5]. The coats of arms inside are proof of the funding of those noble families from Morella for the construction of the chapels between 1325 and 1386. Since 1700 the inside of the church has been coated with a neoclassical facing in the Doric style [6]. The monks abandoned the convent in 1840. From 1909 it was used as a military headquarter and later fell into disuse. For over 30 years it has been under restoration and from 2004 [7] work has been carried out on it to convert it into a National Parador.

2. Methodology

Collecting Data was carried out combining direct and indirect measurement systems. Measurements of elements such as pilaster sections on ground level and floor measurements have been obtained using traditional measuring systems, such as pocket measuring tapes and conventional laser distance meters. However, it was necessary to use indirect systems to obtain data for the highest points of the church, especially vaults covering the church.

A Topcon GLS-1500 Laser was used as an indirect measuring system. This ground-based Laser Scanner, with an invisible, Class 1, eye-safe laser, covers a long range and integrates pulse-based time of flight and phase-based technologies to achieve accuracy and clean scan data. It provides 4 mm accuracy throughout the 1m to 150 m range with 6" horizontal and vertical angular accuracy (2.0mgon). It has a built-in 2.0 megapixel digital camera which is aligned coaxially.

A Total Image Station was also used in addition to Laser Scanner. This station has two built-in digital cameras with a panoramic apparent resolution equivalent to 4.8 Mp, and a Topcon reflectorless measurement IS-203 model with a ± 3 "angular accuracy. This equipment was used for small sweeps and as a topographic support system.

This scanner data have been supplemented with digital photography. We used a 10.2 Mp Nikon D80 camera, with an 18-135 mm sensor and focal length f/3.5-5.6. The photographs were used to support the direct reading of the different constructed elements and the process for application in photogrammetry. Most of the data were obtained with laser scanning technology. This high definition technology, High-Definition Survey (HDS) is a non-invasive measurement method that makes it possible to capture quick, detailed and accurate information from a surface or volume quickly and precisely thanks to a recording tool based on laser scanning technology, known as Terrestrial laser scanning (TLS). Several expanded sweeps of the interior surface of the building were made using this laser scanner, according to a default step mesh based on the distance and the density of the points to be scanned. The limit for this equipment is about 30,000 points per second, meaning it was possible to obtain several point clouds with high density as final result. Each of them was composed by the hundreds of thousands points of the individual measurements expressed in a three-dimensional coordinate system (x, y, z), representing a set of virtual models of the registered objects (fig 2). This is the result of each point reflecting the colour of the scanned surface and thanks to the built-in high resolution camera of the scanner to combine each measured point with the colour of its corresponding pixel in the reference photograph.

Fig. 2: View of the point cloud

The collected data were processed to establish the right connection between the different point clouds, using retroreflective targets and the fixed points identified earlier. This allowed to obtain a single point cloud for all the building vaults. Moreover, it was possible to minimize the presence of shadows in the final result since the scans were taken from different positions.

This process was executed once using the software of the laser scanning equipment. One of these programs is Topcon ScanMaster, which allows to display, measure and edit an initial three-dimensional data model directly from the point clouds.

All this information, obtained with the Laser Scanner, together with data recorded in Total Image Station and photographs taken with the external camera, were merged using another Topcon software, Image-Master, to process the surfaces as a Triangulated Irregular Network (TIN). Thus, it is possible to complete a whole three-dimensional model of the building, as the inevitable shadows caused by the laser scanning system can be filled in with the information from the photographs, although a second processing will be necessary to obtain a stereoscopic or a 3D model that can be used to start working to calculate dimensions, orthoimages, isolines, cross-sections, etc.

This postprocessing work is completed with the treatment of the photographs with specific photogrammetry software, such as Asrix and PhotoModeler. Thus, we can get some additional 3D models of single built elements. As with the laser scanning technology, cameras were calibrated before taking the photographs. The photogrammetry programs are able to calibrate by themselves, but another program is needed for the laser scanner system, in this case, Image Topcon Master Calib.

Finally, the results are exported in several formats for data processing programs, such as DXF, JPEG, LAS, VRML, and OBJ. These are compatible with several programs which allow us to carry out representation and graphical analysis and a better treatment of the polygonal meshes which are finished with photograph textures to obtain a 3D graphic model and the necessary orthoimages to help us to draw all of the traditional planimetric drawings: plans, elevations and sections.

The study included in this paper is limited to the interesting rib vault of the apse of the Church.

3. Geometric traces

Regarding this process it must be noted that when the master builder carried out the construction, he based his work method on the *geometria fabrorum*, simple geometric concepts which made it possible to generate the church plans [7], keeping in mind that cut-stone architecture is conceived and built following the principles and techniques of stereotomy.

The aim of this research process is to determine the geometric laws and perfect traces that guided this construction.

In order to establish the geometric plans for building the apse, it is important to carry out a good selection from all the information of the point cloud. The idea is to follow the same process as in construction (from the base of the walls to the top of the vault) in order to understand the problems and deformities affecting the perfect geometry.

3.1 Horizontal plan

The first step of the construction process was the ashlar walls. By selecting this part of the building in the enormous point cloud, the regular polygon of the floor plan could be established. The resulting layout shows a half decagon, with the addition of two walls, parallel to the nave, the length of which is established by prolonging the diagonals (fig 3a). A nave with diaphragm arches linked these walls with the transverse arch connected to the original church. The length of the decagon diagonal is about 11m, which is equivalent to 48 Valencian palms.

The ribs rise up from pilasters built into the walls, interrupted by narrow sculpted capitals, where the ribs spring and rise to meet the keystone.

The next step of the analysis is the position of the capitals, where the ribs spring, following their rise to the keystone situated in the centre of the decagon.

3.2 Elevations

To work in an orderly manner, it is important to identify all the arches and classify them according to different types. These belong to three groups: diagonal, transverse and former, depending on their position in the church.

The apse was generated using 17 arches. Considering their span, height and radius, these can be separated into 6 different curvatures:

A: Diagonal: I2C0, I3C0, I4C0, D4C0, D3C0, D2C0

B: Diagonal: I1C0, D1C0

C: Former: I2I3, I3I4, I4D4, D4D3, D3D2

D: Former: I1I2, D2D1

E: Former: I1D1

F: Transverse: I1D1

Fig. 3a and 3b: Geometry and traces of the apse. Floor plan and Elevation

The decagonal plan was considered to determine the geometry of the elevation. The floor plan of the *intrados* can be defined taking into account the size and shape of the rib section. In addition, the point cloud made it possible to obtain the height of the springing, and the height of the keystone.

Allowances are made for the master builder's way of thinking. For technical and conceptual reasons, the line of the arch is circular, and the level of the centre coincides with that of the springers. These considerations and the width of the floor plan made it possible to determine the radius.

The results are different kinds of pointed arches:

It is interesting to note that the main arches of the apse follow the basic theoretical shapes of Gothic arches perfectly (fig 3b).

One of the most recognisable is the equilateral form, where the radius is exactly the width of the opening and the centre of each arch coincides with the point from which the opposite arch springs (Radius=Span). These can be found in the C-type of former.

Another theoretical shape establishes the centre of the arches by dividing the span into several parts. In fact, the so-called *tiers point* has been applied to specific proportions [8], and one of these, the radius corresponding with two thirds of the span (Radius= $2/3$ Span), has been used in the transverse F. Moreover, in the A diagonals, another geometric proportion can be found, as the radius corresponds with three quarters of the span (Radius= $3/4$; span = 36 Valencian palms).

The curvature of the rest of the arches, which are fewer in number and situation, depends on that of the other arches. Former E is parallel to the transverse. Former D keeps the same radius as C by changing its centre, and diagonal B is slightly pointed, to reach the level of the keystone.

The wooden boards used to build the vaults had to adapt to the different curvatures. Taking the radius into account, it can be assumed that the same voussoirs, with some variations in their joints, may have been used in the different arches.

3.3 Moulding

Three types of moulding have been identified corresponding with three rib types: diagonal, transverse and former. The shape has been drawn with the aid of information from the point cloud and photographs (fig 4).

Fig. 4: Moulding of the ribs

3.4 Vaulting web

The vault is covered with masonry elements forming flat rows which rise from the springing of each compartment to the keystone. In a horizontal view we can see how these rows are orthogonal to the perimeter walls, so that the intrados of the vaulting web can be considered to be formed by ruled surfaces (fig 5).

In this way, each of the seven compartments is wrapped by two of these surfaces which can be separated into four different surfaces, according to the arches that generate them:

- I: Generated from transverse arch E and diagonal arch B.
- II: Generated from former arch C and diagonal arch A.
- III: Generated from diagonal arch B and former arch D.
- III: Generated from diagonal arch A and former arch D.

It is interesting to note that all web ridges go down slightly from the keystone with a similar slope. This is because transverse arch and former arches are lower than the keystone, and the length of each web ridge is according with the level of the arch where it rests.

The construction of these surfaces as masonry webs is developed from the springing, with a first row made with a single stone. It is due to the proximity of the ribs where they rest. The length between these ribs increases with the height as does the number of stones. The end row has a wedge shape and is used to resolve the differences in the meeting of the surfaces of each compartment. This kind of row is also used in middle of the panels to absorb the length difference between diagonal arches and perimeter arches. [9]

The lower portion of the masonry compartments generated through the former arches is really a flat wall resting upon the ribs [10]. This is because the springing of former arches is four meters over the impost line to reach the necessary level. This would have helped in the construction of the vault because, once the ribs were finished, the use of auxiliary resting elements would only be necessary to make upper rows.

Fig 5. Volume reconstruction of the apse.

4. The real geometry

The geometric plans are the patterns establishing the design of the nerves. Although the construction was based on perfect geometry, in fact the apse is affected by some deformities.

Beginning with the floor plan, the half decagonal walls are quite exact, but the keystone is displaced to the left (about 20cm). This affects all the diagonal ribs that have to adapt to this situation, so that their widths are not exactly the same. The reason for this may be found in the relation with the transverse, because its axis does not correspond with that of the decagon, as the displacement to the left is the same length as that of the keystone, which is not in the centre of the decagon but in the centre of the transverse.

It is interesting to follow the path of the ribs from the springing to the keystone, since their horizontal projection is not always straight. As an example, arch L4C0 starts in the direction of the geometrical centre of the decagonal and later changes direction towards the real location of the keystone.

As regards elevations, although the real curvature is close to the theoretical one, these must adapt to the displacement of the keystone.

5. Conclusions

Laser scanner is an important tool for architectural heritage research, but it should be noted that the interpretation of point clouds must be carried out using knowledge of architecture, geometry and constructive processes, in this case the principles and techniques of stereotomy and cutstone.

The research has provided information on the geometry and construction of the apse of the Church of San Francisco. As regards the results, the lines of the pointed arches correspond extraordinarily to the ideal ones: equilateral, 2/3, 3/4, showing the mastery of builders who were guided by clear patterns in construction. The most remarkable feature of the real construction is the displacement of the keystone, which must be related to some deformities in the nave of the church.

The Church of San Francisco in Morella is recognised as a monument of great historic and architectural value, representative of the Valencian Gothic period. The research carried out provides scientific knowledge that contributes to the global overview of Gothic architecture. The master builder was most probably Domingo Pruñonosa, who was cited as master church-builder in other major churches. It is useful to compare the plans obtained with other examples of 14th-century Gothic architecture [11].

This communication is part of the research project "Methodologies and techniques applied to the investigation of Mediterranean Gothic Architecture. Case Study" funded by Fundació Caixa Castelló-Bancaixa.

The Theory of Linear Shadows and Chiaro-scuro.

(Reappraisal of the text : La teoria delle Ombre e del Chiaro-scuro- D.Tessari 1880)

The *fundamentals of drawing* illustrated with *computer modelling* for a contribution in the context of the *renewal* of Descriptive Geometry.

Antonio MOLLICONE

E-mail antonio.mollicone@um.edu.mt

Abstract (i.n° 070)

The theory of shadows and chiaro-scuro is one of the "**Applications of Descriptive Geometry**".

Re-reviewing the "Theory of Shadows and Chiaro-scuro" (Tessari 1880) the connection-integration between the scientific fundamentals of drawing and computer modelling were confirmed in the context of the move for the renewal of the heritage of the knowledge of **Descriptive Geometry** acquired up to now.

The study tackles the scientific-disciplinary contents expected for the discipline ICAR/17-Drawing.

To avoid a thoughtless work, every problem was re-evaluated, with a computer tool, taking care to:

verify the results predicted by theory;

study the formal shapes of bodies with the study of the behaviour of light on them (search for the separatrix or "apparent contour", level of light intensity or chiaro-scuro), exploiting the potential of the computer medium (accuracy, easy of producing views);

treat the fundamental and/or considerable, anyway possible to solve independently with the various methods, with the construction-visualization (drawing in the space) of the linear shadows, applying all the "operations and elements" of representation (projection, intersection);

deepen the basic notions useful for the visual and practical experience (real life drawing); the knowledge of theory (descriptive geometry); the use of classical representation (technical/artistic drawing); the practice of computer modelling;

The accuracy of the software and the virtual manipulation of the model, have enabled, for some problems, the development of alternative solutions that are proposed as original contribution.

Keywords: Applications of Descriptive Geometry; Chiaro-scuro; Rendering; Modelling; Shadows.

Fig. 1: Classical representation

Fig. 2: 3D modelling

1. Graphic model , computer model.

The operational advantages of computer modelling (accuracy, the possibility to draw in space, the library of geometrical entities, and the possibility to obtain in real time dynamic images, interactive, having chiaro-scuro) reduce the execution times and make it preferable over the exercise of drawing as a representation medium: the ability of “making by signs” (far = making, di segno = by sign, i.e. disegno = drawing) does not seem to be fundamental any more.

The computer model seems to produce convincing “effects” with minimum effort whilst the graphical model gives a static and relatively reliable idea.

In generating both the computer and graphical models the procedure is essentially the same.

The aim is to represent three-dimensional solutions.

To solve/develop/modify a volume in the complexity of space Descriptive Geometry does not rely on formulae: it is a continuous reference and application fundamental geometrical concepts ... always the same ... with rigor ... for the “pleasure” of a final verification.

If the practice of representation “...c'est un moyen de rechercher la vérité...” computer modelling accomplishes this task as a tool to organize the geometrical entities in the construction of models making it possible to evaluate, in real time, the effectiveness and utility of the same representation and facilitating the control of the formal solution in the pre-representation stage.

It is hence possible to dive and think in space: with the software for metric and perceptive checking of shapes (...de représenter avec exactitude...) and with the Science of Representation for the conscious/critical use of the same (shapes) considering both procedures in their entirety, integrated and complimentary with the aim to contribute to the renewal “of a vast heritage of knowledge and of a noble and ancient tradition”.

To solve the notable classical problems the two procedures can be integrated: a) construction of the computer model following the rules of Descriptive Geometry; b) verification, with the software's commands, of the effective reciprocal belongings/relationships etc ... (accuracy). Once the entity object of study is defined the geometrical characteristics are controlled.

The solution of metric problems or the search for particular geometrical quantities has a practical aspect in the design stage. Roof's slopes, ramps ... require checks at the various levels to avoid “intersections” with the paths of users.

In the exercises of Figures 1 and 2 the graphical and computer procedures are compared for the solution of a measuring problem.

Fig. 3: Twisted column

2. Shadow boundary and apparent contour.

The parallel directions of light rays, prerequisite in the study of linear shadows, if tangent to the surface, determine the curve shadow contour between the illuminated and shadow areas.

Said curve coincides with the boundary that appears to the observer in the direction of the light rays.

If the direction is perpendicular to the projection plane, projecting the shadow contour there will be an orthogonal projection of the object, in other cases a parallel projection (oblique isometric) coinciding with the shadow of the same object.

With the possibility of the software to automatically determine the apparent boundaries (isophotes) the theoretical predicted results can be verified as in the case of the "twisted column" (Fig. 3) where the apparent boundary in second orthogonal projection coincides with the projection of the cylindrical helix constructed on the cylinder with base diameter equal to the difference, in plan, between the imprint of the surface (circle) and the generating circumference.

In the computer model the difference between the apparent boundary and the principal meridian section of the surface with the vertical frontal plane belonging to the axis of the surface can be appreciated.

Fig. 4: Serpentine

In *fig. 111a* of Tessari's text a branch of the apparent boundary in second projection, ends tangent to the vertical axial section of the surface, but, helped by the computer visualization, that branch should end at the cuspid point of the apparent boundary, in second projection, considered as shadow of the shadow contour generated by the light rays perpendicular to the vertical projection planes (Fig. 4).

Fig. 5: Indicator curve

3. Accuracy

The possibility to section a surface with a plane parallel to the tangent plane, in one of its points, at a distance of 0.0085 mm. , visualizing the generated curves, enables to graphical prove their conical characteristic (De La Gournerie) (Fig. 5).

If said tangency point is a point of the shadow contour, it is verifiable, graphical, that, considered the light ray through that point (centre of the conical / section), the direction joined to it is the tangent to the same shade contour (Carlo Dupin).

The versatility of the computer medium enables to treat the fundamental and/or remarkable problems, applying the theoretical notions and in the case in question the behaviour of the shade contours of a body bounded by portions of two surfaces geometrical different can be understood.

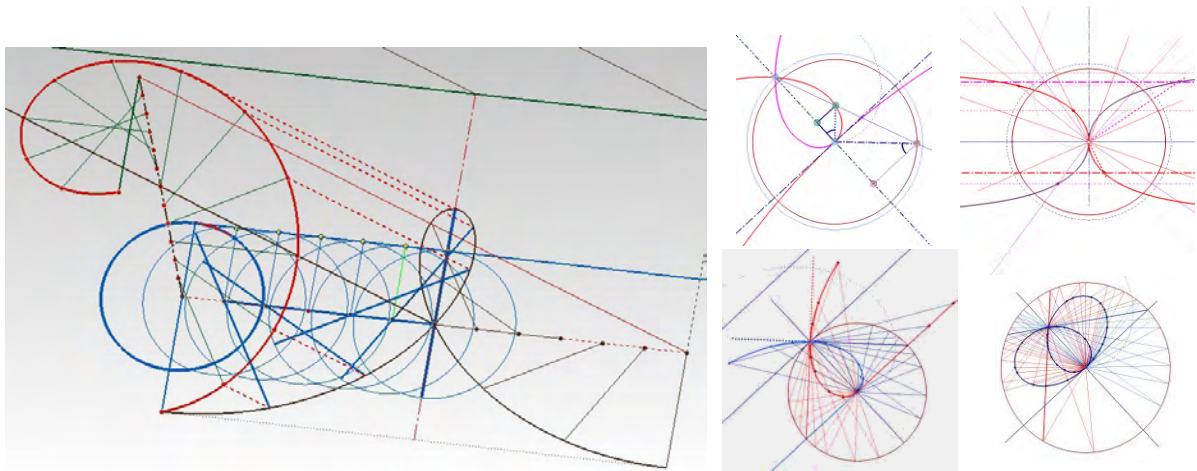

Fig. 6: Triple points and cycloids

4. Verification

Through descriptive geometry we solve problems of representation and measurement that are the basis of the creative design process.

In the various applications, thanks to the automatic creation of projections, we re-discover the original bond with geometry verifying geometrical properties of families of curves generated in the projecting process.

In Fig. 6 the case of cycloids as shadow of the cylindrical helix due to the different inclinations of the light ray.

Fig. 7: Light intensity

5. Applications : chiaro-scuro or rendering

The angle that the light ray forms with the surface determines the effect of tones on illuminated bodies (Lambert's law-1728/1777).

In general the problem lies in determining the lines, on the surface, formed by the points at which the light ray forms the same angles with the tangent and normal to the surface: isophotes.

The study of the behaviour of the light on bodies, through the application of descriptive geometry, bring to a "intimate" understanding of the formal structures of these for the checking in the composition stage of the design idea.

Form the geometrical, physical and finally quantistic point of view the development of the software provided a more and more realistic automatic tool for the visualization of the chiaro-scuro/rendering effect: Flat shading (1965) ; Phong (1972) ; Univ. Utah (teapot 1975) ; Univ. Cornell (box 1986) ; H.D.R.I. . For the solution of the problem in Fig. 8, in the three-dimensional scene provided by the software, it is possible to dive in and think in space for the metric and perceptive checking of the procedure considering both models (graphical and computer) in their entirety, integrated and complimentary.

Fig. 8: Equally illuminated lines in the hyperboloid of revolution

Fig. 9: Hyperbolic paraboloid...

6. Architecture as geometrical exercise

In Elements of Maths-Axioms, or first principles (Odoardo Corsini-Venezia 1765) the fifth axiom reads: "Those continuous measurements, that adapt when over imposed, are equal".

An apparently superfluous statement but that implies a manual operation that in traditional representation translates with the introduction of values/symbols or explicit notes.

The design idea is communicated with a graphical model that has to be re-read / understood / accepted / at least without being able to manipulate the characters with which it is written.

In the professional practice the final product is presented with the warning not to "scale" (manual operation) directly the drawing: in an elevation windows all appear with the same dimensions and evenly spaced for the satisfaction of the client, or else in a geometrical construction two lines that in the end must coincide at a point are "helped" by the imperceptible rotation of the wrist for the correct execution of the exercise.

In the computer model that manual operation is possible both physically in the illusionary dragging of one entity on another and, definitely, with the option to "ask", information about the entities to compare.

To solve the classical remarkable problems the two procedures can be integrated: a) construction of the computer model following the rules of descriptive geometry; b) verification, with the software's commands, of the effective belongings / relationships etc ... (accuracy). Once the entity object of the study is identified the geometrical characteristics are checked.

The possibility to make use of infinite views, in the computer model, enables us to simulate the use of a designed space and verify the objective predicted in theory.

Fig. 10: ... inside a humped surface

Fig. 11: Construction of the torus' isophotes

7. The implications on training

In the practice of teaching, the physical models have a great importance to make the solution of a problem understandable.

With the computer model, having overcome problems of realization, the same model can be disassembled, in parts, according to logical steps, contributing to the enrichment of scientific illustration.

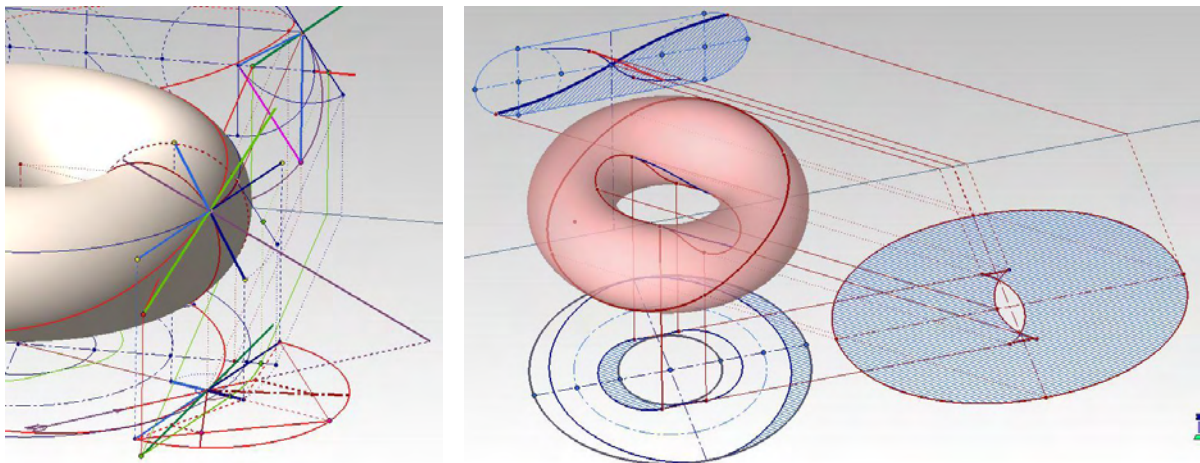

Fig. 12: Shade contours and shadow of the torus

Fig. 13: Inside the twisted column

8. Geometrical vs. abstract

The procedure for the solution of a problem, its rigorous and logical structure translates, in the classical representation, in regular images, precise but essential in number. The possibility, thanks to the software, to produce infinite views, both programmed and casual and/or experimental, gives us a variety of images that are difficult to link to a rational organization but appealing for their apparent abstraction (Fig. 13). Artistic movements tackled the representation, with the graphical tool, of abstract subject and/or concepts, generating images that, at the same time, have a rigorous base and an image-result detached from contemporary standards (Fig. 14).

Fig. 14: Balla (crakweb.it) ; Picasso woman face (Google)

Fig. 15: Sant' Ivo alla Sapienza (Computer model)

Fig. 16: Sant' Ivo (Graphical model)

9. More....less....

The computer model of the vault of S. Ivo, through the geometrical reduction of mathematical models, seems to completely represent the object of survey (Fig. 15).

Some architectural elements were generated directly with automatic operations, whilst for other, before the automatic process, it was necessary to define generating sections and relative directrix.

If the details are to be illustrated completely, i.e. to get to know their real shape, the planimetric position, the nature of surfaces, the wire frame orthogonal views can be used, which however, showing the intersections of surfaces and not the apparent boundary, must be interpreted, cleaned and completed.

The potential of the software was exploited, without making use of photo-realistic effects, but placing classical projections with the aim to understand the design intentions and all the artifices that Borromini used for the management of the composition (Fig. 16).

Hence, in the context of the integration between the graphical and computer models,**plus** the use of the computer tool to obtain the graphical model, in my opinion a scientific basis,..... **less** rendering effects.

Abstract

The stereotomic architecture is composed of ashlar made off-site and laid dry. The choice of the masonry depends on the geometrical, structural, aesthetic aspects and the mechanical properties of the material used. The fragility of the stone prevents the production of thin and sharp angles, which might break. Therefore, the angles formed by planes tangent to adjacent surfaces should tend, if possible, to a right angle. The search for the perpendicularity between the surfaces of the ashlar has brought, in stereotomy, to the widespread use of ruled surfaces (better if developable), used as a facing surfaces, but even more as junction surfaces. The choice of such surfaces is due to the fact that they could be reproduced accurately in the workshop of the stone-cutter through the movement of an auction. Although the story of the stereotomy evidences a recurring use of ruled surfaces, it is with the school of Monge that studies on these surfaces start taking shape. Among the applications of the students of Mezière some cases, brilliantly solved thanks to the properties of these surfaces, stand out.

Re-examining now part of this repertoire and transposing it into a digital environment has a dual purpose: to study and represent through the methods of mathematical representation some properties inquired to date only from the point of view of mathematical analysis; to propose, with the digital tools of design and material processing, building systems that are still highly topical.

Keywords: stereotomy, stone-cutting, descriptive geometry, ruled surfaces, developable surfaces.

1. Introduction

Stereotomy is the science that studies the cutting of solids, and has as object the construction in wood or stone cutting. Stereotomy and descriptive geometry are two deeply related sciences, since the scientific foundations of the first reside in the second one. In stereotomy knowledge of geometric entities and their properties is essential to the entire design process, and it is in the composition of the wall devices that surfaces and their properties are used.

At the end of the eighteenth century, when Monge organizes the descriptive-geometrical knowledge of the time, some geometric theories were already known, and others would be elaborated from his school or in the years to follow. The road to a synthetic theory of surfaces (studied from the point of view of pure geometry) was drawn before the Monge’s theory of descriptive geometry [9] (as deduced from the pages of *Traité de stéréotomie* written by Amédée François Frézier in the first half the eighteenth century [4]), but it is with Gaspard Monge and his school that the theory of surfaces takes the completed structure and the nomenclature that we know today.

The refining of the surface’s theory has significant implications in stereotomy. The progress of knowledge in this way allowed more and more sophisticated experiments, as deduced from the numerous devices

published in those years by the students of Monge. The control of ruled skewed surfaces and developable in particular, that were normally used in stereotomy since antiquity, allowed refined embodiments of apparatus from time to time more sophisticated.

The extent of the impact of the progress of geometry in architecture legitimizes the need of a theory that underlies the project design. In recent years, research in the field of descriptive geometry seems to be devoted to the refinement of the methods of graphic representation. So it seems having lost that original vocation, which, until the last century, made this science an indispensable tool for understanding the properties of geometric figures in space. Today, the evolution of construction techniques, the use of materials with innovative features and, last but not least, the digital tools to delegate part of the workings and operations of representation, encourages the use of complex shapes in architecture. The need for strict control of such geometries, and the capacity to imagine those, is today an occasion to rediscover the heuristic value of descriptive geometry and revisiting the tools. Today the graphical methods of representation are full flanked by digital methods, which allow to describe lines and surfaces directly in the space, in a continuous manner, with high levels of accuracy. Directly represent problems of descriptive geometry in the space, which until now were solved in the plan, allows to verify properties of lines and surfaces, and sometimes, to derive new [7].

The re-reading of the classical heritage of stone's stereotomy is addressed according to these general instances of renewal. Through the illustration of some of the relationships that ties stereotomy to descriptive geometry, we want to go through a design process that makes the knowledge of the surfaces and their properties its strength. This design practice still preserves today all its modernity, both in terms of methodological rigor, but in terms of content. The revisiting of the apparatus of classical stereotomy with the contemporary computer instrumentation has two different purposes: to trace in stereotomy the fundamentals of descriptive geometry; to revisit constructive models that, in solving complex conditions, still maintain their relevance today.

2. Ruled and developable surfaces in the school of Monge

Today we define *ruled* the surfaces generated by the movement of a straight line in space. These owe their name to the remarkable feature of admitting always the possibility of supporting on them, in all its length, a row; in geometric terms, therefore, one can always find on them a family of straight lines. This feature has been, in the past, very useful in the modeling work of ashlar stone for the vaults since their first roughing was done with the help of straight incisions.

The ruled surfaces were known for some time, as the *surfaces gauches*, before Jean Nicolas Pierre Hachette gave them their present name (The term *gauche* in French has a pejorative meaning of deformed, it seemed desirable to find Hachette a name more suited to the aesthetics of these beautiful surfaces) [6]. Hachette is the one who has first studied these surfaces extensively and has given a classification still valid today. Hachette teaches that there are two different types of surfaces generated by a straight line: *the developable surfaces which have the property of being able to be developed on a plane and ruled surfaces that are not developable*.

To understand the difference between these two great families of surfaces is necessary to clarify certain definitions and geometric properties [2]. In descriptive geometry we consider a surface as the locus of a movable curve where the constant or variable form is given in each instant, the law of motion of this curve determines the shape and position of the surface: we call this curve the *generatrix* of the surface. The generatrix may, in its motion, lean on to one or more curves called *directrix* lines. A surface is defined when, for each point of it, we can assign the generatrix line, constant or variable in shape, passing through this point.

A developable surface is the locus of tangents to a skewed directrix curve, that we name *edge of regression* of the surface; two consecutive tangents correspond to two successive positions of the straight line mobile generatrix of the surface (fig. 1). The edge of regression divides the surface into two equal and symmetrical parts. The cones and cylinders, for example, are developable surfaces where the edge of regression is a point. This point is the vertex of the cone, while in the cylinder is a point at infinity, that is a direction. The conical surface is generated by a movable generatrix line subjects to pass through a fixed point, and when the generatrix line is always parallel to itself, the conical surface becomes a cylinder.

Two subsequent lines of a developable surface include a flat element of this surface. Two successive elements are separated by a straight line of the surface and the second element can rotate with the surface around this straight line until it coincides with the plane of the first element and so on. All the elements together on the same plane form what is called the *development of the surface*. It's evident that the development of all oblique or plane curves plotted on the developable surface, and that cut the directrices lines of this surface under certain angles, are transformed on the development plane in other curves which cut the directrices lines of the developable surface on this plane under the same angles. Moreover the development preserves the measures of the lines.

The developable surfaces are the only ones having this property of being able to be developed on a plane *without cracks or overlaps*: those plan elements have an unlimited size along the direction of the straight

Fig. 1: From left to right; developable helical and ruled helical, genesis in comparison and properties of developable applied to the case of a generic cone.

generatrices of the surface (for the bijection, between the developed surface on the plane and developable surface in space, we need to define the surface portion to developed; in general, in fact, the surface in the development tends to overlap itself). The extensions of these elements in all directions of space, form the tangent planes of the surface. In whatever way a plan is moving in the space, the envelope of the space that runs it is a developable surface. This surface is the locus of lines, successive intersections of the moving plane.

In a ruled surface, two consecutive lines, whatever their small distance, never meet and the element between these two straight lines is not a plan; is a curved element that has an unlimited in the direction of the straight lines which include: its shape is that of an oblique plane, and for this reason have been called *skewed surfaces*. The generic ruled surface, as taught by Monge, is generated by a straight movable line (generatrix) rests on three curves dates (directrices).

The distinction between skew ruled surfaces and developable becomes even more evident in the differential classification given by Carl Friedrich Gauss (1777-1855). It is possible to classify the surfaces according to the *Gaussian curvature* (defined as the product of principal curvatures, property that belongs to the individual points of the surface). The developable ruled surfaces are those surfaces that have zero total Gaussian curvature; in other words, for differential geometry, a plane and a developable surface are part of the same class of surfaces, ie the surfaces formed by parabolic points. Instead, the skew ruled surfaces have negative Gaussian curvature and are members of another class of surfaces, ie surfaces with hyperbolic points [5].

The behavior of a tangent plane of a generic point of a ruled surface is an ultimate confirmation of the profound difference between the two types of ruled surfaces. In a skewed ruled surface the tangent plane at a point will be secant the surface along all the other points of the movable generatrix line passing through that point of contact. Instead in the developable the tangent plane of a point on the surface will be tangent to the surface along all points of the movable generatrix line passing through that point of contact. It is also said that the envelope of a developable surface can be generated by the movement of a plane in space, while the envelope of a ruled surface is given by the movement of a ruled hyperboloid in space.

For all these reasons it is natural that, in the history of descriptive geometry, the ruled surfaces formed two deeply separate chapters: the skew ruled surfaces and the developable ruled surfaces that, in summary, we define ruled and developable [1].

3. Descriptive geometric principles behind the stereotomic design

The works in cut-stone are made of ashlar out of work designed and properly laid dry on each other. The design of these prefabricated architectures are articulated around three main stages [3]:

1. the choice of the apparatus;
2. the construction of graphical or digital models of the apparatus;
3. the choice of optimal cutting methods for the realization of the ashlar.

The choice of the masonry depends on considerations of geometric-formal, structural and mechanical characteristics of the material to be used. In this regard the stereotomic design requires knowledge of the surface's theory which make up the bodies, their property, the curves that result from their respective intersections. It also requires knowledge of methods of representation appropriate to the representation of surfaces and lines in the plane or in space. The set of this stereotomic knowledge is the science that anticipates contemporary theory and tools of descriptive geometry.

Before the advent of the computer age and therefore the spread in construction of numerical control machines, stone processing was done by hand in the stonecutter's shop. The complexity of the implementation of some surfaces influenced the choice; so the design of the surfaces, of which the ashlar were composed, was subject to their workability. Where possible were adoperate flat surfaces, alternatively, between the curved surfaces, were preferred developable, finally, the ruled.

The geometric genesis of both surfaces was simply reproducible in the workshop of the stone-cutter through the movement of a shaft in the space, to use as mould to guide the cutting operations. Unlike the ruled, however, the developable permitted the realization of *panneaux*, developments planes of the surfaces, which were made of lead or other ductile material and finally applied on the stone to guide the stonecutter in the processing. The properties of both surfaces guaranteed high accuracy in processing, with significant effects for the entire construction process. Just think of the realization of joint surfaces, that have to adhere at best with those of adjacent ashlar, required considerable rigor in the execution. Although the stereotomic construction systems are known for the dry laying of the blocks, it is frequent to encounter the use of the binders. Their sole function is to smooth the roughness of the surfaces of junction optimizing the contact surface in order to avoid phenomena of cracking caused from a bad structure.

The widespread use of ruled and developable surfaces in stone's stereotomy is due also to the research of the perpendicularity between the joint surfaces and the facing surfaces of the ashlar. The stone is a fragile material, and this feature prevents the realization of particularly acute angles and too thin thicknesses because it would risk to break during installation even before or during processing. Furthermore if the joining surfaces of contiguous ashlars formed, with the respective facing surfaces, corners visibly disproportionate, these resist in a different manner to the stresses, and the angle more acute would tend to break compromising the stability of the structure.

The repertoire of traditional stereotomy is rich in cases in which the perpendicularity between the junction surfaces and facing surfaces is obtained by making use of ruled or developable surfaces.

4. Wall's apparatus and ruled surfaces: the case of oblique vaults

The works that have reached us, and treatises about it, witness the widespread use of ruled and developable surfaces in stone architecture from antiquity. In particular there are different applications between the apparatus of spherical vaults, between those of the spiral staircases, among those of the splayed vaults, among those of the cylindrical oblique vaults (fig. 2) [10].

Fig.2: Developable and ruled applied to the case of spherical vaults, the spiral staircases, splayed vaults.

In the spherical vaults cases, which are among the older models, all joint surfaces are plane and developable, both in archaic apparatus and both in the more complex Renaissance. In both cases, the joining surfaces belong to quadratic cones having the center in the center of the sphere. These are maintained constantly perpendicular to the facing surface of the vault, because all normal's surface of a sphere pass through its center. In the charming cases of spiral staircases, as the name suggests, the soffit is a ruled surface, in particular a right helicoidal, open or closed. In this kind of apparatus the step is the generating element of the form and it is a complex ashlar, consisting of surfaces of different type, flat, cylindrical, ruled. The common junction surface to two adjacent steps is a ruled helicoidal. There are also applications of ruled in a particular type of oblique vault, which takes the name of *arrière de-vousure Marseille*, generally used to cover openings of doors and windows, shaped in such a way as to ensure the opening of a door or of a frame. The surface of splayed soffit is a refined ruled surface, composed of three distinct surfaces arranged between them in continuity of tangency.

The use of ruled and developable surfaces in stereotomy finally finds a significant feedback in applications relating to a particular family of vaults, the oblique cylindrical vaults, which demonstrate the efficiency of the properties of these surfaces applied to the stone's architecture. The cylindrical oblique vaults lie between the more complex cases of stone's stereotomy. The interest derived in particular from structural and formal-geometrical problems that occur in conditions of pronounced obliquity. Usually, in straight vaults, the joining surfaces of the ashlars are flat and belong to the curvature lines of the cylinder intrados of the vault, ie to its generatrices and its straight sections. If you fit the same apparatus to the oblique vault case, the head ashlars will suffer from oblique forces not countered and the stability of the structure will be compromised.

In addition to the limitations of structural nature, in the design of the oblique vaults we must take account of a series of constraints related to flat sections of the hollow cylinder, which are the two elliptical frontal arches of the vault; the equal distribution of the two front arches is a geometrical-aesthetic problem difficult to solve.

These few considerations suggest the kind of problems that concern the complex geometric nature of the oblique vault case study. The history of stereotomy returns many devices that attempt to generalize and solve the issue. Some devices approximate the solution, others are particularly complex because they are composed of ashlars all different from each other that make it very difficult to process and assembly the work. Around the middle of the nineteenth century, spreads a model that is called "helicoidal apparatus". This device, due to the properties of developable and ruled, solves the problem of the oblique vault in all its generality, regardless of the geometrical shape of the vault, with geometric rigor and respect for the stereotomic principle of ashlar's seriality.

5. Helicoidal apparatus

As already explained, the helical device is normally used in the case of the oblique vault: cylindrical vaults in which the axis is inclined with respect to the frontal planes, which generally are elliptical arches.

Fig.3: Development of the cylindrical surface of the intrados and construction of the junction edges of the device.

The design principle from which derives the helical device provides that the surfaces of the ashlar are all perpendicular to each other (unless very small approximations) and that the ashlar that make up the vault are all the same, condition that offers considerable savings in time during processing and assembly of the work. The apparatus which takes shape from these conditions of constraint is formed by ashlar all equal (less than the frontal ashlar and those of the impost) consisting of two cylindrical surfaces (developable), one of the intrados and one extrados, and by four helical ruled surfaces of junction, in particular from four straight helicoids (with director plan). The helices generating these helicoids, edge junction continuous and discontinuous, have the same axis of the cylindrical intrados of the vault.

The following construction, reworked in computer environment, is taken from the lessons of descriptive geometry held in 1931 by Gino Fano at the Politecnico di Torino, culminating in an essay devoted entirely to stereotomy [3].

To control this kind of device, is of great use to build the development plane of the cylindrical surface of the soffit's vault and, in the plane, to draw the desired texture. The development plane of an oblique cylindrical surface returns a quadrilateral composed of two straight parallel lines (**AD** and **BC**) and two sinusoids (**AB** e **CD**), developments of the elliptical profiles of the arc's face of the cylinder.

The continuous and discontinuous junction edges of ashlar are cylindrical helices, since the cylindrical helix is a geodesic curve in its development becomes a straight line (please note that the geodesic is the shortest distance between points of a surface).

The mathematical modelers allow you to automatically construct the development plan of a developable surface. Then, once you get the **ABCD** mixtilinear quadrilateral, you must determine the number of the ashlar you desire on the front of the vault: we can divide the **AB** chord into an odd number of parts, for example **15** (fig. 3).

The joining continuous edges, in the development, are the lines passing through these partition points and perpendicular to the **AB** chord. The ashlar must allocate the surface in an exact number, so the edge belonging to the junction point **A** (and point **C**) must necessarily pass through one of the partition points of the straight line **CD** (**AB** as regards **C**).

You draw the **A-A1** perpendicular to the segment **CD** and choose a point, the **4** point in figure, among the partition's points of **CD** which is as close to **A1**. The straight line **A-4** gives the direction in the development of the continuous junction edges of the intrados.

It is a slight approximation that allows to keep the junction continues helices as much as possible perpendicular to the arches of the forehead. The edges of discontinuous junction are parallel to the chord **CD** and their arrangement is determined, ensuring the alternation, by the passage through the points **G, H, I**, intersection of the edges of continues junction with the impost edges **AD** and **BC**.

Once obtained the design of the intrados is sufficient to fold it on the surface so as to have the edges of junction in space (fig.4).

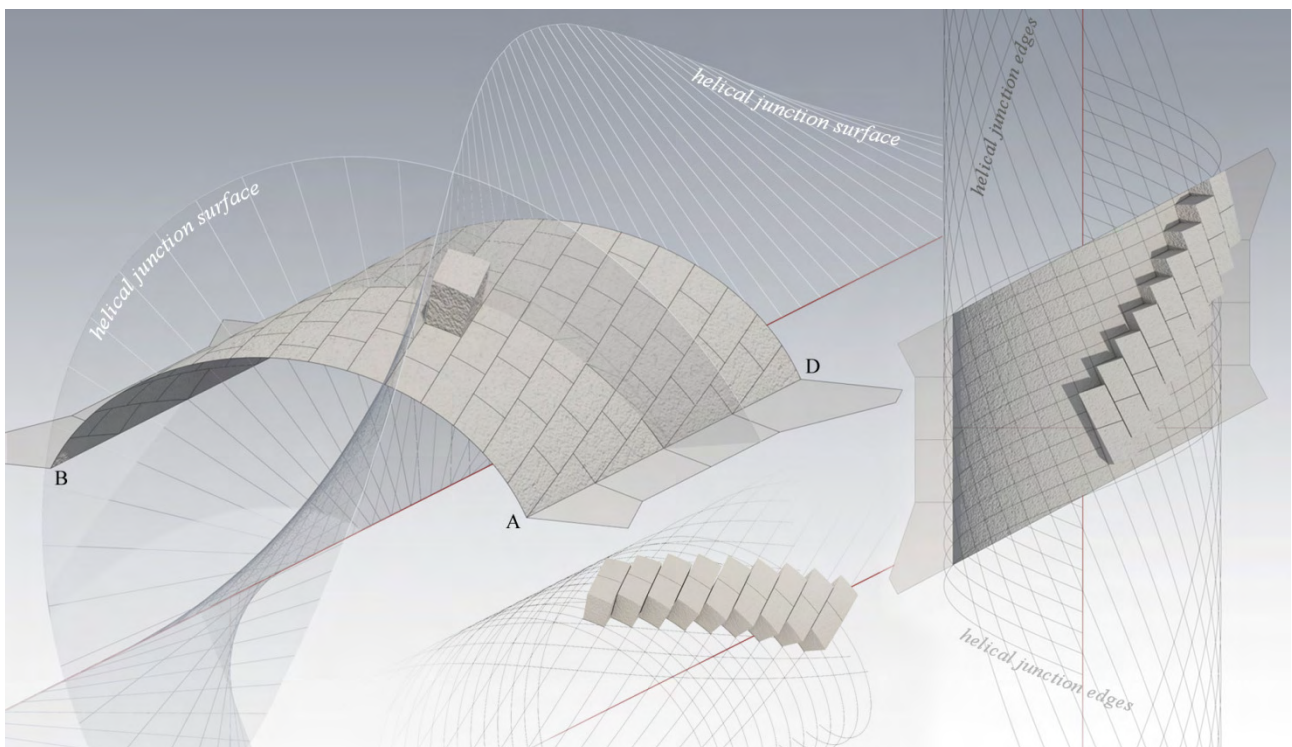

Fig. 4: The helical's serial texture is achieved through a rototranslatory movement of an ashlar type.

Fig. 5: Construction of the three types of ashlars that make up the apparatus.

The helical surfaces belonging to these edges and orthogonal to the cylinder of intrados dissect the extrados according to other helices. So edges and surfaces of all joints are all determined To determine the straight helicoid passing through an assigned helix, it is convenient to take, as a director of the helix and as generatrices, the two straight lines perpendicular to the surface of the intrados at the two ends of the helix.

In helical vault there are three types of different ashlars: the *interior ashlars* (type **a** in figure 5) which are the internal ones at the vault and they are all equal to each other; the *front or head ashlars* (type **b**), similar to those internal, but abnormal because cut along the α planes of the vault; the *impost ashlars* (type **c**) which rest on the piers, consisting of a horizontal base that allows a coherent insertion of the vault in the masonry and that allows to avoid the acute angle into the base. The interior impost ashlar is formed by a right prism with pentagonal section and by a further piece consists of two cylindrical triangular faces, which are those of intrados and extrados of the vault, and two straight helical surfaces (all over the ashlar is constituted by ten faces). The head ashlars are different depending on whether they are in the acute or obtuse corner of the vault over the pier.

In the acute angles the final ashlar of the vault is joined to the impost ashlar, while in the obtuse angle this can be independent. Finally it should be noted that it is always preferable that the impost ashlars have the outer surfaces perpendicular to the planes of the facade in such a way as to facilitate the connection of the vault with the wall apparatus.

6. Stereotomy principles and information technologies

The buildings of cut stone are almost completely disappeared from the shipyards of architecture for at least one hundred years (it is only used in the decorations). The abandonment of such buildings is mainly due to the introduction of reinforced concrete in construction, cheaper and more easily processable than stone. Stereotomical systems design, although no longer in use for years, retain, however, their modernity, both in solution as in the methodological rigor. Rethinking stereotomy in a contemporary way means to modernize the geometric-constructive system of ancient stereotomy through contemporary technologies. Both the technologies for the geometrical control of the shapes, as those for the automatic process of materials, contribute to the economy management of the design and construction process, and promote interesting opportunities for experimentation. The mathematical modeling, capable of describing directly in the space complex shapes in a continuous way, enables the construction of accurate digital models directly readable by the numerical control machines for cutting or, more generally, for the processing of the material. The accuracy in processing complex surfaces, characteristic of CNC machines, allows experimentation in new forms of geometry; in addition the different characteristics of this type of machines allow achievements in alternative materials to stone. The domain of experimentation and the verification is completed with the possibility of realizing rapid and low cost physical models. These prototypes, generally made in resin (can also be made of stone, wood or other material) are useful to verify the morphological and mechanical behavior of the apparatus and its parts.

With these objectives has been made the 3D printing of the helical apparatus described in the previous paragraph (the stereolithographic 3D ABS model has been printed with the Dimension Elite printer at the

Fig. 6: Print stereolithographic 3D of the helical apparatus and relative phases of assembly.

computer lab of the Faculty of Architecture "Aldo Rossi" in Cesena, University of Bologna). In 1:50 scale, the prototype allows to verify through a physical simulation the mechanical characteristics of the vault and also verify that the individual ashlar are coherent with the apparatus in its entirety (figg.6-7). Although technological advances simplify and speed up some processes, their implementation cannot occur without a theory. The experimentation of complex forms and their realizability requires the knowledge's theory of surfaces, their properties and methods of representation capable of representing complex shapes in space. All of this knowledge is necessary to process the apparatus from time to time more complex, designed combining modern technology and geometric-constructive principles of ancient stereotomy.

LEARNING FROM HISTORIC WOODEN STRUCTURES: SUSTAINABLE PERFORMANCE SINCE 18TH CENTURY IN THE TROPICS

Diana LUNA

Architect

San Juan, Puerto Rico

dianalunaserbia@aol.com

Abstract

Puerto Rico is an island in the Caribbean with a tropical climate all year round. Natural and economical resources are precious and land use is valuable. Today most wood buildings from 18th and 19th centuries are still standing due to good construction processes, design and quality of materials. Original architectural design and construction methods were simple and based in actual sustainable concepts, which helped these structures to perform and survive regardless of the climate and human impact through centuries.

In the historic wood buildings the basic themes of: water management, energy conservation, agriculture, safety, waste disposal, construction materials, and other needs were addressed efficiently, minimizing impact in nature.

As an architect for 24 years and owner of an 1882 wood historic house in an urban center, I have lived the process of restoration, understand and respect how the house necessities were addressed originally. I dedicate that knowledge to the restoration, reuse and retrofit of historic wood structures based on the process of my own house.

Learning from the past is essential to get into the present and future economy of sustainable restoration. It is not optional is a moral responsibility.

Keywords: Preservation, Restoration, Conservation, Building Materials, Sustainable Development

1. Introduction

Puerto Rico is an island surrounded by the Atlantic Ocean and the Caribbean Sea, located in the tropics. The island has an area of 3,500 square miles and population is approximately 4 million. Discovered in 1493 by Christopher Columbus, the island has developed into 78 municipalities in which San Juan is the Capital City.

Since the 15th century, structures in Puerto Rico have been constructed in wood, brick and stone. Through the small towns in the island wood houses are still standing as a living witness of our native architecture.

Figure 1: “Montantes”, “Soles Truncos” or transoms, Casa Luna. Picture by D. Luna

The discussion of topics as materials, energy and water conservation, cross ventilation, construction details, structural details, maintenance, restoration, reuse, retrofitting and human knowledge and sensibility, is very important for actual sustainable processes and economy.

The original materials and methods of construction in wooden historic structures that are still standing through the island and are naturally adapted to tropical climate should be constantly documented. Every component of the structure was designed and built for a purpose. At the same time that efficiency was important; beauty and detail were relevant to human occupation and social status. The natural interior lighting prevails in many ways through particular elements such as “montantes” or transoms, fig. 1.

Figure 2: Water metal cistern, Casa Cardona. Picture by D. Luna

2. Typology of wood structures in Puerto Rico

Since their foundation between the 17th, 18th, and 19th centuries most of the towns in Puerto Rico built their structures mainly in wood. It was the most abundant material in the island. Being a tropical island, forests are the dominant vegetation in the center of the mountains. Hard woods came from old trees as “caoba”, “ausubo” or “moralón” and “capá”. These woods were very hard and strong and they could resist force, weight, humidity and fire. The pieces had a lot of resin which made them really strong. So strong that today some of those woods are still standing and is very difficult to insert nails and screws in them.

These historic structures were the creation of the master builders. There is no architect named in the design and construction of the majority of those structures. My grandfather was one of those master builders and my father recollected the stories and the methods of construction from my grandfather. His work tools were my father’s inheritance.

The architectural style that we call “Criollo Vernaculo” is the one for the structures built between 1850 and 1925 in every town in the island. The “Criollo” style is the Puerto Rican version of a mix of English, Spanish, French and North American influences adapted to the tropical climate. The “Criollo” style was mainly used in houses and its main characteristics are considered sustainable in terms of location, materials, water and energy.

Location is the first characteristic of a sustainable property. Since early 17th century in Puerto Rico the houses were located in the urban centers. Those urban centers offered all the facilities for public and private services. A house located in the city offers the experience of walking and gathered all your needs still today.

Almost every house had a semi public space called balcony that offered a transition between the street and the interior or private space. Balconies were used for many purposes. Mainly were used for protecting the interior from the sun and the rain, but also to offer privacy for the front door and for social gathering.

The floors, walls and roofs in a “Criollo” house were built in wood. The foundations were tree trunks which were supporting the beams for the floor. Woods were native and trunks were literally from the trees. This subject was also a sustainable process. Originally the floor of the balcony was in wood also but many of them disappeared as the status and progress were associated with cement and metal. Simple and minimum elements formed the structure of the house, most beautiful woods used in details and others used in structure and foundations.

The roof structure was built in wood trusses and covered in the outside with wood shingles or corrugated metal. The form of the roof was in two or four slopes in order to resist winds and direct the water recollection to the cistern.

Water from rain was collected from the roof through a channel system that directed it to the cistern, fig.2. The cistern was the deposit for all the water used in the house including the garden. The cistern usually had a natural stone filter in order to make the water suitable for drinking. The cistern was located in the backyard close to the kitchen and bathroom and usually was an independent structure. On some houses the cistern was elevated and distributed the water to the bathrooms and kitchen directly after filtering. Water management was simple and efficient.

In terms of energy consumption, natural light was the main source of lighting during the day in the houses. Special openings in walls, roofs, doors and windows were designed and built to use natural light. During the night, candles were used to provide illumination. The hours of the day were used with efficiency; people woke up earlier and went to bed earlier too. In the kitchen, wood was the source for the fire. Daily living and energy conservation were perfectly arranged in a sustainable way.

The natural cross ventilation was one of the main purposes of the design. The interior spaces fluctuated between 12 and 16 feet high. The windows and doors provided all the ways to allow that cross ventilation. The house was located in order to receive the winds from the east and let them go by the west side. The windows and doors were located on opposite sides of the structure to facilitate the cross ventilation. Openings over windows and doors called “soles truncos” or “montantes” were located to help the cross ventilation.

The houses had a double roof, sometimes an attic, depending on the economic status of the owners and the square footage of the structure. The sloped metal or shingle roof was the outside part. The space of the attic allowed cross ventilation and the hot air that was at the top of the interior space moved to the outside and also separated the interior space from direct sun light.

Figure 3: Casa Luna. Picture by D. Luna

The windows and doors were specially designed to serve several purposes. They could be open in full to let people and light in. They could open half of it vertically in order to keep some privacy. They could have the shutters open in order to control light and air. They could be all closed including the shutters in order to keep the interiors dark and get total privacy. The “aleros” are the pieces over the windows and doors that protect the interior spaces from direct sun, rain and wind.

3. Casa Luna

Since I was born the house of my family is called *Casa Luna*. It is a wood structure built in 1882 in the historic urban center of Guayama, very close to the main Plaza. The town was founded in 1736 in the south coast of Puerto Rico.

Casa Luna has all the characteristic of a “Criollo Vernacular” house in Puerto Rico. It has a balcony along the north façade that face the street, fig. 3. The living room is centered in the main structure with two private rooms at each

side. The gallery is an open hallway that connects the main living room with the kitchen, bathroom, and the rest of the house. At one side of the gallery is the patio. The structure is raised 24 inches from the ground in order to let cross ventilation underneath and ventilate the wood floor.

Figure 4: Exterior gallery and patio, Casa Luna. Picture by D. Luna

Cross ventilation in *Casa Luna* has been respected preserving the openings, reproducing original louvered windows and doors, leaving the openings underneath the floor, leaving the openings in the attic. Natural light has been respected respecting the original space plan in which the spaces achieved cross ventilation through windows and openings in opposite sides. The main gallery or outside hall, fig. 4, has been opened as the original, protecting the interior spaces from the sun and rain in the patio. Original wood in floor, walls, ceiling and roof were respected and treated with preservation liquids. Original paint colors were exposed and reproduced, fig. 5.

Casa Luna received some alterations over the years but in 1993 when I graduated from the School of Architecture, I decided to initiate a restoration process in order to have the experience first hand. The restoration took almost one year, some metal windows and doors that were removed during its lifetime were reproduced as the original ones. The front façade was restored to the original of 1882. The wood floors were restored; historic paint in the interiors was recovered and restored. The gallery and the patio were also restored and recovered. The original trees trunks at the foundations were restored cleaned and relocated in the same place since the house had suffered a leveling condition. After a detailed historic study of archives and other resources all the alterations in the structure were

documented and restoration was completed. Most of the original wood was preserved in order to comply with real conservation of the original material.

In 1993 the restoration process for “*Casa Luna*” was submitted to the National Trust for Historic Preservation Awards in the interiors restoration category. The house won the second place. Since then other houses had been saved by the example of “*Casa Luna*”.

Living in the tropics and dealing with earth movements daily and hurricanes and other tropical disturbances. The way the historic wood structures solved all these issues is quick and efficient way to start the solution. The simple way these structures dealt with complex issues such as hurricanes and earthquakes that could destroy, shatter and destroy lives, make it imperative to take a closer look at the scene.

It is necessary to say that preserving the existing wood or reusing existing wood is imperative in order to make it sustainable. Deforestation is not an alternative any more in Puerto Rico. In order to preserve the wood structure it is necessary to reuse the same wood or preserve it with current techniques. Saving the material and not using new one, is part of the process of sustainability. Learning from the managing of the waters and energy conservation through the structure, is a concept that can be reproduced easily today. Installing solar panels into the exterior roof could easily make the structure completely sustainable.

Figure 5: Interior original colors, Casa Luna. Picture by D. Luna

The home garden was a concept developed that attended the need of food for our ancestors. Every kind of vegetables and fruits were grown in small spaces like the urban ones. At the same time medicinal plants were cultivated also in a part of the garden. Home medicine was the first alternative in a time of need. Another concept was the aromatherapy that on ancient times was part also of the garden. Flowers and medicinal plants were separated by concepts and smells. Today still the patio of Casa Luna is invaded by the smell of a tree called “*Ilan-Ilan*”.

4. Conclusions

Learning from the past is essential to get into the present and future of sustainable restoration. It is not optional it is a moral responsibility because we have to carry our legacy and our history into the future generations. A simple structural and architectural solution adapted to the tropical climate has been done since the 18th century and it has survived every kind of distress including human lack of knowledge. The process of learning from previous skills, educate the present generation and develop a sense of responsibility is part of the research commitment.

Recognizing our architectural history could help to protect our past, our essence, our story. Climate crisis is a reality and it is being affecting every country in the world. It is an opportunity and a matter of conscience that we need to attend in our field of work every day.

It is with great hope we reclaim that preserving our architectural historic structures we are also attending our climate crisis in an efficient and economical way. This is the way less is more. Not having the resources to develop and demolish, we are taking the time to reuse and retrofit, and learn from the past. Simple solutions were developed then that are updated in the present. In that same spirit our culture and our history could be saved for the future.

Abstract

Put the attention at the cultural heritage in the vision of the complex relationship between the shapes and the materials of the places and the still life of the peoples which live there is today fundamentally to preserve the architectural and environmental patrimony to insure a sustainable development. The knowledge of the history and the control of the transformation's dynamics are a warranty of a right procedure of preservation and valorization of identity of the territory as culture landscape . The respect of social and cultural identity of the peoples which preserve their self the cultural heritage is the start point for the protection, conservation and valorization of that. So if peoples are informed, involved and can to take part actively in the transformation process with increased knowledge they will be actors of the better safeguard of the cultural heritage. So with the contribute "Huang Cheng Xiang Fu looking for development" the author want to affront the discussion about the Landscape Culture which is preserved in the Chinese Castles and in the architecture which are inside or around the Castles. The several faces which have the Culture Landscape with key element the East Castle as architecture of the Castle, special human habitat, environment as a castle, the tourism industry and the historical culture circle, and how to preserve the culture landscape include the historical architecture restoration.

Keywords: Architecture, Castle, Conservation, Cultural Property, World Heritage

1. Cultural Landscape in Shanxi Province, P.R.China

Shanxi is one of the provinces rich in natural resources such as coal continues to be mined but is also gradually evolving through the development of High Tech and the application of new technologies in the agricultural sector. Shanxi is a mountainous region where the earth, whose predominant color is red, is rich in mineral resources. Pillow mountain near the water, mountains and built magnificent walls, battlements buildings, many ancestral houses, row upon row, a group with characteristics of the ancient buildings. There are also close to those natural resources are the testimonies of ancient Chinese culture and especially of what was the relationship between those who administered the state and the population. In that area the architecture is particularly interesting with the castle and some vernacular architecture. In fact, fortunately, Shanxi province owns a collection of ancient castles but only a minority of them has been developed and protected. The Provincial and Local government are interested to introduce strategic investors to increase the investment in the development and construction of ancient castles and ancient villages. That will be another excellent tourism environment, extend the industrial chain, and for tourists to eat, live, online, travel, shopping, entertainment . Optimizing market resources, and enter the modern concepts of marketing, to give the castles a deeper cultural connotations and characteristics, to facilitate the penetration of the Castle of culture and tourism industry, at the same time to increase promotional efforts, take the initiative to leave the advertising to sell their tourist and cultural resources, and then define a brand slogan ancient castle of tourism, and strive to change the cultural resources on industrial advantages, and promote the development and prosperity of the industries tourist and cultural city.

I have visited some castles and in particular the Castle which was the residence of the minister of the Emperor Kangxi. The building is located in a mountain landscape and its location was chosen according to the dictates of Chinese geomancy (feng shui) for which there are three sides of the mountain peaks while the fourth side there was the river. Entering through the narrow streets of the castle can still hear the footsteps of the ancient occupant and see glimpses of rare beauty that especially in this period are covered with a color that is constantly changing as the sky covered by clouds that sometimes they drop the flakes snow, which reveals the full rays of the sun's blue sky and sunlight. Every corner recalls a moment in the life of the castle, from the places reserved for the family Cheng those of servitude and a lot of people who worked inside the castle. The building consists of two parts, the uppermost, and that is the real core of the complex, one located at the bottom and surrounded by a second sort of walling in which ordinary people lived and where the entrance 'building of the man who controlled those who entered and emerged from the castle.

1.1 Huang Cheng Xiang Fu – The House of Prime Minister of Kangxi Emperor

Huang Cheng Xiang Fu is a castle located in Shanxi Province (山西省), Yangcheng County (阳城县), Beiliu Town (北留镇), Huangcheng Village (皇城村) owned by Chen family. The most famous man in this family was Chen Tingjing, the teacher of Kangxi Emperor in Qing dynasty. The Castle is a kind of rare ancient architecture in China, it has special history, culture and nature condition. After the Cultural Revolution destruction of the Imperial Xiangfu many original buildings have withered collapsed, and many cultural relics lost. Huangcheng Xiangfu precious cultural spend 30 million yuan since 1998, the spirit of "The whole principle of the old as to maintain the original appearance of" Huangcheng Xiangfu protective repair is now the Imperial City Xiangfu area has long been a Jincheng first and only national 5A level scenic spots. This castle is not a rarity in this part of southern Shanxi, but as you can see today it is a sacrament in which the best preserved and sound management to enable their use for tourism with a high quality of services offered. Huang Cheng Xiang Fu will looking for some European Castle's owners or managers to collaboration on development of the protection of site. The research introduce in to the management of the Castle the best practice and the concept of sustainability to develop and preserve the knowledge of past time and help the local community for future generations. The Huangcheng has had a rich history of people who have stood with the emperor and who had the glory for their services rendered. There are many who have studied the Confucian classics and have prepared their minds to successfully confront the imperial examinations. Include a significant number of people who, having passed these tests were able to emerge the dependencies of the Empire. So a deep history that virtually isolated from one place and therefore relatively preserved has found its origins and today he attracted the attention of China as a development model in which the entire community is involved. The Huangcheng is therefore the symbol of a positive act, where as the concept of sustainable development is taking place and where the importance of the place is again placing itself at the top of an emerging system that means even more to deal with other realities, especially from Western which intends to acquire the know-how is still missing. But the conditions we are all in this case because the basic element, which defines the driving force behind the whole operation, is the architectural heritage that is the focus of interest. Redeveloping it and reporting it, though sometimes in a somewhat 'paradoxical, functions and forms of the past, have an extremely educational. So then a study that implements what has already been done and the present day which brings the system on a sound methodology that is respectful of international fees is essential for growth and the future from this type of image that sets you expect to arrive. At the same time, the building process of the Imperial financial official regulation and local traditions as a whole, both the unique architectural style, but also show a strong local process characteristics. Huangcheng Xiangfu on architectural forms and art practices are all strictly follow the system of feudal social hierarchy of feudal ceremony. Vernacular Architecture, traditional courtyard and simple decoration, the courtiers mansion was front sleep system. The Huang Cheng Xiang Fu is located south of the village is divided into inner city and outer city, the peak of the construction began in, Xuande four years, until the Qing Emperor Kangxi 53 years, almost Imperial Chan the rise and fall of the family always. The inner city is the former residence of the Ming and Qing dynasties Chen family. Its building is rectangular in shape, and mountains on the potential and the building, east to the west, the majestic and impressive, a distance of 71.5 meters, a distance of 161.75 meters from north to south, located five Western Wall, two normally open, the rest for construction material transport channel, after the completion of fill real cementing. Over the wall set up forts, important parts Fortifications House, and in the northeast, southeast corner of the highest point of construction of Wenchang Pavilion and Spring and Autumn Pavilion, in order to gods Jingwei protecting. Weeks within the walls of a dense Cangbing hole total of more than 130 wartime retainers stack husband hiding leisure. The northern part of the inner city to build a tall fort floor, it is called "rivers and mountains floor, long thirty feet four feet, wide nijo four feet high feet. Floor, seven points, wall stairway or wooden ladder connected between layers, layer the bottom deep underground, equipped with living facilities such as wells, mills,

wartime tribe to avoid the enemy hideout. The end of construction sub-shrines in the inner city, residential areas and courtyards Di three types of different styles, Chen Ancestral Hall, Temple Building, houses the world Germany ranks Shuter Habitat and Kirin hospital the courtyards private Darongshan Public House and censor government and other. Outside the city for the Rhythm of the Fifth of Sidi. Its construction closely follows the inner city west of the city was built, the basic square, slightly shorter than the inner city, 106 meters wide from east to west and 100 meters long from north to south, the city wall with battlements and watchtowers, four, Simon is normally open, and the remaining locked. The city's main building for Chen Tingjing mansion - -- scholar, the supporting architectural study, garden. Starting in 1995, the Imperial City, the people under the leadership of the Party Branch group of people, firmly grasp the structural adjustment on the main line, vigorously implement the "Industrial Village, Tourism Village, strong scientific and technological village" strategy, initially out of a sustained economic development, farmers continued to increase the road of scientific development. Brand backed by a coal industry, the tourism industry, biopharmaceutical high-tech industries and development of trans-regional, cross-sector and wide-ranging and diversified industrial structure in the Imperial City has basically formed a total assets of 500 million yuan, employs 3700 people of the village of large enterprise groups rise up in this small village, the small village of only more than 700 people has thus become a more than 4500 people in the small towns.

The village of farmers per capita net income reached 11,500 yuan in 2006, while per capita enjoy a variety of social security and welfare of more than 6000 yuan. The village a total of over a hundred cars, 80% of households using the Internet, 90% of the villagers live on the garden-style villas, and 100 percent of the workforce to achieve stable employment; outside the village of more than 3,300 foreign farmers in the Imperial Xiangfu Group work. The villagers were not only enjoying the city people the same social security and welfare, living and city people are basically the same wonderful life and civilization, but also enjoy and city people, infrastructure and construction. Village collective has been awarded "China Top Ten well-off village," "China's famous historical and cultural village", the national agricultural tourism demonstration sites, the " National Green advanced unit ", " national civilized towns advanced collective ", the " new rural star village ", " China's top ten most beautiful towns and villages ", " Charming Country "and" China Top Ten Features Village "; the village Party branch in the 2006" July "was named" the national advanced grassroots party organizations. September 9, 2006, Hu Jintao, Vice President Zeng Qinghong in the Imperial City inspections, new rural construction on the Imperial City and all work to give full recognition and spoke highly of. The Huang Cheng village is a highest quality of life village. The peoples of Huang Cheng village live in a villa apartments and the 60 % of they have a car and computer. All cost for children school as tuition and all pensions for aged over 60 and disease hospitalization are paid for the village. Huang Cheng village Primary School is a demonstration primary school Jincheng 's the only one and Peking University, the school to distance learning point Imperial Village in Shanxi province's first and only "China Top Ten well-off village". Imperial Village is the new gold province in rural areas first and only outdoor soil latrine all become flush automated induction toilet rural areas, even if it is also rare in the country. Imperial Village Chinese historical and cultural village, Imperial Village was named the national agricultural tourism demonstration sites.

1.2 Ancient city of Dǐ Jì Chéng (砥洓城)

The city of Di Ji Cheng have the old wall just on the river and it is possible to see this from the Highway which pass not many far from here. This part of the city is the oldest and was used in the last war as a good military defense of Chinese army. Today the space is used to store the aliments for the animals as the sheep. Not is simple to walking on the wall because the road is very small and dangerous. The protect city is rich of ancient architectural elements and it is possible to see a live glossary of vernacular architecture of China in Ming and Qing Dynasty.

Fig. 15,16: Dǐ Jì chéng (Photo 2012, Author)

1.3 GuoYu Town (郭峪古城 Guō Yù Gǔ Chéng)

The city wall have a height of 12 meters and a width around the 5 meters. The total perimeter of the battlemented wall measure 1500 meters. The wall was opened in three gates. The vernacular built inside the town are of the period of Ming Dynasty. In the center of GuoYu town there is a seven storey building. This construction made with bricks to protect against soldier and bandits from attacking and robbing.

Fig. 13,14: Guo Yu ancient town. The corner defence turret of city's wall (Left) and the Yù Lóu 豫楼 (right). (Photo 2012, Author)

1.4 An ancient temple in Beiliu (北留)

Locate on the top of hill in the scenic area where is possible to see the river and high mountain around. The place is very hard to climb and is protect just for the difficulties to find it. It is necessary to walk for many minutes in the land trough the cultivate private land. At end the vision of the surround area is a absolutely exceptional. The temple was saved for the human destruction for many years but recently the absence of maintenance cause the ruin. The roof is partially broken and the fresco inside are serious damaged.

Fig. 19,20: An ancient temple in Beiliu and the scenic area around. (Photo 2012, Author)

1.5 Ancient castle of XiāngYù gǔchéngbǎo (湘峪古城堡)

The ancient castle of Xiang Yu is very big and at arrival in front of this seem to stay in another country as Franch or east Europe for the impression of the power express from the wall and from the bit tower locate on the main entrance. There isn't not so much new elements but substantially some of those are effectively not correct. As example of this there is the bridge which cross the river. That construction is build recently and not have corresponding with the ancient connection between the castle and the land around. Inside the castle have a lot of building which are expression of mixer of folk architecture and prestigious architectural decorations. In the last periods there is a special program to repair the castle and to promote it in the cultural itinerary. In this case the planning want to develop the management of the place with attention at the original character with a scientific approach.

The ancient estate of Conca at the edge of the pontine marshes, between the views, surveys and historical maps.

Maria MARTONE

Faculty of Architecture, University Sapienza of Rome, Italy
e-mail: maria.martone@uniroma1.it

Abstract

In territory corresponding to the ancient estate of Conca that stretches from Le Ferriere to Tower Astura, coexist elements of strong environmental and social degradation, as a solid waste landfill and the site of a ex nuclear power plant, and natural elements such as the river Astura already Conca, an ancient fluvial corridor that connected the landscapes of the valley of Conca and the coast in a kind of organic relationship between the natural and urban environments.

This area has ancient origins and collects emergencies significant archaeological, architectural and environmental, whose knowledge and appreciation could redevelop and recover highly degraded area and make the valley a product attractive to the architectural scale and of the landscape.

On the basis of an ongoing study that is part of a research on basin of the river Astura [1], in this paper we present a reading of the territory of ancient Conca, highlighting the methodology used to perform graphic investigations, iconographic, literary and instrumental on architectural, archaeological and nature episodes more important, also aimed at the formation of a land information system.

Parole chiave: documentation, representation, knowledge, protection, enhancement

1. Objectives

The territory of the ancient estate of Conca, characterized by the presence of prehistoric and historic and rich forests, was situated between the Via Appia and the sea, at the center of the valley of Astura, in an area on the edge of the Pontine marshes; crossed by numerous water courses, extended mainly on the left side of the river Astura to the banks of the river Moscatello, that will become during the integral reclamation Channel High Water. Among Casal Nuovo and Le Ferriere the estate exceeded the river, growing up to reach the lands of Campomorto; towards the coast, the channel Mastro Pietro separated the estate of Conca from Valmontorio and Tower of Astura, while to the north the fund extended to the territory of Cisterna, owned by the family of the Caetani (fig. 1).

Belonging from always to Rome, and only for a few years to Neptune, now the territory of the ancient estate of Conca, turned and modified in its look natural and urban, is part of the town of Latina with the Borgo Montello (already Conca) Borgo Le Ferriere, Borgo Bainsizza Borgo Santa Maria and Casale Nuovo (fig. 2).

Currently, in this area impends over the presence of a landfill of waste that has contaminated the environment and especially the river Astura, defined by experts highly polluted. Also over the years there have been several interventions that have further altered the landscape of this area as, for example, the construction of nuclear power plant of Borgo Sabotino, built in the late fifties by SIMEA and later purchased

Fig. 1: Part of “Plant Demonstration of the localities Conca, Campomorto, Sea and Lakes pontine” performed by Atilio Mazzoleni in 1911.

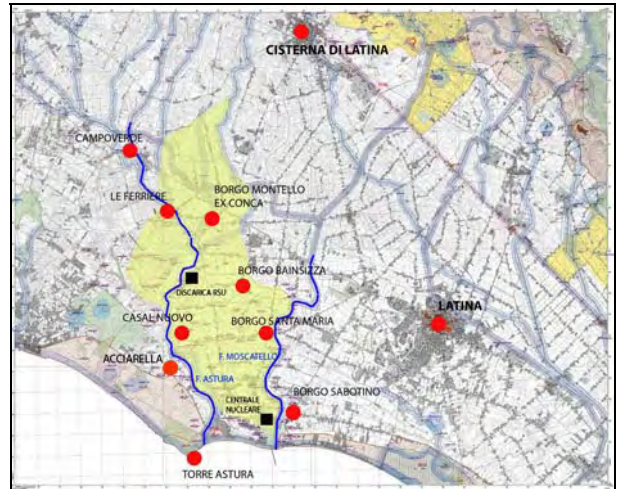

Fig. 2: Territorial framework of the estate of Conca performed on the plan of PTPR of Lazio in 2007, table B35, 400 sheet.

by ENEL. It 's visible still a big metal ball that should have formed the core of an experimental atomic station, abandoned before being completed. The comparison between a cartographic map of 1927 and a satellite view shows how were altered the elements making up the area (figg. 3 and 4). Starting from this state of degradation the paper aims to increase knowledge of places, in order to propose models and criteria for revaluation, directed to the protection and preservation of what constitutes evidence and memory of civilization. Remember that a few recent initiatives, included in programs also european, were performed on the area by municipal and provincial authorities with the aim of protecting cultural heritage and of a tourist development sustainable of the territory [2].

Aimed at the knowledge is the documentation of the processes of transformation that can be read through bibliographic surveys, archival and through examples of historical maps, views and findings. It is believed, finally, note that within the knowledge of a place, the datum of the landscape is, together and in close liaison with the data archaeological, architectural and literary, an important historical document that should be privileged as synthesis of the transformations and of the evolutions of a place both in terms of anthropogenic and natural.

Based on these assumptions we propose a reading of the ancient estate of Conca trying to retrieve also the memory of a relationship that over time man has managed to establish their own land.

Fig. 3: Part of sheet K2 - IGM, 1:5.000, 1927.

Fig. 4: Satellite view on the nuclear power plant of Borgo Sabotino.

2. The territory of Conca. The origins.

Documentary sources attest to the presence of prehistoric populations near the Borgo Le Ferriere, in Torre del Giglio, in which were found numerous stone tools dating to epigravettian period of the upper Palaeolithic [3]. In the estate of Conca, of the same period belong some discoveries of archeological relicts at La Rosa, near the Borgo Santa Maria [4], while stable settlements and frequentations of the first half of the Iron Age had developed near the borders of the estate of Valmontorio, at the coast [5].

An important archaeological site is present near Borgo Montello, already Conca. It's the case of the ancient city of Satricum, considered one of the largest centers of "Latium vetus" in archaic age [6]. Located near the river Astura, the city of volscian origin, was the site of an important shrine dedicated to the goddess Mater Matuta, unearthed in 1896 by the french archaeologist Hector Graillot [7]. The deity, known as the mother of the morning, of the sunrise, of the life that begins and as the protectress of pregnant women and of life itself, has represented the core of the city both from a spiritual point of view that social and cultural. The excavations on the Acropolis continued until 1898 under the guidance of italian searchers. In recent years were found numerous archeological finds preserved in the Museum of Villa Giulia in Rome and it was made a first survey by the engineer Raniero Mengarelli, Felice Barnabei, founder of the Museum of Villa Giulia in Rome and director of the excavations of antiquities and by Adolfo Cozza, expert of classics and designer [8] (fig. 5).

The archaeological site of Satricum is a real city, formed around the temple, as is clear from the excavations conducted in 1975 by dutch archaeologists that have unearthed a large area, still today subject of study by part of the University of Amsterdam [9].

Afterwards Satricum was burned by the Latins and then definitively destroyed by the Romans in 346 b. C., date that marked the slow decline of the city that will become only a place of pilgrimage.

During the roman empire were built numerous villas and villas country, the latter in addition to the function of residence were related to the exercise of agricultural works and productive that allowed the maintenance and management of the fund. At Borgo Le Ferriere by a team of dutch archaeologists have unearthed the remains of a domus type house with three central courtyards, one of which was characterized by a impluvium (fig. 6). Have been found below a floor ruins of hypocaustum, heating system of the rooms characterized by passage of vapor in the interspaces [10].

The territory of ancient Satricum was part of the diocese of Anzio that developed between the territories of the Tres Tabernae (today Cisterna) Lavinium and Ardea. In the seventh century the territory of the diocese anziatina was united with that of Albano, after the defeat suffered by the seaside town by the Saracens.

The Pope Zaccaria (741-752) became interested in the reclamation and cultivation of the Roman countryside including the urban area of Conca in an agricultural organization to gain a livelihood for the city of Rome, that because of the continuous raids of the barbarians, could not freely trade with the countries of the Mediterranean. Were founded for this purpose some domus cultae, small fortified towns, built in the countryside, where farmers worked the land be safe, even in times of danger [11].

Fig. 5: Survey of the acropolis of Satricum (R. Mengarelli, F. Barnabei and A. Cozza).

Fig. 6: Townhouse at Le Ferriere. Plant.

3. The monks of Grottaferrata.

The domus cultae developed also with the Benedictine monks of Grottaferrata, whose presence on the territory is documented from 1116, when at the slopes of the acropolis of Satricum performed the extraction of iron ore, founding Le Ferriere and using the hydraulic structure of Satricum. Being the monastery under the jurisdiction of the Holy See, the abbot elected by the Benedictine monks had to be confirmed by the Pope and his name had to exercise his spiritual authority and civil citizens who owed him obedience. Important document was the bull of Honorius III in 1217 that confirmed the property to the monastery, including that of the castle Concae.

At the time of the Abbey of Grottaferrata was built, near the town of Conca, San Pietro in Formis (now Campoverde), which was also it a rich industrial center.

Conca soon became an extensive estate of the Roman Campagna. Due to its geographical location became an important road junction between the hinterland and the sea. In the medieval town were forged hatchets and were built the churches of S. John, S. Gregory, S. Peter in Turri "et a Grecorum", officiated by monks directly. Of the last two churches, later one took the name of a S. Lucia, while the other was probably destroyed as it is not mentioned in Regestum of Cardinal Bessarion in 1462 [12]. The church gave its name to the country of S. Lucia, where it developed a grange, a farm consisting of houses and locals processing of agricultural products, managed by monaco granciere.

The ancient church gave its name to the immense stain that extended from Ferriere of Conca to the coast, where the wood was taken by the Genoese for the construction of their ships, which unloaded iron ore of the island of Elba to be worked in Ferriere of Conca [13].

The products of the estate were transported from land to sea by means of wagons drawn by oxen or buffaloes, or across the river Astura with special flat-bottomed boats, to be brought to the port of Astura, an important commercial center.

The life of Conca took place along the banks of the river and around the castle, built on "pagus" of Satricum and fortified by Malabranca in the thirteenth century. For its strategic position between the hinterland and the sea, for the Castle, for the riches of the territory, for the industries, the city of Conca soon entered the orbit of Rome. Conca, today Borgo Montello, once Concharum Castrum (fig. 7), developed in the Forest of Cisterna. A beautiful arch leads to a low-medieval urban layout system on a plateau of tufo, a place where the robbers to grant Lateran could claim asylum until 1680 (fig. 8)

The estate of Conca, rich in waters and wetlands, was the ideal place for crops of hemp and flax from the Middle Ages up to twentieth century have had an important role in the economy of southern Lazio. In this period also developed the viticulture and silk processing. Famine in the fourteenth century, due to malaria epidemics, and to the continuous incursion of robbers, struck Conca and the territory of the Roman Campagna.

It remembers that the major works of the Benedictine monks, who administered the property with the consent

of the Chapter of the Abbey and had to be accountable to the pope, were the industrialization of the area, the increase of agriculture, to have made the soil more productive through a constant and assiduous work in the countryside and to have improved the living conditions of farmers.

4. The estate of Conca of the Holy Office. The officinae ferrariae.

The Benedictine monks of the Abbey of Grottaferrata in the territory of Conca remained until 1564, when the city was admitted to the Apostolic Chamber. Pope Pius V in 1566 gave the estate of Conca, consisting of a vast area of about six thousand acres, to the congregation of cardinals of Holy Office, as a private jurisdiction. Many were the privileges they enjoyed the estate, including the exemption from taxes and of the forum, being the congregation the supreme judge of the civil and criminal cases in the territory of Conca. With the congregation of cardinals, developed in a short time, thanks also to the work done by his predecessors, the officinae ferrariae, who became in the seventeenth and eighteenth centuries the most important of Lazio. The purpose of Pope Sixtus V was to create new production facilities in the countryside pontino in order to reclaim an area unhealthy and exposed to risk of malaria. In 1578 was born in Le Ferriere Conca industrial site on the production and manufacture of iron, linked by the

river Astura, through the artificial channel of Fiumetto, to the plant in Campo Leone, founded in 1568 outside the boundaries of the estate, in proximity of the center of Acciarella (fig. 9 and 10). The iron ore imported from the island of Elba was loaded on barozze pulled by buffali that went up the Astura, coming directly to the smelter. The processed product was used mostly from Rome and was then exported in the Grand Duchy of Tuscany and the kingdom of Naples. The skilled and skilled workers came from Tuscany and Lombardy. In the ironworks of Conca were built 5 rims that were used for the restoration of the dome of St. Peter's made by Vanvitelli in 1743 [14].

The two ironworks extracted their source of motive energy from the water of the river Astura that were specially channeled through walls, dams, cataracts resulting in massive hydraulic works. The two industrial sites were united by an organic relationship with the river and then sprang a common interest linked to a proper hydrologic balance. A series of surveys between 1700 and 1861 describes the river and its hydraulic structure about the operation of two ironworks of Campo Leone and Conca.

Dams and locks were built to channel water inside the building and use its power (fig. 11 and 12). The estate of Conca, although it was in an area near the marsh, where there was a high risk of malaria, was developed as a major agricultural and industrial center, preserving the heredity of the organization of the domus cultae [15]. Unlike other estates in the area, which were at the service of a few families, that of Conca included besides the church, both rural and manor houses, warehouses, barns, stables, barns, handouts and everything needed to perform the work in camps and workshops. The water was taken from an ancient tunnel that was used for water drainage.

The farmhouses represented an important structure for the operation of large estates and among the many that were built during this time, remember that of S. Antonio, near the present village of St. Maria, a small

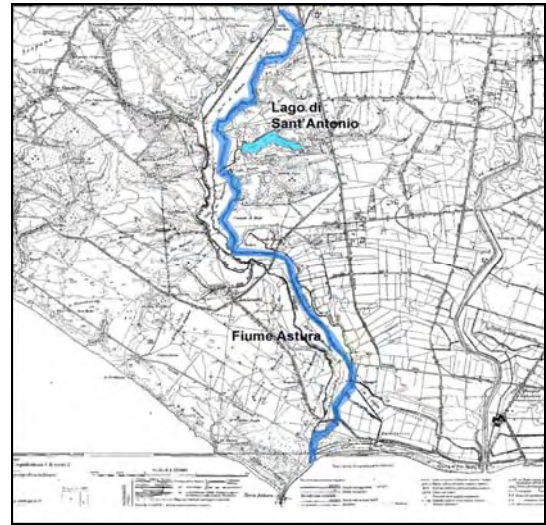

Fig. 16: The Lake St. Antonio. IGM, 1927.

building with three rooms lined up on the ground floor: a kitchen and two bedrooms, and many rooms on the upper storey and that of Conca, near the present Borgo Montello, which became the home of S. Maria Goretti and that had the same distribution characteristics and formal than that of S. Antonio (figg. 13 and 14). Were built the churches Annunziata of Conca, S. Peter in Formis and St. Antonio Abate, the latter built in front of the foundry, not being longer sufficient the ancient grange of St. Lucia.

To operate the ironworks there were the Carbonari, the Fossaroli, the Falegnami, the Facocchi, which were also interested in the maintenance of the many wooden bridges in the estate of Conca. Great interventions of reclamation and regimentation of water, examples of hydraulic engineering at the time, were performed by the Holy Office.

Despite the many wars the foundry never ceased its activities to obtain supplies of iron from the island of Elba. The processed product was sold mainly in Rome where St. Office had a store that provided the ironworkers of the city.

In 1798, the ironworks plant suffered severe damage, resulting in a reduction of work of up to 1809-1810. Since 1817, according to the skill of Dominic Morichini of January 15, on the "Opinion on the manufacture of potassa in the Papal States" [16] it is known that ironworks regained its full effectiveness of past centuries until 1865, when the factory iron activity ceases to be converted in the early twentieth century in a paper factory.

4.1 The forest in the estate of Conca.

The management of the industries of iron also paralleled that of the forests by the Holy Office. Castrum Concharum was surrounded, in fact, by a copious forest called Cisterna Neronis. The most common vegetative species were made of bay-oaks that reached up to 30 meters in height, from the oaks, native trees of ancient origin dating back to the Quaternary, the maples, the ash trees, elms, alders, and a rich undergrowth. Particular attention was therefore given to the administration of this immense patrimony that supplied the coal needed for the functioning of the ironworks. Were avoided any waste, which is why the tenants of the estate could cut trees marked only with the mark of the Holy Office. The conservation of the forest was also linked to the belief that tall trees could work as a sort of screen to the spread of malaria which was rampant in the area around the estate, to the coastal lakes.

5. The changes of ownership until the twentieth century. Change the characteristics of the place.

Following the expropriation of church property, in 1874 the estate of Conca was assigned by public auction to the Count Achilles Gori Mazzoleni who was the owner until 1910, when the estate was sold to the Duke Leone Caetani, to be sold later in the the early twenties of the twentieth century the knight Gustavo Dominici (fig. 15). In February 1933 the O. N.C. (National Opera Fighters) becomes the owner of Conca in the programs of land reclamation.

In the early years of the 900 work began on processing and conversion of the ancient ironwork in paper mill. The factory turned the straw of wheat produced in large quantities in the farm of Conca, into paper. The plant family Dominici remained active until 1979, the year of its closure.

Following the rules established by the Royal Decrees, cav. Gustavo Dominici began the work of reclamation, with address naturalistic in its ownership of the estate of Conca. In this period the activity of fish farming was enhanced with the creation of Lake St. Anthony (fig. 16).

Follow the work of reclamation that alter, for the most part, the environmental characteristics of the place. The farmhouse of Conca Mazzoleni family passes to ONC on the basis of a transformation program of the ancient estate in lands. It implements a new organization hydraulic River Basin Astura and it's executed the processing and regulation of the river Moscatello that will be called High Water Channel.

The estate, following a program that included a new extensive cereal cultivation, was almost entirely deprived of the rich forest cover, which for centuries had covered his land. After all possibility of exploitation to cultivation, the lands were abandoned and left to pasture [17].

6. Conclusions.

The history of this area assumes particular characteristics that must be definitely pointed out and increased the value in a recovery program for the whole valley of Astura.

The knowledge of the places is essential in order to plan any work relating to the safeguard and conservation. Knowledge and awareness, of what the place has been, consent to consider the territory as an asset that belongs to the life of each one of us, and whose memory cannot be canceled by no intervention not even by the most infamous. Therefore, especially in areas most at risk, where there is a sharp decay is even more necessary to know, document and communicate the consistency of cultural heritage present in order to overcome the neglect and to give a input to growth directed to adequate development and sustainable.

Therefore it is necessary to divulge the result of research by producing documentaries archives for cataloging of the captured material and also for allow an implementation of the knowledge over time.

For this purpose, as already experienced in previous studies [18], in this research will be used a standard format of card, in which the goods investigated will be described in the main aspects and characteristic. The data collected will be handled in a informatic way and will be fed into a geographic information system.

Based on a thorough understanding of the cultural resources of the site will be designed cultural initiatives, sporting and play that could stimulate use of the goods that make up and characterize the environment.

Abstract

The use of digital technologies in the survey of archaeological sites arises some interesting methodological questions. This contribution aims to make analysis based on experience in performing in Alba Fucens, Latin colony of the fourth century BC, founded near the ancient lake Fucino for control important routes in the peninsula.

The activity of documentation and analysis that the research center of Rieti Sapienza of Rome "Critevat" is in accordance with the Department of Human Sciences University of Foggia, concerns old and new excavations.

The growing use of digital techniques, such as 3D laser scanner and photogrammetry, has as main consequence the tendency to objectify the data acquisition phase, shifting forward the time of interpretation and analysis.

In the archaeological field, perhaps more than in other areas, this dichotomy is most accentuated. The representation makes more use of rendered three-dimensional models but are often difficult to manage, because they are still not standardized by the professionals or by the people who needs to acquire information for dissemination.

The three-dimensional models often do not have the selection as a goal, but the "simple" repetition of a reality. The questions are: Are these models really objective? Is there a selection in the processing phase?

The quality of a points-cloud where the real space is discretized into a number of discrete points depends on different resolutions, on the presence of voids, on photographic renderings which in turn depends on focus or exposure.

We still think the automatic processes of continuous numerical surfaces and then of the mathematical (NURBS), which often use filters to reduce the "noise", based on algorithms developed for other applications. The paper plans to clarify the problems encountered in the experience of Alba Fucens and proposed some ideas arising from the comparison between surveyor and archaeologist.

Keywords

Digital representation, Archeological site, Alba Fucens, Survey, Scanner laser 3d, Photogrammetry

1. Introduction

The use of survey techniques and digital representation for the documentation of archaeological sites is certainly a very topical issue which can be an important means of optimizing economic resources for the preservation and development of a multitude of small sites known to archaeologists and superintendents, but most often invisible to the community and then out of the local tourist circuits.

Digital technology has an enormous potential, even if we can find some contradictions in its use perhaps due to the cultural differences between specialists and mutual distrust.

The survey and representation in archaeology are disciplines consolidated in the last century that are based on rigorous methodological integration between the topographical instrumental survey and direct survey, then it returned into the various final draft [1]. Rarely, if not for the most important and famous archaeological sites, was used to photogrammetry has always been considered a technique of survey very specialized and expensive.

The digital age has opened new scenarios that are also growing increasingly investing in archaeology [2] [3] [4] [5], with different weights, all intervention phases: prior investigations, planning and documentation phases of excavation, analysis of findings, and management by superintendence, and activities of musealization, scientific publication and enjoyment by the community.

Digital technology, however, implies some contradictions: on one hand it makes the task easier, especially if you think for example of the enormous scope of information dissemination, the other produces strong specializations that sometimes do not communicate with each other. That happens usually when digital technologies are based on different platforms and standards, such as geographic information systems, software modeling three-dimensional or non-invasive diagnostics (for example GPR or modal analysis).

The research center of Rieti Sapienza of Rome "Critevat", for some years carrying out research in the field of diagnostics and monitoring in many areas from the environmental to the architectural and archaeological heritage. In particular, a group of researchers have started some experiments on the use of survey techniques and digital representation for the documentation of archaeological sites [6] that are often abandoned or little-known such as the Terme di Vespasiano in Castel Sant'Angelo, the Roman amphitheater of Trebula Mutuesca in Monteleone Sabino, recent excavations in the Populonia Etruscan site. A recent agreement with the Department of Human Sciences, University of Foggia allowed to start an interesting collaboration between archaeologists and surveyors in Alba Fucens.

The examples described below relates to a particular area of excavation, that of the south-east of the Forum, where survey were conducted in two stages: the first in late 2010 and the second in the summer of 2011.

2. Alba fucens: the archeological site and the area of intervention

The excavation teaching (fig. 2) that the University of Foggia has been leading since 2007 in the southern sector of the Forum of Alba Fucens, Latin colony founded in the late fourth century BC as a military stronghold in fair territory [7], involves an area only partially affected by past Belgian research in the years 1949-1979 [8].

This is a sector that plays a nodal role in the urban, located as it is at the point of 'intersection of the axes of internal roads, - the way of the Pillars and its continuation to the north crossing the way of the Elephant - the point at which converge the political-administrative functions and the economy-trade of the ancient city.

The excavation involving the square and some buildings that flank the eastern side, in particular: a) a *taberna* from the long and narrow plant, in front of the colonnade and divided internally into compartments and different levels, overlooking the back on a elevated main road [9] b) almost half of a sizable monumental public building, articulated on different levels, whose intended character of worship must be confirmed by future surveys [10].

Fig. 1: Alba Fucens archeological site

Fig. 2: General plan with indication of the excavation

The conservation status of the structures elevation is quite exceptional: the bounding walls of the rooms are kept to a height of about two meters, although they were affected, we would say in ancient times, by structural failure.

Compared to the latest discoveries (such as the redefinition of the widths of the square than now appears less offset from the plan road) the analysis of the area and the plans derived from the survey carried out important contributions to the chronological information, either in relation to the first monumentalization of the forum, whose pavement was to be later than previously thought, dating to Giulio-Claudia's age, or in relationship to the later phases of city life, when the area is affected by a series of story building that appear linked, in part, to the destructive action of an earthquake and whose stratification is found in her structural characteristics of masonry

3. The integrated digital survey

The main changes introduced by recent developments in digital technology are basically two: digital photogrammetry and three-dimensional modeling [11].

The first makes it possible to perform, beyond the technicalities and the related costs of excessive analytical photogrammetry implemented until some twenty years ago, survey operations which add up effectively to the pure metric data several additional information that only photography can give back such as for example the most minute textures of the masonry, the stratigraphic differences, the state of preservation [12]. Through digital photography it is also possible, with the commonly used software today, to prefigure project solutions in a very realistic.

Three-dimensional modeling, increasingly widespread, overcomes the scheme, at times too hard, for traditional graphical models such as double orthogonal or axonometric projections because it is unable to return multiple views and, through movement, to propose a new perceptive dimension of the object represented in a virtual simulation of great communicative value.

The combination of the two technologies, namely the photographic texturing of 3D mathematical or numeric models, not yet in common use today, is without doubt the best result that can be obtained as the product of an integrated digital survey conducted with the most modern technologies.

What is the element that unites these two technologies and represents an important discontinuity from the survey, so to say "traditional"?

In the operation of survey, you can always recognize two phases: a metric acquisition as objective as possible and a processing of the data, transcription selective metric information of the second predetermined codes and therefore is essentially subjective, interpretive. In truth they are the classic two sides of the same coin, or at least they were until the computer revolution.

The increasing use of digital acquisition techniques, such as 3D laser scanner and photogrammetry [13], has the main consequence of the tendency for objectification of the acquisition phase of the data, shifting forward, if not delegating to other professionals, the phase of interpretation and analysis of data acquired. In the field of archaeology, perhaps more than elsewhere, this dichotomy is most conspicuous, in the representation, for example, becomes more and more use of textured three-dimensional models do not yet fully standardized and is therefore difficult to manage either by experts or by who need to acquire information for dissemination purposes. Three-dimensional models often do not have as its goal the selection, but the "simple" repetition of a reality as faithful as possible to reality.

One has to ask first how much these models are actually objective or are the result of elaborations that, as such, are selective. Consider, for example, the quality of a points cloud in which the space continuous, real, is discretized into a number of points with different resolutions, with the presence of voids, with photographic renderings which in turn may contain factors inhomogeneity in the focusing or exposition.

We still think the "automatic" processes in numerical continuous surfaces (mesh) or math (NURBS) which are frequently used in filters to reduce the "noise", based on algorithms developed for other applications. One has to ask even if the three-dimensional models cover all the survey objectives or whether, must always use the traditional graphical models (although digital), there is a real integration and interaction between the data acquired with the new technologies.

These are the main questions that the research unit of Critevat was placed on experiments in Alba Fucens, where it became clear how important it is also being acquired as well as the continuous development and constant dialogue with archaeologists and with the supervisors of cultural heritage. One of the interesting aspects of the experience, still in progress, and that the activity of digital survey did not rule out a parallel survey in accordance with procedures of "traditional" made detection of topographic points for reading elevations, levelling for the identification of different stratigraphy, an impressive photographic documentation able to fix the various phases of the excavation and identification of archaeological finds to be placed elsewhere.

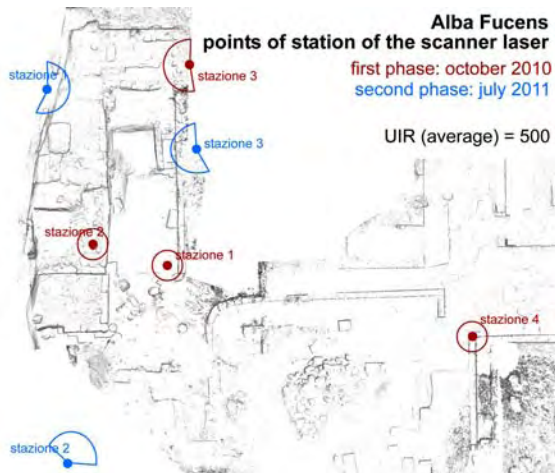

Fig. 3: Plan with points of station of the scanner

3.1 The data acquisition

The acquisition of the digital data of *taberna* of Alba Fucens was done in two stages corresponding to the two phases of excavation described above. A first acquisition was made in October of 2010 to complete the excavation of the tavern itself, the second between July and September 2011, as documentation of the subsequent campaign of excavations, adjacent to the previous one and that has brought to light some interesting remains of a public building in the north area of *tabernae*.

Were performed on both occasions scans with a 3D laser scanner, the Leica HDS3000 and photographic images were acquired using the internal machine and an external machine. Were also made many photographs not related to scanning with a digital camera equipped with a properly calibrated for the target software compensation of distortions.

Figure 3 shows the points of stations with the scanner related to the two different days.

The first day we identified four shooting stations, the first three refer to the area of excavation and the fourth, more distant, useful for a correct position on the archaeological site generally.

The second station was located on land that was later carved into the second excavation. In July 2011, when it had almost completed the first part of excavation of the public building in the area next to the *taberna*, has made a new acquisition with three other stations.

One of the main problems in the acquisition digitally using the 3D laser scanner is linked to the correct positioning of the stations on the context to be detected. The choice of the stations is determinative of a good quality of the discrete model constituted by the so-called point-clouds, from which they can subsequently derive the majority of the metric information, graphic traditional models and the polygonal three-dimensional models.

Each archaeological site presents the specificities although some aspects are applied quite frequently. The elevated structures are usually contained in height although, in contrast, "internal" environments are very small. The area to survey is often located below the horizontal plane of reference, the one which crossed the center of the instrument; should, where possible, to try to integrate the shooting low, ie, those made on the plane of the excavation, with the shoot from stations located as high as possible. The other factor that often affects the project intake is related to the field of view of the instrument that has a shadow on the bottom, with the support stand. Instrument located much higher than the area of survey on the one hand increases the visibility of structures in elevation, but at the same time also increases the shadow under the instrument.

Alba Fucens the shooting was in part facilitated by the topography of the area; station 1 positioned inside the room has been integrated with two other stations located at the top through which we were able to get a very good visual coverage altogether. Station 4 was identified as a docking station for future times that will cover the entire archaeological area and some of which have already been, meanwhile, carried.

The scannings of the second day, made in July 2011, focused on the part of the public building, with again three stations quite high compared to the area of excavations that have allowed a good level of coverage.

The registrations, that is the assembly in a single point-clouds, has been made with two separate procedures: the point-clouds refer to the same working day were recorded by the application in the field of automatic recognition with a target value tolerance of about 1 mm; the overall union of the two days instead was performed with a recognition procedure manual made possible by the many homologous points identified with a very high precision.

Fig. 4: Instrumental resolution and real resolution

It was determined throughout the setting phase of the shootings project the continuous exchange of information between the surveyor and the archaeologist, allowing to optimize all the phase of acquisition of digital data.

An element of concern highlighted by the archaeologists and the Superintendent has covered the wall in large stone blocks of north-west at the time of the discovery had a strong deformation in the central part, a sign of distress is due to natural causes but also to a static condition blocks of stone no longer optimal.

The second season of excavation has allowed much to lighten the burden imposed on the vertical structure even if problems of a static nature remain.

The digital detection was possible to verify, by comparing the scans made at a distance of 9 months the progression of the instability which was fortunately very contained in the order of a few millimeters.

The quality of the shooting done with a laser scanner as well as the careful selection of those stations also depends on a number of instrumental settings can not always be in the reports that describe the activity. One of these is the instrumental resolution, i.e. the amount of points in the unit of spherical sector, which is something different from the real resolution, i.e. the one obtained by the intersection of the laser beams with the object to be detected (fig. 4).

We can define the unitary instrumental resolution UIR (RSU in Italian), i.e. the one referred to a sphere of radius 1, which is obtained from the product $UIR = d \cdot r$ where d is the amount of points per meter, horizontal and vertical (generally equal) and r is the value of the range, ie the radius of the sphere. If, for example, setting an instrumental resolution of 2 cm with a radius of 10 meters, it follows that d is equal to 50, for which the value of UIR is 500. The knowledge of the UIR is important when it wants to estimate beforehand the setting time and the amount of information gained [14].

The real resolution but is never homogeneous and varies greatly depending on the shape of the surfaces and the distance to the station resumed. This has two important consequences in the setting of the project setting: choosing points of station to obtain a resolution as possible homogeneous parts found; choose multiple stations in order to compensate for excessive differences in the real resolution. And again, choose different resolutions, a lower over coating general, and other partial denser according to the specific formal characteristics of the object to be detected.

We already mentioned that all the shots were integrated with panoramic photographs taken with both the internal machine is the instrument with an external machine. Thanks to a special kit supplied, we can place the center of the lens of the camera coincides exactly with the center of projection of the laser beam, thus allowing a perfect match and interchangeability between photos "internal" is often not of good quality, and photos "outside" is best for resolution or for exposure[15].

3.2 The restitution through models

After the acquisition of digital data is followed a first phase of restitution in which a deciding factor was the continuous comparison between the different professional in the field.

If, as we said in the introduction, the phase of data acquisition by means of digital instruments feature tends to be objective, that is not selective (even if, as we saw in the previous paragraph, the quality of shooting is influenced by operational decisions is often not easy), the phase of restitution of the data through modeling necessarily involves a subjective interpretation.

Fig. 5: Render view of points-cloud

The experiments under way at Alba Fucens not replaced the survey techniques and "traditional" restitution that remain in many ways necessary for the documentation of the actions in progress of excavation and finds. This gave way for archaeologists to compare the information is to assess both the reliability and above all the different communicative potential.

One of the most innovative on the digital survey using laser scanner integrated with photography is to have a three-dimensional model consisting of discrete point-clouds which can be associated with the color value derived from the image photo. This new model, available immediately, can be understood as a real three-dimensional photography. The model management is still the preserve of specialists because the need for dedicated software difficult to use and very expensive. But digital technology progresses exponentially is already available software "easier" through which they could use the model "raw" (fig. 5).

Another new feature is the ability to obtain "traditional" graphical models, all digital, but easier and immediate reading, that is, for example, plants at various levels, sections, elevations, possibly supplemented with information such as photos.

The passage is not automatic and refers to the codes of representation consolidated so that no three-dimensional model, as elaborated, will be able to replace. The development of the plan of figure 6 is an example.

We tried to get a planimetric image synthesis can better represent the complexity of the archaeological site where they were still recognizable emergencies that characterize the shape. The development of the point-clouds takes advantage of some of the many views that can be obtained by varying parameters such as for example, the background color, the color map, the point cloud rendering, the density of points viewable.

Nevertheless, it is still necessary to integrate the development made by overwriting certain information necessary for the representation, information that the surveyor was able to highlight only thanks to the determinant of the archaeologist.

Fig. 6: Plan of the excavation area

Fig. 7: overlap of plans

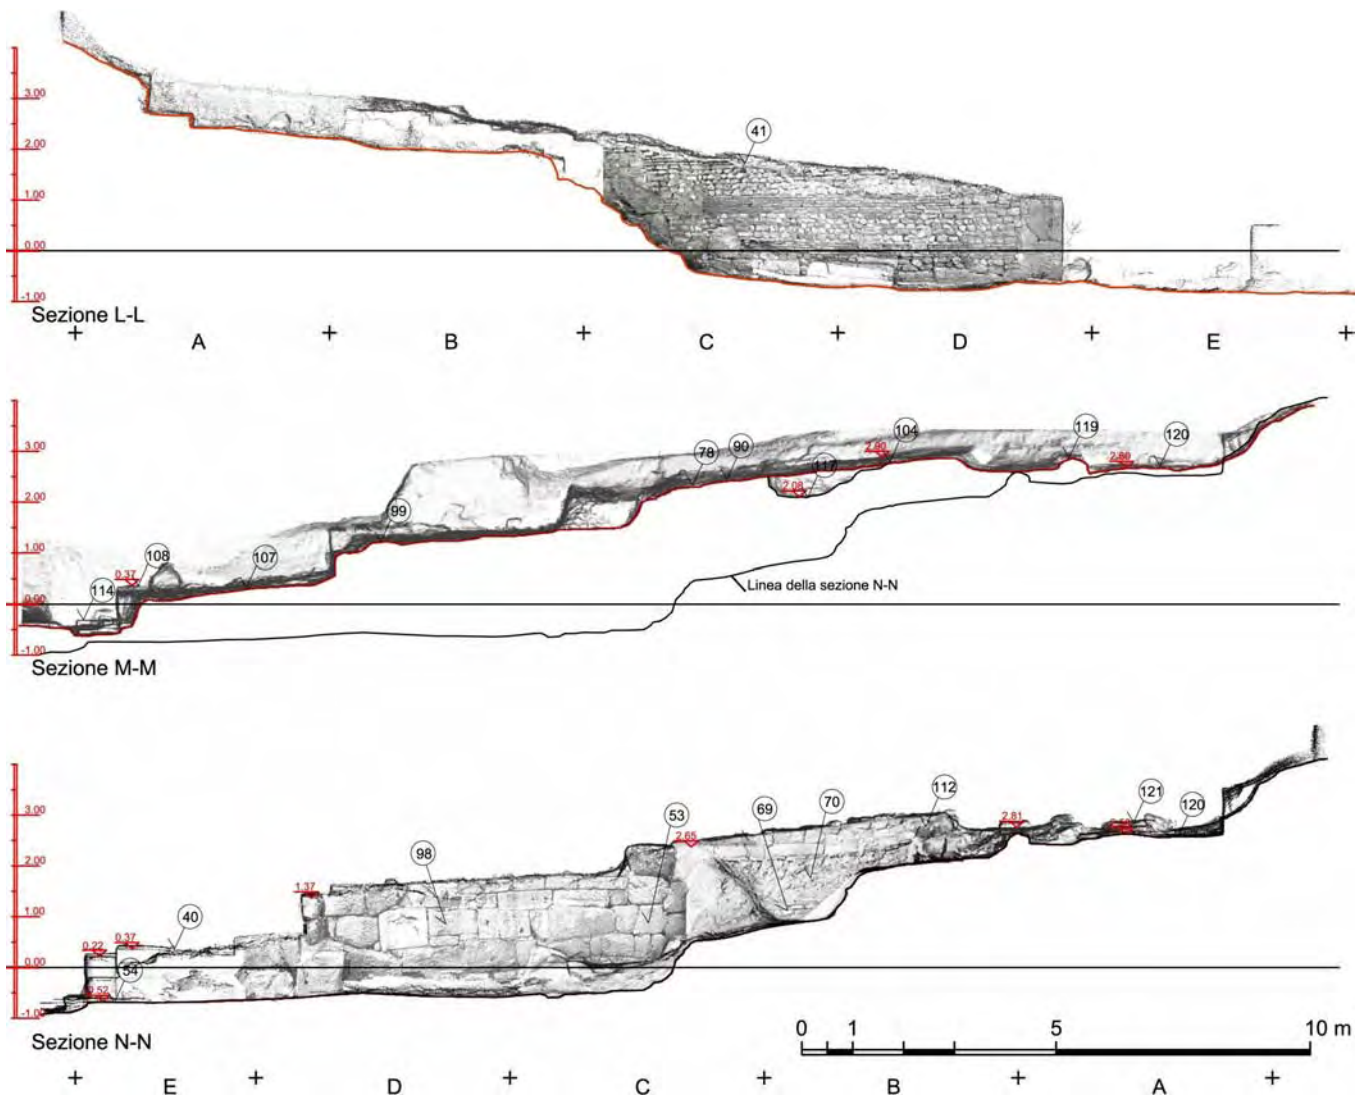

Fig. 8: sections of excavations area

The floor plan was compared with another plan prepared according to procedures previously "traditional" (fig. 7). In comparing the differences are obvious topographical, fairly small, but above all the different graphics made, based on the continuity between the artificial and natural elements of the former over the latter.

The steps identified for the development of the plan was also used for the preparation of sections, some of which were then integrated with the processing of photographic images scaled appropriately according to the corresponding orthographic views (fig. 8).

Research has therefore focused on two distinct ways of representation. The first revival of "traditional" graphical models characterized by an evident desire of interpretation, however, based on objective data as it is, those derived from the three-dimensional digital model of the point-clouds, so in essence the transition from 3D to 2D. The other processing of the same three-dimensional model in a different model 3D of the continuous type, based on polymesh modeling. In the latter case it is necessary to carefully evaluate the operations of filtering of the data "raw" for a controlled reduction of points (the cloud processed in two days and about 7 million and a half points), and noise. The main intention is that for which you want to make three-dimensional model, with a huge capacity that is representative evidently well beyond the 2D models, as much as possible "navigable" experimenting with the conversion of the continuous model in standard communication platforms like such as 3D PDF files.

Fig. 9: 3D surface model

As part of these files in common use is also possible to implement the same files 2D acting on different layers to which associate possible interactive actions, such as for instance the comparison between sections at different heights or levels of activating or deactivating thematic analysis as for example the stratigraphic study or analysis of the degradation.

4. Conclusion

The experiments under way at Alba Fucens has highlighted some interesting issues which through a close collaboration between specialists have tried to give an initial response. The management of digital models that can be obtained from the use of new techniques for survey and representation can be varied according to different levels of usability. There is a first level, on the field, which covers the documentation of the excavation activity, where the processing is necessary to integrate the traditional with the first three-dimensional digital processing. There is a second level for the consumption of the scientific community in which the representation is true instrument of knowledge and verification of the first assumptions made in the field. The model must be able to display all its topographical objectivity but must also be able to return a first level of interpretation. It must be fully supported in order to be implemented through the historical considerations and first assessment of conservation. Finally, there is a third level of usability, the one to use and consumption of the community, in which the model of restitution must necessarily be more easily understood and manageable also and especially by means of disclosure of mass, and for example the web [16], through which give visibility to an immense fortune scattered and for this too often left to his fate. Being able to set a suitable and qualified network of interchange between the different levels is the foundation for the construction of the Knowledge Factory is able to activate virtuous processes not only cultural but also economic in common territory.

Generative Architecture as a methodology of optimisation. Spanish examples.

Angélica FERNÁNDEZ, Zaira PEINADO, Luis AGUSTIN

Area of Architectural Graphics, Escuela de Ingeniería y Arquitectura, University of Zaragoza, Zaragoza, Spain

E-mail: af@unizar.es, zpeinado@unizar.es, lagustin@unizar.es

Abstract

At the present time, with the help of software (Grasshopper, GC or RhinoScript), architecture has undergone a change of design. The use of algorithms makes it possible to solve geometry problems using curves and freeform surfaces, enabling the generation of previously unthinkable fluid spaces and skins. This generative architecture can not only be innovative from a visual point of view, but also sustainable and economical.

To reduce installations, waste, energy consumption or materials may be some of the advantages of these architectures of complex geometry, apparently less functional.

In Spain, a trend has risen in this direction. Examples would be the Barcelona Media-Tic Building by Ruiz-Geli, whose façade is a moving sunscreen that facilitates the control of light and heat; the Villa NURBS coated by ceramic pieces that regulate the intensity of light; the Space Metropol in Seville designed by Jürgen Mayer based on a bioclimatic operation scheme or the project for the National Energy Museum by Cero9 team.

Keywords: Generative Architecture, Parametric design, Algorithms, Optimisation.

1. Introduction

Nowadays, the way of making architecture is changing with the advent of the digital age and automated software processes, which make it possible to create forms previously impossible due to the lack of appropriate tools. Not long ago an architectural project was done, its efficiency was proved and almost never any corrections were made, because they were costly in time and in media resources. Now, new technologies allow to do the project through parametric modeling, a tool that offers the advantage of making any corrections instantly and effortlessly, changing the geometric operations in real time, thereby increasing our expectations compared with the use of an analogical technology.

2. Generative architecture. Concept and technologies

The concept of generative architecture or parametric design means that, through geometry and parameters, a form definition is allowed by applying user-driven relationships, where we can change their properties obtaining different results, getting a great flexibility in designing. This is one way of using generative algorithms.

An algorithm is defined as a list of instructions for solving an abstract problem, i.e. a finite number of steps that convert data from a problem (input) into different solutions (output). A generative algorithm is associated with the steps defined for geometry problems in the design process and the selection of the best variable. They must be seen as a design tool that provides new ways.

The commercial software used is Rhinoceros with Grasshopper plug-in (GH), RhinoScript and Generative Components (GC). The firms define their products as follows:

GC is integrated with Building Information Modelling (BIM), analysis, and simulation software, providing feedback on building materials, assemblies, systems performance, and environmental conditions. This integration also ensures that intent becomes reality by enabling designs to accurately and efficiently flow through to detailed production and fabrication. (BENTLEY SYSTEMS) [1]

RhinoScript is a scripting tool based on Microsoft's VBScript language. With RhinoScript, you can quickly add functionality to Rhino, or automate repetitive tasks. (McNEEL) [2]

Fig. 1: Quad Meshes in Architecture by Benjamin Schneider (TU-Wien) created using Generative Components. [3]

Fig 2: Part of the project "Blurring Structures" by Prof. Grohmann (University of Kassel, Faculty of Architecture, Departement of structural design). The generating script is based on Aristid Lindenmeyer's L-System. In order to dimension the structure automatically, a RhinoScript-RSTAB-Interface was developed. [4]

Grasshopper® is a graphical algorithm editor tightly integrated with Rhino's 3-D modeling tools. Unlike RhinoScript, Grasshopper requires no knowledge of programming or scripting, but still allows designers to build form generators from the simple to the awe-inspiring. (GRASSHOPPER 3D) [5]

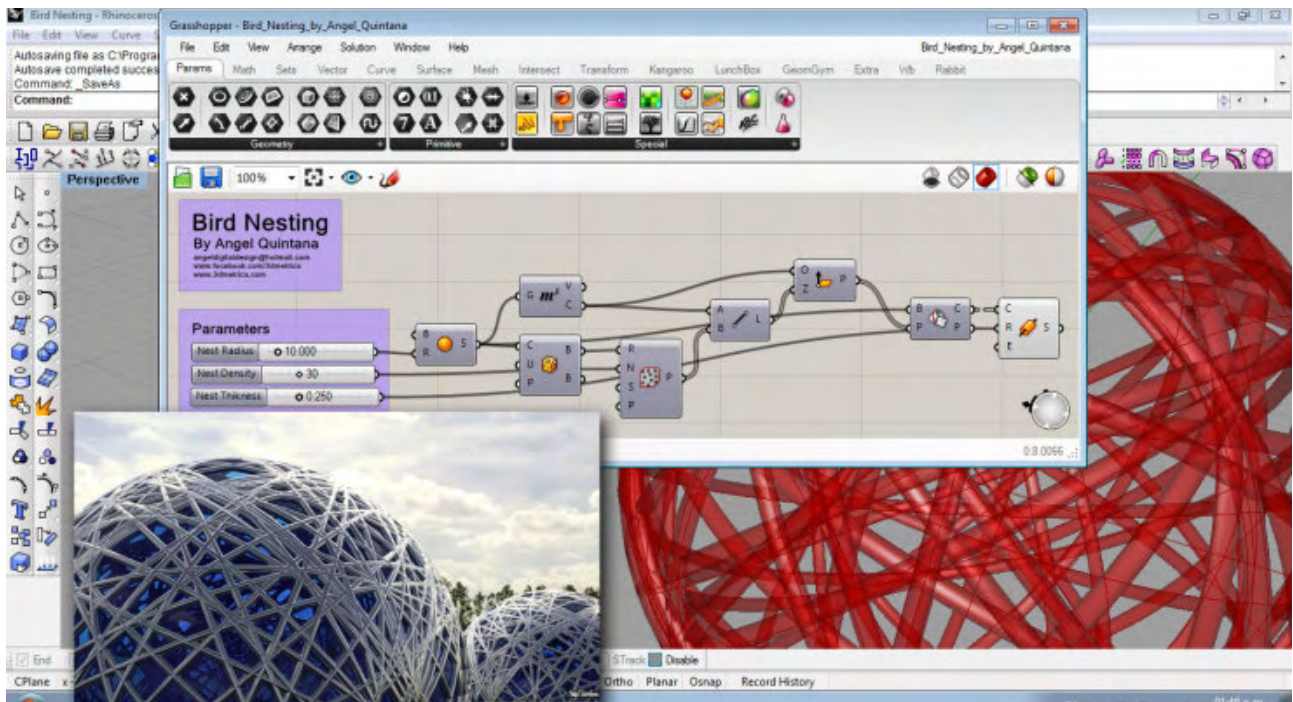

Fig. 3: Bird Nesting Definition by Angel Quintana created using Grasshopper. [6]

Parametric modeling uses manipulative codes that allow the introduction of interacting variables and get a higher level of complexity. We have to familiarise ourselves with a number of concepts: independent variable (or user-defined numeric input) and dependent (output, whose value changes, result), constraints (delimit the

range of variations, rank, series, intervals, sentences), parameter (contains data stored), component (contains action, does things), curves and polysurface NURBS (Non Uniform Rational B-Splines) and finally recorded data flows, data lists and operating functions. [7]

Fig. 4. Example of NURBS forms and Grasshopper code [8]

The use of algorithms makes it possible to solve geometry problems using freeform curves and surfaces, spatial distributions generated by mathematical formulas such as the triangulation of Delaunay or the diagram of Voronoi. Using algorithmic methods, we have a range of computational geometric possibilities while we can manage a large amount of data and numbers. We don't have to limit the project to predefined experiments. We must exploit the potential of algorithms and their numerous possibilities. [9]

Finally we should define the design and computer aided manufacturing (CAD / CAM). It is a discipline that studies the use of computer systems as a support tool in all the processes involved in the design and manufacture of any product, covering disciplines of graphic design, database management for the design and manufacturing, numerical control machines, robotics and computer vision.

CAD (Computer Aided Design) consists of using computers to perform tasks of creation, edition, analysis (FEM or Finite Element Method) and design optimization. CAM (Computer Aided Manufacturing) is the use of computer systems for planning, management and control of the operations of a manufacturing fabrication using the interface directly or indirectly between the computer system and production resources. [10]

Thus, combining architectural CAD / CAM manufacturing and digital laboratories, FabLab has emerged, where numerical control machines are used to make models of objects. Its uniqueness lies in its size and its strong links with society. The Fab Lab concept appears at the beginning of 2000 at the Center for Bits and Atoms (CBA) at the Massachusetts Institute of Technology (MIT). An example is the FabLab house designed by the Institute for Advanced Architecture of Catalonia (IAAC), MIT's CBA and FabLab Barcelona. Fab Lab won the Solar Decathlon Europe competition. This solar house combines parametric design and CAD / CAM. Its climate passive structure uses water, sun and wind to create a microclimate and integrates flexible solar panels. [11]

Fig. 5,6: FabLab House. [12]

3. Optimisation as an ecological challenge

Having arrived at this point, we should emphasise that parametricism is a method – a tool serving the designer. As Robert Aish says, “The abstract concept of parametric design, like other methods, is neutral. Buildings and urban masterplans designed parametrically may have attractive visual properties and other positive advantages partially facilitated by parametric design tools, but a particular methodology or tool set cannot be used as a way of justifying the resulting style” [13].

Software should be therefore open or abstract enough to avoid standard or predefined solutions, that could turn into conventions. *Tools should challenge the designer* [14], instead of substituting him.

One of the architects’ challenges, that can drive them to use the mentioned tools, is optimisation. With a first extended use in 19th-century biology, the term ‘optimal’ refers to “the best conditions of, let us say, light, temperature, altitude for an organism to prosper. (...)The process of optimisation describes the synthetic search for this best state within a model, whether of a biological system or architectural or structural system, usually under a set of restrictions, implied or expressed” [15].

Depending on the mathematical model used, optimisation methods differ. There are stochastic methods, with a random or probabilistic basis; deterministic methods, where values are assumed to be precise and no randomness are in play; and hybrid methods, which combine stochastic and deterministic steps.

On the other hand, the designer has to decide whether constraint rules or purpose rules have to be applied, depending on his objectives.

Through optimisation, important savings can be achieved in the construction phase and during the life of a building. Especially material and energy savings are important, not only because of its economic advantages, but also because of the ecological ones. Ecology has become in the last decade an essential factor to consider in the project. This has encouraged the search for new solutions, and the invalidation of old and accepted models. The integration of parametric design tools in architecture gives a great potential for new spatial possibilities, not only formal, but linked to processes of energy flows, taking into account the concept of sustainability, resource management needs and the relationship with the medium.

Important architecture firms have created their own research offices, that work on developing those new solutions and incorporating them into their architecture projects, as well as offering consulting services to other firms. One example is Aedas R&D, an office in London whose main areas of research are: computational design, advanced modelling and sustainable design. This cross-pollination of interests has led the practice to develop innovative approaches, exemplified by the design for Al Bahr towers, the Abu Dhabi Investment Council Headquarters and the Digital Masterplanning (DIGMA) tool. [16] Another example is SMG (Specialist Modelling Group) at Foster + Partners. They provide expertise in complex geometry, computer programming, parametric design and rapid prototyping and environmental simulation, aiming to provide directed specialist support whenever required. [17]

Fig 7 Al Bahr towers (by Aedas) [18]. The façade employs an adaptive kinetic shading screen.

Fig 8 Masdar City (by Foster + Partners) [19]. It is poised to become world’s most sustainable city.

The structure of a building can be optimised with the help of calculation tools, with the aim of a lower impact on the environment. A plug-in for Rhinoceros-Grasshopper is Scan&Solve™. It is a *plugin from Intact Solutions that completely automates basic structural simulation of Rhino solids. Unlike other analysis tools, no preprocessing (meshing, simplification, healing, translating, etc.) is needed. It allows integrating finite element analysis directly in the graphical programming of parametric design.* [20]

Light and energy savings during the life of the building are another of the objectives of the application of optimisation methods. For that purpose, it is important to know first the specific conditions of the building: the occupancy and uses, the time variations during the day, or the seasonal variables, for example. A greater energy efficiency can be achieved if the trajectory of the sun is taken into account. Tools have been developed for it, such as the ECOTECT software, and the GECO plug-in for GH. They allow variations and dynamic models, where solar incidence can be added in order to generate more efficient and precise settings, and thus simulate, analyse and design strategies for solar control and harnessing. One of the biggest advantages of parametric design is the interdisciplinarity, giving the possibility to involve social or structural criteria, flow simulations, etc... in which a process, and not a specific result, is designed.

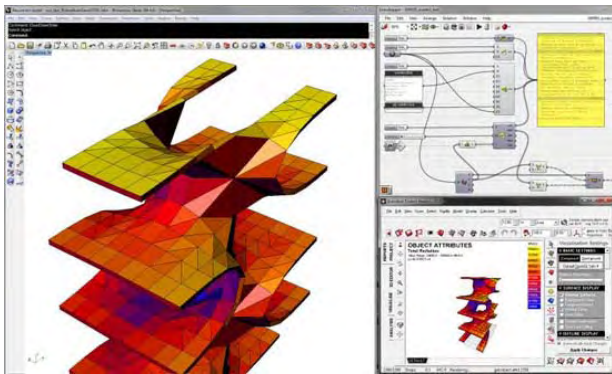

Fig. 9: Geco: component for Grasshopper created by [u t o] (Ursula Frick & Thomas Grabner) [21]

4. Spanish Examples

4.1 Media-Tic Building

Cloud9 (Enric Ruiz-Geli)

Barcelona. Spain. 2006-2009

The building is located within the 22@Barcelona and the ICT and Media cluster. The Media-TIC is an emblem of the digital world headquarters and a meeting place for companies and institutions in the world of ICT technologies. The building was designed and built through CAD-CAM processes and was designed to be a large generator and to optimise its use.

It has a cubic shape (40x40x40m) and its structure consists of four rigid bioluminescent frames braced separated fourteen meters to each other, that produces open and flexible spaces through parametric processes that allow an optimal configuration for the central courtyard and the two vertical communication cores.

Following issues were optimised:

- the evacuation distances in case of fire
- the area with natural lighting
- the flexibility of the floor distribution
- the ratio of sq metres of vertical communication over programmed sq metres (with a loss of 8.5% compared to normal 15%).

With the building energy simulation, heating and cooling demands have been adjusted, minimising the dimensioning of the facilities.

The building envelope consists of ETFE (Etilene Tetrafluor Etilene). It is a transparent plastic coating of three membranes, oriented to the south and functioning as a variable sunscreen. They open in winter to harness solar energy, closing in summer to protect themselves, activated by autonomous lux sensors to provide more transparency or opacity. The western facade is filled with a Nitrogen mist inside and with a great sunscreening factor, which protects users without sacrificing natural light. They also use sensors for temperature and power consumption, so that energy saving is very high. [22]

Fig. 10: Media-TIC by Cloud 9, architect Enric Ruiz-Geli. Photography by Luis Ros. [23]
 Fig. 11: Metropol Parasol, photo by David Franck. [24]

4.2 Metropol Parasol

Jürgen Mayer
 Sevilla. Spain. 2006-2009

The Metropol Parasol project is located in the Plaza de la Encarnación, in the historic centre of Seville. The Parasol with its giant structure unifies the different levels of space, such as the ruins which rise from the subsoil or a market located in the square with a long tradition, and incorporate new spaces on an elevated plaza. It has become a contemporary new urban centre. It is designed using parametric tools, as a lightweight, hundred feet high wooden structure, which offers daytime shade and light input channels of the setting sun, creating a pleasant microclimate.

The structure is one of the largest in the world and consists of 3000 pieces of wood and forms six fungal parasols. It is approximately 150 meters long, 75 m wide and 28 m high, introduced into an orthogonal grid of 1.5 x 1.5 meters. For structural calculation an iterative calculation program was developed with the 3D model to determine the thickness of the wood elements in each of the joints of the structure suitable for optimization.

Metropol Parasol structure provides a shaded area to the intense sun of southern Spain. The hatch covers the public square as the roof of the market. The plaza level becomes the attraction of public space, while the level of the market means a reduction of cooling loads for air conditioning.

With the use of parametric design a continuous and permeable structure is created, allowing light to enter the square and avoiding a screen effect, and also permitting to remove the hot air generated in the square lowering the temperature in the hot months, thanks to the shading. It has therefore been prioritised in the study of the generation of shades in the square in the months of March, June and December in four different times (9:00 a.m., 24:00, 15.00h and 18.00h) of solar incidence.

The microclimate of the Plaza is improved through the wooden structure of the Parasol. Timber hardly stores heat and therefore does not radiate heat generated in the square. The shade prevents heating too. Furthermore a free cooling system is provided through fountains, reducing the sensation of heat. [25]

Fig. 12: Function diagram Metropol Parasol bioclimatic, initial project. [26]

4.3. Villa Nurbs

Cloud9 (Enric Ruiz-Geli) + Jordi Fernández
Empuriabrava (Girona). Spain. 2003-2008

The villa is a private house located in Empuriabrava, a coastal village in Catalonia developed touristically as a place of weekend retreats and second homes.

The building is completely closed to its environment, by contrast opening itself to a private central courtyard. The house consists of a ground floor of curved concrete walls, that turn into a cantilever slab, and a first floor, also with curved geometries, with spaces arranged around the courtyard and the pool. The façades are made of different materials, some parts are translucent and other opaque, coated with original hand-painted ceramic pieces. The roof consists of ETFE cushions, which swell and deflate mechanically.

As can be read in the website of the architect's studio [27] the project was developed following a series of process "rules" set by the designers themselves. Here go some of them referring to the optimisation ideas and tools used:

- 4 measure and construct the 3D landscape as a TOPOGRAPHY
- 6 the geometry is COMPLEX
- 7 the goal and benchmark will be a NURBS
- 9 optimize resources building construction using CAD/CAM processes
- 11 invited industrial designers work from the skin of the Nurbs to the skin of the inhabitants, looking for a CELULAR, chemical approximation of materiality
- 12 the design is always PARTICIPATORY with the customer
- 13 definition of ATMOSPHERES into the skin
- 15 skin is reactive and manages ENERGIES

Fig. 13: Villa Nurbs. Aerial view [28]

Fig. 14: Detail of the roof 'pillows', showing ducts that regulate solar penetration by inflation and deflation. [29]

Mark and Jane Blurry describe villa Nurbs stressing its properties as a NURBS project and its efforts for optimization [30]:

"(...) at Villa Nurbs a performative quality has been introduced by allowing the pillows to control the degree of solar penetration, simply by varying the degree of inflation. This was achieved by screenprinting an image on

one wall of the pillow, with its negative on the opposite wall. When the pillows are highly inflated, more sunlight can find a path through them than when they are deflated (when the positive and negative images align more closely, effectively occluding more of the sun's entry than when inflated).

It is the project's name – Villa Nurbs - that reveals its main conceit. It is as if a CAD project has been directly translated from computer-generated non-uniform rational B-spline surfaces (NURBS) directly to built object, which is of course what has happened - hence the description of the house in its suburban context as 'uncompromising'. (...)"

4.4 National Energy Museum

Cero9 (Cristina Díaz Moreno + Efrén García Grinda)
 Ponferrada (León). Spain. 2009 (concurso)-

The idea of the museum starts from the dismantlement of all the machinery at the Compostilla Power station, leaving two large, roughly built pavilions. They shall be used for housing the museum contents, together with a new volume which is connected with the existing pavilions underground.

The new building contains several exhibition rooms superimposed vertically. The ground level is occupied by an immense atrium, a sort of greenhouse with large vegetal specimens that acts as a climatic hall, receiving warm air from underground conduits. Most striking is the complex geometry of the ceiling, designed considering air flows and its thermal behaviour. This is how the architects describe that geometry in *El Croquis* magazine:

"The roof of the atrium is shaped to accelerate the air rising from the underground galleries. The solid volume is eroded virtually by upwelling flows -produced by air instead of water- generating an inverted geology which feeds the air into the large lateral apertures and the various intermediate chambers on each floor. The interior domes act as massive chimneys, their pressure difference triggering kinetic suction. The roof is a set of two large central pools of air, two smaller lateral units set alongside the facade, three large outward facing funnels which also feed light into the building, and three inverted domes which channel air into the rest of the rooms and shape the space of the large interior." [31]

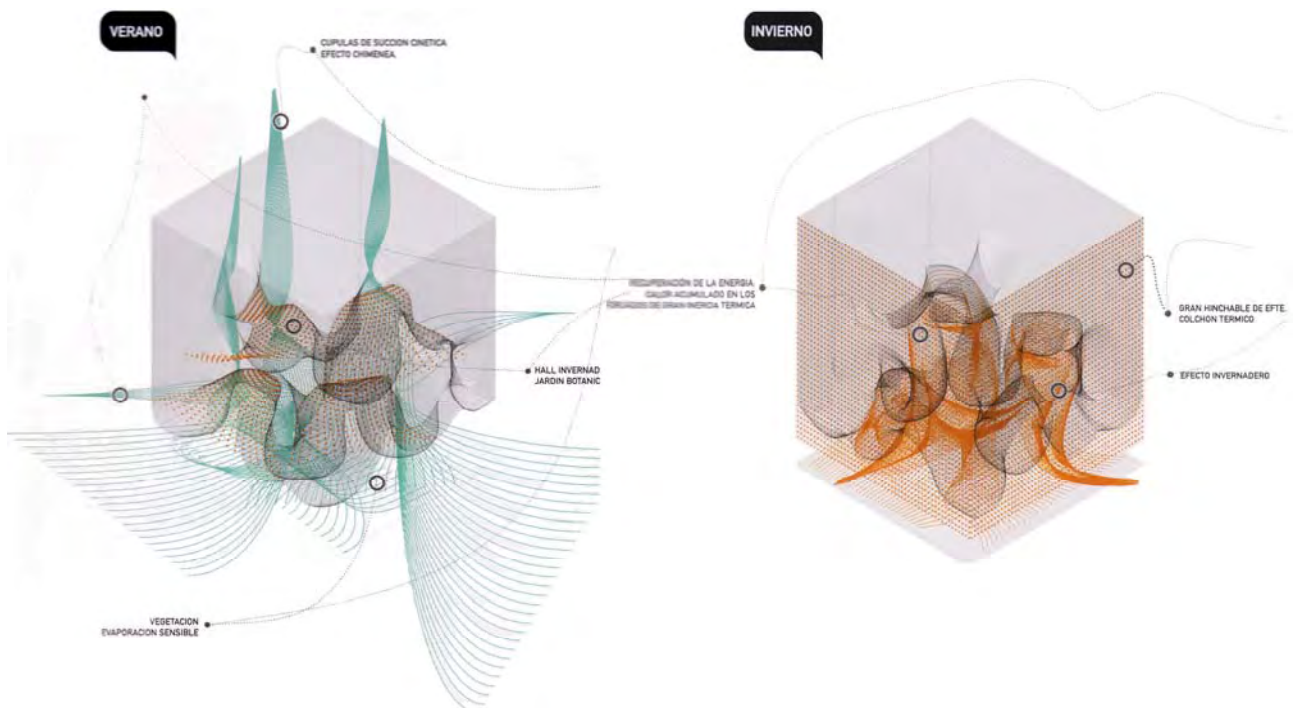

Fig. 15: Air flows and solar incidence in summer and in winter. [32]

The façade of the volume is also designed considering thermal criteria and experimenting with materials, just like Enric Ruiz-Geli. The architects refer to the façade as a "black inflatable jacket", that "acts as a thermal blanket which reflects the position of the interior domes in the geometric pattern generated by the necessary fragmentation of the surface. This discontinuous chamber, subject to overpressure, consists of two successive silicon skins reinforced with bulk-tinted fibreglass and pattern of transparent apertures, with outer

skin made from a composite fluoride film which at the same time insulates and closes off the interior rooms.” [33]

Fig. 16: General view showing the inflatable façade. [34]

5. Conclusions

What one can see through the examples above is that new geometries are not just applied into special projects, or into exclusively academic or theoretic researches. They respond to normal assignments, providing more benefits than a traditional solution. Computational design and parametric tools can in fact be combined with other, more traditional, working methods, giving answers to a specific matter or part of the project.

These tools are nowadays not very widespread, but the use of them becomes increasingly frequent, as more software is developed, more powerful and user-friendly.

In regard to the ecological optimisation, the use of those tools is quite recent and their results have not been broadly proven yet. It would be necessary to keep track of those architectures designed with parametric tools, and to see if its performance is actually better than that of other architectures developed with traditional solutions. This will tell us if the starting conditions and the rules set forth are correct, or if on the contrary, they must be improved. This will allow an increasingly better use of the tool by architects and designers.

It is also important to study comparatively the construction costs of those architectures (due to their complex geometries or materials) with other solutions, given the current technologies available, as well as their ease of use and maintenance.

More or Less... “Drawings” (as Heritage Preservation)

Pedro António JANEIRO,¹ Ivo COVANEIRO²

⁽¹⁾ Department of Drawing and Visual Communication, Faculty of Architecture, Technical University of Lisbon (FA/UTL), Lisbon, Portugal; CIAUD – Centro de Investigação em Arquitectura Urbanismo e Design (FA/UTL) – Research Project *Imagined-Architectures: Architectonical Graphical Representation and “Other-Images”*.

Abstract

The present paper aims to present a new point of view about what “a drawing” for architecture can be. Invented from a true story: the story of a child that in the dining room at the home of his grandmother, with rows of colored wool, tied the door handle to the lamp, and from the lamp he tied the leg of the table, and from there until the nail that hangs a blue watercolor; and from there to another point and so on..., this project we now present is a metaphor for looking at a place (in the present case, an Italian city: Narni) in a new way. With this new approach on Drawing – 3 dimensional drawings done with colored “lines” of wool –, through simple (artistic?) interventions, signal (in order to call people’s attention) the necessity to preserve that city architectural Heritage. As this child, using lines of wool, were built artistic interventions in the architectural heritage in the historic center of a small town.

This installation with lines, with a signaling function, woke up the space and aroused the objects of their quotidian heritage; giving them another sense: from anonymous to main protagonists. From *forgotten-objects* to *visible-objects* that need care and preservation. The purpose of this (art-)work was to intervene effectively in the Heritage of this city, valuing it and putting it in evidence and at the same time giving them other possibilities to be read from new aesthetic experience.

Keywords: Architecture, Drawing, Preservation, Heritage, Intervention.

Paper

My father, when I was a kid drew like anyone: my first contact with this “thing” that is remove from reality, or create from (invisible-)imagination, other-“thing”-similar-like-“it” was through him; he invented landscapes, explained things to me, drew donkeys (still my favorite animal), flowers made of hearts, Speedy Gonzalez, all through drawings.

When I was a child I used to go to my father’s studio, and there, he gave me sheets of paper; in those times I could not even read and I didn’t know the weight of words.

He gave me paper and I drew. I was trying to repeat my father’s drawings.

I was drawing, just drawing: things.

Drawing is good but it has a price. It is true that I was trying to repeat my father’s drawings, but what I really liked to draw was my hand.

With my hand over the A4 sheet and with a graphite pencil I was making the line travel around the periphery of my left hand.

Only much time later I met Lascaux. Only much time later I met *The Life of Forms*, followed by the *Praise of the Hand* by Henri Focillon, first published in 1943. Hands, he says: "They are almost alive beings. Are they slaves?"

The hands, I remind you the text: "[...] in the back light of one witness of the great *Resurrection of Lazarus*, the working and academic hand of Dr. Tulp, holding with a clamp a bundle of arteries in the *Anatomy Lesson*, Rembrandt's hand drawing, the amazing hand of St. Matthew writing the Bible dictated by an angel, the hands of the old cripple in *Coin of One Hundred Florins*, duplicated by the big and naive gloves hanging from his waist." My own hands on a draw, those I made when I was a child, I don't have even one copy today.

The hands are slaves of the Spirit.

(Before continuing I need to say one thing. In fact, several things.

Point one: I consider more *the Human* than erudition, more who-speaks than what-is-speaking-the-speaker.

Point two: I consider more important to talk about what is needful to speak in first person than exhaust ourselves in quotes, bibliographies, and authors, and, above all, that I reject, with all my cells, the (academic?) fear to say what we really think about the things of the world using, instead of the majestically typical plural of scientific discourses, the word *myself*.

Only one more point, please, point three: that I am fully aware, on the one hand, that the speech-about-something is replacing that something; and, on the other hand, I don't have, as human, legitimacy to speak about something that I don't know.

And more, point four: that the Truth in Science is a relative value, therefore a paradox, upgradeable; that the only Discipline where Truth is not is a "continuous movement" is for Theology (which, interestingly, is the study of God); to finish, point five: I am, as the way that Heidegger describe things, *Mortal on Earth* and I can make mistakes and/or review my positions on things.)

It amazes me Lascaux: the silhouette of a man's hand before me on the wall of a cave saying him, saying to me: "I am here and I was here." Here, really here: where he was with his feet in the same place where I am, where he – assuming his verticality – had been with his own two feet supporting his body.

Here, architecture. He and me: men.

Drawing is, among other things, a will of the body. Who draws knows that is the body who wants another draw: one more fixed instant, even if it is the last one.

Marie Antoinette Habsburg-Lorraine, it is said, asked the man who pulled the rope – which was also a line – the guillotine on 16 October 1793: "Just one more minute."

Just one more minute (to see again), a second look, a new look.

One minute to see. To see the world for the last time.

We live concentrated in draws as a product. Finished, if they could speak, they would tell us the world, but the drawings do not speak, they don't say nothing, they are silent, they do not delight us like the words enchant us, they don't deceive us, they don't cheat us, they don't lie to us, the drawings are always true, even those of Escher, and they are always "this", even the *Ceci* from "*Ceci n'est pas une pipe*"; the drawings are the world and from the world itself.

The draws are always *Ceci*, This. They live from This, they replace This (*This* is always the world) I mean: they, as a product, are a vestige of a human moment in the world.

I am fascinated with this idea: that the drawing is a kind of robbery. A drawing *al vif*, among other things, is a kind of fragment that I cut and steal to reality.

Drawing is a permissible robbery: because what one draw steal, gives it back in double or more, to the stolen world. When I say that some draw is good then the world is richer because, as a product, that draw is one more object in the world. I steal but I give it back: what-I-steal don't stay because the movement of the world is continuous, but what I give – this instant of world turned into a thing – replace it.

I say that I steal, but I know that I give it back.

If I draw on a portable support (a sheet of paper, for example) I steal and I bring the stolen world under my arm; if I draw on a surface that I cannot carry with me (on a wall, on the floor, on the glass of one window, for example) I leave a trace of my crime at the scene of the crime; If I draw on the dirty surface of a car with my finger, then my drawing will travel; in this is evolved my body who wants it.

When it was presented to me the concept of "intentionality" – by Husserl and Merleau-Ponty, my guides, through their written word – not only changed my life as I began to see a draw as, like all things that the body produces, a practical posture of one theoretical and philosophical proposal; an effectively encased of the body with the world, a combination of the *body-that-is-world* with the *world-*

itself, a split of consciousness through, not what is surrounding me – because, in fact, nothing is around me – but through feeling the body-that-draws, while is drawing, world.

If I draw on my skin on the palm of my hand or on my neck for example, then the problem is deeper. Who draws knows that while the drawing takes place on a surface we can feel, in the fingers and in the hand that holds a pencil or a pen or a brush, the line; there is a tact that involves the hand that is drawing; we feel the hand seducing the leaf or the wall with points, lines or spots until the world be the world, until the world, anamorphic and labyrinthic, turns into a *form*.

Although even if is not the hand that touches the sheet, we can feel the sheet in the hand. If I draw on my skin then I feel the skin on the hand that is drawing and the skin being drawn: it is one, actually, *interface*, the line is not from the hand nether is from the skin, but, paradoxically, is from both of them.

The function of the pencil is, while I am using it, drop a line. The graphite cylinder that is inside of the dark of my pencil made wood, in molecule, is a diamond (a carbon in its purest state), its function is, through me, my body, feel the glow that flows by the contours of things that make what-I-call world. The graphite inside my pencil, or the cubic centimeters of ink from my pen, can, potentially, build a line with thousands of meters.

From the tip of my pencil or my pen, if pressed against a surface, came out from the *disordered world*, *the world seen* by me: a world reconstructed by lines saying borders between figures and backgrounds, if the lines are intertwined we get clear and darkness, starting points and ending points finishing a draw, finishing sentences if I used them to write.

I do *This* with my hand.

Points, centimeters, meters, and miles of line. A line sleeping inside my pencil, chaotic, meaningless in the cylinder, and because of the will of my body, through the line, decides to wake the things of the world.

Just one more minute.

I also remember how, as a child, I disembarassed a skein of wool line that my grandmother opened with her arms until being built a sphere, a ball. From the incredibly strange skein of wool, anamorphic and senseless, embarrassed and full of nudes of wool, ran a line.

From the open arms of my grandmother to my right hand that rolled over my left hand a harmony, I remember the time (which took the wool ball). I learned only after the *Metaphysics* and the eleven concentric spheres of Aristotle made of an unchanging *fifth element*, a perfectly transparent substance known as “ether”, one immediately beyond the blue, a blue in transcendence, a blue in coma.

I didn't know, at that time, about Eudoxus and Callipus.

Even now for me to draw is this: we are solving the nodes of the skein, catching the end of a line and put it in order (my order) the violent *chaos* of the world. And, perhaps, this is why the drawing interests me more as *process* than as a *product*. I am more interested to run the line than the ball ready, the process than the product.

I am more interested in the gesture of the hand, how many times it stop, the speed the line travels from the skein to the ball of wool than the ball or the skein; I am interested, especially about, the time. Every drawer knows that while he is drawing the time seems to stop: a kind of putting parentheses in the world while we see the line turning into a thing, an *epoché*, a kind of *ek-stasis*.

Ready the wool balls my grandmother built sweaters (it was therefore also in power in the disorder of the thread, through the use of line, the temperature); and I, with these lines of colored wool: tied the door handle (of the little room where we had lunch) to the lamp, and from the lamp, with the line stretched, I tied the leg of the table, and from the table leg, I stretched it well, until the nail that hangs a blue watercolor of the Swiss artist Fred Kradolfer (an underwater landscape); and from there, from that steel nail which is still there today, I stretched the line carefully to the shade of the lamp that was on top of a small table next to the couch, and from there to the key (made of yellow metal with cute letters saying OLAIO) of the closet door where was kept the white porcelain and cobalt, and from there to another point, and from that point to another; point by point I traveled the line of wool, until, after a few hours of creative work, like inside of a web, I stopped amazed, just to see it. Just to see how that room, through my own *intervention* (artistic?), had won other senses. At the time I didn't know, but I built three-dimensional drawings.

After all, the line that comes out from the anonymous cylinder of a graphite pencil or the container that holds the ink inside a pen, is not so different from the line coming out of a ball of wool: in “intentionality”, the line is exactly the same, in the will of body and in use, the pencil line and the line of a woolen ball, are the same; the same line that Pseudo-Apollodoro tells us, the line of Ariadne and Theseus in the labyrinth of Daedalus, in the *Library*.

Actually, I just realized what I did with the line that came out of the chaotic skein, labyrinthine, was a drawing (a three-dimensional drawing) a few months ago (22-29 July, 2011) in an exercise of drawing with lines of wool in a workshop called *The Time and the Happening: Drawings as Artistic Interventions* that I coordinated in Narni, Italy, at the 9th International Seminary of Architectural Design: "*Architecture Town Territory in Transformation, Tradition, Contemporaneity, Sustainability, Project Reflections on Recovery of Historic Towns*".

We are so used to flat surfaces to draw that when we can mark (in) the air with a line of wool, for example, we almost forget that we don't need to stick to the idea of the plan.

With the line I linked everything to everything like a fractal or a mathematical 'curve stitch' by Mary Everest Boole in the late nineteenth century.

My (artistic) "installation" meant that certain aspects of the room were more popular, more noticeable. The line that I used, were pointed certain aspects that, probably, would be forever unnoticed by the inhabitants of the space. This is because the eyes follow the line.

In addition to the aesthetic aspects of the installation, seems that the line had almost a signaling function removing from anonymity certain objects or certain characteristics that without it, without the installation of colored threads of wool, nobody, because of habit of using that space, have seen. My installation, my 3D drawing, woke up the space and aroused the objects of our quotidian heritage; giving them another sense: the passage from *anonymous* to main *protagonists*; they could be seen: in fact, a spatial experimentation at a scale of 1:1.

Anyway: if we draw on a sheet of paper or on a wall, on the glass or on the skin, drawing is always something-between.

Between what and what?

Between whom and whom?

Between whom and what?

Between what and whom?

From drawing and the draw interests me especially the time, I am interested in the meantime that the draw saves. Almada Negreiros said: "A drawing is our understanding to grab a moment."

It is true.

Time, that great sculptor. Time without the tyranny of Chronos, the time invisible, intangible, sensitive: sensitive, means, because I feel it happening; a Kairos, "the right time," "timely," *καιρός*, "mine".

The time that I care about, is because of that, a drawing, is the time of the happening of the draw and not so much the product of that happening. If the Time born from the relation between *me* and the *things(-in-myself)*, then I can tell you, is because this time is (or exists) inherent to that (or in) my relationship. A draw is the remnant, is what remains from this relationship, and drawing this own relationship. That's why I said that drawing is putting in practice the notion of "intentionality" very well described from the Discipline of Phenomenology and Existentialism.

In this sense - the sense that I can admit the existence of a correlation between *the act of drawing that aims to achieve* (the intentionality) and the *target object* - the object is not only a pretext for the construction of a synthesis of subjective identity through which I can become aware of myself; it - the object if drew it - is, primarily, *a unit of meaning* - "[the object] is not, then, more than a face-to-face (*Gegenstand*), and my consciousness the place where those face-to-face exist; more: to tell the truth, those face-to-faces are the only way I know I have something named as conscious; even more: consciousness is not conscious of herself. She always needs an object.

It is through this relationship that I draw things and, is in this process, in this face-to-face, that, in a certain point of view, things are not for me just an excuse to build a synthesis of my identity, necessarily subjective, through which I can I learn about myself.

The things for me, while I am drawing them, are, above all, "possibilities", "timely moments", "right moments" of time, chances to inscribe me in the time (in the present, in fact here being for myself), without which (my) own experience of things would not be possible. If so, if time comes from my relationship with the object and, therefore, in this birth I assist to the constitution of an imminent temporality (where my experiences are inscribed or incorporate), then as a man, I depend entirely from that constitutive possibility of things.

Drawing for me is the happy opportunity to find me with things and with the others; a draw is what stays: paradoxical witness of the relationship between two systems: Me and the World (which has features of both; an *interface*).

"Paradoxical" because me and the World are one and the same thing, especially while drawing.

Utopias of the Radical movement as 'process' for the analysis and design of public contemporary space

Mónica VAL,¹ Marina PUYUELO²

Abstract

The value of representation in communicating and the developing ideal social representations is unlimited. Similarly, the development of architecture and design use this value as something that is determinant and intrinsic to the project itself.

The radical architecture movement arose during the 60s and 70s, as a consequence of the crisis of the postulates of modern architecture, influenced directly by artistic innovations. These architects contributed new concepts of city, marking the opposition between models and Utopian processes. Firstly, by proposing imaginary and perfectly structured and organized places. And secondly, by creating places with the intention of incorporating contingency and complexity as central parameters of the project; Utopia understood as a "good place", is a dreamed place but not a perfect place. In this regard the Greek architect Doxiadis indicated: "Here is the reality and here is our ideal. Why they do not lead me to any site?. Because both things are not connected. Because reality and ideal move in different levels, in different proportions and at different speeds".

Utopias and visions of the radical architectural movement, have contributed to the definition of a collective conscience that has outlined a progressive and critical front in culture and urban planning. In their conscious constant of urban development they created a particular image of the city and of the collective sites of major significance at present.

Keywords: Radical architecture, Drawn Cities, Ideals, Urban Models, Utopias

1. The possibilities of the represented city

Graphic representation of projects that are not necessarily going to be constructed reflects future projects and intentions with fewer determining factors and enables the adoption of any resource or mechanism for expressing ideas. Similarly, the technology, format and mode of representation together with an analysis of the socio-political and cultural context, help to define the author's intention, represent the desires and criticisms of the period and are the consequence and reflection of a given moment in time. These issues, in the case of the architects that concern us here, acquire particular importance if we take into account the fact that all the projects we are going to study never got beyond the paper stage.

The sixties and early seventies are characterised by major innovation and constant and significant experimentation. The incipient social and ecological crisis and the exhaustion of functionalist urbanism generated an entire range of alternatives to established theories that modified the perception of city and its public space.

In this environment, as a consequence of the questioning of the postulates of modern architecture, a series of studies emerged with a focus on hitherto ignored social aspects and an emphasis on the public space and the new redefinition of cities. These projects, influenced by new artistic trends that embraced utopian representations of architecture were, however, ephemeral and soon forgotten in the midst of a new period of extreme formalism and mercantilism.

These authors found a reliable ally in the graphic medium for their inspiration and speculation. The pioneers of planned cities were *Sforzinda* drawn in the 15th Century by Antonio Averlino Filarete, the 15th and 16th Centuries with Thomas Moore, Bacon and Campanella; the 19th Century with French utopian socialists, Charles Fourier, Victor Considérant and Eugene Cabet, and the English socialist Robert Owen, among others. In the 20th Centuries, futurist cities appeared from the megastructures of Buckminster Fuller, Paul Soleri, the Japanese Metabolists, Yone Friedman, etc. The city has been represented from all perspectives. Thinking and representing constitute a single discourse in which new formulas and ways of making require new philosophies.

Drawing, considered from a purely cultural conception and production, defines a world free of any economic and political prejudice and completely free of any institution. Drawing can decide what reality or vision it wishes to represent, it can design cities that never have and never will exist, building impossible structures or spaces not created in daily reality and designing projects with no type of economic, legislative or social opinion limitation¹. Thus, only when the intention is to convert the drawing into a built "artifact", does it have to be transformed into a practical, objective and feasible representation. Only then will it become conditioned by regulations, limited by a budget and made to fit a particular political and social context.

Thus, representations come one after another and organise schemes and formats that can give rise to deep studies and theories on the urban and social issue.

2. Utopia, idealism and futurism as the starting point

The entire discourse of architectural and urban philosophy is illustrated and recorded as graphic documentation, "conceptual architecture" that has remained on paper. The documents reflecting this period are an example of a critical and revolutionary architecture. They contain visions of utopian approaches to the city that attempt to break away from those that already exist and in some cases focus their attention on aspects they consider to be inadequate. These aspects include obsolescence and flexibility introduced by Cedric Price in his discourses and which he illustrates in his *Fun Place* and *Potteries Thinkbelt*. In other aspects, by way of dystopias, unwanted issues are exaggerated, like the proposals that challenge the

megastructure as an apocalyptic scenario, among which we include *The Planet as Festival* by Ettore Sottsass.

On another note, are the reminiscences of idealism identified in the projects developed in the early 20th Century as ideal models. The most representative of such proposals are those by Ebenezer Howard and his *Garden City*, Frank Lloyd Wright and *Broadacre* and Le Corbusier and his *Ville Radieuse* which were developed between 1890 and 1930. Their cities were never designed as real models but as "ideals". All three attempt to understand the logic of the 20th Century city and to determine their inherent structure and their most efficient form, "they attempted to look beyond the distortions that an inhumane social order had imposed upon the cities of their time, and to envision a city based on social justice and equality"²

There is of course also a futurist approach influenced by exponential population growth whose proposals were not made with the intention of improving conditions in the surrounding environment but as a way of thinking about and investigating urban evolution, with the intention of observing what the future might bring and new approaches to urban development. Some of these paradigmatic examples are the proposals of Japanese metabolists which gave rise to the plan for Tokyo Bay.

Fig. 2, 3: Ville Spatiale, 1959 Yona Friedman. Collection Fonds Régional d'Art Contemporain du Centre, Orleans. The image were taken at the exhibition 'Megastructure Reloaded' in 2008, Berlin, by Mónica Val Fiel

But approaches to architecture were not the only ones to mobilise and react; art also rejected the approaches of the initial vanguards and redirected its approaches to new discourses. It must be remembered that since the sixties, the crisis of the object and the dematerialisation of art introduced artistic production outside the traditional circuits (museums, markets, institutions...). In those years art began to show a growing interest in investigating the environment and space leading to the study and understanding of physical and theoretical territories which not only situate it in the urban space and landscape but in interaction with its context. Likewise, the approaches that challenged the mercantilisation of art led to its dematerialisation.

Thus, we find an art that moves from objectual to conceptual where, in contrast to the definitive formal result, greater importance is attached to ideas and how they are expressed. Similarly, architecture moved from objectual approaches, model cities, to a "conceptual architecture" where processes that define new concepts of city became paramount.

In architecture, on the one hand is the issue of exponential population growth together with the appearance of new needs; and on the other the dissatisfaction and exhaustion of criteria which have organised the parameters of modern urbanism into the conceptualisation and construction of the city according to stable, unchangeable definitions. All of this was accompanied by a radical cultural change which generated an entire series of ideas that materialised on paper but which had no further impact beyond the graphic and the manifesto.

3. The radical movement in the context of History and Criticism of Architecture, Design and Urbanism

In Italy, particularly in Florence and at the same time as Vienna and in the legacy of English and American proposals, there was a revolutionary phenomenon, classified as "Radical Architecture", a consequence of the cultural debate in the early 1960s. Other antecedents can be found in the British scene with the seeds of Pop Art and criticism from Team X and the Archigram group, the Austrian scene with the development of Viennese Actionism and figures such as Hans Hollein and Walter Pichler and groups like Coop Himmelb(l)au and Haus-Rucker-Co. Finally Radical Architecture developed in the Italian scene with Arte Povera which led to a more widespread Conceptual art. Outstanding figures include Ettore Sottas as pioneer, the subsequent development of groups like Superstudio and Archizoom and people like Ugo la Pietra and Gianni Pettena, to name just a few.

Andrea Branzi, one of the founders of Archizoom Associati, notes that "Radical architecture may be considered part of the more general movement for the liberation of man from culture, meaning by individual liberation from culture the removal of all formal and moral parameters which create inhibitory structures (inhibitory because not self-engendered) and prevent the individual from fully realizing himself."³

Navone and Orlandoni⁴ identify conceptual architecture as a range of avant-garde architectural experiences from 1968, stemming from art criticism. According to Navone and Orlandoni "radical" and "conceptual" immediately became frequent terms for numerous critics in the world of architecture (Celant, Branzi, Mendini, Higgins, Burns, Eisenman, Haggart, Natalini) and others in the world of art.

Fig. 4: Vita, 1971 Superstudio. The image was taken at the exhibition 'Environments and Counter Experimental Media in Italy: The New Domestic Landscape' in 2010, Barcelona, by Mónica Val Fiel

4. Exhibitions as ideological-cultural development and projection of the radical movement. New historical research practices

Since the early 21st Century there has been growing sensitivity to the experimental proposals of the period. This has been noticeable in the boom in exhibitions of graphic production for architectural proposals from the second half of the 20th Century, characterised by a strong component of utopia and forward-looking projects.

In the United States such exhibitions include those organised by the MOMA department of architecture and design and exhibitions like: "Perfect Acts of Architecture", during 2001-2002. And also the 2002 exhibition entitled "The changing of the avantgarde: visionary architectural drawings from the Howard Gilman Collection", that celebrated the donation to MOMA of two hundred and five drawings from the Howard Gilman Foundation. There was also a monographic exhibition focused on Italy that supplemented the above visions : "Environments and Counter Experimental Media in Italy: The New Domestic Landscape – MoMA 1972", which recreated the 1972 anthological exhibition in MoMA; and "Italy: The New Domestic Landscape", curated by Emilio Ambasz which began in New York in 2009, spent 2010 at Disseny Hub Barcelona (DHUB) and the Swiss Architecture Museum in Basle (Switzerland) and 2011 at the Arkitekturmuseet (Museum of Architecture) in Stockholm.

In Europe, thematic exhibitions focused on different aspects "Arquitectura Radical" was curated by Francisco Jarauta, Jean Louis Maubant and Frédéric Migayrou and was inaugurated at the Museum of Illustration and Modernity, Valencia (Muvim) in 2001. In 2002, the exhibition went to the Andalusia Centre of Contemporary Art (CAAC) and ended in 2003 at the Institute of Modern Art in Villeurbanne of Lyon and the Georges Pompidou Centre in Paris.

Exhibitions with a broader perspective are "Fantasy Architecture: 1500-2036", which took place between 2004-2005 and was organised by the Hayward Gallery (under the London for Arts Council England); "Megastructure Reloaded; Visionary Architecture and urban design of the sixties reflected by contemporary artist", in 2008, in Berlin; "Future City: Experiment and Utopia in Architecture", in 2006, and in 2009, "Radical Nature. Art and Architecture for a Changing Planet 1969-2009" at the Barbican Centre, London. And there have also been exhibitions focused on specific groups or trends, for example "The Austrian Phenomenon Concepts Experiments Viena-Graz 1958-1973.", at the Architekturzentrum of Vienna (Austria), in 2004.

This outbreak of exhibitions in the last decade accompanied by the publishing of catalogues has generated genuine research and a real written record of projects from the period. Of particular interest in this regard is the collection, exhibitions and corresponding publications by FRAC (Centre de Orléans, France) where the excellent work of its director (Marie-Ange Brayer) and her predecessor (Frédéric Migayrou) has led to a long series of monographs with versions in English and French published by HYX. Some of these monographs include: "Gianni Péttena", 2002; "Architectures experimentales 1950-2000", 2003, "No-stop city. Archizoom Associati", 2006, "Ettore Sottsass Jr. 60'-70'", 2006, "Ugo la Pietra, Habiter la ville", 2009 and "Nevers, Architecture Principe", 2010.

5. Conclusions and perspectives

By 1975 Conceptual Art was already widespread and even seemed antiquated. In the early 1980s painting and sculpture became fashionable again and the formalist spirit and old traditions were recovered with the intention of ensuring an audience for whom social revolution was meaningless. It was therefore postmodern art, with no clear definition as to its beginnings, characterised by eclecticism, fragmentation and the loss of moral values which gave priority to increasingly consolidated mercantilism.

However, **the art of the period had introduced into the field of architecture concepts such as perception, transience, image and practice.** Conceptual art, absorbed all the influences of the preceding movements and established its own guidelines, introducing variable architectures which, until then, had not been taken into account in proposals for defining city and public space.

According to Andrea Branzi what was classified as "radical architecture" reflects at international level all the experimentation known individually as: contra-design, conceptual architecture, povera technique,

eclecticism, iconoclast behaviour, neo-dadaism, nomadism... "a period marked by the absence of any strategic unity as well as by a permanent state of uncertainty, a period characterized by the advent of mass production (and design), in which architecture also starts to change status, becoming an intermediate reality between an enzymatic energy and an inhabitable design product, operating inside a city that is no longer a city but a mere local market in the world market of merchandise"⁵. Branzi finds a large number of current representatives of architecture who recognise their debt to the radical movement, an influence that emerges in the way of perceiving links between city and architecture, between the project and the discipline, or as inspiration for their way of doing (or not doing) architecture, including Frank O. Gehry, Hans Hollein, Daniel Libeskind, Arata Isozaki, Toyo Ito, Rem Koolhaas, Bernard Tschumi and others. (Branzi's text was published in 2005 in the catalogue for the exhibition "ARCHILAB. New Experiments in Architecture, Art, and the City, 1950-2005')

Throughout history, art, architecture and design have gone hand in hand on numerous occasions, but it is worth noting that in the period we refer to, art had a significant influence on the other fields. This influence, in the case of architecture, and in one aspect can be seen as the appropriation of codes. Representation is thus considered as an end in itself, as the expression of codes, whose only and ultimate purpose is to communicate a message. Ideas which are the product of experience or imagination, which do not attempt to transcend reality of paper or have materialisation as their objective. In this regard, drawing and graphic in themselves are regarded as the maximum representation of ideals, where the built form is not part of the discourse.

The appearance of concepts such as 'the ephemeral', 'flexibility' and 'obsolescence' introduced by Cedric Price, directly related to the advance of consumerist society and culture, emerge and develop to question the very nature of an art, an architecture and a design that were clearly overwhelmed; or, as Archigram noted, **conviction of the need to combine architecture with other languages and instruments and the transformation of architecture into image**. This idea underlies the virtual developments in many current laboratories of architectural graphic expression.

As noted above, most of the visionary architectures that were designed in that period, given the dissatisfaction with existing realities, **constitute critical proactive documents**. They carry an implicit intention of change and even, according to Lewis Mumford⁶, they propose, to a greater or lesser extent and in relation to their proximity, a real materialisation, utopias of evasion or reconstruction. They are forward-looking visions that design the human environment of the future and, in contrast to the static ideal models of early 20th Century utopians, propose dynamic processes adapted to the contingency and generate new concepts of city, some of which are still valid today.

⁽²⁾ stefano.brusaporci@univaq.it

Abstract

The validation processes of restoration projects in all institutions are still based on communication and training requisites which continue to influence choices during the preparation of projects, and not only in purely formal terms, but also with respect to content.

These requisites are paper documents and digital media, i.e. reproductions of paper documents in PDF format.

Furthermore, project representation and communication are substantially established in two-dimensional form (plans, elevations, sections) with rare inroads into three-dimensional formats for explicative and integrative purposes (axonometric and/or perspective images), with the usual separateness, which is also logical and conceptual, between graphic representation and documentation, during the surveying and analysis phase and during the design phase.

Even considering recent experiences related to the management of the reconstruction phase in the historical centres affected by the earthquake in L'Aquila on 6 April 2009, the intrinsic possibilities of using of architectural 3D modelling is to be examined, with the purpose of building an information system dedicated to architectural specificities, and to building the project proposal, fully directing its communicative complexity to the synthetic and interactive support of 3D modelling.

Key words: Architecture, 3D modeling, Restoration, 3D GIS.

Fig. 1: L'Aquila. Software for visualization, surfing and measurement of point clouds.

1. Relationship between survey drawing and project design in architectural restoration

The theoretical precondition for restoration projects is the inevitable relationship with the existing reality. In this sense, the close interdependence between the survey and the project is particularly significant, as it still represents a general value of the project. However, in the field of restoration, it acquires its own poignant meaning.

The restoration graphical model is a complex system which, for each phase is founded on assembly drawings and part and detail drawings, where, at every stage, there should be systematic specularity between the survey drawing and the project drawing.

Four significant moments in the conservation-restoration process can be identified. Phase 1: preliminary and final plans aimed at controlling architectural and spatial restoration and possible re-utilisation of the building. This is based on an essentially geometric-dimensional survey. Phase 2: project ready for execution-building with all its content including technological features. This is related to first-level surveying of the construction and the state of deterioration, carried out through inspections, sampling, surveys and non-destructive testing. Phase 3: monitoring during construction. This again involves second level surveying of the construction and the state of deterioration, this time in full view. In response to the site monitoring survey, the working project is constantly updated in accordance with the specific contexts. Phase 4: at the end of the works, a

Fig. 2, 3, 4: L'Aquila. Point clouds integrated with measurable true view image based models .

graphical model should be created of the building altered by the restoration work. This final post-works graphical model, together with the products of the previous phases, is the documentation needed for the database, the support for subsequent monitoring of the building and for planning any future conservation work based on certain knowledge. But above all, for comparison and contrast with the pre-works restoration model, it must provide the necessary support for formulating of a judgement on the overall quality of the restoration work.

It is quite clear that, in disciplinary terms, the issue stems from identification of the characteristics for building the restoration graphical model, which intrinsically should be concise, analytical, iconic, interpretive but also dynamic, capable of supporting and sustaining continuous updating of the surveying process. It should nevertheless remain intelligible as the information it holds increases. For all stages it should be comparable, represented clearly in part drawings and other useful forms, it should be included in the relationships between assembly drawings and detail drawings. It should be systematically specular to the project design at every stage.

2. Specularity between the restoration model and the design model as an invariant

Specularity between the restoration model and the design model is an invariant in the surveying-planning process for architectural conservation. This invariance, usually occurring in traditional 2D restoration models, should have full confirmation in architectural 3D modelling.

In terms of surveys done using digital technology, which focuses the process on 3D models, the concept of specularity should be proposed on different and appropriate bases. Different purposes require the 3D model to be capable of meeting multiple demands: it should allow a varied body of information to be collected and, at the same time, be processable and modifiable by the many professionals involved; it should be available for consultation by the competent bodies for approving the project, and browsable, querable, measurable but not editable; it should ensure high quality, photorealistic viewing for communication of design choices.

These are many aspects of the same digital media, and in order to meet these demands, they should have appropriate characteristics, not only metrical but also constitutive and qualitative. In this sense, the issue of defining standards and formats for modelling is inescapable.

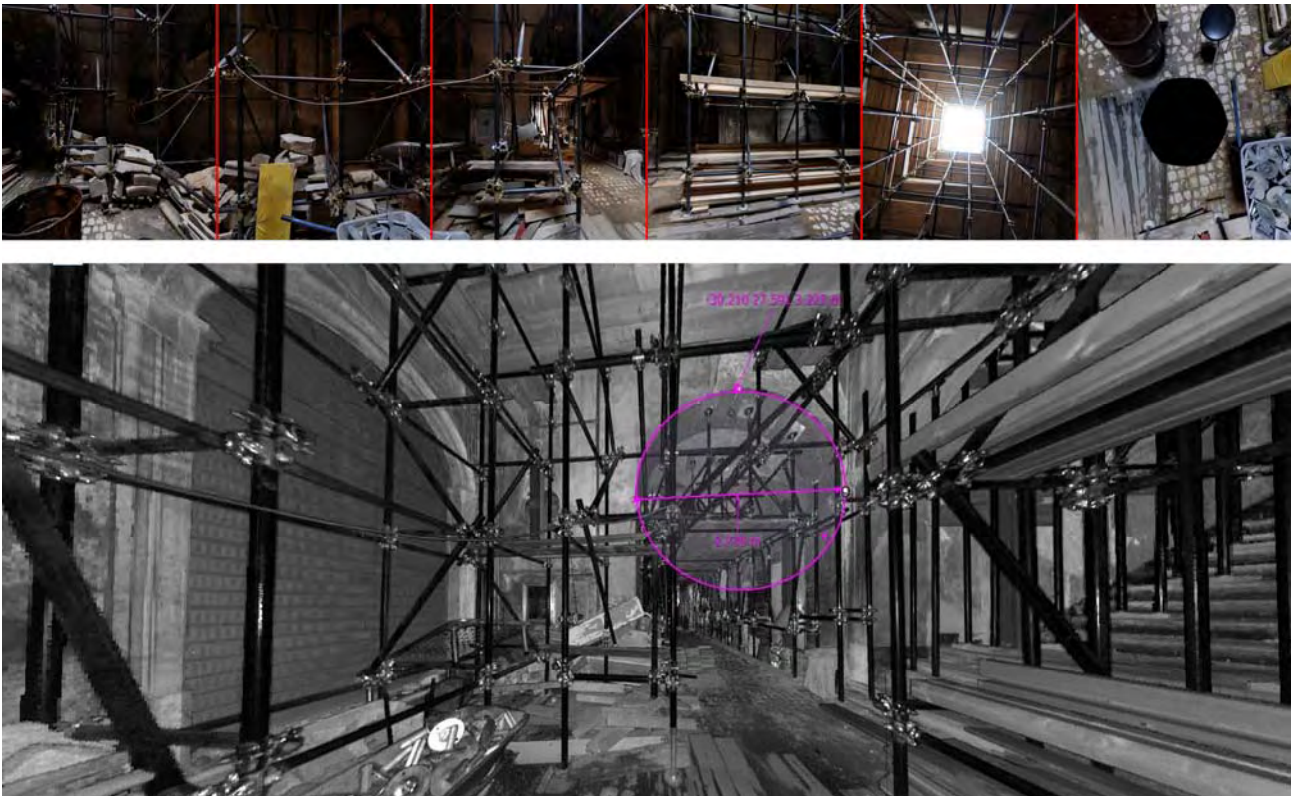

Fig. 5, 6: L'Aquila. Cubic projections of photographic images related to point clouds.

Current practice shows that, in faced with a wealth of metric and photographic information provided by laser scanning and photogrammetry, returns are mostly made using 2D vectors and rasters: point clouds are sectioned and projected orthogonally for layouts, elevations and sections; meshes are made for elevation views, so they can be textured to produce orthophotos; in many cases elevation images are obtained simply by displaying the points in the cloud with RGB colours.

The only concessions to 3D are measurable, image-based models (e.g. true-view systems by FARO Technologies Group), or point cloud viewers (like the one by Leica Geosystems), free and easy-to-use interfaces, primarily aimed at providing designers with metric data without involving them in the processing of point clouds, and thus marking the separation between measurers/surveyors and restorers.

3D is limited to the metric data of point clouds, thereby being influenced by 2D data. In the same way, the project goes back to traditional surveying means: tables of macroscopic surface deterioration, damage and lesions, interventions.

The situation is similar for information systems, used for tried and tested 2D applications, mostly on the urban scale, and therefore unaffected by the most recent acquisitions and developments in architecture - with particular reference to 3D GIS for architecture.

Notwithstanding the usefulness of point clouds for rigorous 2D drawings, their intrinsic potential is not exploited, to favour the creation of 3D models for surveying architectural structures and planning restoration projects. There are rare excursions into the virtual field, but mostly for publicity purposes.

Conversely, the wealth of information knowledge, the importance and uniqueness of the scope provided by L'Aquila's historical town centre and those in the earthquake zone, should allow development and testing of a procedure that would place the 3D model at the centre of the surveying process and the restoration project.

In terms of the purpose of restoration, it is useful to refer to photorealistic 3D models that are also defined on the scale of the construction. This second aspect does not refer so much to the issue of information systems at the so-called LOD (Level of Detail) regarding the number of polygons used to approximate a surface - but rather to the issue of the number of models to be used to describe the building system.

This leads to the issue of managing architectural models that are laborious in computational terms, on commonly used software platforms. A simpler solution would be to organise models in a 'cascade' system, i.e. linking together increasingly defined models.

Fig. 7: Historical window's surveying 3D model.

Fig. 8: 3D Model of a building in L'Aquila historical centre. (modeling: Francesca Cerasoli).

Fig. 9: 3D model for the restoration project of *Aquilinum Collegium*.

There is a wide series of tools available to surveyors for 3D images. The most common programs - often available with point cloud management programs - enable extraction from 2D-processed point clouds - sections and orthogonal views of the clouds themselves - as well as synthesis of MESH or NURBS surfaces, or even models built on 3D primitives to be arranged using Boolean operations, to be defined semantically in terms of their architectural significance.

By analogy, reference can be made to the approach provided by BIM software, an acronym with two definitions applying to the model and to the creation and management of related information, the second of which is more common: Building Information Model and Building Information Modelling.

BIMs place 3D models at the centre of the entire process, on the basis of the idea of building the model as a tool for project development, a common and interoperable interface between the various professionals involved, such as architects, structural engineers and plant engineers. Unlike other types of software, developed for architectural applications from reverse engineering applications - specific to mechanical engineering and design - BIMs are devised specifically for architectural projects.

The concept of information is central in that it involves reference models consisting of objects semantically defined as components of the construction. Therefore, these digital elements are in themselves an expression of the structural components of the building, with regards to its metrical characteristics and in relation to materials and their structural and energy characteristics, etc. Nevertheless, ignoring general basic objects - lines, splines, surfaces, volumes created through Boolean operations, etc. - and referring to components such as vertical or horizontal closures, doors, windows, etc., requires definition of these elements in libraries, i.e. these components must be standardised.

This aspect is difficult to reconcile with the specific needs of surveying historic architecture, where each element has its own historical and architectural value.

The very reasons for the emergence and development of BIM is due to the search for software suitable for developing architectural designs and managing information about the entire life cycle of the building, from its inception to its construction then maintenance, with particular emphasis on economic aspects - measurements and timing. The goal is to optimise the cost-time benefits of the planning process based on the industrialisation, prefabrication and standardisation of commercial components.

These requisites do not coincide with the demands of the process of careful listening and dialogue between the surveyor/restorer and the historic building, based on a system of knowledge that is always open and constantly evolving - e.g. the specifications of a restoration site.

Notwithstanding, BIM can offer interesting elements. In particular, the main types of software on the market are Autodesk Revit, Archicad / Allplan, Bentley Systems, Digital Project. The first two, and the most popular, have parametric modelling limitations, while the latter two allow integration with complex 3D modelling.

The emphasis is on interoperability, i.e. the possibility for the 3D model to be the project's common development interface, which can be processed in different applications depending on different professional needs. This concept, dear to the BIM software houses, is not only limited to these types of programs, since even 3D models constructed with traditional modellers can be usefully employed in architecture and, say, structural calculation.

More generally, 3D models provide the option of being a support and interface for *architectural information systems*. In fact, for the surveying process, the model enables the collection, correlation and systematisation of the large and heterogeneous mass of information concerning surveying and historical-documentary analysis. The 3D model contains metric, geometric, architectural and construction information, as well as information on materials, colour, deterioration, etc. By its very nature, the 3D model offers a spatially structured interface allowing intuitive navigation and querying, in order to facilitate analysis of historical architecture. Hence, a model defined in terms of the construction features of the building may be linked to a database that is editable and implementable in time, thus enabling definition of an architectural information system. In this sense, the 3D model can be seen as a support for a process of involving the 3D re-cataloguing of surveying and historical-archive documentation

Notwithstanding the issues involved in importing 3D models into a GIS environment, which have previously been studied and partly resolved by using proprietary software (see Centofanti *et al*, 2011).

Whereas BIM already offers an opportunity to focus on the model as a useful design tool, nevertheless, the validation and authorisation phases are still centred on 2D representations, where digital features (raster or PDF) are merely simpler means of disseminating and reproducing drawings. This consideration suggests a broadening of horizons, whereby the 3D model might also become the instrument/interface for communicating analyses and the project at all stages.

Interoperability (as a possibility for several operators developing and modifying the model) and use of the model as an interface for communication (so the model is a queryable but not modifiable document) are the focuses of what can be considered two prominent issues: definition of model formats and construction standards and the syntactic composition and exchange of the model itself.

For example, in order to communicate the restoration project to the monitoring bodies, a queryable model could be exported in a searchable format such as PDF or VRML, linked to an open source webGIS system.

Fig. 10: Surveying 3D model of a roof. The model is defined in all constructive components.

Fig. 11: 3D model for equipment and lighting planning.

Lastly, we look at the issue of defining standards for 3D architectural surveying models, i.e. not only the characteristics of metric accuracy, but also the level of definition and the number of constituent components, with numbers and characteristics that describe both the architectural configuration and the construction configuration of the building. In this sense, the following would be appropriate: definition of standards for 3D models in terms of describing the geometric-dimensional morphological-figurative, technical and construction characteristics of the constructions on an architectural scale; establishing standards for 3D models of historic centres, which are suitable for describing the complexity of the spatial, historical and environmental relationships within clusters of buildings; studying multi-scale relationships between 3D models of historic centres, buildings, architectural details, optimised for use on a software platform for normal operation.

In conclusion, some issues remain regarding the effectiveness of the 3D model for restoration projects. First are the definition, validation and dissemination of shared standards relating to the configuration of the 3D model. Secondly, identification of standards, formats and procedures for the exchange, modification and processing of 3D models in various fields of interest (architectural, structural, installations, etc.). Finally, investigation into methodologies linking 3D models in a proprietary or open-source GIS environment. For the development of technical and operational specifications, it would be useful to implement the same cultural change in restoration projects as is already seen in the architectural concept with reverse modelling.

SURVEYING SIMPLE TECHNIQUE

Antonio ÁLVARO TORDESILLAS¹

⁽¹⁾ Escuela Técnica Superior de Arquitectura. Universidad de Valladolid. España
tordesillas@arq.uva.es

Abstract

The graphic surveying of works of art can be seen as a research method per se because their results allow us to deepen the knowledge of our heritage, which is the indispensable basis for its conservation.

In this paper we want to show what and how new low-cost techniques of surveying are capable to do, in a very simple manner, without losing precision and fidelity; applied to the non previous drawn sculpture. In this way we are documenting them for the first time and creating a repository of three-dimensional works, as well as allowing an immediate and wider dissemination via Internet, all serve to safeguard them against any possible fatality.

This technique experiments with the stereovision in two ways: first by the two parallel photos restitution and second, with the single photo made by a two lenses camera, which simplify even more the process.

Keywords: surveying, photography, photogrammetry, photomodeler, low-cost.

1. Surveying simple technique by digital photography

The following paper does not intend to repeat anything already written in many articles in refereed journals, or conference communications about graphic surveying of art works through laser technologies that on today, are well known and whose evolution has achieved in a surprising way to simplify both data collection and in its handling. The reason that moves us to make such surveys usually is related mainly to its conservation, so it is necessary to deepen their formal knowledge in a comprehensive manner.

There is no need to lead how metric photogrammetry tries to get two and three-dimensional metric information from photographic images. In recent days metric photogrammetry is responsible for generating distortion and projection corrected images suitable for multiple uses, mapping or not, as multimedia, animation photorealistic, environmental studies, surveys architectural, archaeological, etc.

However, in a parallel way, and almost dazzling and overwhelming, scanning systems of three-dimensional space using laser beams in a fan, have greatly simplified the process, converting metric photogrammetry in something whose basis is hardly necessary to know. The job has become a mere routine work and almost handcrafted, cleaning and debugging the millions of points (x, y, z), with its colour component (R, G, B), are located in space in an almost magical and immediate. To put the laser in the place to restore brings us more than half an hour, for instance, compared to the three days which means developing the final point cloud. Coloured cloud from a photograph taken by the laser device itself, with a resolution and quality, usually mediocre or dressing it by matching points with another taken from a more appropriate perspective. Three-

dimensional models of objects registered, as such sets of points without further processing, are models that operate only visually.

The laser scanner is today a common tool in architecture and engineering projects that has been transferred successfully to the field of Cultural Heritage. However, even today, involves two major drawbacks: its high price and awkward in some cases, such as its elevation over the ground. There are perhaps, other problems with the laser, as has been the case in this the Research Project, which depends substantially on the surfaces to be swept, both in texture and colour.

And it is in these cases when the projective geometry, the foundation of metric photogrammetry, rises from the ashes deposited by the laser in its incendiary appearance. Obviously, the time is also elapsed for her, and is no longer necessary to have a team of restitution in pairs, both instrumental and human. The developments of computers and software have replaced those and in just a few mouse clicks we can emulate, more accurately still, that laborious work.

The development of photography with his leap to digital and its dizzying technological evolution and economic recession, which have made it accessible to anyone with a capacity of accurate documentation once unthinkable, has been the accomplice of the software to get put a dangerous trip to laser.

The economic question, that voice has become so important in these times of crisis, it is almost indisputable front of some equipment that divides their costs by ten. The first one that comes to mind is if accuracy is acceptable. The answer is of course subjective, as is everything we do in surveying works. The separation of points provided by a laser is much less than that gives us the size of a pixel of a digital picture, for a same distance. However, either method, the accuracy is decided by the surveying author in the taking of some preliminary decisions, and not the machine. Both the laser and the photo can approach both the object as you want, so it does not seem to be being valued by the decision of why choose, when one of the variables is economic decision-making.

Regarding the economic issue, a new phenomenon is emerging and developing also thanks to the rapid change in Internet networks on speed and capacity. Although different commercial software that have appeared are already economically accessible enough to buying a laser, lately there are companies and universities that make it for free. The control over precision and errors of the models are more difficult to assess, but, according to which cases, feasible in the majority. Among the first we have evaluated some programs such as *PhotoModeler Scanner*, of EOS System, while among the seconds we can easily find on the internet others as Autodesk *123d*, *ARC 3D Webservice* or *My3dscanner.com* team.

Furthermore, we find what concerning the instability of the laser against some situations where it is necessary, either raise, or put it in places of difficult access. What anyone who has handled a laser scanner will know how extremely important the stability of the instrument, for which you invest a large preparatory time. It shall be ensure that the laser does not move during the minutes that is sweeping the area. If the object to raise the elevation will require several meters over the floor of the scanner (high weight and fragility), or becomes in motion, this required stability cannot be done except for very bulky and expensive auxiliary resources, which may not always be achievable.

The survey and construction of a three-dimensional point cloud by means of photography and the software that processes, solves these drawbacks of the laser in an almost immediate. Any elevation of the camera, much lighter and less fragile, can be solved, for example, through a telescopic aluminium pole, as we have already done with colleagues at the *Università degli Studi di Salerno*, in Italy. The stability is resolved with a high shutter speed shot of a simple photo. The number of pictures to make, in addition to being fast and independent, is unique and can be easily sweep the entire area to cover and a bonus in the different distances in order to allow up to work with different grades of detail, as mentioned, and allow to approach those holes where a laser and an operator would never more or less skilful invention should be filled in a phase of polishing. And we talk of telescopic poles, to quote the cheapest, because we can complicate as much as we want: balloons, microdones, etc.

The more complex work, in a striking, is to make good pictures. However, it is so basic and so systematized that is not a major difficulty. We know that the confluence of a series of photographs, inwardly and outwardly oriented, i.e. with knowledge of the data defining the conical reference system, are able to locate in the

space as many points as desired, provided they appear in two or more pictures. So taking pictures have to adapt to these conditions of projective geometry: we know the focal length, for which it is necessary that the focus does not move in each cloud to be processed, always will point to a centre or original most always imaginary, and try to make our route, either along, or around the object to be lifted, the distance between photos (base) is related to the distance in order to restore conditions to turn in stereographic pairs, both horizontally and vertically. As a general rule we adopt such a relation (base/distance) is close to 0,15. And of course, it is essential that the images are perfectly focused so that the software can easily and certainly recognize the pixels in each pair related (Fig. 1, 2).

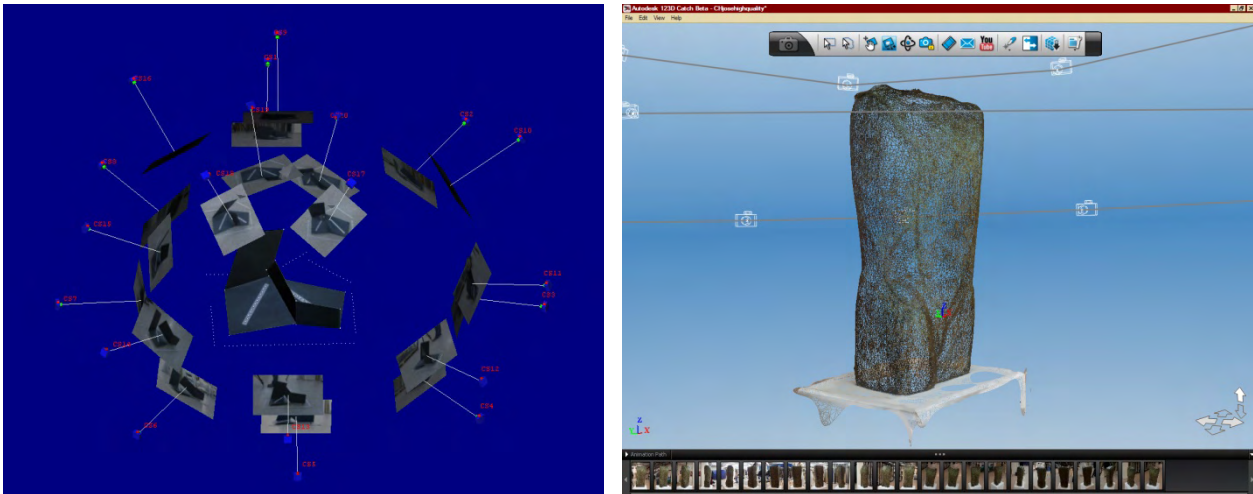

Fig. 1, 2: Position of the photographs on textured 3d model built with *PhotoModeler Scanner* of EOS System; and view of the mesh calculated by *123d* of Autodesk and position of some photographs. In both, we see how the pictures surround the sculpture in two parallel rings separated in height each other the corresponding base for the relationship base/distance of 0,15.

The application objects with which we have tested this new technology have been some sculptures raised by features that were able to test it. Aspects such as size or different textures do not have meant much problem, except for those whose skin is of a uniform colour, especially black, or reflective or bright as some pieces of alabaster or glass. To be decided to work with sculptures rather than larger architectural pieces responds to various reasons:

- They allow us to check as closely as possible margins of error and can compare the original measures taken by the traditional method, with results obtained by the laser scanner, or by reimbursement photo.
- More and more is being applied photogrammetric restitution for the study and documentation of sculptures of artistic and historical value. But to date, it has not been applied with the same intensity on modern sculptures.
- The sculptures, unlike architecture, have never had a graphical specification prior to its execution, so it lacks precise graphical information that would allow its return for research and documentation, including for damage of these parts, given the risk to many of them being in public places. His graphic documentation, through virtual models manipulated by computers, would become an insurance against any adversity, thus gaining more interest. It seems inevitable that this precaution taken ends up in all those works of recognized artistic value.

In Research Project we have conducted the data collection of the sculptures with two different lasers (*Faro Focus 3D* and other portable *ARTEC-ABACUS*) and by digital photography with *Canon 1000D SLR* camera and *Sigma 28mm* fixed lens. The results are very similar, if we disregard, as we have clarified, the subjetibilidad the accuracy of the work. Similar in both simple geometry and texture pieces, as those most intricate (Fig. 3).

Fig. 3: These images show how the flat black color is a serious problem for the algorithms of calculation of any software, by not recognizing the corresponding homologous points. The images refer to *PhotoModeler Scanner* and *123d* of Autodesk, but have also been tested and *ARC 3D Webservice* and *My3dscanner*. The laser scanner is not able to resolve a point cloud right in these cases.

Parts made of welded sheet metal and painted flat black have been impossible to build using the *Faro Laser* and photography, something better with the *Artec*. The recognition of black surfaces for the laser is, as we all know, a problem, until today, impossible to solve. *Artec* laser could provide these better results based on their movement and other possible reference points near, but outside the scanning surface itself. The picture is also unable to survey a cloud of points from an automatic mode given the impossibility of recognize different pixels in an area where everyone is equal. However, the metric photogrammetry *PhotoModeler Scanner* software is able to operate gives us the possibility to manually locate points in space, by referencing each on pictures (Fig. 4). The software is able to evaluate the error in this manual entry by two values: the Root Mean Square (RMS) of the coordinates of all points introduced and higher residual value that occurs at a point (Largest Residual pixels) with an option to correct, according to its or our discretion. The latter is close to one and the other to 0.5 pixels, represent model accuracy considerably good; consider the equivalent size of the pixel in a universal measurement unit.

Fig. 4: Model constructed manually by assigning control points in all photographs. These are both coded targets that were placed to facilitate the orientation of the cameras, as the vertices that define the geometry of the sculpture.

So only the software and photography are able to provide us with the necessary and sufficient to build the sculpture in 3d, and therefore in any of the dihedral 2d projections we want. This has proven to be done in a very economical, simple and accessible to everyone.

However, we tested other possibilities such as the projection of conveniently defined mesh point's images on flat and black surfaces, so the software recognition algorithms can find a way to associate these points in the space of an automatic way and are, therefore able to build points clouds avoiding the problem. Obviously this involves making double issue of photos, and then it would be necessary to replace them with those projected by the original texture.

In a final phase of the research project, is proceeding to build a website that shows the results easily and intuitively, as if it were a virtual museum where anyone can access and walk among them. All this is being done easily from open source VRML environments, such as *Blender*, from Stitching Blender Foundation, or by viewing videos uploaded in *YouTube* or similar.

We believe that the artwork's surveying by this new photographic technique, will become, in all likelihood, a reference method; and this is one of the first trials and research made in Spain, and to works of this magnitude.

Abstract

Several micro urban agglomerations grew in Irpinia and mainly in the Forino valley during barbarian, post-Samnite, Punic and Germanic invasions. They joined together on rises under ethnic and linguistic ties and military needs. In this way several new towns arose with specific toponymic naming, and among these the “Casale Castello” village is an outstanding example. Historical treatises, archive images and on-site researches prove that houses initially were small one-story stonework buildings. Since the year one thousand, an upper floor was built and the wall coursing pattern was improved. Buildings had small rooms and thatches, not including balconies. Air and sunlight filtered through small holes without glasses. Houses were built along narrow and winding paths and were leaned each other. The building passed from the entrenchment around castles to homes located in distant areas and then to country-seats. The territorial joining only arose in twelfth century under the feudal bond, as shown by historical literature. The Roman traces kept their fixed outlines on, affecting the medieval orthogonal layout. Subsequently, enhanced social condition and larger public safety outlined new building practices based on line drawings and rectangular meshes. These ones were dictated by new life requirements and places, and produced a wide variety of building shapes outside the historical town walls. This paper concerns the seismic safety of Casale Castello, based on its urban building development. It derives from a careful morphological analysis of masonry veneer and structural walls and is aimed at highlighting the need to face up to the seismic safety of the neglected medieval villages to give them a new life through tourist marketing.

Key words: cultural heritage, masonry buildings, seismic safety

1. Needs for the seismic safety evaluation of urban agglomerations

Urban agglomerations usually are the result of a complex historic aggregation of buildings due to several reasons (historic events, urban development over time, local uses, construction sequence, material and exigency change, etc.). The seismic vulnerability analysis of buildings that form aggregates requires taking into account the interaction due to the structural contiguity among buildings either connected or bonded to. Though the structural unit to be investigated has to be identified for performing the structural analysis, preliminarily the entire aggregate must be considered in order to identify the main spatial connections, with particular attention on context and mechanisms of superimposition. The preliminary step of such an analysis could be the reconstruction of the historical events that led to the origin and growth of the agglomeration. In fact, this allows better knowing characteristics, repetitiveness and homogeneity in structural behavior of each building unit under static and seismic loads, and then designing retrofit solutions congruent with the original structural configuration.

To this end, as stated in the Italian national seismic code, the process should gather several information as: (i) relation between processes of aggregation of buildings and evolution of the street system; (ii) morphology

Fig. 1: Casale Castello - Sight of building types damaged by earthquake

of the streets (course, width, deviations in plan, misaligned facades); (iii) main events that influenced the morphological aspects of the historical construction; (iv) layout and hierarchy of courtyards and location of the external stairs; (v) alignment of masonry walls (checking orthogonality with respect to the streets, extensions, intersections and sliding of wall axes); (vi) spatial relations among masonry units, as well as proportions of regularity, repetitiveness, modularity of building floors; (vii) geometry and location of openings within the façade walls (axis, symmetry, repetitiveness); (viii) misalignment and tapering of walls, staggering in height of contiguous floors.

All the above data allow identifying the level of building connection, distinguishing the original units from those added successively, and revealing modifications over time. This helps to determine the weak zones and interpret the potential failure mechanisms, identifying sources of possible damage due to vertical and seismic loads.

2. Casale Castello and the development of medieval villages

The castle was the own and distinctive element of medieval architecture, hence the name "Casale Castello" of the village studied in this paper (Figure 1). Architectural and structural development of the castle and the neighboring village is not well documented, but its knowledge is necessary to better assess the structural behavior of buildings under earthquake. At present an accurate survey of the castle plan is not possible, even as the ruins are completely covered by vegetation, and only small parts of the perimeter walls and the quadrangular basement of the formless stones tower are visible. A historical reconstruction has been also difficult to be performed, since the medieval urbanism was rather neglected until few decades ago [1]. Furthermore, the study of small and newly built centers was overlooked respect to large cities planning, despite the small urban centers built in that period were numerous.

As far as possible, the main characteristic and functionality of the castle allowed tracing back to its main development over time. It is sure that expansion and strengthening of the castle, which was built as simple fortress, were made during the Normans domination. Its location had great strategic and defensive importance, because of its dominant place and its inclusion in the defensive system of other castles in the Forino area. Sure data are also the ones concerning damage due to the earthquake of 1627 and the Vesuvio eruption and aftershocks of 1631, as well as its abandonment period, around the 16th century, when the Princes Caracciolo left the castle. In the following centuries the castle underwent ravages of time and men carelessness. Its stones contributed to build the Bourbon prison of Avellino. Nevertheless, the different building types of the neighboring village (tower houses, townhouses, courtyard houses), arising from its urban historical stratification, remained intact and still visible. However, many buildings outside the village's historic medieval core are from the early 19th century, since the village underwent significant damage during the earthquake of 1805.

Therefore, the study of the historic events of "Casale Castello" village has prompted to refer to the building

Fig. 2: Casale Castello - Analysis and cataloguing of defense building types

development in the Middle Ages, since its main period of expansion begins with Lombards and comes up to the advent of Normans and Swabians and then to Angevin and Aragonese coming. But treat medieval urbanism for identifying how building types evolved in the Mediterranean area is a chronological difficult process. This is due to multiple causes, from the problem of why urban settlements were born, to the historical development and distinctiveness of each village. With regard to the city planning, on the one hand there is an insufficiency - not always numerical or qualitative - of reference studies, on the other hand there are studies classifying generic data because of the multiplicity of manifestations [2]. Medieval towns and villages are, indeed, the expression of ten centuries of history that had different origin and development - and therefore forms - from region to region, and in many cases from town to town.

Piccinato through his statement on origin, development and classification of building types in the Middle Ages proposed a new critical approach to study the medieval town planning, assuming it as collective expression of artistic, historical, social and economic values [1]. However, the distinction between "planned" and "spontaneous" urban development is still not totally unmistakable. During the Middle Ages, neither building quickness nor plan regularity allow absolutely distinguishing the intentionality in town planning. There are towns that have irregular plan geometry as result of a defined design, as well as towns with regular building plan determined by the topography of the place only. Furthermore, some researchers challenged the expression of "spontaneous" growth for explaining the complex and random structure of

Fig. 3: Casale Castello - Defense building types: the tower-houses

some medieval urban centers, assuming that the "chaotic" appearance of many towns is only the result of historic stratifications [3].

The difficulty to chronologically fix typical types of the medieval urbanism has been repeatedly affirmed. However, two major periods can, briefly, distinguished. The first dates back to the collapse of the Roman Empire and to the barbarian invasions, which led to concentration of population in the most important and better sheltered towns or in small centers about rural parishes, founding monasteries and castles. In the second period, approximately in 11th century, a civil reorganization and new centers rise - sometimes fortified - in areas more easily defensible, and often far from the main transit roads.

Subsequently, numerous castles together with villages and courts rose under Goths and Lombards. Until the 12th century, castles were isolated, in dominant place and often on pre-roman acropolises or roman castra. After the 12th century, castles also arose within towns and villages, and produced townships, as Casale Castello [4]. According to several authors, centres originated from castles can be divided in townships built on hills, spurs or at the confluence of rivers (where the castle occupies the most exposed place), townships built on sides or at the foot of hills (on which the castle stands) and townships placed in plain [5]. This probably also influenced the types of construction.

The progressive spreading of cities led to the well-known phenomenon of the Communes, and many new civil and religious buildings were built. These had different types and construction typologies than in the past, and defined the characteristic look of many cities. Contemporaneously, the main walls were consolidated and strengthened to include the population settled in the townships [6]. But, in addition to the expansion of cities, many small towns and villages developed [7].

In the case of Casale Castello (Figure 1), the architecture of new civil and religious buildings, the enveloping widening technique, rather than "budding", and the morphology of schemes produced its consistent city planning. However, it is difficult to assess if the village arose spontaneously or grew according to a pre-conceived plan, since only remains can be at the present examined [8]. Anyhow, the irregular shape of buildings arrangement is not seen as symptomatic of strict observance of orographic ground structure, but it seems to rise from the medieval defensive strategies. The Middle Ages city plans were characterized by both linear forms (one road with normal routes or a bundle of roads parallel to the main axis, supplemented by minor cross-roads) and concentric ring-fingers (with access roads connected by ring roads). In that period, the simple linear arrangement was more widespread in the Forino Valley, sometimes with the main street widened at the town's church or within the built-up area, giving rise a spindle-shaped square. Casale Castello has only one longitudinal street, connecting the two main gates, and several minor orthogonal

streets. At a certain point the main road forks, including the oldest part of the village as an island. The castle also is partially enveloped by the only main road below.

3. Casale Castello and the medieval building types

From the point of view of the urban regulatory policy, the Middle Ages lacks consistency. However, anywhere the public administration cared for security, decoration, hygiene, services, and housing regulation issues.

The fundamental factor of the town's security was the town-wall, which became the main defensive system, where the towers, generally square plan, constituted the key element. But the town-wall, either of Roman foundation or due to enlargement [9,10], is one of the characteristics of the Middle Ages not only for defensive function, but also for administrative function. Specific regulations determining duties and rights of who were admitted or excluded from the city body were, indeed, in force since the tenth century [11,12]. Another constant care of the Middle Ages was also the defense of the village against fire. The mandatory use of lobbies among houses, already widely held in Roman epoch, became common when the urban migration grew to be intensive [13,14].

The typological analysis of Casale Castle helped to reconstruct the main characteristics of its building types (Figure 2), outcome of urban layering gone over several centuries. The formal features of buildings identify building functions mainly related to defensive vocation, as expected. There are at least three buildings definable tower-houses (Figures 3 and 4), several townhouses (Figure 5), some courtyard houses (often the court was developed in the middle of several aggregate houses) and, finally, some mansions built as property speculation during the first settlement. The townhouses can be dated back to the first settlement, whereas the tower-houses were subsequently located at strategic points, probably to guard some town gates. The color used for representing the largest buildings in Figure 6 shows that they are sited outside the core of the Castle, except for the large building group along Bruno Alley, which is the result of the acquisition of areas where, probably, many small houses were previously located.

Also type and stonework of masonry buildings can be particularly useful for both reconstructing the historic evolution of Casale Castello and performing evaluations on its seismic vulnerability. However, it must be considered that in the medieval constructions type and stonework vary depending on the physical nature of materials and technical features closely linked to local materials and worker knowledge. In fact, walls in use in western Europe during the Middle Ages include several stone masonries, both ashlar and rubble masonry,

Fig. 4: Casale Castello - Defense building types: interior of the tower-houses

Fig. 5: Casale Castello - Defense building types: tapered masonry and blind alley

with different block sizes and coursing patterns. Walls were made in random ashlar masonry (cut stones in rectangular shapes without continuous vertical and horizontal joints), coursed ashlar masonry (rectangular-cut stones of equal height laid in courses), random rubble masonry (stones of irregular size and shape) or coursed rubble masonry (stones of irregular size and shape laid approximate horizontal courses).

Whatever may be the stonework, a main role in masonry strength is due to mortars. But few information and sure notes on medieval mixture are currently known. Only some enterprise accounting of building yards or some rare books on specific buildings provide useful information concerning the composition and preparation of mortars. Anyhow, it is known that most mortars prepared in the Middle Ages consisted of a mixture of slaked lime, sand and water. Additionally, the medieval mortars often feature for larger amount of silica sand rather than clay that was typical of antiquity. However, although most chemical processes were based on empirical rules, the medieval workers manufactured good quality of mortar using special kilns, today almost all destroyed.

Finally, the constructive standard of foundations of medieval buildings remains virtually the same as those used in ancient time, regardless of the masonry stonework. It is very rare to find foundations constituted by masonry bed, covering all the surface of the building. This foundation type, indeed, was seldom used and on very soft or low strength grounds only. The medieval builders sometimes utilized dressed blocks to build foundations, sometimes deep, but mostly made by debris mixed with baked clay and stones of different quality. Builders of the eleventh and twelfth centuries, instead, often overlooked foundation quality since could not make use of Romans organizational structure and human resources help.

In Casale Castello four types of stonework have been at the moment identified [15]: (i) dressed stone masonry using large blocks, (ii) limestone masonry using different size blocks, untidily arranged and blended with pieces of baked clay, (iii) stone masonry using different size blocks, with rows of clay tiles, (iv) stone masonry using similar size blocks, more or less tidily arranged. Therefore, there are walls built using several coursing patterns, both one-wythe throughout the whole thickness of the wall and multiple-wythe with almost independent external leaves, as well random or coursed ashlar walls and random or coursed rubble masonry. But major problem arose from the consideration that form and consistency of what is now visible strongly contrasts with what was in the past. For example, the large building in the upper area, near the castle, is later than the masonry walls on which rests; likewise, several buildings of the village replaced previous homes of lesser extent.

4. Seismic safety of the medieval structures of Casale Castello

The seismic vulnerability of buildings in Casale Castello is mainly due to the possible out-of-plane failure of masonry walls, as in most historical centers. In fact, this is the widespread proneness to damage in townhouses, since other damage mechanisms (due to in-plane failure) should not be normally allowed. Out-of-plane failure occurs owing to seismic forces acting perpendicular on walls, above all in absence of suitable ties or connection with transverse walls, and prevalently involving “not-bearing” walls. Independently on floor typology, the collapse can affect masonry portions having several geometry and dimension. These can either fall away from floors or buckle between floors and roof. Furthermore, in multiple-wythe masonry walls composed of not-interlocked wythes, out-of-plane failure can be induced by instability of a single wythe under compression, and masonry is either bulged outward or inward. Finally, roof thrust can produce or increase damage in out-of-plane masonry walls, especially if the mass of the roof squeezes or compresses the rafters supporting it.

Other main sources of masonry failure are the lack of structural integrity, that is due to lack of ‘through’ stones, absence of bonding between cross walls, or absence of diaphragm action of roofs. Some walls of Casale Castello are formed by random rubble masonry or by unconnected multiple-wythe masonry, that is ashlar-work faces bound by rubble infilling. As in many medieval buildings, the ashlar work probably is of a good quality and well-dressed masonry, but the infilling normally consists of low quality and strength masonry rubble. Statistics show that most seismic damage concerns buildings with rough-hewn stones,

Fig. 6: Casale Castello - Analysis and cataloguing of building types

where failures due to crumbling and disaggregation are possible. This is more frequent in rubble masonry or in multiple-wythe masonry if the outer wythe is not tied with the inner core. The falling away of half the wall thickness on the bulged side is common feature, since the detachment of the outer wythe can occur.

For what concerns materials and techniques for increasing structural safety, nowadays there is both a revitalization of the traditional ones and a wide spreading of more or less innovative materials, such as the composite ones. Therefore, the matter is how these retrofitting materials and techniques can ensure compliance with the restoration requirements, i.e. preservation of the original static behavior, minimum intervention and maximum reversibility, in a context where the seismic issue is constantly enhanced.

As only just described, the main structural problems to be addressed in Casale Castello are due to possible out-of-plane failures of walls and to low resistance of masonry. In some cases it is also possible to foresee collapse of structures due to the absence of effective connection among different parts of the construction.

Therefore, one target of interventions on such structures is improving the wall connection, in order to ensure the so-called "box-behavior". This can be achieved inserting tie-rods (preferably in titanium) in both principal directions of the building, for jointing the walls allowing a reduction of out-of-plane effects. Furthermore, tie-rods introduced in walls with opening can improve the in-plane behavior of spandrel beams, changing the collapsing mechanisms.

In addition to the revitalization of traditional materials, several new materials can now be used in retrofitting masonry structures: these must have got chemical, physical and mechanical properties similar to the original ones. In fact, the target in retrofit is to ensure uniform suitable strength to masonry and recover the original stiffness of the structural elements.

Increases in masonry strength and restraints against out-of-plane failures can be achieved through the application of composite materials. Their use is widely recognized as one of the most successful technique, since guarantee high degrees of improvement, despite the careful and thorough design required by the application.

The composite materials based on glass or aramid fibers are the most traditional. The former are frequently applied in the strengthening of masonry structures because their high mechanical performance are well exploited, together with lightness and thinness that allow easy and fast installation, even in hard conditions. The latter are used because of lower elastic modulus, which is closest to the masonry one, larger capacity to withstand deformations, and less "fragility" than the one typical of composite materials based on carbon fibers only.

But the composite materials are undergoing a constant development of production, accompanied by a sustainable vision. Among these, the ones based on the use of natural fibers, as basalt, flax or hemp, are beginning to notably spread. Interest in bio-composites is growing since they combine good mechanical properties and high recyclability with minimal energy production and low carbon dioxide emission during the manufacturing process. They are also particularly suitable for retrofitting "poor" structural materials, such as masonry and wood, that do not require the use of materials with large strength and elastic modulus. Between bio-fibers, the basalt ones come from the melting of volcanic rocks composed of silicate of alumina, titanium and calcium oxide. They combine the toughness and strength of aramid fibers with durability, fire resistance and low susceptibility to hydrolysis phenomena typical of glass fibers. Of interest are also the fibers of flax and hemp, especially suitable for retrofitting historic structures. As all vegetable fibers, they have complex molecular structure (consisting of several bio-polymers, as cellulose, lignin, pectin, etc.) and nano-structured architecture that give them attractive mechanical properties.

Fiber reinforced polymers are sold in a wide range of products: textiles, nets with tiny flexural stiffness, bars, cables and connectors. Can be used in combination with both inorganic and organic matrix, and this makes them particularly attractive in retrofit and strengthening historic buildings and monuments, although characteristics and technology are different from those of traditional materials and construction techniques. Therefore, at least in the current state of knowledge, composite materials seem to ensure enough compliance with the restoration requirements, not least the possibility to completely remove the strengthening.

5. Conclusive remarks

Casale Castello is currently almost deserted but it is a place of great fascination, witnessing one of the most interesting periods of history of Southern Italy. The village could be considered as an open-air laboratory, a manual of practical design of stone masonry buildings, where apply the most recent knowledge concerning

seismic prevention and retrofit techniques. To this end, this research is aimed at increasing knowledge and awareness of seismic risks affecting its historic building heritage. The existing building types have been treated by a careful diagnosis of the damage and vulnerability, in order to recognize retrofit material and techniques more appropriate for preserving the historical urban structure and identity.

Abstract

Town is the modern man's habitat and its design must be oriented to guarantee comfort and wellness conditions, to minimize environmental impacts, protect, restore and enhance the natural features and environmental quality of the site. If we use the design as an "action of research" to interpret the phenomena and/or problems related to the human habitat and grasp the links between cause and effect in order to make decisions, through this creative act we can have a catalogue of solutions, especially responsive to the needs and adapted to the environmental conditions which must become the "rules of the game". The Leipzig Charter offers itself as a platform to establish these "rules"; so that strategies become signs, actions, habitats ... "appropriate technologies"!

In fact, our cities possess unique cultural and architectural qualities, strong forces of social cohesion and an exceptional potential for economic development; they are centers of knowledge and sources of growth and innovation, but fail to fulfill their function as social progress engines and economic growth (as described in the Lisbon Strategy) unless they can keep in balance the pressures of the social sphere (which requires fairness and legality), environmental sphere (which requires the protection and enhancement) and economic sphere (which currently governs improperly all systems and it should be reduced at the efficiency management). Among the Leipzig Charter's strategies "Creating and ensuring high quality public spaces" is considered a priority action to attract industrial investment with high know-how, skilled human and creative resources tending towards a "Baukultur".

However, Technology is all geared to "Zero Energy Building" (in accordance with the EPBD Recast: 2010/31/UE Directive) acting especially on the envelope: less energy and other resources' needs and more use of eco-friendly materials, in order to guarantee appropriate performances (without energy sacrifice!) for heating, domestic hot water, cooling, natural ventilation and lighting. All that because: "Europe needs cities where life is good!"

This contribute illustrates a design experience begun during the "Archisostenibile 2010" Workshop organized by the Mediterranean University of Reggio Calabria (urban design phase) and completed at the SUN (building design phase).

Key words: Sustainable Technology, Energy Efficiency, Eco-friendly Design, High-Quality Public Spaces, Innovative Component

1. Design: an "action of research"¹

The growing urban energy and environmental decay, that now appears to homologate our cities's aspect from center to periphery, is not only one of many consequences of the objective difficulty to govern the existing buildings and construction processes for new buildings, but also the contemporary statement of the inability to find the ancient relationship between nature and built that was the prerequisite to found a city.

Town is the modern man's habitat and its design must be oriented to guarantee comfort and wellness conditions, to minimize environmental impacts, protect, restore and enhance the natural features and environmental quality of the site.

Design Quality is an attribute both formal and concrete, the expression of a value judgment that is not always measurable in its complexity with standard techniques, but detectable and measurable in terms of surplus value and perceptive/adaptive comfort.

Today more than yesterday, the construction of the building focuses towards eco-friendly behaviour and high performance energy technology and continually strive to design choices that can efficiently manage all the resources (*passive house, zero waste, zero energy, carbon zero, ...*). This conditions have got a strong tendency to innovation, in which the impact factor of knowledge has a high added value. Designing the innovation requires "knowing how to choose" and the complex mechanisms of development of project ideas have to respond to a question in the meantime evolved / renewed towards ever higher standards of performance.

If we use the design as an "action of research" to interpret the phenomena and/or problems related to the human habitat and grasp the links between cause and effect in order to make decisions, through this creative act we can have a catalogue of solutions, especially responsive to the needs and adapted to the environmental conditions.

New models of design production redefine the powers of the technology industry for innovation. There are necessary in some cases, creativity and courage, in other cases, awareness and sensitivity, but in both cases there cannot be technological innovation without innovation of mind: this is a renewed approach to interdisciplinary project with a range of conceptual lines on which basing methodology and practice. But procedure of the innovation has any intermediate stops; one of these is certainly the ideas generation: the "concept design". In this direction a renewed design awareness, that combines the compositional instances of architectural culture with the techniques instances of the traditional building construction culture (sustainable in itself), involves the use of biophysical and bioclimatic factors to qualify and guide the design choices through definition of a conscious glazing ratios, the orientation of the fronts, the selection of technologies for improved energy performance and the use of integrated passive and active solar systems.

An innovative design approach cannot be deterministic in the use of environmental variables anyway! The biophysical and bioclimatic components must be transformed into "elements of the architecture design". Only in this way, it can become a creative opportunity to mediate between knowledge construction and design culture. The relationship between architectural form and the energy-environmental performance in this way gains the meaning of a link of cause and effect; its aware management is a requirement to obtain an architecture that is not only beautiful and functional, yet comfortable and energy efficient. Therefore, the architect will change shape, colour and orientation in relation to the needs dictated by the stresses of the external environment (climate and environment surroundings), in accordance with the 2010/31/UE Directive (well known as the "EPBD Recast").

In fact, Technology is all geared to "Zero Energy Building" acting especially on the envelope: less energy and other resources' needs and more use of eco-friendly materials, in order to guarantee appropriate performances (without energy sacrifice!) for heating, domestic hot water, cooling, natural ventilation and lighting. In fact, "Europe needs cities where life is good!"

The proposed design experience was conducted with these aims and the integration of biophysical and bio-climatic factors have been the added value that substantiates design choices, articulated into shares for the design and site planning activities for the building.

2. The "rules of the game" of Leipzig Charta²

In May 2007, the Leipzig Charter on Sustainable Urban Development is approved; its main objectives are to strengthen the principles of integrated urban development policy with the creation and guarantee of public spaces' quality, modernizing infrastructure networks, improving energy efficiency, promoting training and innovation especially in deprived neighborhoods.

The Leipzig Charter offers itself as a platform to establish these "rules"; so that strategies become signs, actions, habitats ... "Appropriate Technologies"!

In fact, our cities possess unique cultural and architectural qualities, strong forces of social cohesion and an exceptional potential for economic development; they are centers of knowledge and sources of growth and innovation, but fail to fulfill their function as social progress engines and economic growth (as described in the Lisbon Strategy) unless they can keep in balance the pressures of the social sphere (which requires fairness and legality), environmental sphere (which requires the protection and enhancement) and economic sphere (which currently governs improperly all systems and it should be reduced at the efficiency management).

If these assumptions are transformed into concrete actions (plans / design), they are able to ensure cultural diversity and high quality (immediately translated in terms of livability) in fields such as urban design, architecture and environment.

Among the Leipzig Charter's strategies "Creating and ensuring high-quality public spaces" is considered a priority action to attract industrial investment with high know-how, skilled human and creative resources tending towards a "Baukultur".

The "Baukultur" aims to create open spaces that are attractive and oriented to direct, indirect, potential, and why not future users (in the perspective of the intergenerational equity's principle), but with actions to preserve and enhance the historic and architectural heritage, with a high environmental

standard of the proposed solutions. The infrastructure networks must be modernized through sustainable mobility systems that manage traffic through the integrated mode of transport (bicycle lanes, pedestrian areas, ...), coordinating and mediating the diverse needs of residences, offices, business and entertainment.

City is also a place where everyone can create and disseminate knowledge, for example through school Shipyards, Workshops and permanent networks between industry, business and scientific communities. This promotes the spread of ideas and innovation not only technological but also cultural, both in the way of making architecture and in the way to live it, in line with the statement made by Winston Churchill: "we shape our buildings, but since then they shape us."

The Leipzig Charter calls for a safe city in which the social integration reduces the inequalities and prevents the social exclusion. An integrated urban development and the quality of the physical environment, associated with the social quality, provides useful services for citizens.

3. The design experience of "Archisostenibile 2010" Workshop²

The culture of the built environment's high quality is an essential part of integrated urban development, pursued through the integration of social, environmental and economic aspect, actively involving the "key players" of the process, both in planning and in assessment of urban development programs and their implementation.

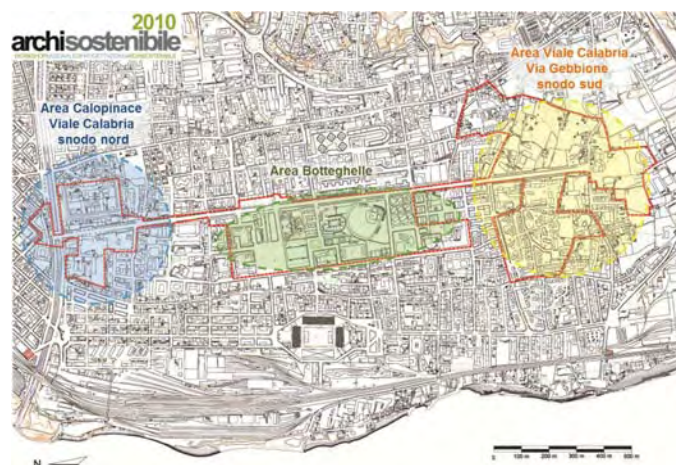

According to these premises and especially to the content and requirements identified by the Leipzig Charta, it is founded the National Workshop of Design "Archisostenibile: Design Ideas for the new quality of the contemporary city", an implementation of the Leipzig Charter on sustainable European Cities in Reggio Calabria, proposed by the Commission for Environmental Quality and sustainability of the Faculty of Architecture of Reggio Calabria³, with the support of the Mediterranean University of Reggio Calabria, Public Administration, Public and Private Organizations.

The workshop aims to define, in accordance with the guidelines and requirements identified by the Leipzig Charter, project ideas on the theme of urban sustainability applied to the city of Reggio Calabria; particularly, on an area located in the southern outskirts of the city it was identified an urban sector that can be considered representative of the objectives of the Charter.

The project area is identified by the urban fabric that extends along the road of Corso Calabria, which currently has the characteristics of "critical" environment, limited to the North by the stream Calopinace and to the South by Gebbione road, near the stream of St. Agata.

Some urban particularly interesting urban areas can be identified along and perpendicular to this north-south axis in order to re-design both urban open spaces and building. Let's analyze them:

- The area of Calopinace includes to the north the disusing General Market (on the left of the stream of Calopinace), the Foro Boario, some disused factories for the processing of frozen foods, offices and Municipal Transport Company (Atam, whose office is being transferred to new premises), a botanical garden with a small building of the Citrus Experiment Station (disused), the Police Station and a school district;
- The Botteghelle is an important multifunctional area where there are the Sports Hall, the new headquarters of the Municipal transport with the new bus station, a city park, a school building, a large parking area used for temporary market area, sports facilities, a covered market and green areas;
- The South area, between Calabria and Gebbione road, includes mainly commercial and residential buildings, as the Area 167, a clear example of urban sector with poor architectural quality, social gaps and degraded space.

Pic. 1: Areas of study.

During "Archisostenibile 2010" Workshop, the design proposed by the working group of the SUN, which approaches the design as an "action of research", point of balance between ends and means, between formal culture and technological culture, provides the functional rehabilitation of Area Calopinace; the project was completed at Sun, where an L-shaped building (destined to tourist information center) and the technology components were designed.

4. The building design experience of SUN work team¹

With specific reference to the contents of the various Manifestos about the Sustainability and Urban Quality (Agenda 21, the Aalborg Charter, the Meeting of Toledo, the Leipzig Charter, etc.), the strengths of the design are:

- Quality of environmental receptors (Water, Air, Land);
- Improving the overall quality and performance requirements of the buildings that characterize urban space;
- "Reinterpretation and Reconfiguration" of the functional relationships between the open spaces that determine the urban fabric, with particular attention to accessibility;
- Outdoor comfort of study' areas,
- Overall Energy / environmental performance,
- Bioclimatic strategies and low environmental impact technical solutions.

The area of Calopinace is strategically interesting, because it is an axis of connection between the central zone of the station and the more peripheral one of the airport. No less important is its location next to the waterfront, the strength of tourism in Reggio Calabria.

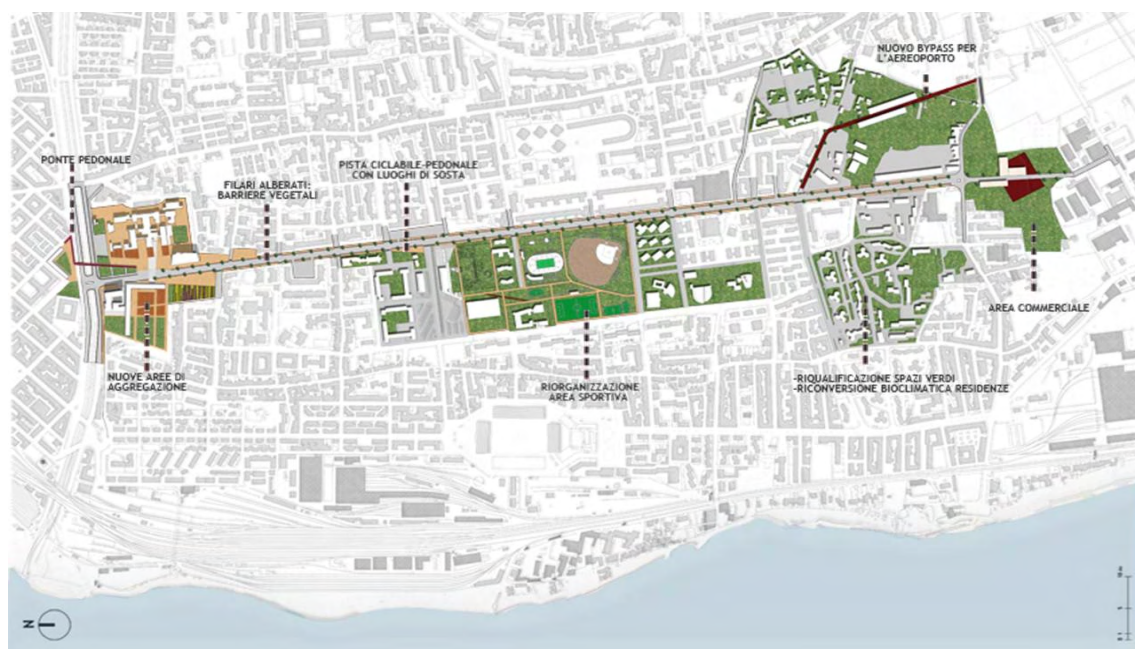

The approach of the "design as an action of research" led to the individualization of criticities and potentialities of the area, from which it has been possible to deduce the main strategies and planning actions to be adopted.

The area of the ex-bus station Atam is characterized by an urban space that, adequately free from the presence of disused structures, has the opportunity to be turned into a new aggregating space, of which this part of the city completely lacks.

In fact the design foresees an equipped square with both elements of street furniture (benches, waste containers, street light) and small and large-sized green space; the large square is separated from the road thanks to an "L-shaped" building that determines its borders in the north and in the east, while the other two borders are marked by the green space. The urban space has been designed as if it were an open room under the sky, characterized by horizontal (celestial sphere, roof and parterre) and vertical (façades of the overlooking buildings) limits.

Dependently on the different functional and control needs of the sunlight, different materials have been used and the role of the green space was important for the bioclimatic comfort.

The parterre is the horizontal limit represented by the ground. The presence of hot surfaces near the project space makes the thermal radiation increase; contrarily the presence in the same area of cool surfaces produces a thermo-hygrometric exchange that favours comfort.

Pic. 2: Urban Design of SUN's work team⁴.

Pic. 3: Masterplan of the area of Calopinace of SUN's work team.

The cooling techniques aim at reducing the superficial temperature, through the use of systems (roofs, pergolas, canopies, ...) intercepting the radiation in order to prevent it from reaching the ground. A remarkable factor is the typology and treatment of the surfaces.

The preliminary study of both summer and winter prevailing winds and shades influenced the building design and the square arrangement. It is possible to enter the square through two entries; one of them is endowed with a pergola with (both a horizontal and a vertical) vegetation cover that leads to the green lung of the square that plays an important role not only for the solar protection but also for the acoustic, visual and streams of air protection. The pergola links three "boxes" turned into small activities: a newsagent's, an ice-cream shop and a coffeehouse. So the pergola becomes an equipped structured path. The square is endowed with green spaces of various dimensions, that increase gradually up to create the large green space situated in the west that is the physical border of the project space. The design of the building, that borders the square to the north and east, is born architecturally through the spatial evolution of a simple volume, modified and rotated according to the sunlight and ventilation; the operations of addition, subtraction and rotation could achieve the architectural lines with the best performance from bioclimatic point of view.

The building entertains different functions: a tourist information centre for the city of Reggio Calabria, a coffeehouse with a refreshment area, a reading room and an Internet point. In order to assure the comfort, the shape of the building itself allows a crossed natural ventilation, thanks to both the aid of openings on opposite façades and the solar thermal accumulation in the wintertime (through the direct sunlight) and the solar shield in the summertime (when the direct sunlight creates discomfort).

For buildings situated in the Mediterranean area, it is not enough to verify the winter dispersions and, therefore, determine the level of isolation of the envelope through the thermal transmittance of the components. In fact, it is essential to analyse the control mechanisms of both heat conduction in a dynamic regime and heat flow due to the solar radiation, which means to verify, for the opaque components, both the coefficients of reduction and lag of the heat wave, and the radiation characteristics of the outdoor surface finish, and to verify for the transparent components the presence and eventually the effectiveness of screening systems.

That's possible thanks to the façades inclined of about 63° , that represents the maximum azimuthal angle of the sun in the summer; in this way the summer radiation results tangential to the façades that are so shielded only thanks to their geometry.

Another part of the building houses artistic laboratories; particularly it is endowed with spaces equipped for painting and ceramics and a musical laboratory, with a small recording studio and an exhibition space, that can be eventually used for conferences on social and cultural issues.

The real designer of this building is, therefore, the building envelope: the frontier between the interiors and the external environment through which checking and monitoring in and out gateway of material and energy. So renewing the concept of building envelope means to present it as a joint product of different approaches: planning, technological, plant, as contemporarily it must answer to compositional and structural, technological and energy, plant and functional requirements.

Pic. 4: The building as a spatial evolution of a simple volume.

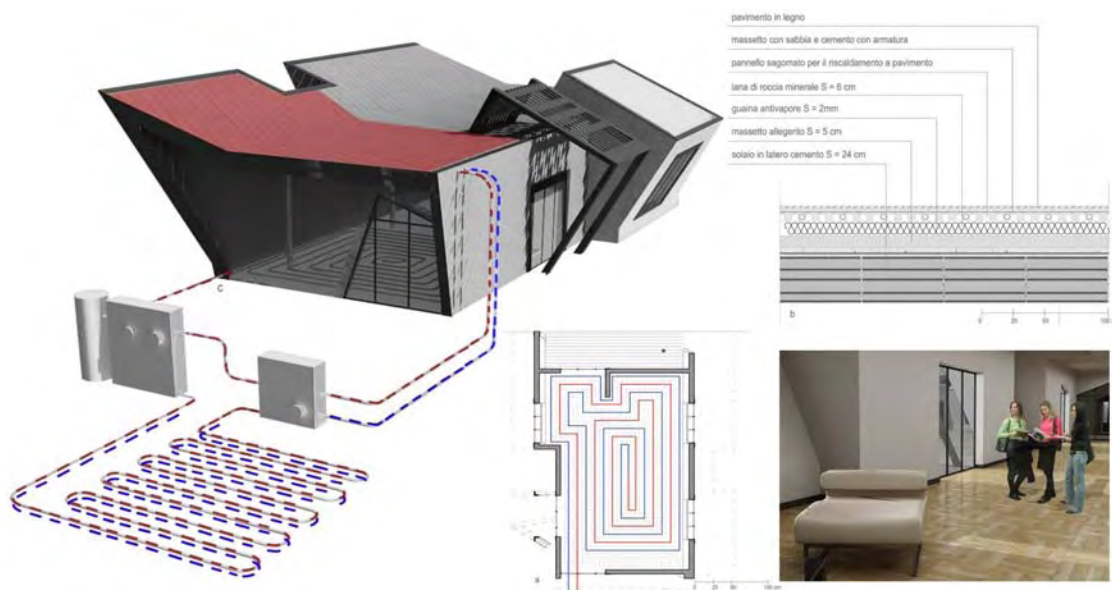

Pic. 5: Façades inclined of about 63° .

Pic. 6: The summer radiation results tangential to the façades that are so shielded only thanks to their geometry.

Pic. 7: Stratigraphy of the wall.

Pic. 8: Solar heating system.

The structure has been carried out using eco-friendly materials. The structure is made of pre-fabricated plywood panels: being the wall inclined of 63°, some steel supporting structures have been used to avoid the breakdown of wood-concrete node. The walls are sheathed with plasterboard with a layer of thermal insulator of wood wool and externally they are covered by zinc sheets isolated with mineral wool. The energy correctness of stratigraphy of the wall has been verified with the computer software "JTempest", that has highlighted a value of transmittance of 0.39 W/m²K, suitable to the minimum requirements required by 311/06 legislative Decree (0.48 W/ m²K for the B climatic zone), an attenuation equal to 0.126 and a bewilderment equal to almost 13 hours.

Glass walls with double insulated glass have been provided; this allows to increase the thermal isolation avoiding the heat loss. Particularly, the glass walls set in the tallest part of the façade can be opened through the aid of an automated system, guaranteeing the natural ventilation of the interiors. This kind of opening is protected, besides, by the summer direct sunlight through a fixed shield.

About the roof, an innovative system has been designed to produce sanitary hot water that, contrarily to the thermal solar panels commonly sold on the market, doesn't work with the principle of the greenhouse effect, but it uses the direct sunlight accrued by the zinc sheets to heat the floating water in the pipes. In order to avoid the overheating of the interiors in the summertime, besides the isolation with mineral wool, also a double cavity wall, ventilated when needed, has been provided.

Solar heating system is combined with a geothermal energy collector and a heat pump: so in the summertime the heat pump keeps the building cool downloading the heat in the ground that acts as an environmental sink. The geothermal heat pump uses either the soil or the water that can be found in the soil as a source or as a heat sink; it can work in cooling also in a passive way, extracting heat from the building pumping the cold water in the system without the action of the real heat pump. An air-conditioning system under the floor controls heating and cooling.

For the recovery of rain water, a collecting system has been provided through a gutter fixed to the roof so that it cannot be seen from the bottom. Through a pipeline system, meteoric water reaches the earth and, passing through a filter of purification, it is stored in special reservoirs buried in front of the building, but with the possibility to be inspected in case of maintenance. In this way the reuse of meteoric waters is possible for discharging the toilet and irrigation.

A conclusive consideration: it is necessary to aim at a "Possible Quality" for the public building heritage where the technological solutions adopted for the improvement of the energy-environmental performances result to be the mean and not the goal.

Abstract

This study, started by a collaboration of representation and mathematic researchers, intends to verify the correspondence between the geometrical and the built shape of the dome of San Carlino in Rome, designed by Francesco Borromini. The transition from a geometrical model to its construction, in fact, is also influenced by factors related to the building yard practice, which can also lead to significant changes over the initial idea. For this reason a new survey has been conducted, which analyzed the vault in detail, especially in the sequence of panels which characterize the soffit. The comparison between the model derived from instrumental survey and a mathematical-analytic model, based on parametric curves and arithmetic progressions, has allowed us to understand the transition from geometrical form, measured on the impost of the vault, and his space development; at the same time, the comparison between design drawings and the survey model has allowed us to formulate some new hypotheses about the relationship between Borromini's design and constructive method.

Keywords: Survey, three-dimensional model, mathematical model, Borromini, San Carlino.

1. The dome, project and building. Preliminary remarks.

This paper shows the first results of the research, which is currently being carried out, whose subject is the study of the vault of the *Church of San Carlino alle Quattro Fontane* (Fig. 1) in Rome, built by Francesco Borromini, inserted in the conventual complex of the Trinitarian Order. The church was built in stages from 1634 and was completed in 1680 after the death of Borromini in 1667 [1].

Our aim is to make, through the data obtained from the survey and the resulting three-dimensional model of the dome, a mathematical model which, on the one hand, identify a possible rule in the dimensional sequence of the symbolic elements of the dome and which, on the other hand, may help to understand the shape of the surface.

Defining the role that the geometric drawings played in the Borromini design is not simple. It is generally agreed now that the series of autographic geometric drawings made for the *San Carlino* was done after the building, in preparation for the publication of the *Opus Architectonicum*, and that the creative phase, probably, started from the plastic models [2, 3].

In relation to the possibility that mathematics can have served as a support for the project – it is necessary not to forget that mathematic knowledge and drawing have always been deeply related in architecture – it is important to highlight that even if the cultural background within which Borromini worked was the one of the 17th century Scientific Revolution, his building technique was still deeply linked to the Renaissance tradition [4].

The mathematical ferment which had characterized the previous century would lead, during the 17th century, to differential calculus and its applications together with the general solutions of polynomial equations of fourth degree and an explicit use of geometrical curves defined by kinematic rules.

However, in Borromini, stimuli towards a design which can gain its own “scientific reliability” look more like a “form of thought” [5] than like the basic tool of an ideal prefiguration.

The classics were a reliable source of inspiration and comparison on which he directly drew, detecting and noting down, in ancient monuments, structural and formal solutions which didn't always correspond to what the treatises had passed down.

It is necessary to consider that, generally, the operating practice was the most direct way to find answers and solutions to any design idea and, in this context, the use of models constitutes a fundamental way of planning and checking.

Issues linked to the design, to its conception and prefiguration through scientific-mathematical methods, materialize in the need to give instructions to the skilled workers. The operating practice leads to thinking about *how to do* and it is just to this question that the new survey and the consequent mathematical model try to give a possible answer.

In relation to what has been said so far, the creation of a mathematical model doesn't aim, according to our intensions, to hypothesize that the design of the dome be the result of a mathematical thought, as far as the creation of the impost curve, the arrangement and deformation of the decorated coffers and the setting up of the entire surface are concerned.

The issue is that if the geometric rule which Borromini seems to have used can be related to a mathematical model and if that can be useful to understand the building procedures.

It being understood that the *building* represents a further design moment, during which what is realized not necessarily correspond to what has been previously thought.

An example can be the perspective adjustments located “at the top of the vertical arm of the crosses on the dome impost, where a portion of mortar was added later, in order to optically correct the height size from the bottom”, according to what emerged from the latest, recent restorations [6, 7].

Geometry, therefore, establishes itself as a design background whose rules can be infringed because of the more pressing perceptive rules, as it happens in the coffered part of the niches about which Borromini explains, through a caption in the drawing Alb. N. 208, that “*Li sfondati non devono andare al Centro perché quelli più vicini a detto centro resterebbero troppo piccoli. Saranno numero nove li sfondati senza quello che occupa l'aggetto della Cornice*”.

1.1 Geometry

In the Alb. Az. Rom 169 drawing the projection of the oval impost of the dome is drawn through two opposing equilateral triangles sharing one common side, whose base vertices are the centres of the curves that joint the two shortest circular arcs, drawn on the barycentre of the triangles (Fig. 2). This is in line with the *modus operandi* of Borromini who, also to obtain complex geometries, used curves which could be obtained through simple circular arcs. This geometric construction is called “canonical oval” and it is characterized by the possibility of being divided into equal parts. However, as already mentioned, the drawing may be subsequent to the realization of the dome and probably “made for mainly symbolic and not formal purposes”, since this drawing (constituted by triangles and circles) is not necessary to trace the oval, but it is used to include the Trinitarian symbology, largely evoked in the building, also in the plan [4]. To build the oval Borromini proceeds from Serlio's suggestions, with the two triangles disposed transversely.

One of the interesting data on which we focused was the information emerged from the surveys carried out within the restoration works, from which it emerged that the geometric tracing relative to a canonic oval would be “only at the first row of coffers, about one meter above the plane of the impost” [8, 9]. Another datum resulted from studies aiming at restoration works which highlighted that, “up to the level of the platbands of the windows it is possible to notice a pseudo-horizontal course of bricks” [10] and that “the curvature [of the vault] stands out against the octagonal windows” [7].

Taking these considerations into account, we put forward, starting from our survey, some hypothesis about the impost geometry and the development of the vaulted surface, which will be described in the paragraph 2.1.

1.2 The building

Between the drawn form and the built one there are the building yard practice, rethinkings along the way, needs and hitches which can occur. There are also static aspects to take into account to which Borromini finds a solution according to the tradition: the calotte of the “dome is partially united to a thick ovate tiburium” [3].

Static aspects could also have determined the deformation of the oval figure which appears more flattened than in the drawings: the study of the strains along the connection points among the four curves which draw the calotte impost could explain the adjustments made to the shape of the canonic oval.

Drawings and models, useful also during the operating phase for planning the construction of the centrings, were probably used to design the dome. As a result of the studies made during the restoration works, it emerged that “frames and coffers bottoms are made of bricks and are an integral part of the masonry” [9], so it looks plausible to us that the dome be built through some centrings, whose shape had to be very precise and reproduce in the negative the drawing of the coffers.

2. The new survey of the dome of the *San Carlino*

The idea of carrying out a new survey of the dome/dome of the *Chiesa di San Carlino*, therefore an already accurately studied and surveyed building, aims to be a further research and analysis occasion/opportunity linked to the willingness to deal with the subject concerning the link between geometric form, project/design and construction/building.

Survey works focused on the check on the geometric layout, relative to the dome impost, which was in some drawings kept in the Albertina's Archive in Vienna, and on the hypothetical geometric-spatial shapes of the dome, within three domains:

- 1) The determination of one or more generatrix forms of the plan;
- 2) The drawing of the octagonal and cross-shaped coffers, which characterizes the dome intrados, useful for determining the geometries that regulate the sequence of the coffers;
- 3) The drawing of the horizontal and vertical sections, which helps to determine the spatial development.

On the basis of that a new survey was carried out following an integrated method, using topographic measurements obtained through points/dots (about 1000 points) surveyed by two stations inside the church, complemented by photogrammetric measurements made through the use of about 30 photographic images and a multiple images photogrammetric rendering software (about 600 rendered points). The use of this software made it possible to overlap, in virtual 3D, the archive drawings and the images of the dome intrados with the spatial model obtained through the survey.

2.1 The planimetric shape of the dome

As far as the determination of the planimetric shape is concerned, we tried to determine, with a sufficient approximation, the geometric form relative to the curve of the tambour frame, the ones relative to the horizontal alignments of the coffers at the several levels and the base one of the small lantern.

The analysis of the surveyed points and of the overlapping of the different geometrical constructions showed two significant aspects: the curve, relative to the tambour corresponding to an oval, is centred compared to the rectangle described, in the plan/layout, by the lateral apsidal domes and the couples of twin columns arranged diagonally; the ovals passing through the characteristic points of the crosses and of the octagons of the four levels, as well as the ones of the base ring of the small lantern, are, instead, related to the development of the dome. Since this series of ovals built by dividing the longest axis into three parts (Fig. 3), originates from the intersections between the continuous surface of the dome intrados and the horizontal plane of the various levels of the coffers, these ovals are similar figures, i.e. characterized by the same shape, but layered dimensions following a geometric progression.

The system of the tambour, linked to the layout/plan geometry, and the one of the dome are different and aren't aligned with each other (Fig. 4). The variable space between the tambour corona and the dome impost, clearly visible in Fig. 5, is hidden by the overhanging tambour corona decorated with palms and flowers.

Comparing the projection of the oval in the drawing Alb. Az. Rom 169 with the series of ovals that describes the tambour and with the ones that describe the dome, it is necessary to highlight that only the first series is similar to the construction of the canonic oval.

Moreover, the overlapping of the project/design with the survey of the alignments of the couples of columns supporting the correctly oriented pendentives is signaled.

2.2 The coffer drawing

There isn't any information about the coffers which characterize the dome in the archive drawings. It is possible to suppose that Borromini used, besides a series of scale models, orthogonal projection drawing of the coffers, accurately deformed along the single *tessella* in which the base form had been divided, in order to have the possibility of replicating precisely the alignments of the coffers, not only horizontally, following the

different levels, but also in elevation (only to then make corrections for a better perspective perception, where he thought it was necessary, cf. par. 1). Some information can be deduced from both survey data processing and the analysis of the mathematical model, from which it is possible to infer that the ribs are oriented following five centres, arranged on the longitudinal axis: one in the centre, for the coffers arranged on the transverse and longitudinal axis, two, apart from the centre, relative to the elements disposed on the diagonal lines and two others in which the intermediate/halfway gores converge (Fig.6).

As far as the project of the coffers in elevation is concerned, the only document preserved is the Alb. Az. Rom 224 (Fig.7) in which the notes that Borromini writes down in the margin, are very helpful to understand the drawing. As a matter of fact he often shows his willingness to divide the dome into eight alternate crosses and octagons, following four horizontal series, whose dimensions are reduced from the lower to the upper level. Each level is divided into 16 *tessella*, which split the surface, following predetermined dimensions, written down in the drawing (6 palms horizontally and vertically for the first and second coffer levels, 5 for the plain impost band. Horizontal dimensions were modified, during the construction, by the introduction of the different convergence centres of the ribs, which determine angular magnitudes from 21° on the longest axis to 25° on the shortest one.

It is interesting to note that the complexity of the coffers final drawing is the product of geometry and proportion simple rules, adapted to the building practice (Fig.8); consequently, if Borromini had decided to use formworks to make the coffers, he would have to make only those formworks which repeated several times, considering that the coffers are symmetric two by two so they are equal on the transverse and longitudinal axes, on the two diagonals and on the intermediate gores; as a consequence of that there would have been five types of formworks, multiplied by the four levels, so twenty out of sixty-four in all.

2.3 The surface geometric model

It is difficult to understand the spatial structure of the dome, which has given rise to different interpretations. Certainly, as it has already been surveyed, the surface is not a rotation surface, since a series of curvilinear generatrices, which vary from the shortest one on the transverse axis to the longest one on the longitudinal axis, correspond to a directrix determined through the construction of the horizontal polycentric curves. The total height and the heights of the different levels of coffers are, obviously, constant, and the symmetry is bivalent for the axes and tetravalent for the diagonals.

It has been noticed that in the longitudinal section the section correspond to a quarter of a circumference, whose radius is equal to half the longest axis, cut on the top hand by the impost plane of the small lantern. The fundamental elements to be considered, in order to make a both mathematical and digital model of the dome relative to the construction hypotheses, are determined by the impost elevation and by the main sections: transverse, longitudinal and diagonal. The new survey showed that the surface curvature, starting from the ring of the small lantern, goes on, with a lightly curvilinear, almost vertical movement, up to the first level of coffers, aligning with the vertical plain band (Fig. 5). The oval of contact between the two surfaces, located at a 16,27m elevation, is the impost curve of the dome. This assumption is supported by the fact that the limit of the application of the finish stucco, noticed during the analyses aiming at restoration [7], is just located at that elevation and that putlog holes are located at 15,20m lower quote, by the band decorated with palms and flowers. Besides, analyzing the vertical development of the vault on the basis of the unit of measurement of that time, i.e. Roman palms (22,3cm.), it is possible to notice that: the vault is 8,02m (36 Roman palms) on the shortest axis, 11,37m (51 palms) on the longest axis and 5,13m (23 palms) on height, the tambour band is 2,23m (10 palms) and the small lantern ring is 0,22m (1 palm).

3. Mathematical model of the dome surface

In order to understand the geometrical model of the vault it has already been proposed [11, 12] a general mathematical model which depends from a generic planar parametric curve. This model has been used to study both the surface shape and the geometrical structure of the tassels sequence. With the new survey, the abstract model is integrated with the coordinates of surveyed points to obtain a new mathematical model which make use of the data from the survey and keep questioning it to get new and more specific answers.

3.1 The abstract model

The model depends on a general parametric curve $\gamma(t)$ which represent the base of the vault. Such a curve has been extensively studied with respect to its construction and regularity properties: the oval suggested by the project design or its similarity with an ellipse, together with models of the surface shape, has been tested in recent papers [11, 12] were a new type of curve, similar to the oval and closer to the observed realized curve, is suggested.

Here we derive and use a model with the same type of curve,

$$\gamma(t) = (6 \cos u + \frac{1}{3} \cos 3u, \frac{9}{2} \sin u + \frac{1}{3} \sin 3u)$$

which has the same regularity of an ellipse (in particular it has a continuous second derivative) although more studying is necessary to have a better fit with the three-dimensional relief.

Starting from the basis of the vault $\gamma(t)$ the model of the surface is constructed assuming an ellipsoidal shape, in parametric coordinates:

$$S(u, v) = ((6 \cos u + \frac{1}{3} \cos 3u) \sin v, (\frac{9}{2} \sin u + \frac{1}{3} \sin 3u) \sin v, \frac{25}{6} \cos v)$$

A model for the position of the lacunars can be derived (see [11,12]) starting from the selected surface, using arcs of "parallels" and "meridians" in a regular pattern: alternating crosses and regular octagons on increasing levels seems to rescale towards the top of the vault.

Given the n^{th} vertical level and the number N of lacunars for any level ($N=16$ in our case) we can define position and size of a tassel of the surface by the spherical coordinates of its centre (u_0, v_0) and the angular "radius" in horizontal (u_r) and vertical (v_r) direction:

$$u_0 = \frac{2\pi}{N} \quad v_0^n = (\frac{2\pi}{N}) 2b^n(1+b) \quad u_r^n = u_r^0 = \frac{\pi}{N} \quad v_r^n = \frac{\pi}{4} b^n(1-b)$$

where b is the ratio between vertical radii of two successive tassels, that is

$$b = \frac{v_r^{n+1}}{v_r^n}$$

In order to fix the value of b and of the vertical size of the first tassel we make the hypothesis that it would be possible to fit an infinite number of successive tassels of constant ratio which ends up at the pole (the same description can be applied with more than one pole) and which looks like squares with some accuracy. The first hypothesis implies that the sum of the vertical size of the infinite tassels in angular coordinates would be exactly $\pi/2$, which gives the condition:

$$\frac{\pi}{2} = \sum_{k=0}^{\infty} 2v_r^k = \sum_{k=0}^{\infty} 2v_r^0 b^k = 2v_r^0 \sum_{k=0}^{\infty} b^k = 2v_r^0 \frac{1}{1-b}$$

that is

$$v_r^0 = \frac{\pi}{4}(1-b)$$

The condition of tassels of similar size on both vertical and horizontal direction, in a spherical approximation of the surface, can be fixed by the condition (which depends on the vertical position of the tassel):

$$\sin(\frac{\pi}{4} b^n(1+b)) = 4b^n(1-b)$$

In the proposed model we applied such condition fixing $b=0.75$ and checked the levels from the second up to the fourth one: the first level is particular and also the model of a full simple ellipsoidal surface is good with respect to its mean distance from the points of the relief (which is around 5 cm) but the position of the lacunars seems not to be perfectly aligned (Fig. 9).

3.1 The mathematical model and the survey

A different model, closer to the new survey, is constructed which leaves the same geometrical description for the position of the lacunars but change the shape of the surface of the vault.

Starting from the baricentral points of crosses and octagons of the last three levels: we note (Fig. 10) that the vertical projection of these points are almost aligned and they meet in a symmetrical and uniform way.

The point of intersection are different from the centers of the arcs forming the oval shapes but are center of symmetry for the construction of the corresponding part of the vault surface.

The model is then constructed as a three-dimensional version of an oval: we take for each of the four symmetrical part a vertical axis through the point of intersection of the converging lines and construct the four parts of the vault as the surface of revolution along the base curve with an elliptic profile.

The beauty of such model is in the simple regularity of the merging vertical curves (Fig. 11).

Conclusions

Research is still ongoing but, starting from these first data it is possible to make two hypotheses about the methods used to build the dome, both of them are based on the idea that centrings were used for the general conformation of the surface described by the coffers ribs [7]. Centrings could have been built following a vertical sequence, corresponding to the transverse, longitudinal and diagonal guide sections, and a horizontal sequence which, starting from the impost oval, replicates and layers the initial figure following a progression determined by the vertical guide sections. The shape of each centring is constituted by circular arcs, in particular the longitudinal centring is made from a semicircle with radius equal to half the longest axis.

The first hypothesis is based on the use of standard formworks (in all, twenty, as stated in par. 2.2) placed on the centrings structure (or made at the construction site [7]).

The second hypothesis, drawn from the mathematical model, would suggest the idea that a scaffolding with wooden beams which describes the surface determined by the curvature of horizontal and vertical centrings. On this scaffolding it would have been possible to place some formworks shaped on the basis of the single *tessella*, adaptable to the change in curvature and dimension. It would make the alignment of ribs, following the centres shown in plan projection (Fig.12) and after positioned on dome surface. Further analyses and details are expected from following research.

THE INTERIOR AS AN EXTERIOR. Precedents for the addition of a new hall in the old Gymnasium Neapolis, Crete.

Nikolaos SKOUTÉLIS

Faculty of Architectural Engineering, Technical University of Crete, Greece.

nskoutelis@isc.tuc.gr

ABSTRACT

Designing interiors as exteriors has always been a great challenge in architectural design. As a compositional principle this method highlights the capacity of the architect in combining scales and as a final result, it enriches the character of the buildings as *containers of life*.

The current proposal is concerned with two interventions for the construction of halls in the towns of Chaniá and Neapolis in Crete. The design approach should be that of the proposal of the external space qualities in these halls that should demonstrate a rich atmosphere made by the minimal architectural effort. The study of precedents has offered several ideas, in order to improve continuity and the severe control of our decisions.

In Chaniá the design of the internal walls combines row wood strips and photographs, trying to create the compact image of reed, moving by the wind. In Neapolis, the existing courtyard space is imagined as being covered by a large tent which curves downward, toward its centre and is pulled back by its four corners creating tension.

This method, where it can be applied, gives more welfare using less architecture. For the interventions in existing historical buildings it can offer the idea of the natural elements with which time involves buildings and creates the *patina*. The interiors designed as exteriors can offer a deeper architectural thought beyond buildings as a kind of a primitive euphoria, as life in the inbuilt.

Keywords: Interior design, Council Hall, Tent, Reed.

Fig.1: The frescoes from the "House of Livia", Museo Nazionale Archeologico Romano.

Introduction

The inner purpose for architecture is to treat and configure the relation between the external and the internal spaces, the definition of the limits and the relations these passages creates when people move from outside inside, from one place to another. The immense of the natural countryside, then the continuous of the open air spaces in the urban settings, usually conducts into a covered, concluded interior, public or private.

For Piranesi the external spaces must be “*severe*” but the interiors must be “*gentle*”. For Loos the exteriors should have the character of the “*provocative*” but the interiors that of “*reassurance*”. Architecture has created its world explaining the autonomy and all the possible relations between these polarities. When the criteria of the external space, as size correlations, images, light and color are combined in the construction of an interior, architecture arrives to the description of the real world.

Examples as the Pantheon in Rome, Ayia Sofia in Istanbul and the Berlin Neue Nationalgalerie by Mies van der Rohe, try to include as a continuous, inside, working on and with the walls, the qualities of the open air urban landscape. In our first example, making rain and cold to come inside an interior which is composed by the repetition of facades, in the second, filtering light in, as in a covered public square and in the third, using the surroundings as permanent scenario in the interior, as walls. Designing interiors, architects have the opportunity to improve different materials and treatments and are able to incorporate in a fixed structure levels, themes borrowed from the visual arts. More or less murals have created the internal atmosphere in the greco-roman antiquity and then, between renaissance and neoclassicism. Gobelins and asian carpets are the fixed scene in the medieval domestic interiors.

For historic architecture, the composition of a space capable to incorporate the purpose of other arts has been considered as its highest goal, and in this kind of creations that of the total art. In our contemporary world we have changed the names of these basic intentions but the themes are unchanged. We don't paint murals and we don't cover by golden mosaics our walls. We focus on transparency because it is the solution for the introduction of a filtered image of the real life outside our buildings. Otherwise, we stamp leaves and row textures on plaster and glass, in reference to the natural and the time's dimension. Our “murals” are emanations of photography, and secondarily of the cinema. We desire architectural space as creation of a total art.

In Crete, Minoan architecture proposes interiors as outdoor areas with murals presenting scenes from country or marine landscapes. The painted walls in the house of Livia in Rome (Figure 1). and the “Camera degli Sposi” in Mantova by Andrea Mantegna, introduces moments of that inner happiness of life in the countryside, under the open sky, for private rooms in the city. The gothic cathedrals recompose all day's moments outside into a total natural light experience out of time, each time.

Contemporary architecture after the history's lesson of the eighties, confused by the promises of the digital era, introduced more and more nature in the design of the external public spaces in terms of landscape, thinking sustainability and environmental criteria as new substance and ethics in its workmanship. In the same moment, working with the elements of this lost naturalness in the internals donates to architecture the sense of lightness and porosity to its natural limits, the walls. Staying inside becomes easily a walk to spaces of the fantasy and immensity of the open air space. In these terms, an interior could become as the most expansive exterior. [4] This experience of the built could be combined with human inclination for freedom, delight and profane entertainment.

Fig.2: Erik Gunnar Asplund, cinema Skandia, Stockholm, Perspective design for the interior.

Fig. 3: Mies van der Rohe Neue Nationalgalerie, Berlin, view of the interior.

2. Modern precedents

The need for examples, structured on this subject in more recent times has given the instruments for further verification of the initial hypothesis. Asplund's cinema Skandia in Stockholm, (1924), has been designed on a nostalgic mediterranean reality: feast in a small italian square, by night. Low balconies and rows of chairs appears in a dark interior, where hanging lamps replace the stars. (Figure 2).

Alvar Aalto in his Concert Hall in Helsinki, (1962-71), follows the ceiling's movement on the lateral walls by a decorative pattern evocative of a dense reed bed or the wood around his villa Mairea. It is a typical example of many of Aalto's hallmarks and motifs. [7] Generally, in Aalto's interiors, large asymmetrical movements, lighting and the use of wood transfer the outside, into the finish landscape.

Mies van der Rohe, in his Neue Nationalgalerie in Berlin (1962-68) doesn't need to create an interior space. His captured images of the surrounding urban landscape, replace the walls of this gallery. Architecture becomes a flat roof, flying on the earth, somewhere in Berlin (Figure 3). This last solution had several applications and we can say that the modernist persistence for transparency and immateriality has been approved in several solutions, specially the last ten years. The most evocative of all could be appear the Onichi Civic center by Kazuyo Sejima and Ryue Nishizawa, (2009). Here interior and exterior penetrate completely one into the other giving a sense of life in the open air.

This short excursus shows that composing interiors with the elements of exteriors, creating a light atmosphere of pleasure, has always been a great challenge in modern architectural design. As a compositional principle this method highlights the capacity of the architect: First, in proposing ironically, as a literary transfer, a double sense in his rooms. Second, in combining scales of different working criteria from the city to the individual object and third, it gives the instruments for the incorporation of the so-called decoration in the final solution.

Examples like those presented above, as final results, enrich the character of the buildings as *containers of life*, in the same way that the public space functions, giving continuous opportunities for the collective expression. These thoughts composed the mosaic of the intentions in the two proposals in Crete.

3. Designing two halls in Crete

The Skoutelis & Zanon architectural studio in the 2006 had the opportunity to intervene in the abandoned Horticultural Market twelve kilometers southwest of the town of Chaniá, western Crete, with a project for the restoration of the whole complex into the Region's new administrative center. The given structures should be used totally, so new outdoor corridors, as transition areas have been proposed for the communication between the parts. The solution employed the introduction of a Council Hall in the ground floor, in an internal part of 180 m², which cannot receive natural light.

The ideas for the interior of this hall has been originated from the very present groups of reed in the surrounding area, closed the lake Ayiá. The plan's shape of the hall led to a movement between the existing walls and the new sound absorption panels. These panels are two kind of structures: most of them are made by strips of iroko in different dimensions, leaving a void of 2 mm between them. The rest are webs by gypsum plaster, where photographs of the real reed and trees are involved on the walls. The new layer of Iroko wood panels reaches up to 2.20 meters while the rest of the room's height (totaling at 3.80 meters) is completed by a zone of semi transparent sheets of glass concealing the artificial lights. They fuction as substitutes of windows, bringing natural life inside. This stable lighting creates an atmosphere composed by green and blue color while the direct working lights are positioned on the ceiling. (Figure 5).

The second opportunity for the design of an internal hall has been given in 2010, by the Municipality of Neapolis, eastern Crete. In the historical gymnasium, converted into a cultural center, a hall should be added, for the unification of the rooms quoted in series. This late times monument consists of three ground floor wings forming a Π, which enclose a courtyard open to the east. The building is located south of the cathedral of the Assumption, in the most central point of the large urban area comprising the public buildings, east of the elongated central square. The two lateral wings, north and south, bridge the difference in level from the square towards the east, while the smaller central wing makes up the main elevation towards the town.

The existing building's total area is approximately 788 sq.m. and the courtyard 590 sq.meters. The building's architectural merit is limited to its robustness; its presence as part of the monument complex of the garden beside the church of the Assumption; and its uniformity to the other buildings of its time (the Courthouses, the Prison, latter mid-war residences) The value of the authenticity of materials which could have led to argue for the building's conservation is almost lost due to the restorative works (2000-02) which presented a freshly rendered and freshly painted building with new floors and roofs. The building's historic value is rather more significant. Here studied youths from the prefecture of Lasithi who came to be bright scholars and politicians, capable of elevating Neapolis to an important intellectual center for the island. The community's deeply rooted sense for the building's historical value led to its declaration as a preservable monument.

In 2009 Neapolis is integrated within the framework of the new Municipality of Mirabello, with Agios Nikolaos as its capital city. It could be stated that owing to the cultural activities and the overall dynamic which is developing; though especially due to the number of public buildings and the unique character of the central garden, Neapolis could serve as the region's cultural center; especially when considering the absence of such places in Agios Nikolaos and other regional settlements. This is a means by which Neapolis will reclaim its lost prestige.

In the meanwhile, the inhabitants appreciate their old Gymnasium as it has been the first formal educational institution in Crete in the modern times. Most of the people involved have expressed their hesitations and gave different conditions in order to agree with the project. Designing in these conditions seemed to give more restrictions to the architect's intentions, but by the end this new interior should appear as an outdoor area. The existing courtyard space has been imagined as being covered by a large tent which curves downward toward its centre and is pulled back by its four corners creating tension, much like when trying to fold a sheet of fabric. Staying inside should create the idea of an exterior space like in a bazaar or an Asian ceremonial tent.

Around this roof there runs a continuous band of wide blinds 1.73m tall sub-divided into strips of blinds 27cm wide; so that when the blinds are open, during most of the year, the courtyard space becomes semi open and the whole structural system serves as a shelter (Figure 6). Staying inside should create the idea of an exterior space like in a bazaar or an Asian ceremonial tent.

During the winter months the blinds shut and the courtyard space, supported by mechanical ventilation, may support any activity. The curved volume of the roof is pierced by five cone-like light wells, which let in and disperse the natural light; another means to render the space light and airy, recalling the openness of the school's courtyard.

The technological solution of the double roofing rewards the architectural invention, by the creation of two separate structures: one is the iron external structure elevated 7,50 meters high by eight iron beams composed pillars. The second is the so called "sheet", made by gypsum plaster panels, suspended between 4,80 to 6,90 m over the hall. A marquee divides it from the band of wide aluminum horizontal blinds giving the sense of an independent piece which takes part of the internal.

3. Conclusions: towards a method

In this opportunity a theoretical approach can emerge as result of our attentiveness in the study of historical examples. We tried to give the instruments of a method which consists into:

A. Searching a pretext from the surroundings, in order to propose an ironic, double sense of an interior, as an open air space.

B. The combination of different architectural scales in the interior's design.

C. Working in this field conducts to the incorporation of the so-called decoration in the solutions of the several parts and the internal facades of the construction.

D. One could add one more compositional principle as a new contemporary approach in this theme: The interior rooms as continuous undulation of one only surface or material, as happens in the so called *diagrammatic* process. Also in this context the fusion between interior and exterior is guaranteed, as the traditional, modern or classical examples have highlighted previously.

The instruments for such a procedure vary from the mimetism of the dominate elements of the natural or the urban landscape outside, to the real presence of those through glass walls, inside. The interaction between the design's scales as another carrier of irony provokes the users mind in a kind of entertainment and an expectable astonishment. The redesign of the external elements as direct transfer and as metaphor for the needs of the internal function, in this process, contains automatically the production of decorative elements or surfaces as complete works of art.

This method, wherever it can be applied, gives more wellbeing to the users, building "less architecture" in a metaphoric sense, as it proceeds combining existing images and forms, leaving light to come inside, creating a kind of suggestion of continuity. For the interventions in existing historical buildings it could find even further applications. It offers the idea of the natural elements with which time involves buildings creating the so called "value of age", on architecture's materials [6].

If we try to redefine again our method, transferring these principles into restoration projects, they collaborate in this, by:

A. Proposing continuity between the natural elements and the aged architecture reconsidering John Ruskin's theories on buildings' life.

B. Suggesting higher scales of intervention in the interior's design could help into a major revitalization of the existing for the collective life.

C. Incorporating natural elements in the so-called decoration in the solutions, could replace the re composition of lost or partly destroyed historic elements.

Composing interiors as exteriors could emerge as that congenital method which contains the instruments for the stress of relation with the time dimension, enhancing the *atmosphere* values given by the presence of nature's action and the so called "patina" on the aged surfaces. The metaphor of fragments from the natural environment inside, emphasizes the presence of all the conditions of aging and the duality between the built and the unbuilt. One more time thoughts coming out this method, brings to the conclusion that the effort for the production of *less architecture* could add more substance into our creations.

The transmission in the future of the works of architecture, time by time becomes more pressing and the most of the times we are guided to apply contemporary values in the existing. That happens not only because of the commands of the international congresses and charters on monuments' restoration but also because of the less possibilities that are given for totally new constructions. Working on the existing is the near future, not only in countries with a huge stock of historic buildings but in all countries. In later or very old buildings these interiors could become the intermediates between the time of construction and the long time of the building's life, presenting values of our way of acting today. One of these is the landscaping process and then the design as a folding of continuous surfaces as experienced in the natural terrain.

We tried to analyze and to reconsider the nature of the external spaces as instrument for the interior design, because of the variety and the conditions they offer to real life and collective expression. Introducing the natural into the internal space could guide the users to unexplored results for their behavior. Interiors designed as exteriors can offer a deeper architectural thought beyond buildings as a kind of a primitive euphoria, as life in the inbuilt.

Abstract

In the old town of Chieti, at largo dei Martiri della Libertà and corso Marrucino, stands the palace of the eighteenth-century belonging to counts Mayo, located between the church of S. Dominic and the Provincial Government Building.

Its recent restoration is a tangible urban redevelopment by the "Fondazione Cassa di Risparmio della Provincia di Chieti", and acts as a boost for the cultural, social and economic community.

The monumental building, really precious in architecture, shows some important collections of the Foundation's permanent exhibition, an art-library opened to children, rooms dedicated to temporary exhibitions, an auditorium, a garden for concerts and actings, an underground archaeological area, rooms for workshops and two cultural centers international. In Palazzo de 'Mayo, a location of FAI's day of spring, there was the placement of Mozart's salons, homonymous subject of the annual music festival of Chieti.

The size and the feature of the building have joined with the large architectural spaces, intellectual inputs useful to a modern renaissance of cultural activity. For these reasons, the program of work, initiated in 2004, has conducted with the objective of enabling a new social role of the building in the town and boost the historical heritage from the old town in a contemporary dimension.

Parole chiave: recovery, building, Chieti, cultural center

1. An aristocratic palace transformed in its function

Architecture is communication, in that it transmits images, at times emotions, and satisfies at the same time precise demands, alienating mere formalism. In some cases, architecture acquires the ability to interconnect, when it is able to hold together operativeness and several functions. It becomes the fulcrum of productive activities, a melting pot of thoughts and actions directed towards courtesy and the citizen, namely to improve the quality of life and promote new professional competence. Therefore, architecture is a medium which is capable of expressing itself but it is also vectorial. This is what is found in Palazzo de' Mayo in Chieti, an ancient aristocratic building heralding changes that keep pace with the times.

More and more frequently, critical-preservative restoration allows the functional upgrading of a historical building, confirming the modification of the conditions of a location and, consequently, of the behaviour of its inhabitants. The restitution of one of the most meaningful examples of baroque architecture to the city of Chieti – after more than thirty years' work – has become the occasion for the renewal of a state of wellbeing for the province and the whole of Abruzzo. Palazzo de' Mayo, with its 6,800 s.m. of surface, rises in the historic centre of the city, between the Provincial Palace and S. Domenico degli Scolopi's church, and the belvedere with three spires above has been the symbol of middle-class Chieti life since the nineteenth century.

In an ancient city like Chieti, in which the different types of architecture testify to an interesting historical-cultural stratification, the constant work of preservation and recovery of the architectonic patrimony restores its identity to the community. The pre-existent Roman remains, the religious buildings of the Middle Ages, the seventeenth-eighteenth-century churches and palaces and the nineteenth-twentieth-century transformations are a tangible, meaningful testimony to a recognizable identity of great value.

The President of the Fondazione Cassa di Risparmio of the Province of Chieti, the architect Mario Di Nisio, has been supporting the aim of protecting such an identity for years with great self-abnegation. In line with the philanthropic aims of the Cassa di Risparmio Marrucina, founded on 6th July 1862, the Foundation has pursued goals of development of the cultural, scientific and social patrimony of the provincial territory since the beginning of the 1990s.

In 2004, the Foundation acquired Palazzo de' Mayo, an ancient building belonging to the Valignani barons, sold in 1788 to the brothers Saverio and Severino Costanzo, rich Chieti traders active in Naples, Trieste and Marseilles. After restructuring and extending in the seven years before 1795, the building shows a classical character of a late baroque style, unique to Chieti and in the whole province. More than being a palace, it is a building complex substantially composed of two buildings of three storeys arranged in the form of an L containing three courtyards and a large garden open towards the eastern panorama. The Costanzo brothers rented most of the palace, assigning for their own use a residential quarter on the second floor overlooking the garden, with the rooms hung with prized silk with painted faces on. Because of a controversy which arose in 1808 between Saverio Costanzo and Celidonio Farina, a business partner, half of the property passed to the latter, who very soon sold it because assailed by debts. Ten years after the death of Severino Costanzo, in 1821, the heirs, who found themselves in straitened circumstances, transferred the remaining part of the building to Count Levino Mayo, the General Collector of the Abruzzo Citeriore Province, who undertook to recover the whole property and improve it. He realized an unusual covered roof-terrace with pagoda-like roofing, an elegant Italian-style garden in which he placed rare essences, and he had the vaults of some of the rooms overlooking the main street decorated and polychromatic concrete floors carried out in Venetian-style.

Besides being a civic residence, in 1827 the building was used as an office by the reunited Financial Department of the Abruzzo Citeriore Province and, from 1907 to 1946, it has hosted military Headquarters.

Fig. 1: Chieti, Building de' Mayo on the course Marrucino and square Martiri della Libertà.

At that time, it was placed under protection and declared a national monument in 1934, under law No. 364 of 1909. In the postwar years, many rooms were the seats of cultural and philanthropic associations, some run by the archbishopric.

In 1977, the last descendent of the Mayo family, Countess Laura, sold the whole complex to the Cassa di Risparmio of the Chieti Province which, two years later, began a notable intervention of restructuring, restoration and reinforcement of the foundations, walls and vaults, and restoration of the roofing and plaster. In 2004, with the passing of the property over to the Fondazione Carichieti the restoration work carried on, reaching its completion for a new multipurpose use for not only the city's community. The works carried out constitute a tangible testimony to the cultural operation effected on the historical building by the banking Body, which has established its new operational office inside, considered right from the start in an interactive relationship with the city projected towards stimulating a new social role in the territorial context.

The aim of the Foundation was clear right from the start: to carry out a series of works so as to transform the palace into a cultural centre which would function not as a mere container, but rather as a social rendezvous and diversified cultural production. A strongly attractive centre capable of contributing to the revitalization and upgrading of the whole historic centre. The dimensions and multipurpose character of the well-organized organism straightaway revealed the opportunity to join intellectual input to the wide architectonic areas, useful for a modern rebirth of the prestigious eighteenth-century structure.

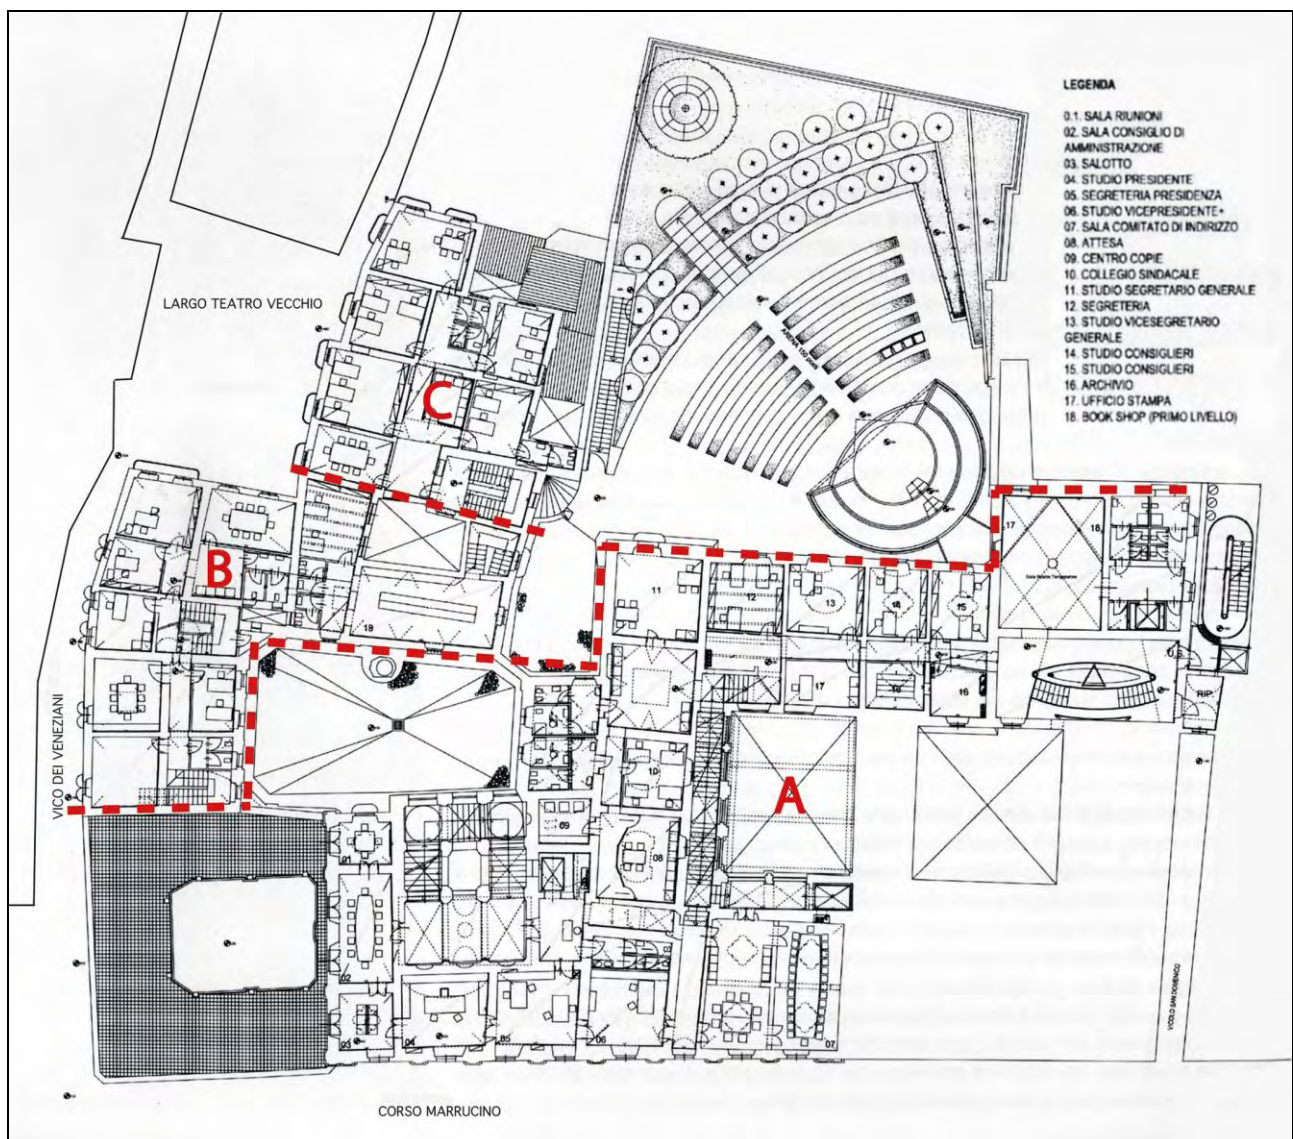

Fig. 2: Chieti, first plane of the de' Mayo building project, with the intended use, orig. scale 1:50.

The opportunity allows for the activation of a mechanism which is able to offer a range of activities and ideas directed to reviving the patrimony inherited by the ancient city in a contemporary dimension, brought to fulfilment in a cultural centre which, by means of the Foundation's support, proposes to promote the development of Chieti and its territory, reviving them through opportune cultural initiatives, from the point of view of sustainable progress.

1.1 A brief description of the building.

The volumetric organization of the building can be divided into three main blocks, identifiable in distinct building units which, for clarity, we will indicate by the letters A, B, C. The most sizeable and representative part of the palace is block A, an element of great value of eighteenth-century features, with a stone entrance onto the little Martiri della Libertà square, initially the San Domenico church square. It develops laterally onto Corso Marrucino with three floors out of the ground and a low-angled volume in which there is the entrance to the court, whose role is to link up with block B situated in the Veneziani alley.

The façade on the main street welcomes the most prestigious areas of the Palace by means of an elegant score punctuated vertically by eight fanciful breves defined on the ground floor by a high base strip marked by ashlar-work parastas. Above, the façade alignment includes both floors of the building, marked horizontally by a series of gabled windows, curved on the first level and triangular on the second. The openings are interspersed by a double series of smooth parastas placed on an axis with the ashlar-work ones underneath. The façade also hosts an entrance corresponding to the entrance of the original residence, still set out just next to the patio where a mannerist-style portal is situated. Its scenic façade led into the first residential complex of the Renaissance period, by means of steps with opposite flights. The original covered roof-terrace concludes block A, an elongated volume covered by three pagoda-style roofs.

Fig. 3: Chieti, de' Mayo building, Eighteenth-century staircase furnished with classical statues.

The stone entrance onto the small square leads to a short entrance hall open on to an elongated, octagonal-shaped court, and from here one can reach the grand, monumental staircase and laterally the great court onto which the stables overlook and the entrance onto the large back garden. The octagonal court, in its blunted corners, houses four recesses mounted by frames which, together with the parastas, alternated on the lateral walls, punctuate the external surfaces, repeating the design of the external strip. The vestibular area welcomes the visitor, directing him frontally towards the main wing of the palace which dominates it, leading to the elegant flight of stairs.

Block B, elevated over two floors, is situated in the Veneziani alley which leads to the ancient eighteenth-century Theatre, and does not present marked architectonic qualities. On the east side, it closes the great court with a series of rooms once intended for the servants and services. On the side and a little behind, block C rises over three floors, from the sober, seventeenth-century style architectonic score facing onto the Theatre square, and on the opposite side it benefits from the garden.

The restoration, which was concluded in 2010, was carried out according to the usability and function demands of the Foundation's operational office, without neglecting the historical-architectonic importance which required specific intervention of a preservation nature, diversified for the several building units which make up the historical structure extended in the entire town sector.

The main block of the palace on Corso Marrucino, in the basement, houses an auditorium set up in a big room facing the internal garden. From here it is possible to visit a small, hypogean archaeological area consisting in a portion of the "via tecta" in opus mixtum of the Roman epoch. The three higher levels are connected by a state flight of stairs in metal and wood, purposely planned according to elliptical geometry which, by joining up with the posterior rooms, at the back of the San Domenico alley, solves the distribution of a part of the building by dividing up its access.

The spaces on the ground floor are devoted to the library, which faces onto the garden, organized in such a way as to satisfy the users and the management with several rooms reserved for the files, book deposit, video library, multimedia room and reading room. It is a library specialized in art publications and it contains a special section dedicated to children. At the back, the garden of about 700 s.m., besides the usual decorative functions, contains a cavea complete with terraces predisposed to host concert and theatrical shows in the summer season.

Fig. 4: Chieti, de' Mayo building after restoration; stateroom used as a conference room.

The first floor houses the administrative and managerial offices, and a series of rooms for temporary displays and workshops. The second level contains a picture gallery of contemporary works, which one can access from the eighteenth-century grand staircase of honour, and a conference hall set up in the state hall. Finally, the higher covered roof-terrace is a charming, panoramic belvedere on the city and territory and contains a bar-refreshment room connected to the underlying picture gallery.

Also, inside the palace the Centro Studi Abruzzese di Studi Manzoniani and the Centro Internazionale Alessandro Valignani have their seat, which are bodies organized through the initiative of the same Foundation Carichieti in collaboration with institutions of absolute, international importance.

The desire of citizens to visit the palace at the conclusion of the restoration works was answered through the organization of a great cultural event, the exhibition called "Mimmo Paladino and the new Warrior. Sculpture as cosmogony" inaugurated on 26th January 2011. The extraordinary works of the Campania artist animated the halls for five months because of the temporary exhibitions and the internal courts of the Palace, and constituted the first step pending the opening of the entire structure, making the registration of the number of people present really meaningful and winning the approval of the national press.

During this initiative, the Palace was included in the circuit of the Italian National Trust Fund days in spring, with guided tours. Subsequently, it housed the exhibition of one of the greatest Italian photographers, Pepi Merisio, and was the stage for one of the Mozart salons set up during the ninth musical festival which Chieti dedicates to the genius from Salzburg every year.

Therefore, expectations were certainly not disregarded and the very numerous testimonials of esteem received for the work done testifies to it.

The palace thus becomes the support of every modification and, at the same time, subject to modifications. The necessity to make known its active presence in the regional territory and in national territory was satisfied first through a report which took place during the yearly event, "Urban promo, city, transformations, investments" held in Bologna in the first half of the month of November 2011. For the occasion, the corporate image was promoted by means of a video realized by us in which, in just a few minutes, we gave an overall picture of the whole matter of the palace and the Foundation's activity. From the survey drawings to the planning drawings, from the condition before the works to the final situation after the restoration, together with historical data and programmes to illustrate a route orientated towards the improvement of knowledge and delightful activity.

The Foundation was presented through a series of selected images, centred on the concept of a productive industry of goods and services. The visual cuts of various frames were studied and pre-established by means of a storyboard and on the basis of the instructions imparted by our client body. We realized the editing and visualization in HD 1280 x 720 size, considering the place of projection: a transit area, often crowded, set up by various monitors on which the film clips would go in a loop, with the sound not too audible (or not audible at all). We weighed up the type of visual formatting model, having in mind simple, direct communication, devoid of effects, that shows, at all times, the subject and the client of the film clip.

The cultural event of Urban promo, regarding the themes of town regeneration and town and territorial marketing, was a moment of reference for the exchange of qualified knowledge and updating of experiences carried out by the civil service and private citizens, organized for the purpose of promoting innovation in the administration of the territory.

At the end of the event, our film clip was inserted in the Foundation's web page, an aim which was foreseen technically at the time of the realization in mov H 264. The communicative activity is unceasing, satisfies a useful and indispensable process for a case such as ours, in which the building and the whole city live on the active participation of the citizens and tourists.

Thus, the meaning of the term 'communication' is reinforced and is often linked to that of development and growth, implicating job, exchange, knowledge and property relationships, relationships between individuals, groups, bodies, institutions. The basic component of communication is still the regulative system with which management of the relationships of a main centre with subordinate centres is made possible, and the first type of regulation is information, popular knowledge suitable for diminishing the distance with the unknown.

The system of forts of Rome

Mariella LA MANTIA,¹ Fabio LANFRANCHI²

Abstract

With the sesquicentennial anniversary of the unification, we believe it may be of interest to focus on the choices and strategies made in the field of defense by the newborn Italian.

Among the possible sites considered by a committee as "sensitive", the choice fell on Rome, the new capital of the Kingdom of Italy. The construction of the Roman fortress system was then started in 1877 to end in 1891.

Once completed the building of the defense system, it resulted anachronistic undergoing in time a series of adjustments and transformations, operated by the army, which still retained the property until a few years ago. As most of the artifacts is now in charge of municipal administration, the lack of funds still does not allow the possibility of conversion to the use of citizenship.

There are no suitable documentation of the complex system, still preliminary to any type of recovery or reuse. We think that this fort architecture could be considered emblematic of the treated area, the Roman one, and at the same time, of the building military art at the half of the nineteenth century.

Given the size and architectural characteristics of the sites, we value as fundamental a targeted intervention aimed at understanding the documentation as well as at future opportunities for intervention by outlining a possible line of inquiry learning

Keywords: Fortress, Heritage, Survey.

1. More or less military architecture

The reading of the transformation of an area from rural to the urban condition is an activity that finds in multidisciplinary its only possible decryption key.

The phenomena of evolution or sometimes of involution, can not prescind from economic, political, and social filters.

The reasons of a territorial transformation in fact, still find, before the technical or more properly city planning, their motives in will depending on strategies, needs and interests.

In principle, every mark on the man-land is therefore an outcome decision, in other words we could then define a local map as a book of memory from which to extract concepts, aspirations, decisions. The physical reality and therefore perceptible, tangible, is accompanied by the passage of time, that has always been a vital means of evaluating the choices, strategies and guidelines.

1.1 The post unity defense system**

With the sesquicentennial anniversary of the unification, we believe it may be of interest to focus on the choices and strategies made in the field of defense by the newborn Italian.

Choices whose impact on the territory are, in most cases, still visible today; choices that identified, in an articulated system of fortification works strategically spread throughout the country, the response to possible

actions of invasion by foreign states or, as publicly less acceptable, but perhaps the most historically plausible, from possible internal unrest.

As the defense system interested as mentioned, the whole country, a number of strategic points were however identified, within which the organization of the defense was not limited to specific interventions, but in real embedded systems. This is the case, just to name a few examples of interventions implemented in the Verona area, of those relating the defense of the Straits of Messina, and of those relating to Rome, the new capital of the kingdom, territorial areas of strategic, or perhaps only symbolic, importance.

1.2 The “Entrenched camp of Rome”***

The causes that pushed the Permanent Commission for the general defense of the state in 1871 to the calculation of providing the capital city of an integrated defense system-defined as "the entrenched camp of Rome" - can be identified in the fear, then probably felt, *"to cover and defend the capital of the kingdom from a coup that an enemy, most powerful of our on the sea, could attempt by a landing on one of the many defenseless and easy landing points of the Tyrrhenian coast."* [1].

The enemy, perhaps only a pretext, was represented by the French or even better by the memory of their invasion of little more than twenty years before. Their landing at Civitavecchia, the subsequent attack from the West, convinced the government to allocate, in 1875, an initial sum of 10 million lire to encircle Rome with a first series of Forts to be implemented as quickly as possible on direct routes to the Tyrrhenian . [fig.1]

In 1877, a Royal Decree declared as public interest the construction of fortifications, roads, warehouses and other buildings connected with them in defense of the capital: *"So in a span of just five years and cost around 23 million, it has been built around Rome a ring of permanent works, consisting of 15 detached forts, which will put the capital under cover of a bombardment, and with a small garrison, mostly composed of mobile and territorial militias, will oppose attempts that an enemy, landed in the near shore, could do to seize the city, at least until the arrival of a rescue army. And now here they are the forts, severe in their simplicity and intrinsic strength, which turn the face to the enemy from any direction it comes, vigilant and faithful guardian of the capital of Italy."* [1].

In fact, the completion of construction of the last element of fortification, called “Forte Antenne”, saw its work completed in 1891, about 14 years after laying the first stone of the first post-unification Roman Fort. [fig.2]

In the same year France subscribed with Russia the first phase of the Dual Alliance; the aims of an invasion of the capital of the new Italian state by the French appeared perhaps overcome, as well as the sense and defensive capability of the Roman fortified camp appeared anachronistic and outdated within a few years, even under coeval ballistic progress.

2. The Roman Forts: from defense system to a possible urban system through the survey **

A territorial system thus defined as a military strategy for defense against possible dangers from landing on the coast near the capital or from possible uprisings of domestic origin. An integrated system of fortifications, batteries, roads, warehouses and other related buildings that, located annularly at an average distance of 3/4 miles from the Aurelian and Vatican city walls - then in the first peripheral cincture of the late nineteenth century - are nowadays fully incorporated but, in some cases, not exactly integrated in the meshes of the city now established.

Military compendia that in recent years, in a framework of national interest facing the alienation and enhancement of buildings of the Ministry of Defense, have made possible, in particular, the acquisition by the City of Rome, of a further series of forts including the Boccea, Pietralata, Tiburtino and Trionfale forts.

2.1 Towards the protection and enhancement**

With the Memorandum of Understanding signed June 4, 2010 between Defence and the Municipality of Rome, you have the "Plan of transfers and improvements of military buildings of the city of Rome" with the consequent allocation of a new urban destination for affected areas, as a variation in the Master Plan approved in 2008. The fortification system is now - if you exclude some structures still in use by the Ministry of Defense - almost at all belonging to the built heritage of Roma Capitale. A fundamental "handover" even if still insufficient if framed in objective reality - effectively described by Prof. Carmine Gambardella in the *call for papers* of this meeting - of *"... an era, like the one we are living, in which the economies of Western countries are aimed at readjusting their operating budgets of expenditure cuts, rather than to invest its assets to create wealth and jobs."*

A reality that has long led: *"... in relation to the claim of mere conservation of a heritage so large compared to the small resources available, both in the inability or unwillingness to define a destination and a business model ... to follow the development of the problem in a sporadic and bounding way, up to condemn the forts*

and the resource they represent to a sort of degenerative embalming, as unlikely as improvident, whose results are evident."[4]

In analogy to what has happened with other similar architectural realities distributed within the Peninsula – as example we refer to a part of the fortress of the Strait of Messina – also in the case of Roman heritage, the momentum to the protection and enhancement is born from spontaneous associations, among whose intents is clear the desire to spread the awareness of these assets through environmental, social, artistic and cultural initiatives, aimed at raising awareness and enjoyment of their own.

The patient work made over the years by experts and citizens now joins the help of FAI - Italian Environmental Fund, with initiatives aimed at promoting a culture of respect for nature, art, history and traditions in the optical of heritage protection to be considered as a fundamental part of the roots and identity - among which we mention the round table set for the month of April 2012 at the Library of the Senate "Giovanni Spadolini" entitled: "*A wealth buried in neglect and rediscovery: the forts of Rome.*"

Among the initiatives aimed at the enhancement of the Roman fortress are included, in addition, several publications and studies conducted jointly by institutional structures, such as the Department of Interior Architecture of Sapienza University and professionals founders of Campotrincerato Association of Rome.

The results arising from the joint study open to possible design addresses of feasibility, which we define as indicative guidelines shaped both on the basis of individual architectural reality, [fig] and on hypothesis of coordinated conversion between the different fortification units. The studies, conducted largely on the basis of archive documents and on the basis of locally acquired surveys, made a first evidence about the peculiarities of the Roman defense structures, characterized, as a whole, by the distinct distribution and fairly complex function, considering the peculiarities that characterize usually the underground architecture.

Architecture and at the same time urban planning structures in which the design of the general planimetric, although in some cases it appears to be significantly restructured by changes depending on neglect or - as we shall see later – on changed functional requirements, still manages to survive by virtue of spontaneous tree equipment that, adapting to the original architectural features of incorporation, have essentially modeled their margins and then the planimetric trends. [figg.3-4]

2.2 Toward a hypothesis of survey, analysis of the architectural and building features of the system of Roman fortress **

With regard to today and then actual state of the artifacts, we believe it is essential – in a disciplinary perspective more properly applicable to the survey intended as a synonym for knowledge – to reflect and consider that: "*While the military and its impassability has in some cases resulted in a greater level of conservation of structure and appurtenant areas, most often the demands inherent to military use have resulted in substantial modifications of the original implant, even by very invasive interventions and uncoordinated with the natural organs of competence.*"[5]

In fact, the various laws regulating the works for the Defense, have taken away in time much of the same to the appropriate verification of urban and architectural aspects, the results of what has just given situations ranging from construction essentially unchanged from what was originally built up, to cases characterized by complete transformation.

A wealth then, that as made available by the recent laws, can be considered partially known and documented, a part of a complex system now demilitarized and thus available, which is at the same time abandoned when not illegally occupied. The entrenched camp in Rome, the existence of which is just beginning to be known to the citizens, 120 years after the construction, needs prior to any desirable care, a prompt and thorough set of analyzes aimed at understanding and documentation. In the end, it needs a series of operations, capable of expressing the spent and current state in the fundamental characteristics of the Vitruvian *firmitas*, *utilitas* and *venustas*.

The military architecture of the late nineteenth century is characterized by a series of architectural and functional works of a defensive nature, that were created in early 1800 by the engineer of the French military engineering Nicolas Carnot, and were widely used both in new buildings and in the defensive improvement of existing forts, in particular within the Austrian school of military architecture.

The set of walls in the Carnot style, with numerous loopholes for riflemen, and caponiers - structures similar to bunkers with different weapons depending on the strategic function - are elements actually external to the central nuclei of the various garrisons.

The caponiers finding normally their place at the top of the Carnot style walls, in the most advanced points of the front of fire as well as protection of the only entrance to the fort, can be defined as recurring elements and then characterizing the whole panorama of the Roman fortress. [Figure]

To characterize the elements described above and, more generally, the individual architectural episodes contribute - like building materials used as typical of the Roman area as tufa, brick, travertine, basalt, iron -

also the construction methods and, no less important, the stylistic characters that find in access portals, for example, the strongest expressive moment drawing inspiration from the architectural styles of the Renaissance repertoire [fig.5-6].

The *military building art* of the Roman fortress system is, in effect, albeit within the limits of territorial and functional specificity, an interesting textbook example of construction techniques not free of technological fascination.

The minimalist functionalism unifying the different fortress structures, emphasizing the character of the state of abandonment and consequent degradation offers, in areas where interventions of conversion were carried out, an interesting case study on construction methods. Real technological slices related to walls, vaulted systems and general details, architectural and stylistic elements, all united by the evidence of compositional rigor resulting both from evident careful planning and design and from an executive ability made possible by customary operation of competent workers.

The present-day configuration of Roman forts is, as already stated, the result of changing operations related to various military needs; the facilities created for the defense were in fact in some cases, since their completion, immediately converted to different uses.

Of the entire system only a few elements preserve today the original characters, including the Portuguese Fort - one of the less extensive and among the first to be made - which is perhaps the complex which has undergone minor changes over time.

About this fortress - which, we repeat, however complies with the other - the walls of the border against the ground as well as in general elevation ones such as caponiers, corner mumps, powder kegs, etc., are made of squared blocks of tufa with well defined elements of style spaced, close to ground connections, by individual lines of bricks. The bricks also become the recurrent material element in the definition of padding architraves and lintels of doors and openings. The laying of the bricks - which is coplanar to the line of the facades - in padding is elegantly hooked to tufaceous segments.

In some cases, slabs of architraves - generally low arch or flat arches - are made of travertine, as well as travertine are the bases, capitals and friezes of brick pilasters placed as frames to the access gates to forts. [fig.7]

Among the recurring stylistic features, we also point out the gorges with overhanging bulls placed to finish elevations of nuclei, - like caponiers, powder kegs and containment walls in general - the top of which are normally protected. [fig.8]

The Roman fortress system is then a fascinating mosaic, whose "cards" so far treated, have the ability to restore the physical image as well as well the slow passage of time. But an objective analysis of the complex cannot absolutely prescind, both from the technical-constructive point of view and more generally from the structure point of view, by the system of horizontal structures, almost exclusively composed of vaults.

The constructive ability, as already mentioned, the work of craftsmen who built the various complexes, finds in the vault structures interposed between the various levels and systems of coverage, perhaps the most obvious example. The tuff that, as already written, characterizes the image of the building elevation, leaves into the environments, the place to tile roofing systems. These same environments, that are almost exclusively underground, never exceed the heights of the keystones, over 400 cm. The types of vault used range from simple barrels, or lunettes, up to rampant vaults mainly used in the vertical distribution spaces. [figg.9-10]

The exact geometry constituting the same vaulted systems and the accuracy of laying the bricks and the relative elements of style, characterize, jointly with the intensity procured by marked natural "light blades", the same environments with formal rigor. A system of vaults to be understood as an element of self-crowning, as regards the type of material used, but at the same time perfectly integrated with the functional and composition logic of the elevation walls. Design choices appropriate to the functional requirements which meet the criteria for speed of construction, ease of use, affordability and availability of materials on site.

The methodology of the survey operations of this type of architecture cannot but take into account the considerations expressed above: the extension of the sites, their technical and structural peculiarities and the special geometry characterizing the large-scale plants are factors that we believe should address the organization of work on three distinct yet osmotic levels of survey and documentation: the general survey, the survey of the architectural elements, the critically-thematic survey.

2.3 Integration of instrumental techniques for the detection of urban scale and architectural documentation of the Roman fortress system *

Since it has not yet realized no procedure to detect, model, and communicate this type of architecture, it is proposed here to program the most suitable approach in terms of both feasibility and reliability of potential results obtainable, which provides the integrated use of different detection techniques. The quality of the

results is closely related to the technical performance of different sensors and their proper use revealed through the recognition of their more appropriate scope. A significant amount of experience in the detection of complex architectural systems together with good knowledge of the techniques in terms of advantages and limitations inherent in each technology are just some conditions that guarantee the successful completion of device discovery. The use of different techniques with the integrated use of multiple sensors, active and passive, as total stations, laser scanners, photogrammetry, and modeling by Image-Based Modeling (PhotoModeler, ImageModeler, Google SketchUp, etc. ..) must be carefully planned and contemplated on the basis of several factors. First among these are considered the morphological shape of architectures that are being measured in terms of size, geometry and material, together with their setting logistics: in our case we are examining fortress architectures of defensive nature with the relative difficulty of accessibility and suitability of sites for the acquisition of images or scans. Complexity, occlusions, a variety of structures and sometimes inaccessible locations represent a range of obstacles to capture all the geometric details of these structures. For example, to inaccessible areas such as roofing, the solution is to use images taken from a hallway at low altitude. The images produced in combination with detection, laser scanning and existing plans, will provide all the necessary elements to elaborate even a complex architecture.

Secondly, it is to be considered the target of detection both in terms of scale of restitution (urban, architectural and detail) that of expendable resources to direct the best use of the different 3D measurement techniques. This leads us to consider technologies with a high level of automation and the use of procedures that permit the integration of 3D models created independently from different data sets by eliminating overlaps and filling any gaps in order to develop a valid model for documentation and visualization, as well as possible visualization tools of the produced elaborations. We wish to recall that representation, even in the field of survey, assumes an important role as it aims to communicate effectively to the reader the knowledge acquired and deemed necessary for the understanding and documentation of the work. The modeling is the most significant and functional processing for excellence. From prior knowledge given by inspection and retrieval of existing infographics documentation, we pass to survey and collection of measures so that we finally have a graphic restitution of the work with processed items that make up a comprehensive system of representation, which shows, in analytical and synthetic terms, the set of results derived from the various thematic investigations conducted.

So, from the acquisition of direct and indirect metrics (with the integrated use of different measurement techniques), you get two-dimensional and three-dimensional graphics processing, ie the most reliable morphological and material registration of the product. In particular, this technique operates in the field of architecture with a variety of purposes including the documentation, representation, materials and degradation diagnostic, enhancement, preservation of the property, etc. .. The individual 3D modeling that can be derived both from real life (photogrammetry, topography, laser scanning) and from graphics processing resulting from the conversion of existing 2D drawings (by measures and techniques for direct detection) will necessarily be integrated to each other and georeferenced. Consequently, we highlight the opportunity to consider establishing a repertoire of three-dimensional digital models of the architectural elements preserved also in order to explore the possibilities, when required, of a virtual reconstruction.

This necessitates the collection of large amounts of data from various positions which then must be accurately recorded and integrated together. Although each of the forts is a different challenge, we should develop a general approach that can be applied to this kind of architecture and architectural complex systems in general. The results will consist of complete and highly detailed models that can adapt to a variety of purposes, ranging from documentation to the conservation and reutilization and conversion.

Do not forget also the various layers recorded over the years and the numerous works of change. Some of these buildings were completely destroyed or in ruins with a high degree of difficulty for collecting and processing data. From the foregoing it is clear that the geometric survey of the building will require to be integrated with knowledge both of the transformations undergone (and, to this end, we can be aided also by historical and archival sources) and the composition of its supporting structures.

2.4 The two-dimensional representation and three-dimensional modeling of point clouds from photographs *

Photography has always been considered an ideal solution for recording reality, I would say essential for the documentation of built heritage. Over the last few centuries, photogrammetric techniques, based on the principles of stereo-photography, have established a close relationship between the space of photography and that of representation. The space of representation becomes definitely three-dimensional while photography represents one of the possible points of view of this space.

So, if the geometric model of an image is known, you can learn the projection of a point in the scene, starting from the optical center of the camera and its projecting through infinity. But, if one has two images of the

same scene, 3D coordinates can be retrieved by the intersection of the projections of the two homologous points on selected images.

We must point out, now, at first the possibility, with the use of specific software, to reconstruct the perspective beam that gave rise to the single frame and secondly that, having pairs of images which relate to the same object (ie, that reproduce partially the same part), by the search and comparison of homologous points (ie, different images of the same point belonging to the two real images), allows to define pairs of points that can be considered images of the same real points.

These purely mathematical processes - they overcome, then, the conditions that the photogrammetric technique had to respect in deference to the physiology of the human eye - are based on criteria aimed at measuring and comparing RGB values at the points considered, and in their immediate surroundings. The process ends with the reconstruction of the virtual model of the object photographed in the form of a cloud of points comparable to that obtained with the electronic scanning.

From the cloud of points we pass to the definition of a surface composed of a triangular mesh that connects all points between them. The process of transformation and union is governed by algorithms, different for each program, able to connect the corresponding vertices for the realization of edges and faces. Then, with the application of certain modeling software (automatic and not), it is possible to reconstruct a 3D surface and consequently obtain a two-dimensional representation starting from a set of vertices in three dimensional space.

The potential of this technique are varied with a good compatibility, in both metric results and representative instructions, with needs of architectural detection in monumental and detail scale.

For most of the fortresses, methods of image-based applications are the ideal choice. The images can be taken faster with a greater and easier degree of viability than the laser scanners that are more cumbersome and slow. However, considering the complex kind of architecture, surrounded by narrow spaces, it is difficult to take pictures from ground points of view that may cover the entire surface. Therefore, we appeal as aforesaid to images captured from a lowflying helicopter.

The time to collect data is estimated in about a week for each fortress while it takes on average a couple of months for data processing and modeling.

The architectural modeling from photographs can be a useful cognitive exercise based on a combination of panoramic images and laser scans. The methodology to be adopted for the accurate and detailed modeling of these complex architectures will use active and passive sensors in order to exploit the advantages inherent to each technique. The following points summarize some help for a correct approach to detect them.

1. Use of existing documents to be digitized and/or digitized as a basis for further processing;
2. Surveying and georeferentiation of individual models (total station and GPS)
3. Accurate calibration of digital cameras in the lab for all the different settings used in the field;
4. Using images from a helicopter for the realization of a comprehensive model of building exteriors, walls, courtyards and main courses. This model will integrate the other models generated with different techniques
5. Take pictures on the ground for the parts of the model not visible from aerial photographs;
6. Use rectified ground images to derive high-resolution details of windows, doors or other important elements of architectural interest.
7. Use average radius (1m-50m) laser scanner to capture the details of selected internals that are less suitable for modeling with Image Based technique;
8. Assemble and integrate all models between them.

3. Conclusions

If only rarely may it is possible to frame with absolute certainty and immediacy the salient features of historical monuments, we can easily imagine how, in the case of the entrenched camp of Rome, only a thorough knowledge could, and with many difficulties, return its relevant and current consistency.

The near future of the system of Roman forts is not yet clear today; if on one side the conditions of the buildings do not seem to allow a general framework for action aimed at the easy recovery of the remains, if aimed at an effective functional reuse, on the other side it seems in some respects incorrect and simplistic a future use as a mere "archaeological" site.

The only certainty is currently represented by the views perceived from afar, that the various complexes offer today: a series of non material images, due to non-availability of the complexes, and unfortunately "dangerously" similar to the images returned by electronic records.

This contribution comes from the organic collaboration of both authors at each end have agreed to assign, respectively, the points marked by asterisks, (*Mariella La Mantia, **Fabio Lanfranchi).

An integrated survey to digitally reconstruct the courtyard of villa Rufolo in Ravello: from *less* to *more*

Abstract

New electronic survey technologies generate points clouds by recording multiple points on the surface to be surveyed; when manipulated by suitable software these points clouds can, by themselves, anticipate the shape of the surveyed architecture thanks to their greater or lesser density. The first automatic treatment of points clouds (mesh) helps to enhance comprehension of the spatial shape of the architecture and provides the observer with a viable reconstruction of the surfaces concerned. In both cases this involves automatic mathematical operations rather than actual architectural representations since there is no critical interpretation and discretisation by the operator. However these operations are the starting point for any scientific study which aims to reconstruct very complex architectural forms and how they have changed over the years.

This paper will present the intermediate results of an ongoing study on Villa Rufolo in Ravello, an excellent example of the Arab influence on architecture in Southern Italy. In particular, the paper will illustrate the study of the small courtyard with its colonnade of small, slender and graceful coupled columns supporting the intertwined arches clearly inspired by Islam. There's reason to believe that the courtyard was rebuilt after it was destroyed during the wars in the last century. Integrated survey and digital modelling techniques will be used to perform an in-depth analysis of the courtyard as it stands and also propose a figurative reconstruction of the elements in the courtyards, adding (+) – where only fragments remain – what is no longer visible (-).

Key works: Amalfi coast, 3D laser scanning, digital anastylosis, Islamic influences, geometric composition

1. Villa Rufolo: forms and geometries of a Mediterranean architecture between East and West¹

If it's true, generally speaking, that architecture modifies nature by interacting and dialoguing with the context, 'built space' along the Amalfi Coast is an excellent example of the delicate relationship between man and the territory where he lives, where natural and anthropic space merges to create harmonious beauty. In actual fact it's a 'one of its kind' location with its own distinctive characteristics and features – in some cases recurrent, in others unique; together they help to create the identity of this part of the world. The Amalfi Coast is a cultural resource that should be protected and promoted in terms of knowledge, first and foremost formal knowledge and geometric configuration. Only then will we be able to enhance and disseminate information about our heritage as part of a gradual but crucial process of awareness and appropriation by the community which often lives with this heritage without understanding its deeper meaning. This is why it seems logical to identify its compositional rules through specific graphic studies of typical and therefore symbolic forms in order to understand the pure, invariant and recognisable essence of its geometric and structural genesis (quite apart from the configurative complexity of each form) and interpret them correctly.

The study presented here focuses on one of the most famous and important architectures along the Amalfi Coast – villa Rufolo in Ravello; an emblematic example of merger between architecture and landscape. If villas and their gardens normally reveal man's desire to rationally orchestrate and anthropise the landscape, this becomes even more obvious in villa Rufolo: the reciprocal harmonising effect created by the villa and gardens shows how an architectural concept can be turned into geometric measurements and forms. A stylish architecture with elegant geometries which together become extremely interesting, a design influenced by the landscape and the historical, social and artistic period in which it was designed and built. During the Middle Ages Ravello became famous thanks to the Rufolo family's input into the shipping industry. At that time, the entire Mediterranean basin was in the throws of a cultural and commercial rebirth due to the presence of so many different civilisations – Latin, Greek, Hebrew and Muslim. The Arabs were particularly instrumental: the advance of Islamic populations from the East to north Africa and the lower reaches of western Europe changed the social composition of these occupied territories. The Arabs imposed their own religion and political and administrative set-up on these regions and imported completely new customs and traditions. However, the lack of rigid aesthetic and formal rules in the field of art and architecture allowed Islam to remain versatile and free to adapt to the diverse requests of local patrons. In fact the Arabs had no figurative codes of their own, so they absorbed those of the lands they conquered; this created an art which, albeit based on uniform principles and programmes, was imbued with local expertise and know-how. This social and cultural mix allowed very different artistic traditions to find common fertile ground, destined to further enhance the magnificent Islamic civilisation. The Moors were particularly adept at using several different forms, skilfully merge them and give them new expressive force. Although the Arab presence in the Mediterranean, especially in southern Italy, was temporary and not as long-lasting as in other geographical areas, it did leave an enduring mark. In fact, the different artistic styles absorbed by the Arabs proves how their flexibility became a powerful source of expression. Never before had the arts of conquered populations so influenced the conquerors; by imposing no cultural dictates the Arabs succeeded in creating a universally accepted style that everyone could identify with. The Arabs' influence on western culture naturally spilled over into the world of art and architecture. In Italy, as in almost all the rest of Europe, Moorish art wasn't limited to a single architectural complex, instead it spread far and wide, incorporated into architectural elements which often blended so perfectly with local

Fig. 1: Ravello, villa Rufolo. The dome of the entry tower shows various Islamic influences

cultures it was often difficult to consider them as foreign and not part of the local repertoire. This artistic heritage includes objects produced either in Arab-dominated Europe or imported from other countries, or forms invented thanks to a profound knowledge of Islam, in other words unconsciously interpreted by local craftsmen. In fact, in the regions occupied by the Arabs architectures were embellished with typical Islamic decorative and constructive elements. Elements that remained even when they were absorbed by western architectural styles: intertwined arches, ribbed vaults, mosaics and marble capitals with fretwork or stone grilles to embellish windows are merely the more obvious signs of an architectural style influenced by the Arabs; they are all, however, based on the geometrisation of forms inspired by specific religious ideologies rather than aesthetic research as an end in itself.

The construction of villa Rufolo coincided with this cultural historic period, a period towards the mid-thirteenth century - the heyday of trade and cultural exchanges between the Rufolo family and the Arab world and Mediterranean in general. Villa Rufolo is a superb example of medieval, Campania-style, Norman-Arab architecture: this perfect merger of western and eastern forms is truly amazing and breathtaking.

The villa is surrounded by a masonry wall and defended by two towers, one of which acts as the entrance. This is a typical architectural solution adopted by the Arab-Norman world, probably invented in Sicily but quickly adopted by local craftsmen in the Campania region. The towers, however, were far from being used merely for defence purposes; their formal and decorative embellishments were created using simple geometries and contrasting colours – grey tuff blocks, some shaped other regular - inserted into the bare masonry wall. Even the entrance hall of the villa, a square room open only on two sides, shows obvious traces of the style and culture of Moorish architecture: the two side walls are embellished with elegant grey tuff arches resting on twisted coupled marble columns, the first are pointed the others lobated. The arch pattern is repeated on the drum below the dome, with a nearly identical system: the small coupled columns, this time cylindrical, support a double system of superimposed and intertwined grey tuff ogee arches. Grey tuff is also used to emphasise several horizontal sections of the vaulted system when the decoration changes significantly: a cylindrical ring marks the impost of the dome, a sort of ‘umbrella’ where the decorative embellishments of the surface are created by chromatic as well as formal variations: yellow, red and grey sections alternate in a rhythmic sequence that induces the eye to roam.

Fig. 2: Ravello, villa Rufolo. The dome of the “Arab bath”, conceptually similar to that of the entry tower

The unique spatial design of the dome above the hall is an absolutely novel design concept: instead of the more or less complex vaulted structures found in private buildings along the Coast – all ascribable to typical Italian architectural forms – here the formal solution tends towards a decidedly geometric approach: geometry is used not only for the structural elements but also for the aesthetics of the designed forms. In fact the dome is geometrically similar to a solid of revolution, but with a sculpted intrados and it is this sculpted intrados with its natural forms that expresses a spatial logic and absolutely inflexible compositional rules. Nature used as inspiration, nature that provides endless methodological and formal solutions which in turn inspire the genesis and beauty of those forms based on specific geometric principles. In fact the dome is visually comparable to a discontinuous shell; its surfaces are generated by the homothetic variation of the equatorial horizontal section, a thirty-two point star, according to the law imposed by the curve of the dome.

A similar system is proposed, albeit on a smaller scale, for the dome of the so-called “Arab bath” in villa Rufolo; however the decorative elegance and workmanship are slightly less striking. In fact, while the dome of the hall marked the entrance to the villa and was therefore a public area, the Arab bath was a private, family area that didn’t need to be so lavish because no-one but the family would have used it. The small rectangular room, approximately 4.20 x 3.20m is completely sealed off except for a small door and two embrasures along the south side. The interior is very bare: there are no intertwined arches on the walls which instead in the hall continue up to the dome. However the dome of the Arab bath is designed using the same morphological criteria; it rests on a horizontal section similar to a thirty-two point star, albeit slightly smaller, and has small but important differences compared to the one in the hall. Here, for example, the discontinuous sections are red and yellow and, as interpreted by Caskey, reveal a slight rotation, almost as if they were twisted around the axis of the surface [2]. This theory isn’t entirely convincing; an on-site inspection revealed that the movement of the lines of the dividers at the intrados of the dome appear to be the result of an imperfect finishing of the surfaces. However it’s interesting to note that the two domes, even when compared to similar domes found in the nearby town of Scala, are not an identical replica of a stereotype. All the domes are different, even in the same building: the proportions, the surface of the intrados, the materials and colours – everything is different. These differences were used not only to characterise each house according to the owner’s rank and social position, but also to characterise each room in the house. Varying the ornamentation was a way to design a house as an ensemble of different spaces which often played a very specific role.

Fig. 3: Axonometrical projection of horizontal sections and sketch of its sculptural intrados

Another exquisite element testifying to the influence of Islam is the courtyard of the villa. In fact despite the many changes it underwent in later centuries it has maintained the amazing configurative and ornamental elegance created by the merger of different cultures. The grey tuff arches of the upper order resting on slender marble columns are intertwined like delicate lace; below, ten columns support the lower order of pointed arches. The natural motifs embellishing the intertwined arches clearly recall the different styles of the Islamic repertoire, as do the graceful movement of the lines of the decoration. The upward thrust of the arches of the loggia are interrupted by a horizontal grey tuff strip supporting the slender terracotta twisted columns which in turn support another order of small arches with natural motifs.

Everything in villa Rufolo, from the vaulted surfaces to the simple flat ornamental decorations, betrays a natural penchant for an eclectic style which we should consider the artistic embodiment of the ethnic and cultural diversity of the Amalfi Coast: a world suspended between the West and the East in which geometry is physically expressed in a unique style – literally a Mediterranean style – with dynamic, outstanding decorations based on the formal beauty of strict generative geometry rather than expressive figuration. For all the above-mentioned reasons, the use of geometry - from the geometry governing volumes to the flat geometry that inspires decorative design - has become the leitmotiv of this presentation which will focus on the most representative parts of villa Rufolo to try and reveal the pure essence of such a complex architecture. Based on the digital acquisition of metric data - suitably interpreted and reciprocally integrated with other kinds of information - and the reconstruction of the geometry and composition of the structures using digital modelling, we intend to propose a figurative reconstruction of the now fragmented spaces by recreating its original spatiality using infographic representation.

2. The digital survey of the courtyard of villa Rufolo: our experience³

In the past few decades electronics and computer technology have helped to gradually develop new measuring techniques in the field of architectural survey. To be precise, electronics and computer science have not only helped to improve topographic and photogrammetric techniques, they have also assisted in developing new tools – such as laser scanners – and in fact today we talk of electronic survey. As a result, we now combine traditional techniques and measuring procedures (direct, topographic and photogrammetric methods) with electronic surveys, in particular scansions. Each technique has its own specific features and procedures; very seldom will just one of these techniques fulfil the multiple requirements intrinsic in the geometric measurement of a building. For example, photogrammetry has to deal with the problem of “gaps” (i.e., the parts the camera doesn’t see), a problem common also to electronic scanners (parts not touched by the electromagnetic waves emitted by the sensor). These and other problems associated with survey can be solved by combining all the techniques and procedures associated with each technique; one excellent example is photographic rectification compared to photogrammetric restitution.

Based on these preliminary considerations a study is currently underway to establish the possible criteria and procedures required to combine all these architectural survey and study techniques, for example in the case in question: the courtyard of Villa Rufolo in Ravello. We will report here on progress which has so far focused primarily on experimentation with the most innovative technique: electronic survey.

No matter which technique is adopted, reliable measurements have always been a problem during survey. Clearly, the problem is even more important when indirect measurement tools are used, for example photogrammetry: we are all aware of the interpretative nature of any photograph taken during photogrammetry (and the effects caused by materials and the light). This “filter” has been studied for years and has helped to gradually improve the photographic technique and the way it’s used. In fact, nowadays we have almost complete control over this technique and therefore obtain reliable measurements. No similar studies have been carried out on electronic survey, at least on the applications used in the field of architecture and, as far as we know, no information has been published in specialised literature. We consider that this is still an experimental field in which many reliable and committed initiatives are undertaken, but one in which misunderstandings often arise between *surveying* (taking measurements) and *survey* (critical restitution of the measurement), between measurement and critical interpretation. Almost as if to imply – incorrectly – that survey is still merely measurement, in other words an updated technological version of measurement using electronic scansion and visualisation of the ensuing points cloud. We shouldn’t forget that the points cloud is not the real survey of the scanned object: what we see are just forms because the points cloud still has to be elaborated, and the problems associated with the first readings must be considered during the survey and measurement stage.

In this paper we will examine the various electronic survey stages carried out using a 3D scanner in Villa Rufolo. We will start with the preparation which considered three specific aspects: the *position of the station*, the *resolution of the points*, the *shadow areas*.

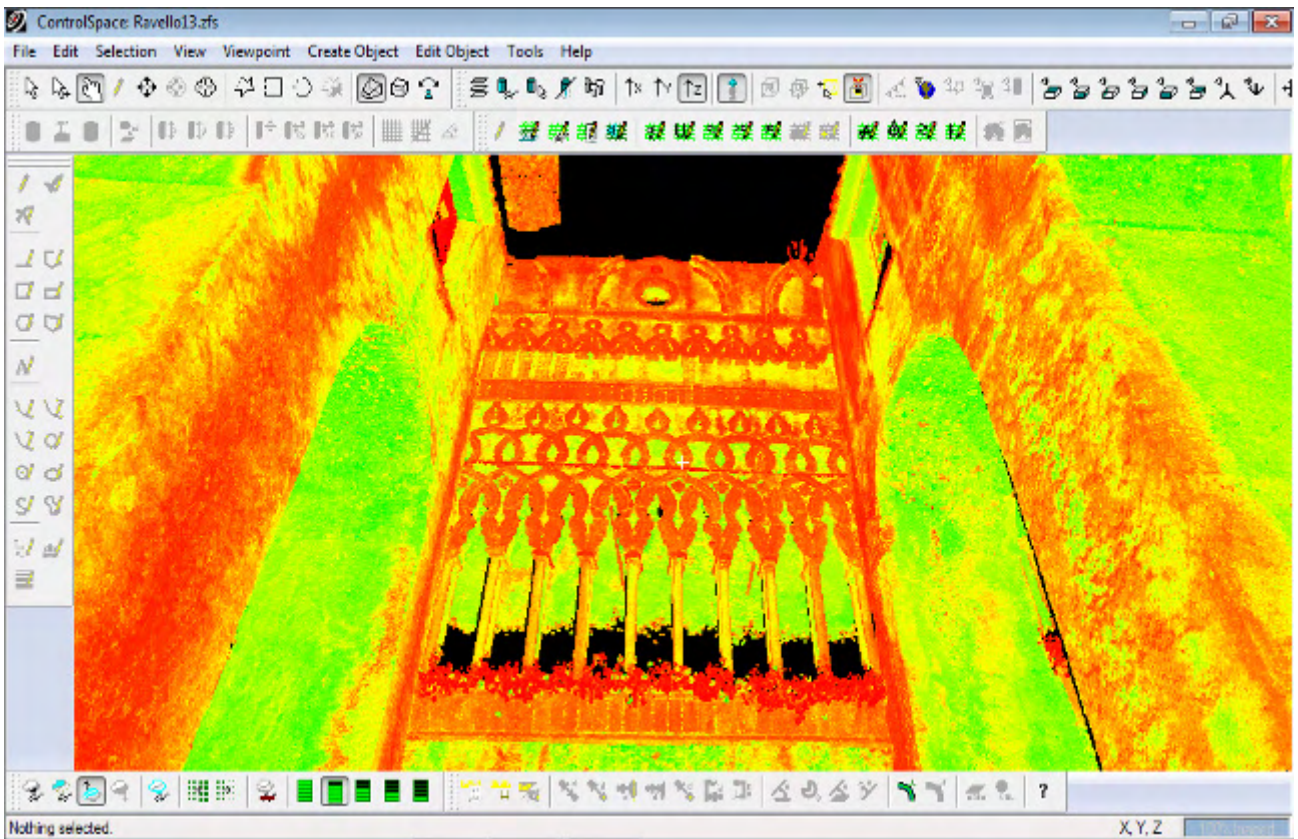

Fig. 4: View of the scansion, station shooting inside the cloister

When *positioning the instrument* we have to remember that a scanner exploits the principle of polar measurement; the direction of the beam (for the motorisation of the instrument) varies on both the horizontal and vertical plane; if we consider the instrument as the centre of a (theoretical) sphere, the beam will create a grid of meridians and parallels on the spherical surface; the extent of the grid will usually range between a -45° angle compared to the horizon and its zenith. Clearly the grid on the spherical surface will be more or less dense depending on the density (or resolution) of the beams; furthermore, considering that in the real world the instrument records surfaces that are very different from the hypothetical sphere, it's obvious that the instrument has to be positioned correctly. Depending on the laser scanner, the emitting cell either rotates and changes the direction of the beam, or the latter is steered by a moveable mirror; in both cases, we can consider that the lateral oscillation of the beam remains constant, while its direction varies on the horizontal plane from -45° to the zenith. It's clear that the closer we get to the upper limit, the denser the points. In this case we had to consider the reduced work space because the courtyard has more than one floor.

The *density* (or resolution) of the points varies according to the distance between the surface and the point where the beams are emitted; in most cases, the ensuing grid on the theoretical spherical surface twists and adheres to the examined surface.

Of course it's possible to calculate how many points will be recorded based on the density/resolution chosen and the angles of the explored field (on the horizontal and vertical plane); the reason why it's possible and not certain depends on the fact that the instrument emits a certain number of impulses corresponding to the envisaged density, but not all impulses provide the same answer; the impulses hit the nearest surfaces and generate a points cloud; there will be no response, for example from the impulses emitted skywards. In Villa Rufolo we used a ZF 5006 image laser scanner with a medium-intensity density and high acquisition of points.

The third aspect to consider are the *shadow areas* or *gaps*; they can occur for two reasons: strong contrast in the light or other objects located along the scansion trajectory. Regarding the former, electronic scansions are best performed with diffuse light (cloudy sky) so that the "response" of the materials is as comparable as possible; with regard to the latter, it's possible that another object (a tree, a person) is located between the scanner and the surface to be surveyed, or that something sticking out from the object hides the part next to it. In both cases the points cloud will have gaps which will have to be filled by taking more scansions or using as

Fig. 5: Recognition which points in the points cloud corresponded to the same points in the topographic network

mentioned earlier, an architectural survey is rarely based on just one scansion; since multiple scansions are almost always required, we need to organise a network of points (recognisable in the scansions) that can be topographically measured and used to recreate the different clouds. For the courtyard we used a network of topographic points which was later used as a basis to unite the points cloud and fill the gaps using dedicated software that recognised which points in the points cloud corresponded to the same points in the topographic network. This stage is still ongoing.

In fact in some cases it's possible to identify the same elements in different scansions and reassemble them. Instead, the scansion of smooth plastered surfaces requires *targets* to be applied in advance. As far as architectural survey is concerned, this technique still presents three major problems which have yet to be properly researched and solved:

- a – the effects produced by the type of response provided by the intercepted point according to the density of the material;
- b – the distortion caused by the forms (corners, acute angles and rolling surfaces);
- c – critical reduction of the number of signals recorded.

Let's take the first problem. We know that architectural surfaces are made of many different kinds of material – more or less compact stone, plaster, face brick, marble cladding, etc. – and that these surfaces can be treated in various ways (extremely smooth and polished, coarse, rough or uneven); the reaction of a rough stone surface will differ from that of a well-polished or plastered surface. Different surfaces provide different responses and create natural dissimilarities. Official literature doesn't seem to have studied this aspect sufficiently, so although it's true that these are novel problems within the field of architectural survey and that technological research will certainly contribute to minimising the problem, the key issue still remains: these instruments require new professional skills. However, we must bear in mind that one scansion is often not enough to record the overall model of the surveyed object: several scansions will have to be taken in different directions in order to cover all the surfaces and acquire uniform resolution; multiple scansions are a problem that should be solved during the preliminary project (for example in photogrammetry). Other issues (as mentioned earlier) include:

- measurement and correlation of the points from which the shots are taken;
- topographic measurement of a sufficient number of points on the scanned surfaces in order to successfully link the different clouds.

Fig. 6: Views of the photographic image applied to the cloud of points – mesh

It's true, however, that we can directly link several points (at least five) if they are accurately identified in each area where the two clouds overlap; nevertheless, it's best to have a network of control points (measured topographically) regardless of the electronically recorded clouds.

Laser scanners are currently produced with internal devices that survey points similar to the ones recorded by a total station and, as a result, are also capable of recording single points.

However, although the topographic measurement of a network of control points makes it possible to direct and correctly assemble more than one cloud, it's also possible that one or more of the measured points are illegible in the decimated clouds. Vice versa, laser scanners with accurate gauges do present risks: if the instrument is not properly calibrated this will affect the recording of the cloud and each point.

Many laser scanners allow the operator to photographically record the scanned surfaces at the same time; this helps in the analysis of the points cloud.

We shouldn't forget that it's very difficult to repeat a scansion. In fact, a scansion is a bundle of beams emitted by a source whose position in space has to be accurately prepared. It also depends on the initial direction of the instrument (very difficult to repeat) and the density of the scansion. Nor can we solve the problem by applying *targets* to the surface to be scanned, they will be useful when we merge the two points clouds, but they can't guarantee that the beams hit the same points in both scansions. So we have to conclude that each scansion is an *unicum* with its own "genetic heritage" based first and foremost on the effects of the density used in the scansion.

This is the starting point we must use to try and find a procedure that can unite all the information required to fully understand the object in question and compare the results of more than one kind of survey technique. This comparison is successful when the results produced, for example, using the photogrammetric technique, are perfectly in line and correspond to the results of the electronic scansion. As mentioned earlier, during the study of the courtyard in Ravello we combined the digitally surveyed points cloud with the results of a direct and topographic survey as well as with the superimposition of the photographic image on the suitably elaborated points cloud (not to be considered as texturing).

Once we obtained the digital scansions of the courtyard of Villa Rufolo, we worked on the points cloud; since they were very dense we asked ourselves which was the best way to proceed: either to break the cloud up into several parts and elaborate each part separately, or proceed to "decimate" the cloud. The latter can be performed either using the criteria provided by the operator (perhaps based on a comparison with the

photographic documents to avoid eliminating points that correspond to important elements of the scanned surface) or using software that performs the same operation automatically.

A decision was taken to use automatic decimation to elaborate the scansion, apply the photographic image and obtain an initial result: this allowed us to focus only on the decorated part of the courtyard. Decimating the cloud produced a grid, albeit not very dense, which we used to define the mesh surface to which we then applied the photographic image we had obtained separately using the laser scanner (high resolution image). Similar points were identified without using targets but simply by letting the software recognise the RGB points nearest to the point chosen on the photograph and then again on the points cloud. The first results, albeit partial and therefore not conclusive, are however already very satisfactory. Experimentation is now focusing on the geometric forms used for the small coupled columns (once the gaps have been filled) in order to create a three-dimensional model similar to the real one, if not exactly the same. These experiments are part of an attempt to propose the figurative reconstruction of the elements in the courtyard, adding (+) – where only fragments remain – what is no longer visible (-).

3. Toward a total digital fruition of architectural heritage²

Cultural heritage, as we all know, is nothing new. However, not long ago architectural or cultural heritage in general could be enjoyed only by visiting the site itself; only then was it possible to see it firsthand and learn more about it. When people began to appreciate the diversity and beauty present in the world, they also realised how difficult it was to access these sites. This inspired change: the visitor no longer went to the site, the site came to him. To satisfy peoples' desire to "see" what the world had to offer in places far away from their own cultural and geographical borders, paintings, topographical surveys, architectural surveys and written descriptions began to be produced and circulated far and wide; it was a way to convey the impressions of those who were lucky enough to have travelled there. The trend that started in the eighteenth century with the advent of the Grand Tour is still ongoing. These paintings, surveys and reports were nothing but an *ante litteram* database of heritage information for those who wanted to know more. Whether it was either for entertainment or scientific purposes, the data played a key role in scientific research: technically and architecturally speaking it led to improvements in the reproduction of the asset and its forms, in other words in the objective acquisition of its geometries, tectonic and material characteristics and, as a result, building techniques – all elements crucial to the survey of buildings and the landscape.

Exhibition material and cultural information has always been part of a visit to an artistic or architectural site. People's desire to learn about cultural heritage has grown over the years; in the twentieth century not only has our approach to a cultural asset evolved enormously, so has its presentation. There are many different ways and methods to present information, for example about architectural heritage. Apart from the purpose for which they are used, these methods depend on the final user's level of culture as well as on the power of the tools available. Each one (heritage photographs, elaboration of graphic models to provide a gradually more discreet and symbolic description) has its own intrinsic difficulties associated either with the support needed to represent it, or the experience required to interpret the information provided.

I will focus here on the presentation of heritage information after a well-designed and executed survey. Technology used in the field of Cultural Heritage, specifically in the study of cultural and architectural heritage, has established and is establishing scientific research paradigms; it requires the constant use of several instrumental methodologies and the conceptual sharing of the procedures involved. This gradual stabilisation of the elaboration stages is not, however, slavishly followed by the presentation and public fruition of the results. In practice, we are still waiting for convergence (to be more precise, "standardisation") between the material/information produce by Cultural Heritage and the chance to use it.

Today several models can be used, improved and turned into applications. First and foremost, immersive photography: this is the most immediate tool and represents the natural evolution of the visual impact of an architectural heritage or landscape when reproduced by a camera. What we did for decades, i.e., show the heritage we wanted to study or visit, can now be enhanced by the dynamism of panoramic visualisation. Spherical projection of an anthropic or natural environment allows us to involve the user who can virtually experience a heritage, even if it's very far away; this also allows him to avoid the intellectual effort which is sometimes necessary to recreate a single shot (not always a positive experience!).

Immersive photography is a relatively simple technique that can be digitally enjoyed; it's become a perfect alternative to different kinds of virtual or mixed reality. Although the latter play a role in culturally conveying heritage, they still remain marginal due to the computational burden and economics associated with the use of physical devices. Furthermore, as regards mixed realities, where georeferenced virtual models are made to interact in real contexts, the problems associated with the above-mentioned limits of use are compounded by the possibility of digitally exploiting three-dimensional models. Using 3D models to represent built heritage has always helped to formally convey architectural works, their current state and past configurations.

However, apart from very special cases, interaction is not moving in the direction of digital sharing; this is due to problems involving the reduction required by models as well as their material rigidity.

Although digital mediums are used to convey three-dimensional models (even though the latter are also the result of a survey), in the digital world there are not enough platforms capable of generating an interface suited to these representations. This is the reason for the delay in exhibiting the graphic results of orthogonal projections – more flexible in forms of multimedia sharing and less burdensome from a graphic and computational point of view. Only recently have digital three-dimensional models and elaborations become more widespread, however very rarely is the definition of detail in line with the restitution scale considered to be the most suitable. In most cases these models remain part of specific projects and sometimes only involve part of a bigger object that cannot be fully represented. This hampers one's understanding of the heritage in question because it's increasingly difficult for people to understand the information provided when the representation becomes more and more abstract – from photorealism to the graphic and then conceptual model. Information about cultural heritage differs depending on the target audience. Now, as in the past, each user, with his own level of culture and diverse intents, will interpret a heritage differently. However, if in the past different presentations and elaborations were used for different users, large-scale computer technology is slowly changing this penchant for differentiation. The current trend involves proposing one way in which users can view and enjoy cultural heritage. Although it's wrong to talk of simplification, we mustn't underestimate the fact that some computer technologies are still in the pioneering stage, so much so we can't really consider them fully-fledged methodological tools ready for widespread use, but merely young chicks about to hatch.

Apart from the computational difficulties involved in representing geometries and related information, the way in which we will be able to enjoy cultural heritage in the future depends on interaction between the heritage and the information provided; in turn this depends on the dynamic use of representation. Conceptually speaking, the ensuing semantic distortion is enormous. If in the past there were specific, differentiated moments (and know-how) that provided different in-depth information about the heritage, this limit will soon be history. On the one hand, interacting with the heritage and related information involves having a container in which every semantic element (textual, technographic, photographic, photorealistic, etc.) is simultaneously present and can be enjoyed either alone or with others; on the other, it means that the precision we hope will be used to build the digital graphic project will not use traditional graphic supports and therefore eliminate their spatial and temporal limits. Furthermore, every element or part of the heritage could represent a container in a bigger, open, flexible and multi-scalar database

Hopefully this convergence will one day be achieved; we will then be able to talk of digital fruition of architectural or artistic heritage. It will be a successful promotional tool especially for morphologically complex and culturally varied systems, for example for the heritage described in this paper: the Amalfi Coast - a crucible of culture and workshop of multimedia infographic experimentation. The many ways in which we can use a digital (and also virtual) environment to describe and improve the fruition of cultural heritage and its management means we will soon be able to talk about "culturally smart cities", new worlds and new ways to use cultural objects by creating real, virtual and immersive environments in which the cognisant components of each element are expressed using the tools and platform provided by the world of ICT. By exploiting communication infrastructures that use state-of-the-art advanced digital technologies, we will be able to view graphic and digital models of architectures on mobile and portable devices and combine them with avant-garde services and applications.

Water-ways from Naples to Miseno

Maria Ines PASCARIELLO,¹ Maria Rosaria TRINCONE²

Abstract

Over time, the water-ways that lead from Naples to Miseno have mapped out the area and changed the lines of its appearance. They have shaped the landscape and developed intertwining networks across it, both above and below ground. At times these are visible, at times submerged. Here they are natural; there they are the result of human intervention. They are the signs of long-term phenomena, of large environmental and territorial transformations which have characterised the different interaction between man and landscape. In this perspective it is evident that integration of knowledge and an interdisciplinary approach to actions is all the more necessary.

Analysis and reconstruction of the water-ways that lead from Naples to Miseno, a special section of our urban landscape, are the subject of research work that aims to identify and develop the qualitative relationship with the places where we live, woven into history and technique and unavoidably linked to the sea. The investigation route follows the traces of these ways from the city to the surrounding areas, filling in gaps and making hypotheses where traces have been lost. It focuses on defined architectural and archaeological points (such as springs and reservoirs), on the network elements, the aqueducts, and goes up the coast to the ports of Baia and Miseno, and the seabed.

At the same time, analysis conducted on representative artifacts of archaeological sites in the Phlegraean area and on sunken tracks (both underground and under the sea) can be identified as parametric and, as a result of media mapping and thematic and dynamic support, representations of the region's archaeological potential take shape that allow us to understand and plan for intervention work and land transformation.

Keywords: water-ways, survey, representation, database

1. The region (Maria Ines PASCARIELLO)

Water, an indicator of life. A resource to be found in the most remote corners of the earth. "Humile et pretiosa et casta" water.

It has always been the subject of poetry, music and literature.

Throughout the ages it has played a leading role in architecture, which it is closely linked to for functional and aesthetic reasons. It has been a key figure in defining the region and changing its linear appearance. It has shaped the landscape and developed an intertwining network across this, which runs both above and below ground, is sometimes visible and sometimes submerged, sometimes natural and sometimes the work of man.

Eternal, deep, and essential – the bond between water and the region contains and, at times, manifests the deepest reasons behind settlements, urbanisation, the economy and life.

The subject of ongoing research work carried out in the region, the analysis and reconstruction of the water-ways that cross Naples and branch out into the region of the Phlegraean Fields (mapping out an important

1.1 Lines, networks and points

In a multi-centric, network-based vision of the space surrounding us (where individual identities constitute an amazing resource for learning about the region), surveying and drafting enable us to describe an urban landscape that, crossed by water, is often unable to see continuity between full and empty, between under and above, between inside and outside. Architecture becomes a vessel for water and the water, in turn, brings it to life. The engineer becomes the technician and the water becomes the governing fabric of the region.

In a reading of the urban area, differences emerge in habitats and in the ways we live in a region; different ecologies map out a network of urban and social geographies with specific macro and micro scale identities. An “established” city exists, or rather the historical city that continues to persist in the layout, architecture and shapes. The “sea” town exists, the “linear” town made up of crossing paths, connecting lines, borders, profiles and edges.

A reading of the Neapolitan region, as a collection of specific identities, has involved the micro-scale in this work. The micro-scale is to be seen as the local neighbourhood (a centre of life and expression of the society that calls for the reconfiguration of urban liveability) and also small-scale architecture, the architectural detail, which makes the difference in the identification of quality. Study and survey data collection aims to understand the city and outline its cultural and social identities, according to the rationale of belonging to a place and the recognition of a precise urban centrality.

The region around Naples is complex and the multiple parts that compose it and describe its essence manifest this complexity; the interior of the city, meanwhile, seems to be made up of multiple, distinct potentialities. This approach, which seeks to combine concrete experience (or rather reality) with vision, finds its synthesis in the creation of a possible observation of the city, in the translation of that which, in the making, should be or we would like to be our city. The privileged object of this vision is architecture, which is represented through images and designs that convey the essence of the city without having to draw the whole every time, in every fragment. With design, the context can be understood and situations can be communicated. We are able to make a critical reflection on the things that came before use. Using survey we are able to face things with *modus*: what arises is a way of being in reality with moderation, expressing the need to give shape to a complex spatiality according to a linguistic code that studies the substance of architecture.

Of course, the representation space still remains forever an artificial space that overshadows but does not entirely embrace reality. Points, lines and planes are abstract entities of space that, through geometric language, are transferred in formal units commonly known by the name of pictures. Yet right in the space instantly stopped by drafting, points, lines and planes are released from their positional value and acquire relational value and - investigated in their reciprocal relations, evaluated in their dynamic equilibrium and used in the proper degree of belonging to the visual system - are reorganised in a new and original image: the water-way.

2. Water tracks (Maria Rosaria TRINCONE)

«Places have a meaning for us as they are tied to sensations and images that bring them to life and that are not necessarily ours. The soul of places, the sense of their being, is independent from us. But this soul is determined by their temporal fragility. Time modifies them and gives them an enchanted aura. Nostalgia, as essential sentiment, takes control. Puddles, ruins, fragments of the world, places that are not necessarily noble are the sense of being.» [1]

Everyone can identify with a place established in terms of elementary organizational patterns of topological type, which enables us to read and reread certain spaces of reference according to the concept of figuration. Everything that is objectively concrete has that property, determined by the “shape, colour or disposition that facilitate the formation of vividly identified, powerfully structured and highly functional environmental images. It could be called readability or perhaps visibility in a wider sense where objects can not only be seen but are also acutely and intensely presented to the senses”. [3] retracing past events in the memory, simply because they acknowledged both the practical and emotional meaning of an architectural object and its function within the “existential space”. [2]

In this way, a structure is The city therefore becomes the appointed place for this sensory experience, rendering tangible its legibility in the architectural space as a representation of its memories, its history and its daily events; the symbolic-formal and evocative place that guarantees individuality and the recognition of those meanings which are potentially present in the structure of the urban environment.

Pict. 2: Database example: by clicking on a placeholder, the image appears on the artifact concerned, then again by clicking on a portion of the image will open a zoom to detail. (The tab, shown in picture 2, of the database was developed by Maria Rosaria Trincone).

Location of water tracks (Layer 1 – Water tracks: the fountains in the center of Naples):

1. *Fontana Fonseca or del Sebeto*, Cosimo and Carlo Fanzago, Salomone Rapi, 1635;
2. *Fontana del Marinaretto*, (or *del Pescatoriello*), Raffaele Marino, XX sec.;
3. *Fontana del Mergogliano, del Leone*, unknown author, XVIII sec.;
4. *Fontana della Sirena*, Onofrio Buccino, XIX sec.

Pict. 3: Finally, the next step allows to connect to each element, selected while browsing through the database, designs and drawings produced by the survey of each objects under study. (The survey and the drawings have been performed by Maria Rosaria Trincone).

The streets, squares, urban voids (which can be recognised by the wealth of their symbolic values, activities or functions) relate qualitatively with the constructed in a bi-unique manner, despite having constructive and formal characters, independent from the shape, type and characteristics of the buildings that define them. The square, which by its spatial connotation meets the community's need to have a place in which public and private activities can be carried out, is the place where events and architecture face each other in a very strong manner. More than any other urban space, the void-square qualifies as a place of excellence because it relates to everything through a representative image in which the monuments and civil and religious buildings have determined its image "soaked with memories and meanings". [3] Unfortunately and ruthlessly, the variable of time modifies the signs of shape. Squares, buildings and streets become fragments of different tales. It is as if the relationship between architectural space and space of existence which the city has had since the act of its foundation is lost. [4] With its geometric centres of mass and symbolic fulcrums as archetypal and psychological references fundamental to man, the matrix of the ancient city fades with the passing of time, eliminating those elements that render it recognisable.

The perception of the existential space, seen as a sequence of images from the same narrative, is however unrelated to the variable of time. Its memory cannot be lost because even the critical reading of urban fragments (like a public fountain, a façade, a part of a street) reminds us of it. It is possible to grasp its configurative complexity by interpreting the fact in itself, crossing the material limit of the object itself to build a conceptual reference grid where each characteristic element of the place can be inserted. A conceptual operation which, only by observing the phenomenon and "the places where conflict hides", [5] is it possible to reconstruct the system that helps us understand the architectural object. Measure and design are necessary aspects in the re-appropriation of the meaning of place as a space for time stratifications, flowing ruthlessly and determining the fragility of things. Withdrawing time from representation, recovering the corresponding image of the historic memory through the passage of lines and surfaces in the dimension of design, is not the nostalgic vision of past reality, but the true perception of the sense of being part of time.

In this way it is possible to take possession of the city by exploring it in the dimensions of the drawing. Through the logical consequence of geometric-descriptive methods, it gives the image of the space the ability to evoke perceptual relationships that settle between the observer and the observed. Graphical drafting becomes the dialogue between the parts in this relationship which, through the symbolic code of graphic signs, builds the concrete structure of the architectural spaces. The design, therefore, will no longer be seen as intellectual opportunity, but the opportunity to preserve the memory of places, with hypothetical forms that develop the ability to distinguish those spatial configurations erased by time and transformed into fragments.

3. Considerations and aims (Maria Ines PASCARIELLO)

Research ideas concern the problems connected to the acquisition and processing of data in drafting the region and the environment. Morphology, in particular, is investigated through architectural and archaeological emergencies following survey practices and methods, including photogrammetry, laser scanning, remote sensing (including under water), digital and thematic mapping, and the development of graphical models.

Furthermore, if the aim of analysis and development work is the respect of local identities, guaranteeing a better quality of life, this needs to be directed not only at the emergency issues but also towards less well-known buildings, those which perhaps are more at *risk* and which have undoubtedly maintained a closer relationship with the original social and cultural context. This can be facilitated by direct involvement by local people and the cultural associations which have a socially active part in the project.

A special role will therefore be given to awareness raising among all social strata of the population, to promote the fact that conservation and development of archaeological heritage helps enrich everybody's existence. This will be followed up with field documentary work which collects and summarises results from the research work and spreads the content in scientific terms.

The need for analysis that is designed to provide a sharable system of knowledge is to be carried out through targeted observation of the architectural and archaeological heritage, the result of the need to preserve the cultural heritage by proposing a precise monitoring methodology.

One possible line of direction is to work in accordance with the one individual rationale that, at the same time, considers the typical approach of the surveyor, with urban and environmental analysis, and those who decide and those who carry out the work in sync.

This way, the data collector becomes the interpreter of a tool and the populariser of a methodology which does not exclusively aim to describe and represent the actual conservation state of the analysed environment, but aims to bring out the priorities of the work in a general programme for regional planning and redevelopment.

Starting with an analysis of the individual architectural property, and reaching the region, the aim is to propose an investigative approach which makes it possible to carry out instrumental analysis and data collection, which can be updated over time compared to coded assessments. The tool aims to define a classification system with which to monitor the state of preservation and vulnerability; both the factors responsible for the deterioration of property and the hazard and risk areas. The investigative approach will aim to provide themed documentation in which to present an area, as a physical entity, morphologically defined in relation to its social and economic essence.

Creating an alpha-numerical language with which data becomes code, and code becomes graphical sign, will therefore respond to the aim of providing the necessary data for defining the values that characterise the property under analysis.

It is hoped that the research activity carried out by the unit will lead (through a completed study of a sample area) to the creation of a disciplinary methodology, structured on its own methods of investigation and clear aims, which can define the renewal of field intervention procedures in the area of protection and development. Archaeological emergencies, therefore, seen as structural elements of the landscape, will be studied and analysed in architectural, archaeological, geophysical and touristic terms, which together contribute to the planning of regional development, its transformation, use and development.

Abstract

The study of efficiency to document Cultural Heritage aims to develop a management strategy where new technologies and current dissemination strategies melt unequivocally, with maximum performance. The plurality of emerging techniques for documenting tangible heritage sometimes mistakes their proper selection, so this comparison is articulated in three blocks. The first one refers to **Data Capture** from different technique and technologies:

1. Terrestrial Photogrammetry Documentation form HD cameras using Dense Stereo Matching algorithms (image based information)
2. Terrestrial Laser Scanner captures. Equipment: Faro Photon80 (range based information)

Second and third block deal with **Data Processing** (1), obtaining a dense point cloud and a mesh with and without color, and the **Geometric Comparison Process** (2), taking into account economic costs and investment of time for each product.

The efficiency evaluation of the “Dense Stereo Matching” photogrammetric technique will result in it being considered a feasible and competitive alternative for studying and documenting Architectural Heritage in Urban spaces. The evaluation also aims to check the capacity of this technique to substitute or complement other non-contact digitalization techniques like Laser Scanner.

This paper pretend evaluate the efficiency of the “*Dense Stereo Matching*” photogrammetric technique to document Architectural Heritage in Urban space, with the next specific aims:

1. Set the conceptual and methodological basis of the “Dense Stereo Matching” photogrammetric documentation technique as opposed to those of the 3D Laser Scanner.
2. Compare the data obtained from the “*Dense Stereo Matching*” photogrammetric technique with that from the 3D Laser Scanner.
3. Evaluate the efficiency of the “*Dense Stereo Matching*” technique.

Keywords: Photogrammetry, Cultural Heritage, Sensors, Dense Stereo Matching, Virtual Reconstruction.

1. Introduction

The tangible cultural heritage documentation has two main objectives: setting a documentary basis for Architectural/Urban intervention and as a spreading tool for heritage (also as a conservation tool).

¹ The work has been financed by the MICINN (Spanish Ministry of Science and Innovation) within the ADISPA project BIA2009-14254-C02-01/BIA2009-14254-C02-01 and was part of the master degree thesis of the researcher Jorge García Fernández

² English translation: María, SAN JOSÉ SÁNCHEZ, Student Degree in Translation and Interpretation.

The intervention process of a building or a building ensemble with heritage value must be carried out very carefully. The process is hard not only when the building is a declared monument, but also when it has inherent values related to the historical memory of the region or special typological features that are worth taking into account.

The spreading process is one of the most useful ways to protect and preserve Architectural Heritage in Urban space. The process helps people having a better knowledge of what surrounds them and developing an attitude of respect towards familiar heritage. The loss of identity regarding the past and the heritage elements has highlighted the role of diffusion in our society. Diffusion is “the act that enables people to be in touch with their Heritage and to acquire interpretation mechanisms to help them understand the facts and the objects.”³ Both technical documentation and cultural heritage diffusion undergo an analysis of the data capturing process and the data processing in order to obtain high-quality products.

Currently, the proliferation of techniques and technologies for architectural heritage documentation offer a wide range of possibilities. The diversity and heterogeneity might, however, affect the adjustment between demand and results. The current paper is engaged with a thorough study of two ways of carrying out the three-dimensional documentation process of objects: through image correspondence and through 3D Laser Scanner. Both the geometric quality of the final product and the investment costs of time and software and hardware equipment have been taken into account for the study.

2. Fundamentals of documentation through Laser Scanner and Photogrammetric Technique (Image correspondence)

The use of **Laser Scanner** or **3D Scanner** for Heritage documentation is quite recent. The possibility of getting a point cloud with pinpoint accuracy of both small and big surfaces has turned this device into a great tool to document Cultural Heritage, specially the Architectonic-Urban one.

The laser mechanism (Light Amplification by the Stimulated emission of Radiation) consists of the stimulated emission of a light signal and the optical feedback. According to the definition given by the Architectural Photogrammetry Laboratory of the University of Valladolid: “A laser consists of an amplifier in which stimulated emission happens and also of a set of mirrors that make the light beam go through the amplifier again and again.”⁴ The raw product of laser scanners is the point cloud. The cloud shapes both the surface of the object being documented by means of the laser beam and the setting of the spatial coordinates of each point according to the different operations.

In view of the high costs of laser scanners and its dependence on hardware, automation of three-dimensional reconstruction of a setting using **photogrammetric techniques** (currently digital images) has long been one of the greatest challenges for photogrammetry and computational view. Automation consists of taking two or more pictures with different cameras at the same time (stereo) or with the same camera at different times (motion). Reconstruction of geometry and point cloud creation includes three main parts:

2.1. Obtaining Internal Orientation parameters:

The process consists of reconstructing the perspective beam shape, i.e., reconstructing the camera’s internal parameters, as well as the distortion caused by the lens flaws and the lack of alignment of optical parts. In order to obtain the vector between the point of view and its projection on the photogram, several calibration systems for non-metric cameras are used. The process is then carried out under different algorithms. In this project the Photomodeler Scanner 6 was used to achieve calibration through the “test field” method.

The system consists of taking pictures of a set of characteristic features located on fixed positions. The identification and measuring of these control points, designed in accordance with a fixed parameter, allows us to calculate the parameters of the geometry of the camera (focal and main point) and the distortion of the lens system (radial and tangential distortion.)

Regarding analog photogrammetry, the camera being calibrated was placed on a specific position from the control point grating. The development of position and direction calculation thanks to pictures taken from different points of view has enabled simultaneous calculation of internal orientation parameters.

⁴ Various authors, 3D Laser Scanner, Photogrammetry Laboratory of the H.T. College of Architecture–University of Valladolid, Spain, 2009.

2.2. Obtaining the Relative Orientation parameters

The aim of this process is to direct both beams of a model in a way that all the equivalent beams converge. The result is a 3D model of the object within the chosen reference system.

From a photogrammetric point of view, there is no difference between calculating analytical relative orientation in an analog machine and calculating that of a digital one. The process of analytical restitution consists of obtaining a set of coordinate pairs both in the left and the right picture of a number of points. The operator will then recognize those points as equivalents. Once points are measured, relative orientation parameters can be calculated using two methods based on collinearity and coplanarity conditions respectively. The advantage of digital restitution is the possibility of identifying equivalent images through statistical methods, which allows measuring without visual intervention.

2.3. Dense Pixel Correspondence: Stereo-Matching Algorithms

Several algorithms have been suggested with a view to solving the problem of point correspondence between two images of a stereo-pair. According to L. Nalpantindis⁵, algorithms can be grouped depending on whether the outcome is sparse or dense; being the latter classified in local (based on area) and global (based on characteristics). It is necessary to know speed, accuracy, scope, time consumption and disparity range parameters in order to evaluate algorithms. There is a third classification based on symbols referred to methods that compare the symbolic description of images instead of comparing the resembling geometric features. The current study does not deal with this method or the sparse outcome one.

The Photomodeler Scanner 6 software has been chosen to carry out the correspondence in this study. The application permits the matching of various geometries, both the basic one, i.e., the point, as well as lines, curves, silhouettes and more complex ones.

3. Case study: San Martín Church in Segovia (Castile and León, Spain)

San Martín Church was originally Pre-Romanesque. At first, it had a small temple with three naves and three sections, which were extended according to the Romanesque style of the 12th century. The renovation led to a three-nave ground plan with an equal number of semicircular apses, a transept and a brickwork tower. The gallery, which was originally surrounding the whole building but the east end, was built in the following century and has many craved capitals. Afterwards, the central apse was replaced by a rectangular ground plan apse which, in addition to the damaged apses that flank the central one, contributed towards the loss of interest in that part of the building. The Romanesque-Mudejar brickwork tower with small semi-circular arch windows has a great base width and a shale end.

Figure 1: San Martin Church in Segovia, Spain.

The great architectural complexity of this heritage work is due to the uneven land where it stands and the constant renovations and building phases. Diversity in materials, geometric and radiometric patterns, and context facilities to obtain angles of view and different distances to test several configurations, made it possible to choose San Martin Church for this study.

4. Reconstruction of the object surface through Laser Scanner

The documentation process of San Martín Church was carried out with the Faro Photon 80 scanner. This scanner uses phase shift between the emitted and reflected wave to calculate the time-of-flight and, therefore, the distance to the object. The laser emits a periodical, constant and moderate sign. Measurement accuracy depends on frequency and wavelength. For this reason, the scanner operates with multi frequency ranging, using the highest frequency to calculate the distance to the point and the lowest to solve

⁵ Nalpantindis, L. *et al*: Review of Stereo matching algorithms for 3D vision, 16th International Symposium on Measurement and Control in Robotic-part 1, Brussels, Belgium, 2007.

measurement ambiguity. Radiometric information is then added to the point cloud through high resolution pictures taken with a reflex digital camera incorporated into the scanner.

In order to document the church, a 1/4 resolution was set with the highest point quantity available. The studied areas and the scanning positions have produced resolutions (gaps between points) of 6 mm every 10 meters. The repetition frequency for this resolution is 12 Hz and pulse duration is 0,00190 sec. The point clouds of the captures in which the scanner was closer to the object are denser.

To carry out the comparison, a surface mesh was obtained from the point clouds of the laser scanner. The clouds were then exported to PoliWork-IMAlign, where the surface was reconstructed under high reliability levels, at the risk of losing data of some parts of the setting. No smoothing, tolerance or reduction was applied to the clouds. The mesh created with IMInspect was entered as a "Reference Object", which lead to an automatic georeferenciation thanks to the inherent information in the scanner.

5. Reconstruction of the object surface through Dense Stereo Matching

The reconstruction of dense point surfaces from images has been developed as an alternative to point cloud generation through laser scanner. The Photomodeler Scanner 6 software was used to carry out the comparison, as it allows a much easier data management and it includes many quality control tools. The software also offers a wide format and product range that allows browsing and creating.

The dense pixel correspondence project entailed taking stereo-pair pictures with a quite significant base relation (gap between captures)/ distance (between the base line and the object). Thus, a 1/3 relation is considered quite distant from the usual stereo configuration of 1/5 and 1/10. Increasing the relation means a considerable loss of overlapping surface, which can be solved by selecting a slightly convergent configuration. The area within the overlapping section is the surface of the setting that contains the point cloud product.

The camera always had a similar orientation in order to obtain a quality capture of the stereo-pair. No significant changes were made regarding distance, and convergence or lack of parallelism between capture axes was not excessive. Although quality is almost assured, there might be some errors related to capture conditions when these are too distant from the ideal situation.

5.1. Internal orientation

Camera calibration was required for every configuration used in the project. For this purpose, the team used a calibration grating to take pictures of the object. Thus, every time a section was documented with different parameters, calibration shots were obtained.

In order to get an optimum calibration, the team took 13 pictures of the grating: 1 horizontal and 2 vertical every 90° (12 pictures in all) and 1 upside down. For every capture the calibration grating width was adjusted to the sides of the image. The calibration pictures were taken in broad daylight, which allows using high f numbers (minimum aperture) and high shutter speeds. This way, the field of focus is maximum and images are clear even when the model stands closer than the object. This allows using the highest shutter speed in order to avoid out of focus images. In the current project the team took 4 sets of calibration pictures for each of the 4 typical configurations depending on shooting conditions.

5.2. Relative Orientation

The modules "Automated Coded Target Project" and "Point-Based Project" were used to obtain captures with and without coded targets. In both cases equivalent points were set within the stereo-pair. Those pairs with coded targets are automatically detected and allow a stronger correspondence.

Coded targets were previously created with the same software. Their size and diversity depend on the parameters selected for the project. The design of the targets takes place in the "Create Code Target" section. The team designed 10-bits targets for an estimated distance of 7 meters to the camera. The targets are then distributed in a balanced way all over the area being documented.

Once the orientation process begins and reaches an acceptable range, the rest of the points are set according to the visualization of the epipolar line over the target image. It is much easier to set the point over that line, as just the definition of a spatial component is required.

The correspondence and deviation assessment of the equivalent points is crucial to know how accurate *Stereo-Matching* is. The equivalent points from the object features that were entered manually show deviations between 0,50 and 0,01. When deviation is less than 1,0, correspondence is correct. Rotation and

scale can also be set at this stage. The rotation of the model is set from two point pairs that frame two of the three reference axes. Scale needs to be corrected depending on the initial distance between the targets, except for those cases in which coded targets are defined in the automatic recognition process. For this reason, the team decided to get the measurements from the point clouds of the laser scanner. However, it is vital to bear in mind that a margin of error exists, as the scanner accuracy and the establishment of a dimension from discrete points is the foundation of the process.

5.3. Dense Pixel Correspondence: Dense Stereo Matching

Dense pixel correspondence was carried out with the *Dense Surface* module of the Photomodeler Scanner 6 application. Once Internal and Relative Orientation has been calculated, the only thing left is to start the process of matching the pixels of the stereo-pair. The application also allows adding different parameters to control the product (point cloud) according to the nature of the scene and the object.

The sampling rate of the cloud is defined by the cloud density requirements as well as by the size of the GSD. By calculating the pixel track it is possible to know the maximum resolution possible in the correspondence. The data for the current project is as follows:

1. Camera's sensor size: 4/3" diagonal 22.50 mm; width 18.00mm; height 13.50 mm.
2. Focal length: 14mm and 30mm (Telephoto lens for the belfry)
3. Image size: 3648 x 2736 pixels
4. Distance to the object: Variable depending on the shot⁶.

Every image has a pixel size in the CCD of 0.004934mm, although the track changed depending on the focus and the distance to the object. In order to match the pixel distribution of the camera, Bayer filter was used, where color data is stored in each of the 4-pixels modules. The team chose a configuration in which at least one point of the cloud was representative of 4 pixels of the image. For this purpose, the minimum enlargement distance is $2\sqrt{2}$ (diagonal distance of the square within the unit side). In the project, the value entered in the Sampling Rate was the track size enlarged 3 times.

6. Comparison of laser data with photogrammetry

The modules IMAAlign and IMInspect of the PoliWork application (10.1 32-bits version) were used to compare the data from the Photomodeler Scanner 6 with that of the Faro 80. The data obtained from the laser was turned into a high-accuracy mesh, from which deviation vectors were calculated in relation to the cloud created from the stereo-pairs. In the process, the data from the Photomodeler Scanner 6 was included, gathered together with the Apse and the Belfry projects. The scale was corrected manually and the data was aligned using the "N-Point Pair" and "Best-fit-Alignment" options.

Case 1: Northeastern Apse + Facade:

- GSD: 2.41 mm
- Sampling Rate parameter: 7.23
- Number of points: 110,235
- Residual Quality: 0.26
- RMS: 0.06
- Sampling Rate: 1 point every 7.23 mm
- Depth Range: 1,000 mm
- Matching Region Radius: 6
- Texture Type: 1

⁶ The estimated GSD matches with a single point of the object, taken on the most favorable point or on the scene center. This leads to "optimistic" values of the GSD for the rest of the object. For this reason, a 3X or higher amplification makes sense in that it avoids higher cloud densities than those of the CCD. The maximum density could be limited more precisely if the real GSD was sampled from different distances to restored points within the worst parts of the scene once Relative Orientation and model scale is solved.

Figure 2: Displacement ratio (apse-facade)

125,844 points of the 130,376 were compared at a range of $\pm 35\text{mm}$, for 96.524% of the points within the comparison range. The average was 0.052 mm with a standard deviation of 10.189 mm, while all the points converge within 3 times the Std.Dev.

Case 2: Northeastern apse detail:

- GSD: 0.70 mm
- Sampling Rate parameter: 2.10
- Number of points: 998,017
- Residual Quality: 0.11
- RMS: 0.03
- B/H relation: 0.30
- Sampling Rate: 1 point every 2.10 mm
- Depth Range: 230 mm
- Matching Region Radius: 6
- Texture Type: 2

Figure 3, 4: Photogrammetric point cloud detail and Displacement ratio (apse detail)

863,034 points of the 876,809 were compared at a range of $\pm 15\text{mm}$, for 98.43% of the points within the comparison range. The average was -0.061 mm with a standard deviation of 3.01 mm, while all the points converge within 5 times the Std.Dev.

Case 3: Northern section of the belfry

- GSD: 10.57 mm
- Sampling Rate parameter: 31.71
- Number of points: 98 734
- Residual Quality: 0.23
- RMS: 0.08
- B/H relation: 0.32
- Sampling Rate: 1 point every 31.71 mm
- Depth Range: 500 mm
- Matching Region Radius: 4
- Texture Type: 1

Figure 5, 6: Tower image and Displacement ratio (belfry)

94,271 points of the 98,733 were compared at a range of $\pm 20\text{mm}$, for 95.48% of the points within the comparison range. The average was 0.170 mm with a standard deviation of 18.09 mm, while all the points converge within 4 times the Std.Dev.

7. Results: Efficiency in obtaining 3D products

Efficiency always depends on the application context. What is efficient under certain circumstances might not be efficient under others. In general terms efficiency is defined by “the rational use of the existing resources to reach a specific goal.” In order to evaluate efficiency, the data produced by the Scanner Faro 80 regarding clouds generated by *Dense Stereo Matching* have been taken as a reference and collated: economic cost, time cost and cloud quality cost.

7.1. Economic cost

The process to obtain a cloud through stereo-pair correspondence includes the cost of the camera and the lens, as well as the license of the software to manage photograms to create the product with *Dense Stereo Matching*.

- Olympus E-3 camera: €1,400.
- Olympus Zuiko Digital 14-54 and 45-150 lens: €1,000.
- Photomodeler Scanner 6 Software: €1,530.
- Total: 3,530 Euros.

The equipment and software used in the project to obtain the cloud was:

- Laser Scanner FARO Photon 80 + Réflex Nikon Digital Camera + Point Cloud Management Software: €75,000.

The difference on hardware costs is significant (20 times more expensive). However, the rent price of the Laser Scanner (€1,200 per day) is important to carry out a correct comparison. The rent fare would allow a lower investment for individual or isolated projects.

7.2. Time cost

Time cost depends on the project’s magnitude and complexity. The total time spent in creating the 5 point clouds was similar, as just one stereo-pair was used for each example. The allotted time was as follows (for one of the case studies):

- Generation and printout of coded targets: 30 min.
- Photographic pair capture and calibration shots: 30 min. (once in the location).
- White balance and distortion correction on RAW files: 20 min.
- Camera calibration with Photomodeler Scanner 6: 30 min.
- Generation of point cloud (Internal and External Orientation, and Dense Pixel Correspondence): 45 min.
- Total time: 2 h. y 35 min.

With Faro 80 Laser Scanner (for a single shot at 1/4):

- Object scanning: 15 min.
- Picture taking: 10 min.
- Total time: 25 min.

The difference in time costs also depends on the size of the project. Laser Scanner is more adequate for bigger projects. Besides, it is not necessary to calibrate the scanner for every data capturing configuration, but just once in a while. It is important to take into account the time spent in transporting the equipment. In this regard, using the camera is preferable to using a big and heavy laser scanner equipment.

7.3. Cloud quality cost

Cloud quality assessment has been the central comparison aim of the project. From a radiometric point of view, point clouds are similar. The data obtained from *Dense Stereo Matching* always present chromatic accuracy, as the points of the cloud are pixels with correspondence on the stereo-pair. The pixels include the radiometric information. There are certain scanners, which do not allow to include color information in point

clouds or in which color information is not completely correct. This happens when the scanner operates with non-visible light waves. However, it is always possible to color the point cloud during the post-process using pictures taken from the same position.

The Faro Photon 80 scanner includes a high-resolution camera, which provides reliable radiometric information. However, the quality of the image registration on the point cloud depends on a process which is not entirely automatic. The process is normally less accurate than the photogrammetric solution. It is necessary to work out the camera's forced centering towards the scanning source and the calibration mechanically. It is also essential to reverse optical distortion as well as to decide the axis orientation of the pictures with regard to the point cloud through the identification of equivalent 3D (from the cloud) and 2D (from the picture) pixel pairs.

Point clouds created by *Dense Stereo Matching* are more efficient when the economic cost is more important than the time and quality cost. Efficiency will depend on the user's needs, the project aim and the available economic resources.

TEMPORARY ARCHITECTURES

Daniela DE CRESCENZO

Faculty of Architecture, University of Naples, Italy
e-mail: daniela_de_crescenzo@hotmail.com

Abstract

In a society where economic problems and the continuous transformation of the environment make unthinkable built huge and long term projects, is coming out a new way of conceiving architecture: beautifully designed structures, projected to last for a short time, replacing traditional architectures, which become multifunctional containers able to accommodate concerts and shows, expositions and museums but also transportable residences with dynamic design which are able to appear and disappear within a week or less. Temporary architectures have not many of the constraints which weigh on traditional buildings and so architects can act with more creativity, playing with different materials and structures that often cross the boundary between architecture and art.

Remaining in a constant balance between *less* - quick construction and quick dismantling of the structure, small size and low cost - and *more* - careful choice of materials, wide range of uses and highly innovative - the temporary architectures, with their forms, are expression of the actual time, unstable and constantly changing, assuming the features of attractors of the contemporaneity.

Keywords: temporary, quick, innovative

1. Temporary architectures

In a society where economic problems and the continuous transformation of the environment make unthinkable built huge and long term projects, is coming out a new way of conceiving architecture: beautifully designed structures, projected to last for a short time, replacing traditional architectures, which become multifunctional containers able to accommodate concerts and shows, expositions and museums but also transportable residences with dynamic design which are able to appear and disappear within a week or less.

By definition, architecture is something temporary and its ephemeral component is closely tied to the quality of the construction elements but also the time factor plays a key role in major cities, constantly subject to trasformation that challenge even the most architectures consolidated.

1.1 Pavilions

Great protagonists of contemporary architecture become the exhibition pavilions which in most cases already have a date of demolition but may also exist some exceptions proving the different meanings of the term "temporary" in architecture. The Eifel Tower is the most prominent example of how structures basically "useless" can become a symbol of the city hosting them: built as the gateway for Expo 1889, although at first it was planned to keep it up only twenty years, today is the most visited monument in the world.

The architectures designed for large international events such as the **Expo 2010 of Shanghai**, China, is an important driver for the design and construction of ambitious temporary buildings, as demonstrated by the **Spanish Pavilion**, designed by **Benedetta Tagliabue** (Miralles Tagliabue EMBT), a steel structure that uses a complex three-dimensional grid of tubular elements created with computer technology, the most visible

element of which is a cloud of wicker, which makes the pavilion an irregular and movement structure. Selected as a typical example of Spanish handicraft, architects have placed the wicker so as to form Chinese ideograms alluding to the friendship between Spain and China. The solidity of the other pavilions here is replaced by a temporary appearance, suitable for an event like the Expo 2010, where folklore, national pride and strong modern are combined.

Another notable contemporary structure, built in 2010, is the pavilion **21 Mini Opera Space**, designed by **Coop Himmelb(l)au**, installed in Marstallplatz of Monaco, Germany. Through forms obtained with the computer, the pavilion 21 has the classic pointed shape easily recognizable in the work of Coop Himmelb(l)au. This remarkable explosion has allowed to experiment a touch of contemporary architecture that probably would not have been accepted so willingly if it was permanent.

The stone house, designed by **John Pawson** at the Salone Internazionale del Mobile 2010 in Milan, for the Think Tank Interior, on land within the University of Milan, gave a good impression of minimalist solidity despite its ephemeral character. The project also highlights another advantage of contemporary architecture: to build the structure, in fact, has been used the Lithoverde, an innovative recycled material consisting for the 99% from waste of the stone and for the 1% from natural resin. Located in an architectural context in which modernity could not be the easiest choice, the look hard, almost funereal of the stone house made her look older of the surrounding buildings.

Solidity is not the watchword in the case of many contemporary pavilions. **Rendez-Vous** (Tokyo, Japan), a structure of 52mq designed by studio **Atelier Bow-Wow**, Tokyo, was an installation mostly made of bamboo that was at odds with the rigidity of the near National Museum of Modern Art by Yoshiro Taniguchi. The young Japanese architects said they would "mitigate the feeling of austerity, while maintaining the respectability of the place but at the same time lightening the atmosphere, to make it a nicer place." Thanks to the flexibility of the bamboo, Atelier Bow-Wow has wanted to push his idea to the extreme, imagining a giant animal that runs through the woods of the Imperial Palace. This playful way to deal the temporary architecture also represents a contrast with the dense urban fabric of the surrounding city.

Another lightweight structure is the research pavilion of the **ICD/ ITKE**, designed in 2010 by the **Institute for Computational Design (ICD)** and the **Institute of Constructive Elements and Structural Design (ITKE)**, both managed by the University of Stuttgart. Built entirely with strips of birch plywood bent, the building consisted of at least 500 different items designed by robots and products in the establishment robotic's of University.

Fig. 2: Coop Himmelb(l)au, Pavilion 21 Mini Opera Space, Munich, Germany, 2008-10.

Fig. 3: ICD/ITKE, ICD/ITKE Research Pavilion, Stuttgart, Germany, 2010.

1.2 Container

Many architects have realized that the containers, symbol of a globalized economy, can easily turn into a home or shops. Curiously, in this case, objects that are designed to be moved may instead be anchored to the ground, where they can prove to be more solid and durable of the traditional architectures. A container classic is made of galvanized steel and corrugated and may be long or 6 or 12 m. Generally it is possible to stack up to a maximum of seven units by means of hooks standard. A steel box is not the most appropriate structure for a house or other building, and yet in the early eighties the ISO containers began to be used precisely for this purpose.

Phillip Clark, owner of a company Miami's in 1989 obtained a patent for a "method for transforming one or more containers steel in a house inside of a building site or as a product of the yard". But previously, in 1985, the Australian architect **Sean Godsell** informed that he had started working at the hut of the Future, "a home-transferable, mass-produced for use as emergency housing. The container recycled acts as the main volume of the dwelling while a canopy is introduced inside the container. When it is mounted, the canopy will shade to the container, reducing the thermal load. By the container will come out the support columns, to be able to place without having to make excavations in rugged terrain" [1].

The American architect **Adam Kalkin** has specialized in architectures based on container. He is the creator of a system, called **Quik House**, a kit consisting of a prefabricated house designed by the same Kalkin using recycled containers. The house consists of three bedrooms and two bathrooms and a toilet. The architect says: "The outer casing can be mounted in one day, you will get a completely enclosed building. From start to finish it should take no more than three months to finish the house". Can be stacked on each other four or five or more containers with orange or natural rust finish, within five months from the time they are ordered at a cost that can range from \$ 76,000 up, including shipping costs. His house **Illy Push Botton**, exhibited at the Venice Biennale in 2007, is just to show how to transform in a few minutes a simple container in a real house with hydraulic systems and an intelligent design [2].

The **COP 15** pavilion of the study of architecture **MAPT**, located in the northern port of Copenhagen (Denmark, 2009-2010), using used containers and other recycled materials will fit in the efforts made by cities to encourage sustainable urban development. Underlining aspects such as the reduced price and sustainability, MAPT is noted that the containers are deemed so devoid of economic value that sometimes the transport company estimate that is more convenient to abandon them that bring empty to their point of origin. After exposure, the city will use two containers as a venue for cultural events and local meetings.

The Italian study **tamassociati** has created **Emergency NGO housing** at the Salam Centre for Cardiac Surgery (Soba, Khartoum, Sudan, 2009), with 95 containers of 6 m intended for housing and other seven 12 m used as a café. Obviously the steel transmits the cold or warm, almost instantly, which is one of the disadvantages of the container when they are used as housing. The architects have solved the problem by means of insulating panels of 5 cm inside the structure and by a system of sunscreens in bamboo which avoids the direct irradiation of the steel. It was tested an innovative conditioning system with a solar panel and a refrigerating machine which will allow to considerably reduce energy consumption. The solar panels also provide hot water to the entire complex.

1.3 Stand

By a long time now, the exhibition stands are an area of experimentation in contemporary architecture. Since these structures do not usually have to bear heavy weights or perform the traditional functions in architecture, can explore new lands or neglecting certain rules of construction. It also aren't exclusive competence of architects, because in this area are also present designers, sometimes specialized.

The architects of Madrid **Camila Aybar** and **Juan José Mateos** design stands for the glass manufacturer **Vitro** to the IFEMA fairgrounds in Madrid since 2006. That of 2006 was constructed with at least 170 tonnes of glass from 25,000 pieces recovered by the remnants of the cuts of larger sheets of glass. The mounting technique employed by architects had created effects compared to the works of artists like Bill Viola and James Turrell. If it comes to visual effects this type of stand suggests more a work of art that an architectural element in the traditional sense. Surely this is one of the reasons that makes this industry so interesting for architects. Aybar and Mateos have used the glass as a malleable material and variable because, if on the one hand is able to create an artistic effect, on the other decants the virtues of the products of the customer.

The draft by **Ammar Eloueini** for exposure of 2008 "**The Tramway**" in the Pavillon de l'Arsenal in Paris examined the new tram lines in Paris, that should be turn around the city along the Boulevard de Maréchaux. Installed on the upper level of the pavilion, which has a large empty space with a bridge, the show used a polycarbonate "skin" suspended in the middle of this space by dividing it. The use of this type of light materials, present also in the retail sale, exemplifies the ability of the architect to take space in a manner similar to that who are looking the artists, occupying it and turning it, while maintaining, at least in this case, just a reminder of their intervention at the conclusion of the show.

Fig. 6: Ammar Eloueini, "Le Tramway", Paviillon de l'Arsenal, Paris, France, 2008.

1.4 Shows

The term "ephemeral" in its original meaning ("that lasts only one day") could easily apply to architecture for events such as concerts: are significant in this area the shows of the major rock bands, that does not skimp on resources and on size. The British architect **Mark Fisher** has designed the sets most publicized of the Rolling Stones, U2 and Pink Floyd. Among his most important projects, the sets for the world tour of 2005 by Rolling Stone, "**A Bigger Bang**" that combined the idea of "decadent fantasies and colorful decorations of the great opera houses of the nineteenth century" with a high resolution screens and an innovative arrangement of seats, which had to remember the stages of opera. The fundamental structure, which required 30 hours of assembly, was composed mainly of standard components for rent.

For next performances were needed three sets of basic structures. Only panels, video screens, stage and other technical components travelling show by show, were installed in the last 24 hours prior to the show and were removed immediately after for being transported to the next town.

The laptop upper structure weighing 180 tons, designed by Fisher for the U2 world tour, "**360 °**" (2009-2011) not only surrounds the stage, which resembles a spider, but also several thousand spectators, and at the same time also serves to support 200 tonnes of technical equipment. As the name of the tour, the structure is made so that viewers can see the band from all angles.

Mark Fisher is the author of one of the most amazing opening ceremony of the Beijing 2008 Olympic Games, the "**Dream Sphere**," a globe of 19 m, consisting of nine latitudinal rings, hanging from a tree capable of supporting 60 people during the show. The surprising spherical structure, combined with lighting and the acrobatic performances of the participants, give to this project an unreal and fantastic.

An example a little less extreme of spectacular architecture is the **Massimiliano** and **Doriana Fuksas** setting for **Medea and Oedipus at Colonus** of greek theater of Syracuse (Italy, 2009). Based on the concept of catharsis and on the idea of the lost horizon of the first representations of these ancient tragedies of Euripides and Sophocles, the architects envisioned a "concave blade" that acts as a mirror to the action stage and involves the audience, inviting to reflection. This reduction to simple and pure forms is in perfect harmony with the power of the plays represented on stage. Once again, freed from constraints such as weight or functionality, Fuksas architects are able to prove that they are able to break the shape and to reframe the issue of space.

Fig. 7: Mark Fisher, U2, 360°World Tour, 2009-11.

1.5 Temporary additions

If at times the temporary architecture is ideal to create architectural innovations away from traditional patterns, in other occasions it is necessary to pay great attention to its functional aspect, especially in cases where it is used for expansions of existing structures.

The inventive studio of New York **Diller Scofidio + Renfro**, who in the past had built a structure shaped like a cloud (the Blur building for Expo '02, Yverdon - le Bains, Switzerland, 2000-2002), proposed a "**Bubble**" for the temporary expansion of Hirshhorn Museum in Washington. This pneumatic membrane, designed to accommodate up to 1,000 people will be mounted twice a year, in spring and autumn, and pushed out of the central courtyard of the modern structure without touching the internal surfaces. The idea of an elastic space, in the context of a strictly modern building, is something very contemporary and the inflatable structure is one of the most obvious manifestations of ephemeral architecture.

In a completely different style, the French multimedia artist **Laurent Grasso** and his brother, the architect **Pascal Grasso**, have created a small restaurant temporarily mounted on the roof of the Palais de Tokyo in Paris between April and June 2009. Call "**Nomiya**", this 18 m long structure was built in two parts in a shipyard and consists of a glass booth with a perforated metal screen that covers the central cooking area, between the metal coating of the glass structure and the heart were introduced LED lights.

Working in turn with obvious practical limitations, the dutch architects **Ira Koers** and **Roelof Mulder** had accepted the daunting task of creating a temporary structure for the **library of the University of Amsterdam**. Although this was an area of 2,300 square meters and 235 workstations, the budget for this project was quite modest. Koers and Mulder were able to associate bright colours (1,105 red boxes to hold the books) to an abstract feature, that offering ample spaces for reflection, which earned the project The Great Indoors Award 2009.

Although some interesting temporary projects can escape the limitations of traditional architecture, both brothers Grasso that the duo Koers/ Mulder are managed to give life to ephemeral environments that have been successful because of their looks but also for the efficiency solutions which they have been able to solve practical problems relating to their duties.

Fig. 8: Laurent & Pascal Grasso, Nomiya, Palais de Tokyo, Paris, France, 2009.

1.6 Houses

For the temporary architecture, as well as for the permanent, one of the most significant is to stay the human being. Modernity has brought increasingly to the fore the transient solutions. We have already discussed the use of containers to create homes to be transported easily, but there are other categories of temporary accommodation.

The German designer **Werner Aisslinger**, inventor of Loftcube, a temporary home to use as an installation on a roof (2003), has created more recently **Fincube**, a "modular home, sustainable, portable and by low power consumption" (2010). The fact that the site preparation is minimized, and the use of recyclable and durable materials, such as larch, are the most noteworthy aspects of this project, which provides answers to many questions on housing, such as the nomadic lifestyle coveted by certain populations, including developed countries.

At last, the New York architecture firm **OBRA** created a prototype house emergency (**Red + Housing**) for exhibition in China set up a year after the devastating earthquake in Sichuan province in May 2008. Using red cloth for parachutes and plywood, OBRA was demonstrating that "in terms of planning, the emergency accommodation is no more than an extreme form of architecture." With a surface area of 45 square meters and an estimated cost of \$ 5,000, this type of housing, made from renewable materials and prefabricated, was thought to be cheap, portable and easy to assemble.

Finally, there is no doubt that the whole architecture is temporary, although some structures are created to last longer than others, the interest by ephemeral architecture lies primarily in its design process: temporary architectures have not many of the constraints which weigh on traditional buildings and so architects can act with more creativity, playing with different materials and structures that often cross the boundary between architecture and art.

Remaining in a constant balance between *less* - quick construction and quick dismantling of the structure, small size and low cost - and *more* - careful choice of materials, wide range of uses and highly innovative - the temporary architectures, with their forms, are expression of the actual time, unstable and constantly changing, assuming the features of attractors of the contemporaneity.

Abstract

Eco-efficiency for the historic environment is decisive for energy-conservation, especially in the case of the Italian "traditional" urban heritage. The complexity and the heterogeneity of "the traditional dwelling" force to define the specific analytic tools and procedures to survey its Energy-behavior. The latest applications on rating the energy-environmental performance of historic buildings, such as Project A.T.T.E.S.S., US LEED, and GBC LEED have represented the reference points of this paper. The understanding of the specific Energy-environmental performances as well as the energy-lacks and losses, and the reasons why they bred, would be essential to set compatibly up a consistent conservation strategy for these fabrics today. The rehabilitation, the reuse, the updated development of the features and the configurations that the traditional dwelling has taken throughout its history within its surroundings, creating a *local material culture* based on the bioclimatic criterions, represents a proper strategy to achieve the suggested goals. Defining how these buildings have historically found the practical solutions for the bioclimatic-environmental peculiarities and how these features have been altered during the time, this work tries to suggest a procedure for a specific rehabilitation compatibly with the conservation of the building. The study has been applied to survey a "traditional" block in the old town of Sarno (SA) erected between the eighteenth and the early twentieth century. With the support of the building-stratigraphy and of digital ortho-photography and thermograph IRT surveys an articulate comparison has been developed among several structures that have been differently altered and changed in the course of time, considering some possible and sustainable ways for their energy-improvement.

Parole chiave: *traditional* building, energy efficiency improvement, thermograph IRT

1. The building heritage energy-environmental improvement [1]

Eco-efficiency for the historic environment is decisive to elaborate proper territory planning policies, as it entails sustainable consumptions and the best energy-environmental performances. As a matter of fact the sustainability – which involves a reduction of the ecological footprint as produced by each organism to maintain its functioning – represents a typical prerogative of an historic architecture, only if the coherent and continuous building functioning has not been altered and compromised, introducing frames and systems that have interrupted this organic working. Especially in the second part of the twentieth century, the outcomes of many building restructurings and renovations have often unwittingly and deeply compromised the main qualities of the traditional architectonic production, by removing and modifying authentic components and frames. The substitution of materials, elements and frameworks (as stones, plasters, floors and pavements, facings, casings, systems, vaults, wooden roofs and floors), which represent the material attestations of a traditional regional culture with products and arrangements that have shown themselves incompatible from a physical-chemical viewpoint, the building increase at height, the blocking up of inner courtyards and common external areas, as well as the balconies, terraces and verandas bricking up, these all are indeed actions that basically modify the energy-environmental historic buildings behavior, as well as they can influence the complex of relations that each fabric establishes with the next structures thanks to different bond aggregation typologies. Indeed the way whereby buildings aggregate to themselves forming an urban

block influences this behavior too. The alteration of the proper historical building resources, especially the bioclimatic ones, has increased the energy-consumptions causing by the heating and air-conditioning systems installation, with the environmental pollution outcomes that we all know well.

The understanding and the qualitative-quantitative rating of the energy-environmental historical building behavior are decisive to define instruments and procedures for reducing consumptions and eco-footprints. The more, trough the accurate comprehension and recording of fabric operating modes in the course of history it's possible to reach the "energy efficiency enhancement" adopting criterions and proceedings compatibly with a real conservation of the cultural heritage [2]. This must be a priority for the contemporary energy issue, above all within a context as the Italian one so much characterized by a wide presence of this kind of handworks.

A realistic rating of energy-environmental historical building behavior firstly entails the understanding of its dynamics as the environmental and temporal specific conditions change. Several researches have recently tried to respond to the reported demands. Waiting for the MiBac "Guidelines for the energy efficiency for the cultural heritage" coming on, because of which some well-know representatives of the architectural restoration and of the technological research have collaborated to the preparatory studies, in Italy the A.T.T.E.S.S. Project distinguishes itself particularly. The whole program comes from the partnership among "Bio-building Meta-district of Veneto", "Cultural Environment Meta-district of Veneto" and "Cultural and Landscape Environment Regional Direction of Veneto", with the involvement of IUAV and the University of Udine, among other corporations and bodies [3]. The "Guidelines for environmental sustainability in historic buildings" therein developed suggest a rating methodology of the energy-environmental, historical, building, behavior, fusing together the environmental design principles with the fabric investigation methods derived from architectural restoration and technological research. Basing on an analytic, *in situ* fabric survey on the typological, morphological, functional, environmental and building factors that can influence this behavior, actually the research has overcome limits and deficiencies presented by the ITACA Protocol applied to historic fabrics [3]. Thanks to dedicated software, A.T.T.E.S.S. method allows also a dynamic, eco-consumptions, building reading as the specific environmental parameters change. However, it's important also to underline that the potential, fabric, energy contributions emerge through *in situ*, building investigation. According to the principles of sustainable conservation culture these "proper resources" could be above all exploited through a more appropriate use of the specific, massive, masonry behavior, as well as through the rehabilitation and the updated development of features and configurations, which have allowed to better use local, environment qualities historically.

A critical understanding and interpretation process representing the typical conservation approach is decisive to identify building materials and techniques, as well as typological, functional, morphological and historical, building aspects of a cultural asset and then its patterns of operations and working modes. As a result diseases and their roots can be dealt with designing compatible "exploiting"

Fig. 1: Sarno (SA), map of the city, abstract. Above left are the city *castrum* medieval ruins and walls and the ancient built-up area of *Terravecchia* below.

Fig. 2: Sarno (SA), inner-city. Still today it's ordinary to substitute "traditional" building components with incompatible materials and features.

operation plans. That means project plan must take historical building to its optimal performance levels by protecting authentic material assessments too. From a quantitative viewpoint these goals achievement can be difficulty standardized and *a priori* graded, because historical, building, performance levels are consequences of specific fabric arrangements and local conditions too, as they have evolved with time. Thereby default, performance levels cannot be achieved by standard, operating, constructive procedures, in particular if planning actions are "invasive" as, for instance, when using exterior insulation and finishing system (EIFS) called "thermal coating", usually recommended in case of fabric on which it works is not a listed one.

2. The traditional heritage and its energy-environmental improvement

The so-called *traditional* heritage is a substantial part of building estate because it represents the whole unlisted, historical, architectural production. Its energy consumption and eco-footprint rationalization and reduction represent a priority, provided these aims fulfillment does not contrast the protection of *cultural meanings* materially stratified in local building tradition. Knowledge, information and memory so stratified are not less significant than what masterpieces and famous building can stand for. They all are *cultural assessments* and to be protected. Consequently according to restoration methodological unity principle, the same conservation design approaches reserved to the main sights are to be reserved to traditional heritage too, as developed by regional constructive cultures. Even if urban restoration building designs sometimes caused conflicting outcomes right on conservation viewpoint, without having official landmark status and specific urban restoration planning policies, old town traditional heritage was left to property speculation arrogance and to the most reckless unauthorized building particularly, never actually prevented by development planning public policies. Moreover the removal of traditional building materials, components and frames, which widely affected traditional heritage during later 50-70 years, was further encouraged by architects' substantial misunderstanding of traditional constructive culture patterns of operations and working modes. So it was for wooden floors and roofs, masonry vaults, pavements, plasters and facings, frames and casings and so on. Only after their removal the incompatible physical-chemical reactions of new materials and building procedures were recorded. To avoid these mistakes it's necessary a careful "fabric learning program" to detect building prerogatives, resources and crucial matters, which are the main elements of an appropriate conservation plan. The restoration methodology just focus on these aims, so it could be profitably used for solving energy-environmental matters. The critical learning process by which the conservation architect detects historical handworks focus on building deterioration pathologies and then on factors and reasons leading to them, establishing actual building

conditions. These are the conservation plan requirements to remove pathology phenomena without compromising cultural assessments safeguard, rather enhanced thanks to new compatible building materials and features. By a close rigorous building survey, also supported by specific methodological tools as, for instance, the masonry-stratigraphy, it's possible to record building and bearing-wall discontinuities, so favouring specifically proper crucial matters and pathologies recognition and solution. The use of the mentioned learning building process represents therefore the focus role as to this paper targets, detecting building factors and behaviors, which jeopardized building working modes in the course of time, causing the worsening building performances. In particular, this methodological approach involves also the record of the bioclimatic building prerogatives removed or abused by recent past renovation works. The rehabilitation, the updated development of features and configuration the traditional dwelling has taken throughout its history within its surroundings, meeting its specific environment requirements, can represent a sustainable strategy to decrease energy-environmental matters, especially if the building working context widely altered by above mentioned renovation works.

3. Learning approach and applications

To elaborate a methodological proposal replying in a practical experience the above mentioned concerns, a traditional urban block in the old town of Sarno (SA) has been chosen for operating on. The sample building block is particularly representative, including different altered configurations and features by the 20th century second part renovation works, favouring more careful considerations about their influences on the energy-environmental matters. This urban block transforming building dynamics recorded throughout its history thanks to archives documentary survey, iconography and historical, contemporary cartography collection, in comparison with the *in situ* building analysis data-gathering. The building census involved each fabric including in the sample block, concerning its material, technical, typological, morphological, functional and environmental qualities, recording building-up and shapes as well as actual deterioration phenomena, especially the ones influence the specific thermal-hygrometric behavior. Building survey concerned walls - with special focus on the external ones as well as on skirting, tops and eaves - floors, roofing, plasters and pavements. Considering building facing walls the morphological, typological and room layouts analysis focused on basements, ground-floors, hall-ways, inner courtyards, common external spaces, staircases, verandas, balconies, terraces and attics, also recording the actual distances among facades, facing streets and external spaces, often altered by recent building renovation works substantially.

Fig. 3: Sarno (SA), piazza M. Capua. On left is “palazzo Ungaro”, one of the most interesting fabric of 18th century.

Fig. 4: Sarno (SA), via Cavour, sample block, Est front. (designer M. Bicco). Above is the northern part, below the southern one.

Technological and systems survey concerned frames, gutters, downspouts, heating and air-conditioning systems, as well as ancient wells and cisterns, useless fireplaces, brick ovens and chimneypots. Thanks to masonry-stratigraphy and thermography IR surveys the *in situ* data-gathering recording enabled to detect main building discontinuities, as well as the organic fabric behavior lacks and losses. Traditional buildings materials and features removals by the reinforced concrete elements introduction (as floors, frames, roofs, cantilever floor slab, etc.), the walls breaking through because of wider or new-opened windows and doors, these all “masonry walls-box” renovation works deeply altered the masonry massive behavior and so the related performances. But these building discontinuities represent precious clues to understand each fabric historical transforming dynamics in the light of the building block changing in the course of time, detecting the previous features and configurations, whose rehabilitation and updated development can be useful for dealing with the energy-environmental matters.

4. The historical context and the environment qualities

The town of Sarno's is one the main center of the homonymous river Valley, the heart of Latins' *Campania Felix*, called *Royal Valley* under the *Angiò's* dynasty in the late Middle Age. Placed among the districts Salerno, Avellino and Napoli, in ancient times this valley had been characterized by frequent inhabitations, being crossed by a stretch of the Roman *Popilian Way*, which linked Capua to Reggio, along the Nola-Palma-Sarno-Nocera itinerary [4].

But the geological characteristics of this side have always jeopardized the environmental development. The plain consists of alluviums and volcanic melted deposits. Behind Sarno's inner city the mountainsides cover with different deposits, which made them seriously shifting [5]. Historically, landslides often disrupted the built-up area, as the latest event on 5th May 1998.

Sarno's inner city urban framework is a NW-SE bounded spindle-shaped at the foot of the mountainsides, bordering Nola's Plain northwards and Lattari's Mountains southwards. Depending on the layout of Nola-Palma-Sarno-Nocera ancient road, the historical urban spindle-shaped development lengthways shaped-up by sloping belts. This distinctive feature of the Sarno's old town framework “made it exemplar within the national urban survey” [6].

The more ancient built-up area (*Cibitate veteri*) is placed at the foot of Sarno's Monte about in the 11th century. The *castrum* was founded in the Middle Ages, although its ruins, as the urban-walls ones, can be dated between the end of the 12th and the 13th centuries, with developments and renovation works can be dated back to the *Angiò's* and *Aragona's* ages (Fig. 1). The more ancient built-up area called *Terravecchia* was walled between the end of the 12th and the mid-thirteenth centuries, widening the *castrum* fortified circuit. Between the 16th and the 17th centuries the ancient centre developed

westwards, ensuing from the earliest factories economy and population increase. Thanks to the mills they produced flax, flours and paper. Since the 18th century, in the second fifty years above all, the urban area spread over the next sloping belt, beginning to build along the inner side of ancient Nola-Palma-Sarno-Nocera's road [7]. This urban development historical phase ended within the end of the 19th and the early 20th centuries, when the industrial revolution reached its peak thanks to spinning particularly [8]. Only by the 20th century, second fifty years, property speculation the building development blocked up the plain area, until then visibly left free because of the above mentioned geological qualities.

The sample urban block stretched trapezium-shaped occupies the southern side of the 18th-19th centuries urban sloping belt (Fig. 7). The NW building block head overlooks to M. Capua's Square, the ancient *Capo dell'Orto* place, where two important eighteenth century fabrics front onto: *Immacolata's* Church built in 1752 with a precious Nocera's tuff stone portal, and *Ungaro's* Palace, which still maintains the original granary attic, even if heavy transformed by the latest renovation works.

The sample block building use began below, in the west side on the Nola-Palma-Sarno-Nocera's way inner portion (via R. Laudisio). Except the northern portion, as we said, just urbanized, most of the east side was built during the late 18th and the early 20th centuries (via Cavour), as the smaller block head and its surrounding fronted onto XXIV Maggio Square. A second world war air raid hardly strake down the sample block about in the middle. Still today few ruins are maintained with interesting assessments on via Cavour, while a flight of terraces clears the height difference between the two main streets (about 3 m).

5. Learning approach and outcomes

Comparing today properties distribution with the first cadastral map (1877) and others archive data, some proper architecture qualities pointed out interesting analysis factors [9]. The map shows minute cadastral parceling out with the exception of only two large properties (Fig. 8). As in coeval urban belt the sample block prevailing building typology is so-called *casa palazziata*, an eighteenth century urban gentry dwelling from Napoli, in which the owner's apartment was on the foreground, while other two floors rented. With inner courtyard open on a garden just opposite the entrance this fabric was roofed as well as covered terrace. In the sample block this building typology first occupied the west side, while gardens were lied to east. The 3-storey fabric, sometimes with an attic too, has the main body on the street with *botteghe* and a vaulted masonry entrance with local stone portal. At opposite ends of the courtyard were service rooms, warehouse and cellar. Sometimes these dwellings had a well (Fig. 8: nn. 3601 and 4510). Above all it were widely attested fireplaces and walled chimneypots [10].

Fig. 5. Sarno (SA), sample block, cross-views (designer M. Bicco)

Figg. 6-7: Sarno (SA), sample block, West front and plan (designer M. Bicco).

Respect of *Strada di Sotto* (today via R. Laudisio) the *Strada Sopra Capo dell'Orto* way (today via Cavour) was a secondary one, maybe because more opened to flood risks. From the top, where was *Slargo di Capo dell'Orto*, the homonymous way slopes to south-east, stopping at XXIV Maggio Piazza. The building use of this side of the sample block is dated between the late 18th and the early 20th centuries as other *case palazziate* attest today. This building operation probably occurred together with the way widening and rectification work, as its morphology suggests.

The other historical building typology characterizes the sample block is represented by more modest *casa privata* [11]. In the 18th century these dwellings had two floors and sometimes the second one was shared in two different small apartments. The main body was a block with external staircase. More similar building bodies joined around common small inner courts during the course of time, in particular on the block NW side and middle portion. Since the end of the 18th century a gradual building development of these typologies occupied every free space, but only in the second part of the 20th century this increase blocked up courtyards as small inner courts.

5.1. Building materials and procedures

The traditional masonry is built with *pietra di Sarno*, a local type of limestone that normally appears very unhomogeneous and stratified, is slightly manufactured to the horizontal layers and assembled in periodical horizontal courses. At the ground floor level the thickness of the masonry is about 1.50 mt. The basements and vestibules normally present vaulted roofs with the exception of a single wooden ceiling supported by chestnut rounded beams, according to the supposed traditional predominant ceiling shape. At present the original ceilings have been generally replaced with modern concrete

Fig. 8: Sarno, “Mappa urbana desunta dalla mappa originale rilevata nell’anno 1877 ed aggiornata nel 1903”, foglio XX, allegato D, scala 1:1000.

structures. Similarly the original roofing – which presumably presented a pitched structure with the attic used as granary similar to the above mentioned *Palazzo Ungaro* – has been generally replaced with terrace roofing built with modern materials (bricks/concrete) and covered by a waterproof bituminous surface. The coating and stucco didn’t have a better luck. The original lime plaster has been often replaced with cement plaster, this is confirmed by the evidences of decay on the facades. The external pavings – made either in beaten lapillus or in vesuvian stone (*pietrarsa*) slabs – still present original evidences worth of interest. Yet the original timber door and windows frames, with the exception of a few houses that retain the early 20th century frames, have been replaced with anodized aluminium frames. Fortunately the original carved stone features, such as portals and balcony slabs made in local gray sandstone (*tufo grigio di Nocera*), are still *in situ*.

The greater alterations, which are the main topic of the present paper, mainly occurred in the second half of the 20th Century and increased the intense construction activity that had started at the end of the 19th Century filling all the available urban void. Besides the traditional materials and features being generally replaced with modern elements and construction systems which were not compatible with the physics and chemistry of the historic fabrics, the open public and private spaces were considerable reduced. To the internal small courtyards (*vanelle*), with no consideration of the limited available surface, full height building extensions were carried out, the openings of balconies were sealed with glazing surfaces or built up with bricks and cement blocks. The external/opened staircases, which were important common areas, were built up too. These alterations led to a major heavy reduction of both natural lighting and air ingress to the interior areas.

Not compatible material use to facing and covering pavements and floors increased damp and moisture deterioration phenomena, as on the east side widely attacked by biological deterioration events. Missing gutters and downspouts maintenance work these problems recently worsed.

With the support of digital ortho-photography and thermography IRT surveys – thanks to Phd “Conservation of architectural heritage” Arch. Luca Ferri (BECON s.c.a.r.l.) – the building block analysis underlined lacks and malfunctions caused by contemporary renovation works. Especially it recorded energy losses provoked by not compatible material and procedure use (modern concrete structures, brick/concrete ceilings, chimneypots removal, not transpiring plasters, etc.), as well as damp, moisture, biology deterioration wall phenomena. Moreover thermography IRT survey detected building discontinuities, supporting historical development building understanding (Fig. 9).

Fig. 9: Sarno (SA), sample block, inner southern front. The thermography IRT proves the masonry stratigraphy.

6. Conclusions

Although as abstract of an outgoing research to elaborate methodologically the operation aspects of the traditional heritage energy efficiency improvement, this first part of the study focuses on proving how these aims are consequences of the removal of the deterioration effects provoked by recent building materials and procedure not compatible uses. Contrary to the energy behavior adjustment operations fixed to a standard performance, the energy efficiency improvement focus on proper building qualities compatible exploitation. From the energy viewpoint that means massive masonry behavior and bioclimatic functions exploitation, reducing consumptions. According to sustainable conservation the rest of these consumptions can be satisfied by energy renewable sources, using common central systems as well as the newest photovoltaic devices on films and woven. According to the same principles building eco-footprints can be reduced too, defining settings and perspectives without further on compromising historical heritage and environment.

Measuring and Representing the city: past and present in Giovanni Antonio Dosio's map of Rome (1561)

Antonella MARCIANO

E-mail a.marciano@unina.it

Abstract

In 1561 Bartolomeo Faletti published Giovanni Antonio Dosio's map of Rome, just ten years after Leonardo Bufalini's plan (1551), the first printed map of the city. If Bufalini's plan reveals an antiquarian and conceptual vision, by including many ancient monuments depicted as complete even if they were only ruins or totally disappeared, Dosio's map is a step towards a new objectivity, it is a clear synthesis of past and present: contemporary architectures appear with their real aspect, such as St. Peter's dome under construction. The aim of this work is to focus on the method Dosio used to make the map, a landmark example of his strategy in measuring, drawing and representing the ancient and contemporary city. Furthermore, other specific topic is his ability to synthesize single volumes drawing few signs and giving a lot of informations with less. This will be shown through some examples from his great graphic corpus and by reconsidering his technique in the cultural context of late sixteenth – century Rome, suspended between antiquarian tension and the beginning of technical and scientific survey.

Key words: Dosio plan Rome topography

Ancient Rome inspired researchers, artists, authors, and as it's known, it's in the Renaissance that an increasing attention on the rules that drive the classical architecture was manifested, and the interest in the ancient city is at its maximum curiosity. At the end of the fifteenth century even the urban survey is again considered to be an essential discipline to understand the city and the territory, especially for military purpose. At the same time there is an evolution of the direct and indirect measurement systems, and begins to take place the treatises of the subject. Regarding this we can remember Leon Battista Alberti's *Descriptio Urbis Romae* of the 1450, of which the related drawing, no more available, included the perimeter of the city consisting of the Aurelian Walls, and some architectural landmarks, while we have the scripts accompanying the map, where the working methods and surveying systems are explained. The instruments used were principally a protractor fitted with magnetic needles for land surveying, a graduated mobile radius, a rod target and a plumb bob [1]. As far as we know, the plan's scheme was based on a virtual circle that lays out surrounding the city so that all points within Aurelian Walls can be referenced by the circle's coordinates. Leonardo Da Vinci's map of Imola, designed for Cesare Borgia in 1502 can be considered the first modern plan of an Italian town, but for its uniqueness it has remained an "*unicum*" example for centuries, not only for choosing the orthogonal view, also for the precision with which the individual buildings were shown, the differently coloured yards of each block, and the most important buildings of which the plan is also delineated. This map anticipates nearly two centuries the eighteenth cadastral mapping of property. During the XVI and XVII century, the development of surveying instruments and the possibility of measuring precisely the distances between buildings for plotting them on a map, favored numerous publications whose audience was made up by antiquarians and scholars who exchanged information on the ancient Rome, by the pilgrims flocking to the capital of the Christian world, to those who admired the magnificent modern architecture of the "*Roma Risorta*". Since 1551 to 1650 many new city maps were published, the production increased especially in the Holy Years (1575, 1600, 1625) [2]. Many of these maps went lost, others are literally around the world because were sought after by many collectors and some of them became also unavailable. Among the authors of

the plans there is the young architect Giovanni Antonio Dosio (San Gimignano 1533 - Caserta 1611) [3] that left his native town San Gimignano, not far from Florence, to go to Rome, where he first worked for Raffaello Montelupo, his first mentor, then under the protective wings of his first clients and patrons, Torquato Conti, Annibal Caro, Ippolito d'Este, devoting himself to antiquity and to contemporary architectures. His presence is documented by the most important roman sites as St. Peter, the Campidoglio, and Del Monte's Chapel. We also can find him designing and setting up the garden with ancient statues at Villa Giulia and at the casino of the Boschetto in Vaticano. In this period there were available polymeters, surveying magnetic compasses and primitive theodolites, and Dosio was a skilled surveyor. In 1561 he drew for the presses of the publisher Bartolomeo Faletti [4] a perspective map of Rome, engraved by Sebastiano Del Re, with a north-south orientation, the south on the top, where appears the written "Meridie". The map is an engraving with etching and measures 42X 55,5 cm [5]. At lower left there is the inscription: "GAB. PALAEO TIO PONTIFICO STLITIB IUDICANDIS DUODECIMVIRO INTEGERRIMO. Expressi iandudum mi Reuer. Dne meis aeneis tabellis Io. Antonii / Dosii floren. manu delineatis Urbem Romam Urbium, ac Terraru, / gentiumq, omnium, Reginam qualis qualis his temporibus apparet, / et, ut ea in lucem prodiret audentius, tuo nomini dicata exit, quod hu- / iusce Urbis te amantissimum fuisse semper accepi: proinde editam / tibi, do, dicoq, ac trado. Vale Barptolaemei Phaletii tui nominis semp / obseruantissimi memor. Romae Calendis Ianuarii MDLXI. Sebastianus a Regibus Clodiensis in aere incidemat". Dosio's map represents Rome around the 1555, period in which Giulio III (1550-1555), born Giovanni Maria Ciocchi del Monte, died after a short but intense pontificate, spent in excesses and complicated by hard health problems: «22 marzo: alle ore 19 di detto di morì Papa Giulio III nel Vaticano, e sparato vogliono dire che morisse per le troppe medicine che usava pigliare+[6]. Giovanni Antonio Dosio's bird's-eye view shows an original orientation of the map, which tends to put in a nearly equivalent position Villa Giulia [7] and the Vatican, both in the foreground at the edges of the table, the first on the left and the second on right. A short foreground cortege is represented while moving to the villa. Villa Giulia and its monuments were illustrated by chalcographs during the second half of the sixteenth century. Dosio's one was defined by Rodolfo Lanciani "the best perspective map+[8] for the precision with which the Villa is shown, followed by the map of the casino with the garden published by Antonio Lafreri. The Villa, whose current appearance is similar to the one of the XVI century, except for the two wings added afterwards, was built on two floors, a block that dominates a big portion of land cut off from the path that led to Via Flaminia. It appears for the first time in Leonardo Bufalini's map of the 1551. This and Bartolomeo Marliani's map have in common the orientation, on the left at the top there is placed the north and at the lower end the west and the Vatican. Villa Giulia has a strong urban characterization.

Fig. 1: Giovanni Antonio Dosio's map of Rome, 1561. Detail

As an araldic tribute to the owner "del Monte", it stands on a small hill that is depicted in the frescoes of the Villa on the main floor, like a hill from which you could enjoy a wide view around [9]. Its scenical function, the physical connection and the visual dialogue between the places of the religious and secular power of the contemporary Rome, are enhanced by the rotation of Dosio's map. Dosio's choice tends to appreciate the importance of the papacy and the figure of Giulio III. According to some generally accepted assumptions the map would set a date and a particular moment, the death of the Pope. In this hypothesis, the bottom figures who go towards the villa would represent the funeral cortege. But this hypothesis raises some concerns, in fact we wonder why Dosio, according to his attempts to be part of a high society environment, had to make such admirations towards a defunct Pope, much criticized by his contemporaries. To my mind the cortege could simply represent a moment of Giulio III's life. He had the habit of tracing the river from the Castle to Albero Bello until Porticino. He used to cross the river on a boat driven by the faithful Andrea Schiavone. He also ruled the Papal barges, used for the transport of many art works, such as marble tables which decorated the Villa, some of which were elaborated by Raffaello da Montelupo. When the papal cortege got on the left bank of the Villa, after climbing a short flight of steps, it found a shelter under a shaded bower that was linked to the portal on Via Flaminia, which Giulio III had to cross to find his property. The bower is clearly legible in Dosio's map and also in Venetian cartographer Giovanni Francesco Camocio's map, later in 1669. The days when the Pope visited the works directed by Vignola and supervised by Baronino, were days of celebration, in fact memorable meals and festivals were held in the Villa, documented by the records of the expenses of the Apostolic Chamber. So many expenses, that a few months after his death, even though his brother Baldovino del Monte on September 16th in 1555, was proclaiming his natural son Fabiano as the heir, in August 1556, during the pontificate of Paul IV, the Apostolic Chamber seized everything "*pel motivo che i beni ereditarii erano stati acquistati e migliorati con danaro sottratto al pubblico erario*" [10]. The cortege designed by Dosio, shows a kind of spanish sedan chair with two horses, one of which is in the front and one in the back, followed by guards armed with spears. The boat of the faithful Schiavone is waiting. Another interesting feature is the parallel of the fresco on the main floor of the Villa, which represents the view of the same building, as used in that period, attributed to Taddeo Zuccari. In this fresco, which certainly captured Dosio's attention, the building is shown in the background, the papal sedan in the foreground followed by the guards armed with spears. Practically the same type of cortege depicted by Dosio. So the date of March 23rd 1555, the year of the death of the Pope, can't be used as the exact date of the inspiration of the view of the city, furthermore, the nature is clearly shown in a moment of full summer bloom. Probably the choice of the orientation of the map and the celebration of Pope Giulio III, in addition to Dosio's will, who also went often to the Villa Giulia, must be connected to Gabriele Paleotti's dedication, appointed as legal secretary by Giulio III.

Gabriele Paleotti in 1550 [11], the year during which he was nominated, edited the volume "*De nothis spuriisque filiis liber in quo omnia quae ad hanc materiam pertinet copiosissime tractantur*". The first pages are filled with generous dedications to Pope Giulio III and to Alessandro Farnese. He came from Bologna, and had studied there. At the age of twenty one, he supported a legal dispute in the Basilica of San Petronio dedicating it to Cardinal Alessandro Farnese, Pope Paul III's nephew. Witnesses tell how the event was followed by a particular audience. Pope Paul III himself took part in the ceremony as he was going to Bologna to meet the Emperor Charles V at Busseto. The Pope was accompanied along his trip by his nephews Alexander, vice-chancellor of the Roman Curia, who to the theses were dedicated, and by Ottavio and his cousin Guido Ascanio Sforza. The three young men had studied in Bologna at the Ancaran College.

Fig. 2 – 3: Giovanni Antonio Dosio's map of Rome, detail with Villa Giulia, compared with Taddeo Zuccari's fresco

Also Gabriele, with his brothers, had been admitted to attend the same boarding school where the Farnese cousins used to study. With the dedication to Cardinal Farnese, he pointed the old fellow student. The occasion for him to highlight the close link with Pope's nephews was again then presented four years after the dispute, when, having completed his legal studies, at the time of pronouncing the public findings in order to obtain the enabling to read at the City gymnasium, Gabriele repropounded the same dedication addressed a few years before to Cardinal Farnese: the relationship established between Farnese and Paleotti during the years of training, offered Gabriele the opportunity to create a valuable partnership for the benefit of his future career [12]. In March 1565 Alessandro Farnese favoured Gabriele Paleotti in obtaining the rank of Cardinal. Years before, the young Alessandro Farnese was the promoter of the application of Del Monte, during the suffering conclave that elected him as Giulio III. He had been a filo-Bolognese Pope for his whole brief pontificate. This gives a clearer idea of the eventual links between Paleotti and Julius III. Pope Giulio III's pontificate (1550-1555) was remarkable for the occasions that the Pope had been able to give to the artists of that time. Proclaimed on february 7th in 1550, he immediately began the works for Del Monte's chapel in San Pietro in Montorio on the Gianicolo, headed by Giorgio Vasari and Bartolomeo Ammanati. The great Michelangelo was the "*garante fiduciario della committenza*" [13]. Maybe because Raffaello da Montelupo was initially involved in the project as a sculptor before the coming of Ammanati, also Dosio managed to be present. One of his well-known drawings tells about a construction phase. So, the young Dosio frequented the construction sites of Giulio III during his early Roman years of apprenticeship, but it is not known whether alone or accompanied by Raffaele da Montelupo. Certain is that the gallery of statues and antique pieces of Giulio III remains memorable and returns in Dosio's sketchbooks [14]. Since then Dosio, despite the solid reputation as an architect designer, didn't miss not even the opportunity to engage the restoration of antiques and trading marble for his new customers, as evidenced in the correspondence with the florentine Giovanni Niccolini in the occasion of the project of the homonymous chapel in Santa Croce [15]. In any case, Rome's map was prepared before its publication and during the pontificate of Giulio III. About the graphic details, the bird's-eye view is inserted in the vein of the renewed interest for the description of the city. The orthographic map of Rome published by Bufalini in 1551 [16] who died just a year later, is the first modern map of Rome prepared on the basis of a campaign of surveying. It shows an horizontal ground plan with all elements shown to scale. Contrary to measured appearances, the map presents a specifically antiquarian vision of Rome. It is an ichnographic map [17] that included the plans of ancient monuments, in some cases completed and modified by the imaginative effort of the author. A map, although almost simultaneous to Dosio's one, designed in a completely different way, different for the technique of representation and for the results. In 1553, Pirro Ligorio [18] published a perspective map or better a pseudo-perspective map, which facilitated the reading of the urban structure with a plastic emersion of the architectural volumes between the urban walls, green areas and road network.

Fig. 4: Giovanni Antonio Dosio's map of Rome, detail with Campidoglio

As noted by Christian Hülsen, Bufalini influenced Pirro Ligorio, however it turned out too imaginative because of the incredible amount of temples and antiquity contained within the circle of the Aurelian Walls. It is also very interesting the bird's eye view plan, designed by Ugo Pinardo and published by Antonio Lafreri, where many buildings are represented with remarkable fidelity. No wonder then if the work of Pinardo were often imitated and copied. Dosio's bird's eye view, was independent from that of Bufalini, and was more accurate than that of Ligorio's, but perhaps because of its unusual angle in favour of Villa Giulia it has remained isolated and without followers [19]. Instead, a critical source which Dosio drew on was Bartolomeo Marliani's map of Imperial Rome, included in the 1554 edition of his topography, a prototype and a source of inspiration. To understand the reasons for Dosio's map we need to consider the professional experience of the author, his intellectual ambitions, the cultural climate of 16th century Rome and its converging spheres of interest, the knowledge of the ancient city and the celebration of the contemporary city. The classical monuments are represented as ruins, with a logic of truth that can be overlaid on the findings and views of the collection already called by Hülsen "*libro della antichità*". "Book" because all the views could logically be part of a sketchbook, composed from the arrival of Dosio in Rome until the time when he took other commissions and commitments, leaves his studies and the surveys of the antiquities to express himself through the architecture designed and built. But which were Dosio's skills during the drafting of the plan, potential clients and patrons, his knowledge in the field of surveying and his knowledge of the city, its monuments and its constructions? Dosio completes a work in his early twenties, which requires a high degree of technical competence as a surveyor and data collector. According to contemporary sources, he was engaged in military works of architecture working on the fortifications of Castel Sant'Angelo and at the service of Torquato Conti. We must also imagine that while working on the fortifications of Castel Sant'Angelo he learnt the art of measurement and thus gaining a significant and direct knowledge, at least in part, of the defensive circuit of the urban area and certainly the major urban transformations. These architectural and urban renewal campaigns were often accompanied by the notion that modern Rome had equaled ancient Rome, which the educated elite recognized its greatness now. A principle undoubtedly shared by Dosio who had filled his sketchbooks of important ancient and contemporary architecture in equal measure. In his map, Dosio shows the construction of the dome of Saint Peter, with double columns laid. We know that the construction of the drum was started in 1554 with the supply of stones of Fiano [20]. We find Campidoglio square, the walls and fortifications, thermal baths, churches and major buildings of the city, with special attention given to the surveys of the most famous buildings he has directly already measured. Probably He made direct measurements of portions of defensive perimeter, in any case, there were available many accurate plans that recorded the walls for military use. Certainly, He had to fix the position of the most important landmarks, by using a primitive theodolite with a protactor, determining the bearing from point to point, by means of several station points and then connecting the results using the well - known triangulation system. The mutual distances between the monuments attests the accuracy of the topographic measurements made upstream, while the architectural volumes, seen in perspective and elevation, are oversized and are highlighted with a more pronounced light and shade effects. The ancient monuments individually detected by Dosio are present on the map as isolated and highlighted. For example, on the south of the Campidoglio, less than 500 meters, we find the *boario forum* with the monopter temple of Portuno, that for the relative proximity Dosio draws almost adjacent to the Campidoglio, without interposing any obstacle, neither constructions nor orographic obstacles, as that the Roman forum and the Boario Forum are separated only by the great emergence of the Campidoglio, with the Michelangesco oval already marked and the equestrian statue in the center, the stairs in Palazzo Senatorio's facade. At the boario forum we find the four-faced arch of Giano also designed by Dosio, still conserved by the church of San Giorgio al Velabro.

Like many maps of the time this is characterized by the strong sign of the Tiber river. The civil construction is not strongly characterized, only with the view engraved by Antonio Tempesta (1593) we have a first urban map that depicts the minor buildings with a certain attendibility. The Roman countryside is plotted in the most characteristic elements. A few years later he worked at the Palazzo Conti di Poli (1563), whose client, Torquato Conti, is a collector of antiquities involved in the excavations of the *Forma Urbis Romae* [21]. This consists in a marble plan sized 18.10 in width and 13 meters in height, composed of individual slabs applied on a wall of the *Forum della Pace* adjacent to the Basilica of Saints Cosma and Damiano, dating back to the Severian era and at a later time in 203, date of the construction of the Septizodium, which appears in one of the fragments, and prior to 211, the year of death of Septimius Severus. The presence of Dosio, which makes copy of *Forma Urbis*, is echoed by Gamucci in the *Libri quattro dell'antichità di Roma* who warns about the *Forma Urbis*: *non ritrovato nè tempi nostri per M. Giovanni Antonio Dosi da San Gimignano*+[22] This discovery will be crucial for the evolution of later roman topography and cartography, and it was important even for Dosio's career. The search for success in the field of architecture remained a constant inspiration, as evidenced not only by early recognition of the Gamucci and early patrons, but also by eloquent dedication to Cosimo I of *Urbis Romae aedificiorum illustrium quae supersunt reliquae*, an elegant repertoire of Roman antiquities drawn for the engraver Giovanni Battista de'

Cavalieri. That Dosio had expanded his career from a sculptor to a designer and architect well before the seventies is now certain. Borghini, his biographer explained that he entered at the service of Torquato Conti: "...è lavoro ad un suo Castello molte cose di stucco, di marmo, e servi detto Signore per Architetto sopra la Fortezza d'Anagni; perciocchè egli delle cose d'architettura intende molto, e fece arme di marmo e altri lavori per detta fortificazione" [23]. It is certain that between 1565 and 1566 Dosio signed financial documents as *100 Gio. Anto. o Dosio architetto di detta fabbrica.*" In a letter dated July 22, 1564, Annibal Caro answered Torquato Conti in Anagni: "Quando questa mattina ricevei la lettera di V.S.I.M., Giovanni Antonio architetto era di già partito alla volta sua, e penso che al arrivo di questo sarà capitato. E con questa occasione ne le raccomando, essendo molto mio amico, e molto più suo servitore. Se V.S. ha modo di fargli alcun bene, certo sarà ben allogato, essendo un virtuoso, e da ben giovane Di Roma, alli 22 di Luglio 1564 [24]. Annibal Caro, as is well known, will dictate the iconographic decoration of Caprarola, Poli, the Palazzo Orsini in Bomarzo. We point out the existence of a later plan, dated 1562, attributed to Dosio. This plan, entitled "La città di Roma deliniata nel ponteficato di Pio IV. L'anno MCLXII 1562." is the size of 40x54cm in which putting the north on the right, the Vatican is in the background at the top right side, Villa Giulia is cut off from the plan, the Aurelian walls stand out, reflecting the interest shown by Pio IV in strengthening the fortifications. In fact he was devoted to strengthening the defense system of the Vatican even having new doors built. Dosio's map of Rome with its realistic view, its original orientation, fixes a physical and conceptual path of experience of Dosio as a designer of the ancient and modern. Although this has not had a great spread, it was successful in launching the artist towards new commissions and new opportunities, demonstrating his skills as a draftsman and his technical abilities. It also demonstrates his sensitivity to the urban space, that he is able to read and express with few strokes, highlighting the main characteristics, capturing the essential aspects. Dosio communicates a lot with less: a city in which some elements and architectural aspects served as optical milestones for the next city-planning of the Baroque era, when these targets will be enhanced by the axes no longer virtual but real.

Abstract

The current historical moment necessitates a reflection on the integration of knowledge for the purpose of identifying strategies to improve human life, the environment, and the memory of man's wealth for the future. The integration of scientific and humanistic knowledge, in the acquisition of data from the building to the territory, may allow a greater awareness on what, why and how to preserve, modify, demolish, and protect. But is this integration, accompanied by direct investigation, and research in the archives, and a rigorous analysis of the data collected, always sufficient for an awareness and knowledge of the real ways of becoming of history, of the form and the meaning of Architecture in the past, present, future? We know that this is not so obvious. The knowledge that one thing *is* does not mean knowing *why it is* and why it *is* precisely as it appears. Since "*form in the strict sense is nothing more than the delimitation of one surface by the other*" (Kandinsky), we cannot really know why similar cubic meters of matter can have so many different meanings; or why don't buildings which have the same historical dating, geographical location, stylistic choice, formal and functional type, have to the expected extent a similar artistic and semantic quality. But perhaps it is precisely this, or at least this too, that we have to seek and understand: what is it that makes the differences not a only a matter of chance? Why is it exactly there, precisely with that shape, on that stratification?

Key words: knowledge, memory, importance of history

1. To know to understand the existing reality

Fig. 1: Didymes, Temple of Apollo, 325 b.C.

The present moment, now in a severe crisis of degradation which cannot be easily overcome in the short period, obliges all of us to think deeply on the general sense of current human activity for the present and for the near future and in our field of work on the specific meaning, goal and way of intervening in architecture, cities, and territory seen as entities and places which will have to host and sustain our human future. "Modern" technology has certainly shortened, and will continue to shorten, the amount of time needed to transmit and integrate knowledge coming both from different technical and subject sectors, and from different geographic and mental places.

But perhaps even now man isn't yet – and certainly all individuals now operating still aren't – sufficiently prepared to perform the correct (and useful) reading, interpretation, connection and choice of intervention among the many different pieces of knowledge to decide the right operative strategies for his species, country and future; to decide the right operative strategies for a focused improvement of man's life, environment, memory, and memory's wealth for the future; strategies able to restart or strengthen processes of "social" growth and re-enforcement of guiding principles which have permitted man, up to now, to live, grow and improve through the centuries of his existence and in the territories he inhabits (though not all with the same quality and standard of democracy). In our specific field of operation, too – architecture, city and territory – we must, without taking anything for granted,

Fig. 2: Metaponto, Table of Palatine, VI cent a.C.

Fig. 3: O. Schlemmer, The two epic figures, 1927

Fig. 4: Efeso, II cent. b.C.

continue to ask ourselves about the meaning, the ways and the goals of our doings. It is true that the integration of both scientific and historical knowledge for the acquisition of data on the building, the city and the territory allows more awareness on the what the how and the why to intervene, preserve, modify, destroy, reconstruct, and protect but...

But we must always ask ourselves if (and how much) a close analysis of an existing reality done through direct investigation and archival research, (and rigorous analysis of the data gathered) gives us enough information to be aware of the concrete ways of the material becoming of architectural history, form and meaning and therefore to know the value and the quality of "that" architecture or city studied, and to know the deep meaning of its conservation, transformation, demolition, integration...

We must also ask ourselves if the data gathered can give us enough information to decide case by case the specific interventions – new building, restoration, urban development - to achieve the pre-fixed goal of that

Fig. 5: Luxor, Colonnade of Amenophis III, about 1400 b.C.

Fig. 10: Rome, G. Valadier, Casino di Pincio, 1816-37

intervention on that "architecture" or city...but also to achieve the protection to the future of the value that generated, maintained or transformed that architecture.

But we know this isn't easy. We know that the knowledge that something *is* does not mean knowing *why it is* and why it *is* precisely as it seems.

Since "*form in the strict sense is nothing more than the delimitation of a surface by the other one*" [1] we cannot really know why analogous cubic meters of matter can have such different meanings; or why do buildings that have the same historical dating, geographical location, stylistic choice, formal and functional type, not have necessarily the same artistic and semantic quality?

But perhaps it is this, or at least also this, that we need to investigate and understand: what makes chance not just chance? Why is it exactly there, with that exact form, with that stratification?

The images that accompany the text are a visual explication of this essay's questions.

What "value" of architecture must not be lost? Must we save the historical prototype in the material reality of its origins?

Or must we save its being, or having been - the idea-model - in the evolution of critical thought and of human knowledge?

1.1 Knowledge and memory for the project of transformations

The question again is: are surveys, archival research, "diagnostic investigations", sufficient instruments of knowledge for the project of intervention on what exists?

Of course the scientific instruments of knowledge for a project of architectural restoration or transformation are determinable or perhaps already determined, though they can obviously be perfected.

But does this type of analysis always tell us the reason for the existence of the architecture under examination? Does it tell us the meaning of its having that form? Does it tell us why we are trying to maintain it and therefore how it is being restored? Is architecture's being that linearly given by what is seen there?

And is its knowledge so deterministically defined by what is shown there? It's not so simple. Knowing its exact name and knowing the exact measurements and characteristics of its meters tells us little about why its form is exactly that one and not another one of the forms that was there possible.

Simple and linear knowledge is too easy. "Knowing" is not really understanding why similar cubic meters of matter manipulated by man can have such different historical and aesthetic value, or understanding why buildings built even in the same place, historical period with the same stylistic choices and formal and functional typology don't necessarily have the same artistic and semantic quality: "Doubt" cannot be eliminated, also because we know from history itself that *"the city is a whole in which many pieces can be changed without anything happening"*, or at least without the city itself dying. *"This has been the case, century after century, up to now"* [2].

So the first question is how to choose what to preserve. This must be done before deciding "how" to restore. This is because the deep meaning of the work on which we want to intervene and its cultural importance cannot linearly be deduced through patient archival

Fig. 15: Lubiane, J. Plecnik, street lamp, 1926

Fig. 20: Rome, A. Brasini, INAIL Palace, 1929

research, careful analysis of the material, and serious diagnostic tests.

The material, temporal and spatial beingness of an existing piece of architecture, the fact that we can list and quantify what it is made of (matter, technique, style, typology, function, dimension...) are of course real data.

They are necessary and objective parts to its beingness, to how it appears, and therefore to our aware way of intervening. We need these data to fulfil our desire of knowing and to intervene to preserve materially that piece of architecture.

But these data are not enough to tell us why we need to preserve that very piece of architecture among the many that exist. And these data cannot tell us what of that building we should preserve/restore of its whole history which through the centuries of its existence has over time marked and modified it.

The data just mentioned are similar to those we need (would need) to understand (and restore) a bee-hive, an ant's nest, or a coral reef.

These dwelling elements are similar to those of other animals and to their way of living together. These are products of the work activity of the different animal species; this activity modifies the naturalness of the environment in which these animals live to produce an objective improvement for their living together. These dwelling structures have also been passed on from one generation to the next through history and inform us

humans about “their” way of living in groups.

Every living species, with more or less awareness, transmits to itself the goals and ways of its inhabiting both in the case that it stays over centuries in its original place, even if it can continually modify the dimensions of its primitive nucleus, and in the case of migration and founding new nuclei in different geographic and climatic places.

However, despite these and the many other possible parallelism with human activity, these constructions are not the same things as our cities.

At least not for us human beings, not for the meaning we assign to our being and operating on Earth: our human architecture exists in its ways of being because there is a meaning, or a will to meaning, in its production, transformation or conservation; *“among the meanings of the word tradition there is also the one coming from the Latin tradere : ‘to take further’.* In other words tradition also means looking ahead, but starting from the past “[3].

This goes much beyond the primordial necessity to survive and to defend our species. This is what, more than its specific forms, distinguishes man’s house and his architectural settlements from the many other *dens*, and their agglomerations that every animal species builds on our planet.

What is essential in man’s buildings lies in the speculative value of the formal models; it lies in the stable correspondences, which need to be defined and verified each time, between the ways of taking *form* through *matter* of (man’s) architecture and the *meaning* that it expresses through that “form and matter”.

It’s to the ethic and aesthetic values of architectural *things* and to their correspondence to the material data that these values bear that we humans entrust our message. And it is in this that we recognize our historical on-goingness.

It is in the interlinking of thought and action, imagination and work, meaning and goal that *homo faber* is completed by *homo sapiens* and that his learning becomes knowledge and his knowing becomes recognizing and memorizing: now he attributes meaning and sense to his work which goes beyond the indispensable solution of contingent problems (surviving, residing, working, defending...) and permits the re-cognition, if and when it is there, of the ethic value and of the aesthetic quality in the human constructions that precede him and/or are contemporary to him.

These constructions were consciously wanted and produced and it is among these that he (homo sapiens and faber) moves and acts.

For all men *“a place is never only ‘that’ place: we are also a little bit that place. Somehow without knowing it we had that place inside us and one day, by chance we got there”* [4]. But it is for this reason that the architect *must* become aware and therefore able to know, re-cognize, and consciously operate in the different *places*.

Therefore we need *“Matter, Form and Technique”* alongside *“History, Style and Type”*, for the building of knowledge about architecture, its construction, preservation and restoration.

But then what?

Is the relationship between on the one hand the abstraction and imagination of architectural project principles – and of the aesthetic / formal premises of architecture – and, on the other, the concreteness of its material beingness – and of how it is in the gravitational heaviness of its materials and in the correspondence of the techniques that form it to the strict laws of statics – linear and univocal or is there something else? Is there something else which is able to give meaning to what is seen there to who sees it?

Is there something else which can give significance, not only a functional one in a strict sense, over and beyond simply a reason, for its being there in that precise geographic and urban place and in that precise historical moment, with those forms and not others, with those particular dimensions and those precise materials?

Fig. 26: J. Soane, Barn à la Poestum Warwickshire, 1912

Fig. 27: J.C. Escher, *Doric Column*, 1945

Fig. 28: C. N. Ledoux, Bourneville Park Gate, 1785

These are of course all necessary and objectively describable and measurable elements. They concur to define the material, metric, and visual characteristics of what exists there, of what exists everywhere, of the temporal and spatial uniqueness of what exists.

But the architectural response to the primary necessity which determined the demand, and its building organization, even if always related to the technological knowledge of its historical moment, have deeper implications, less linear meanings, and solutions which are never univocal or aprioristic with respect to the infinite number of other possible forms, materials and dimensions which could have analogously responded to what there was asked for and to what there was experienced and is being experienced.

But maybe it's not a coincidence that they didn't do one of the alternatives and that there isn't one of them there. Maybe this is exactly what, or what we also, must investigate and comprehend: what is it that makes chance not pure chance? Why is it right there, with that exact form, that colour, that material?

Maybe it's in this investigation of the relationships between the existence of the meaning (abstract) and of the way (concrete) through which man builds his space and perpetuates his memory that we will be able to reach an understanding, even a rational one, of why one architecture is better than another. Why is one of these architectures, more than others which also exist (or have existed) more representative of a historical, political, ethic, or aesthetic moment even when these moments have lost some of their relevance?

Why do they continue to exist and to function in the urban context while other buildings which have analogous characteristics of formal, dimensional and constructive appearance get destroyed, or forgotten or transformed both in their meaning and in their matter? Architecture is undoubtedly concrete matter, real measurements, objective tri-dimensional forms which get combined and are therefore unique.

But not only. Architecture is a measured and direct response to the physical and biological necessities of man, which can be resolved again and again in time. But this still isn't all.

Architecture is culture, history, testimony of man's being on Earth. In this it can be objectively recorded. But it still isn't only this if it is considered as an objective temporal sequence of happenings.

Architecture is also something else. Something less linear and univocal than the more or less elementary equations of form-function-history or matter / dimension / technique, which certainly are

Fig. 29: J. Bowring, Freemasonry Initiation, 1819

Fig. 30: Jerash, Oval Piazza, end I century

relevant. Architecture as form, matter, use and meaning, and the geographic, historical and mental places which host this architecture and which are characterized by this architecture are also something else.

They are perhaps less linear and absolute than the modern rational certainties.

They are something else and probably more complex and variable than the univocal and repeatable answers that are allowed by the careful but acritical respect of the rules for "good building" of the academy and tradition.

It is something else that is always and no matter what in dialogue (even if the how and outcome of this dialogue are not always foreseeable) with the collective historical memory, with the individual subconscious, with the perceptive laws, with the subjective aesthetic pleasure towards what there is seen, experienced, lived in, and passed through.

Therefore, without diminishing the fundamental importance for any project (whether to build something new or to preserve, or to restore) of individual responsibility and autonomy of choice, and of the seriousness of the gathering of the data needed for the project, we must never forget the principles through which man, as a human being, sees, perceives, memorizes, learns, thinks, elaborates, comprehends and transmits to himself and to others.

Since "we, human beings, never think alone and we never think without instruments"[5], our ability to recognize reality and therefore to organize our intervention in it is structured also by, and on, systems of signs – which are symbolic, mimetic and metaphoric – which "stand for", which "represent", the objective and the subjective of what surrounds us, of their meanings, of their apparently obvious positive or negative value, their value of beautiful or ugly, of continuity in tradition and in history or of rupture towards the future and the new.

The reading of reality, not only urban reality, just like our architectural thoughts, are tightly linked to our memory of other forms, the suggestions of other spaces, historical citations, or negation of the past, the reinterpretation of what already exists or the invention of what has never been seen before, faith in the becoming of appearances or the certainty in the stability of being.

And our architectural thoughts take their form from these. Perhaps they are our thoughts and our architectures.

This is so because, whatever our individual position, *"without memory man cannot trace any history, he cannot know his becoming in time, ... Factual reality, images, memory, language and history are correlated along all of the Western tradition, within a single horizon of knowledge: what is real and factual is represented in the conscience, both individual and collective, in function of an understanding that occurs through permanency, in images and within the vast territory of memory, not only of what happened but also somehow of its 'being present'. Therefore what has once been is potentially always present, in image, in the individual and collective memory"* [6].

Therefore we can only take a position and make personal distinctions on signs and values recognized in, or attributed to, what, not only materially, exists; but it's on them and with them that our positions and distinctions are

Fig. 31: Los Angeles, Caesar Palace Sight

formed and expressed.

This is so because our cognitive capacity and our activities to accomplish are profoundly structured, as value and behavioural judgements and as reactions against what lives and is seen there, by the whole network of institutions in which we grow up.

Our mental procedures are constantly articulated by the languages we speak and by the forms in which we grow up. These languages and forms are superior to our individual being and for a large part indifferent of our individual doing.

They speak to us of logical and organizational processes, of principles, judgements and selections which centuries of ethical and aesthetic history have perfected and privileged.

All of this is what we constantly find in existing architecture, independently of its form and of its historical period, of the style and of the building material through which it becomes concrete.

It is its "historical ways of being", both in meaning and in aim, which, perpetuating itself underground for centuries, or perhaps I should say under the exterior surface of buildings, tell us the whys and hows and the quality, and the value, and the meaning of each single piece of architecture independently from the specific "appearance of form" with which they are each time realized.

MORE COMPLEXITY, LESS CONTRADICTIONS Concept Maps and Contemporaneity

Maurizio UNALI

Dipartimento di Architettura, Facoltà di Architettura, Università 'G. d'Annunzio' Chieti-Pescara, Italy
m.unali@mclink.net

Abstract

The dawn of the new century appears to be characterised by revolutionary transformations of scenarios that motivate the search for new visual media capable of 'broadening observation' to critically comprehend the complexity of reality and the *modus vivendi* of its inhabitants.

There is a clear necessity to seek out processes for representing phenomena capable of managing and positively re-elaborating that pervasive flow of information produced above all by globalisation and the net as 'knowledge'.

The fields of our interest – architecture and design – historically delineating an existential unicum with space, life and the 'objects' of time, exploring the complexity and contradictions of the contemporary scene at all levels and seeking adequate instruments of representation for elaborating a structured vision of knowledge. As known, the development of digital representation is producing epochal changes in this sector, from design to surveying. Experiments are being made with conceptual representations conceived as the visual synthesis of processes of classification or the critical comparison of complex and heterogeneous information, exploiting new technologies to the full, offering new categories for comprehending events, designing scenarios within which to manage specific contexts; relating facts and opinions; observing macro-themes 'at a first glance', focusing attention on details; accessing banks of data and references on the net, etc.

The principal objective of this essay is thus the identification of some of the most interesting works of research examining the theme of the concept map and experimenting with systems of visual representation capable of producing knowledge by uniting the traditional narration of information with sophisticated interactive systems of visualisation.

Keywords: representation, map, complexity, contemporaneity, interaction design.

1. Concept Maps and Contemporaneity

Contemporary culture appears to be crossed in an increasingly more pervasive manner by the idea of the *concept map*; a revolutionary actualisation – nurtured by globalisation and technological development – of the historical human understanding of geography-cartography, the archetypal representation of knowledge, in its space and its time.

The techniques of elaborating these maps and the expressive-communicative apparatus that characterises them are vast and diverse, embracing various professions and disciplines that, from 'traditional' *nomography*, arrive at the more general concept of 'Information Visualisation' (InfoVis).

This text considers above all digital concept maps; a kaleidoscopic universe that describes a stimulating interdisciplinary field of research oriented towards the study of and experimentation with systems of visual representation, capable of producing knowledge by uniting the traditional narration of information with sophisticated interactive systems of visualisation.

Though the reasons for this vast production of concept maps are many and can be defined with respect to the theme of study, the context and the discipline examined, I believe that common motivations may be identified above all in the collective necessity dictated by the contemporary *modus vivendi* (to quote Zygmunt Bauman) of elaborating and testing processes of transforming information into knowledge. A common interdisciplinary feeling has generated the progressively acceptance of the idea of developing methods and techniques of visualisation capable of managing and positively re-elaborating, as 'thematic knowledge', the pervasive and undifferentiated flow of data and information (increasingly overflowing and readily available) produced above all by globalisation and the net. As known, there are problems with the 'translation', interpretation, reading, de-codification and management of increasingly more complex, vast and broad data and information available to anyone. From the real to the imaginary, from the survey (i.e. the relations between the web and Territorial Information Systems, as in the case of the polyhedral interdisciplinary projects triggered by Google) to design (i.e. in the sector of semantic 3D models that can be shared online and, more in general, as part of the BIM - *Building Information Modeling*), we have ever more need for models of representation to 'see', to broaden our vision, to contain it and render it interactive, implementable. In a word, *representable*.

1.1 Representing Complexity and Contradictions

From architecture to design, from the visual arts to the landscape, representation – historically delineating an existential unicum with space, life and the 'objects' of time – explores the *Complexity* and the *Contradictions* – to quote Robert Venturi (*Complexity and Contradiction in Architecture*, 1966) – of the real and the virtual on all levels, seeking and testing suitable models of visualisation for a structured and thematic communication of knowledge.

Driven by the techno-cultural (digital) revolution, the development of representation is producing epochal shifts, many of which are positive, above all in the sphere of the interactive visualisation of knowledge, from the survey to design, from the general to the detailed, providing the actors in this process with the instruments of representation, while users are able to listen to, interrogate and analyse the diverse themes presented. There are many methods at our disposal for the representation of knowledge that stem from processes of cataloguing, classification and the critical comparison of complex and heterogeneous information. By exploiting new technologies to the full they offer additional instruments for observing, amplifying and comprehending phenomena, designing maps in which to be able to read specific contexts, relations between facts and opinions; observing macro-themes at 'first glance', accessing databases and references on the net, revealing infinite layers of information, etc.

This brings to mind, for example, these non-linear concept maps, somewhere between art and science, that allow for a reading of the new 'cartographies' of our planet, further investigating the projects and necessities of its inhabitants; we can represent and enter into new virtual worlds or manage the bursting flow of data and information produced by the media.

This brings to mind, for example, the latest frontiers of digital simulation: refined semantic architectural models, *n* dimensional and which can be shared online, *thesauruses* of scientific repertoires or vast archives focused on classification and the automated or guided search for documents or typological forms connected to one another by reciprocal links, or using particular codes, or based on metaphors, affinities or hierarchical dependencies; the more general and professionally known BIM, or, that complex process of elaboration focused on the representation and management of a virtual model of architecture.

This brings to mind, for example, the relations between the web and various methods of surveying – in particular Territorial Information Systems (TIS) – which are generating representations of reality (from architecture to the city to the territory), so innovative as to open up, in this phase of the evolution of 'connective intelligence', fascinating conceptual scenarios, explorative and elaborative, as in the case of the polyhedral interdisciplinary projects triggered by Google. Representations similar to concept maps that surpass the decline of the two-dimensional urban-territorial drawing and favour the new reading of the real with a matrix that is no longer 'analogical', but semantic-digital.

2. Towards an Atlas of Concept Maps of Architecture and Design

The study presented here anticipates some of the results of an articulated work of research, on-going, examining the general theme of concept maps of architecture and design. The following pages outline a synthesis of the knowledge acquired to date concerning the theme, moving through successive examples drawn from the vast repertory available during this first decade of the twenty-first century. We are also aware that works of this type, for the vastness of the issue and its infinite deviations, are 'open' and to some degree 'incomplete', inevitably leaving certain things out and not paying enough attention to others. Studying the evolution of the idea of the concept map – observing the phenomenon also as the result of interdisciplinary

relations – moving through its incredibly vast iconographic production – but also literary, ideal, utopian, virtual, stereographic, etc. – signifies considering and accepting, from the outset, the characteristic of a ‘work in progress’ typical of this type of research: a thematic reading of ‘a subject’, structured on the themes of representation, which analyses a complex phenomenon atop which to trace a *fil rouge* that links events judged to be amongst the most significant, with the objective of designing scenarios, proposing paths, and highlighting links.

It is evident that we are dealing with a study that requires a project of communication.

The examples studied in the research presented - in addition to being thematically catalogued, classified and analysed in relation to the various critical elaborations made – were ‘ordered’ by a project-database of representation, whose results are synthesised in the interactive map known as the *Atlas of Concept Maps*, whose images accompany this text. Representation – to this day amplified and integrated as part of a working project somewhere between research and didactics – through the thematic selection of visible information, consents multiple investigations and perceptions that vary from the general to the particular, in relation to the interests of the reader. In a continuous link between the personal and the universal, between everyday reality and the imaginary world, in the oscillation between time and space, when looking at these maps it is possible to become lost in the details (infinite visual fragments, the tiles of a sort of free puzzle of the memory) designing a personal path-story, or seeking an gestalt vision that synthesises the various creativities proposed. Of these possible visualisations we present three, referred to the same number of fields of work, in turn composed of multiple sections, which constitute the general structure of understanding achieved by the research to date.

The first field of study surveys prior events and references to concept maps – cf. map 01 *References*.

The second presents and analyses some of the principal websites that thematise concept maps – cf. map 02 *Web Compilation*.

The third field of study brings together some of the authors of concept maps – cf. map 03 *Authors*

2.1. Prior Events and References

The first part of the research begins with the section *References*, used to investigate what appear to be the prevalent prior events and references (historic, modern and contemporary) of digital concept maps.

The history of architectural representation widely documents the invention and use of methods and techniques of visualisation that can be referred to the contemporary language of the concept map. There exists a vast scenario of examples in which the idea of the concept map is manifested as a design pulse, uninterrupted over time: a sort of spontaneous anthropological necessity to represent – between the real and the virtual – the spaces associated with life and to nurture the personal and intimate spaces of the mind.

Numerous testimonials of this laboriousness can be traced out, in which the idea of the map is among the fundamental elements of the representative process, nurturing thematic visual actions that, case-by-case, specify the semantic context, touching on almost all of the theoretical-operative declensions of architecture and design, to express, understand and manage the complexity of the real and the imaginary. We present a few examples.

In the field of historical references, I can imagine, for example, the first experiments of a geographical-cartographic nature in antiquity; from the invention of perspective to the model of the *Ideal City*; to the increasingly more precise representations of the globe elaborated during the modern era; to the pervasive contemporary visualisations of a particularly political-social dimension (which has to do with equalities, opportunities, emergences, rights, etc.) and a ‘functional’ support to the activities of mankind during his progressive evolution.

Among these prior events and references to contemporary concept maps three are mentioned here.

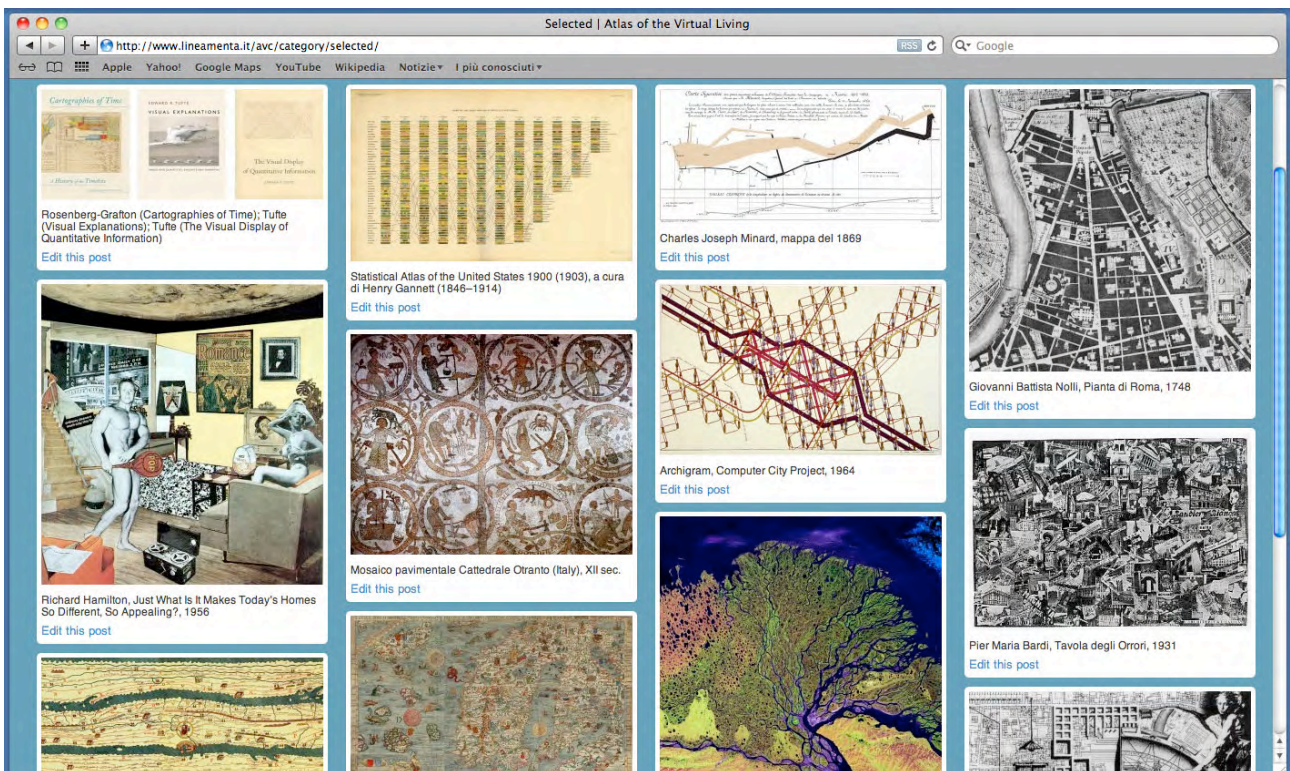

The first is the mosaic floor of the Cathedral of Otranto, realised between 1163 and 1165 by a group of artists under the direction of Pantaleone (mosaic artist, perhaps a monk of Greek origins). This exceptional visual-spatial work is among the cultured predecessors of the contemporary idea of the conceptual digital map. Using the visual language of the most fascinating late medieval culture, by employing enigmatic figurations the mosaic represented the human experience, from original sin to salvation, using scenes from the *Old Testament*, the *Apocrypha*, the *Carolingian Cycle* and the *Medieval Bestiary*, composed according to the development of the *Tree of Life*. Entering the cathedral, whose floor is entirely decorated in mosaic tiles, one has the sensation of being immersed in an enigmatic horizontal interface to be experienced through successive interpretations of visual links, rendered part of a system by the evident network of the *Tree of Life*. In other words, the mosaic represents an optimum prior event to what we now refer to as ‘hypertextual communication projects’, among the founding characteristics of digital concept maps.

The second reference is drawn from the ‘pioneering’ British Pop Art of the late 1950s: the famous collage by Richard Hamilton – *Just What Is It That Makes Today's Homes So Different, So Appealing?* – for the

exhibition *This is Tomorrow*, presented in London in 1956. This emblematic image anticipates, both at the level of aesthetics and that of communication, many of the pop themes that distinguish the conformation of many contemporary concept maps. This is evident above all in the dynamic approach of communication (the fruit of the pervasive role played by technologies and the media) that transforms information into a 'mass event' that belongs to everyday life. It is the beginning of mass representation; it is the birth of a pop space of communication.

In a historical continuity with the fertile and heterogeneous phenomenon of '*Disegno di Architettura*' – I can think, for example, of Nolli's *Plan of Rome* (1748), the *Campo Marzio* (1762) by Piranesi, the *Capricci Palladiani* (1756-1759) of Canaletto, and the *City of the Captive Globe* (1972) by Elia Zenghelis and Rem Koolhaas – the third reference is the *La città analoga*, a conceptual representation composed of beloved projects and memories, drawn in the 'ancient style' in 1976 by Aldo Rossi; a precious document that recalls how, in architecture in general, and in that of Rossi in particular, theoretical study is a necessity, a solid base atop which, together with historical memory, to found any conceptual process. Simplifying greatly, we can observe that *La città analoga*, between the real and the virtual, between survey and project, resembles a concept map, a space of elaboration in which to test processes of understanding and design.

As made evident by these reflections, there opens a vast and complex issue that, over the centuries, has interested the work of architects and artists, involving, suspended between science and art, human ingenuity; representations that generate a plurality of orientations and which visualise, as recalled many times, the idea of the multi-dimensional concept map. Understanding the cultural mix that emerges from the concepts introduced, studying the technical-evolutionary aspects of the theme, deciphering the expressive ingredients and analysing the significant multi-sensorial dimension of representation, allows us to enter into that poetic dimension of design that has generated epochal turning points, amplifying the languages and configuring the new 'hypotheses of space' that are the intended object of reflection here.

2.2. Web Compilation

During this phase of the research we studied a selection of websites that can be classified as concept maps, thus exposing understandings and themes useful to the issue of study. This panorama revealed some of the most interesting research elaborated in the field of the realisation of concept maps for architecture and design, in particular within the vaster territory of Information Visualisation (InfoVis).

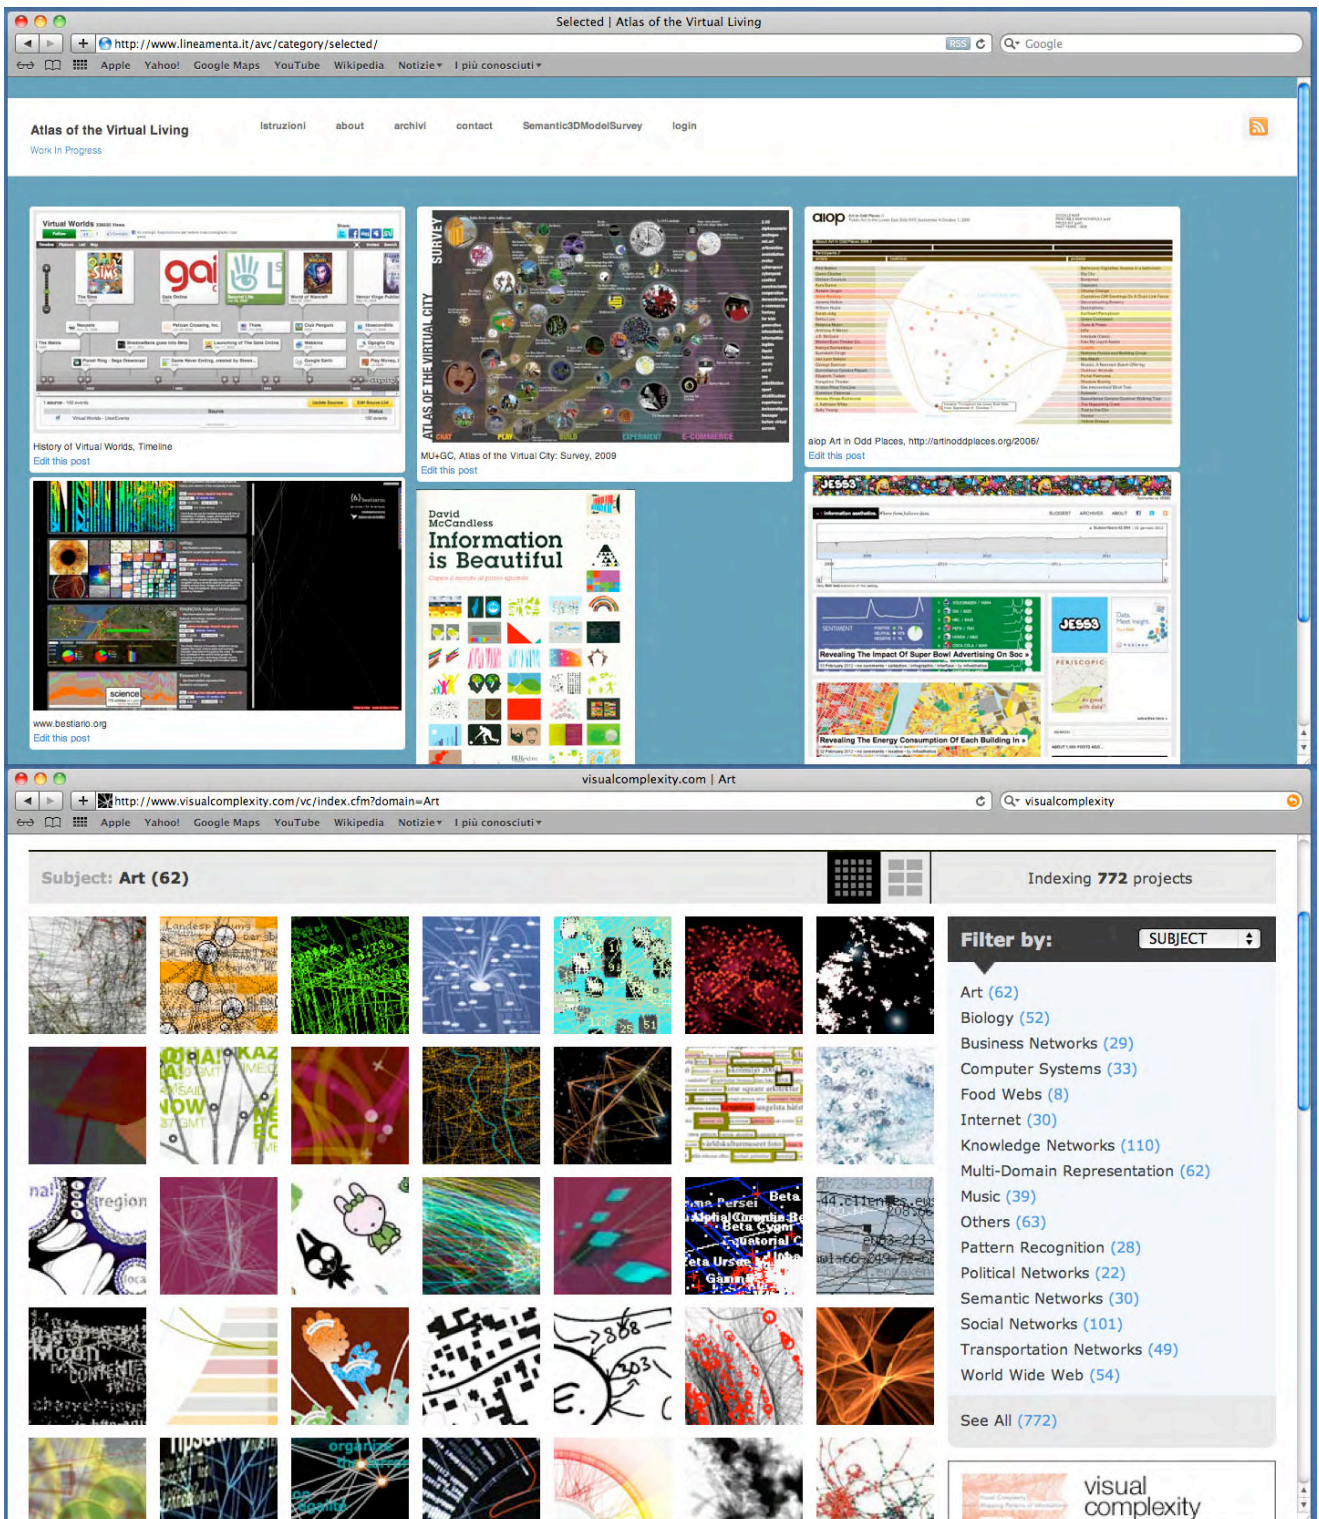

Of these online 'web compilations', synthetically described below, we will focus on two.

The first site is www.CyberGeography.org, the 'historic' cyberspace atlas curated by Martin Dodge, co-author of the book *Atlas of Cyberspace*, among the first publications that proposed to classify the representations that, over the past decades, have visually expressed the 'inexpressible' space-idea that is cyberspace. CyberGeography illustrates 15 categories of maps: Conceptual Maps of Cyberspaces; Artistic Representations of Cyberspace; Mapping Cyberspace Using Geographic Metaphors; Mapping fibre optic networks, submarine cables and telecommunications satellites; Tracing Paths Through the Internet; Census and Statistical Maps of Cyberspaces; Topology Maps of Elements of Cyberspace; Information Space Maps; Information Landscapes; Three-Dimensional Information Spaces; Maps of Internet Service Provider (ISP) and Internet Backbone Networks; Maps of Web Sites; Surf Maps Visualising Web Browsing; Multi-User Dimensions (MUDs) & Virtual Worlds; Historical Maps of Computer Networks. Merely reading these categories it is possible to understand the vastness of the issue: a kaleidoscope of new landscapes of net communication, cyber-maps (with a strong aesthetic value) that reveal the space beyond our computer screens, interfaces that represent impalpable things, such as the cables of global communications networks, online databases, etc.

The second 'web compilation' mentioned here is www.VisualComplexity.com, a site founded by Manuel Lima (a Portuguese researcher), which offers an extensive repertory of concept maps from the scientific and academic world. The examples selected are many (to date over 772 projects) and include all the various declensions of the theme, presented in a catalogue subdivided into 16 themes: Art; Biology; Business Networks; Computer Systems; Food Webs; Internet; Knowledge Networks; Multi-Domain Representation; Music; Others; Pattern Recognition; Political Networks; Semantic Networks; Social Networks; Transportation Networks; World Wide Web. This catalogue is accompanied by other possibilities of research in relation to: method; trend; year; top authors.

Map 02 Web Compilation. From left to right: www.cybergeography.org/; www.visualcomplexity.com/vc/

Map 02 *Web Compilation*. From left to right: History of Virtual Worlds, Timeline (http://www.dipity.com/WebHistoryProject/Virtual_Worlds/); MU+GC, *Atlas of the Virtual City: Survey, 2009*; aiop *Art in Odd Places*, <http://artinodddplaces.org/2006/>; www.bestiario.org; McCANDLESS, David, *Information is beautiful*, ed. Rizzoli, 2011; www.infosthetics.com; <http://www.visualcomplexity.com/vc/index.cfm?domain=Art>.

2.3. Authors

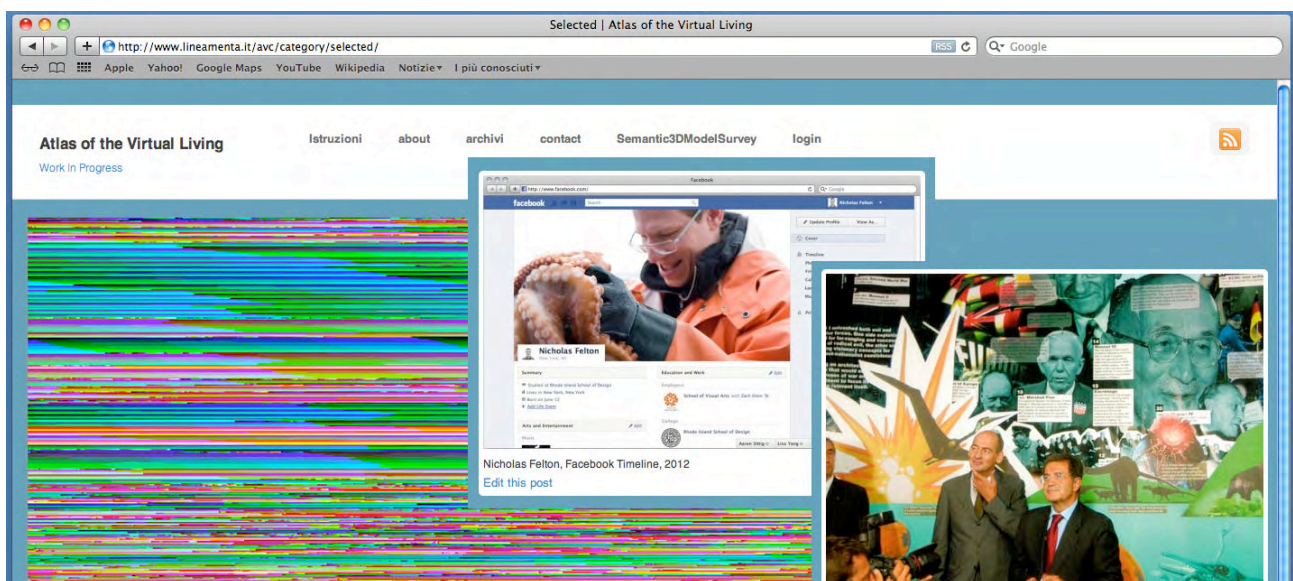

This part of the research studied the works of some of the most interesting authors of concept maps, both in terms of technique-methodology and at the level of creativity-aesthetics. The analysis was also extended to those who utilise the idea of the concept map in their work, even if they are not directly the authors. Upon a close examination of contemporary design, we can in fact note that particular works of architecture, art and design are, themselves, already 'concept maps'.

Of the many figures studied (artists, designers and architects), three are mentioned here.

The first is the author and artist Lisa Jevbratt, who has managed to unite art and technology, elaborating an interesting visual language of synthesis. This work is of interest to our studies above all for the original research into models of Internet visualisation; polychrome maps of the web generated through the punctiform association of a colour (or tonality) with an IP address, accessible (present, utilisable) at the click of a mouse. One good example is the project *1:1*. As the artist's website tells us: «1:1 was a project created in 1999 that consisted of a database that would eventually contain the address of every Web site in the world and interfaces through which to view and use the database. 1:1(2) is a continuation of the project including a second database of addresses generated in 2001 and 2002 and interfaces that show and compare the data from both databases» (cf. <http://jevbratt.com/>).

The second author selected for this brief examination is the designer Nicholas Felton – known above all in the field of interaction design, and as the author of the *Feltron Annual Report* (infographic yearbooks dedicated to different topics) and *Daytum* (a site that allows for the creation of personalised graphic reports) – one of the figures responsible for the future visualisation system to be used by Facebook, now partially deducible in the new *Timeline* (the new design of the profile page used by each citizen of this social network): a representation of life, a map of personal memory, visible by 'scrolling down' the web page. This simple action of vertically scrolling through a chronological list of infinite information (scriptographic, drawings, photographs, video, music, links) is the new simple idea for sharing one's life with friends online, metaphorically sharing our virtual culture.

The third author we propose is an architect, Rem Koolhaas, a figure who in more than one way defines (uses) the conformational potentialities typical of concept maps: in the elaboration of the idea and representation of design – I can think, for example, of the aforementioned drawings (with Zenghelis) for *The City of the Captive Globe* (1972), or the master plan for the *Parc de la Villette* in Paris (1982) – in communicating the mission of his office, OMA, to the public, be it a lecture, a printed document or a video project – for example the images projected during his lectures or the many concept maps in the books edited by Koolhaas and his office. As one example among many I mention the concept maps that describe the *Roadmap 2050* project, developed by AMO (the research and design office founded by Koolhaas in 1998 as the reflection of OMA) in 2010, those published in *Mutations* (2001) or in *S,M,L,XL* (1995).

Map 03 *Authors*. From left to right: Lisa Jevbratt, *1:1*, project 1999-2002; Nicholas Felton, Facebook Timeline, 2012; Rem Koolhaas (with Romano Prodi), *The image of Europe* (AMO), Bruxelles 2004.

3. Post Script

Even keeping to these limited considerations, it appears evident how the idea of the concept map offers a renewal of the more experimental dimension of architectural design, both at the technical-methodological level (the simultaneous ability to utilise multiple media in the same platform; diverse points of view, some moving; the online sharing of the same project, etc.), as well as at the aesthetic level. Within concept maps the theme of representation, variably defined both historically and thematically, confirms its profoundly design-oriented role; representation as a stimulus and exercise in creativity, an intellectual act that consents a broadening of vision and the tracing out new scenarios of interest. It is thus another occasion for investigating and testing the relations between drawing and design, between an idea of representation and how its outcomes conform to space.

It is also a theme that deals, to the same degree, with the so-called 'design of the real' and, more in general, with processes of architectural and urban surveying, the visual culture of photographic and video representation, leading all the way to the spectacular applications triggered by Google, which announce the dawning of a new era that we can define as one of 'generalised visualisation', of interest to a vast public of specialists and laymen.

Tridimensional modeling as an opportunity to express projects never implemented: the case of Palladio

Alessia MAIOLATESI

Dipartimento di Architettura, Facoltà di Architettura, Università degli Studi "G. D'Annunzio" di Chieti-Pescara, Pescara, Italia

alessia.maiolatesi@gmail.com

Abstract

There are poems that have never found a "voice" of expression and architectural plans that will never materialize. The sole expression of the design lies in the value of the drawings and theoretical sources, the turning point for tridimensional evolution and the development of a digital model of architecture. These organisms exist only because they have found an appropriate form of representation, evolving into complex configurations of knowledge, structured as a web of information. The need for these interventions was created to give reconstructions the same value as what was actually built, so that they become products to be experienced digitally, involving the whole sensory system. What is of interest in the field of non-materialized architecture, in this case, that of Palladio, is the possibility of examining, enjoying and visualizing architectural prototypes in a three-D environment, implementing the information system with the addition of specific content on the subject. This digital information process opens up a new dialogue with the study of architecture and disseminates knowledge of cultural heritage.

Key words: digital model, architecture, Palladio, information

1. Three-dimensional modeling for architecture

One of the reasons that validated the approach using three-dimensional modeling, understood as an opportunity for architecture to find a new configuration within the contemporary landscape concerns the architectural heritage which was never translated into reality, and which did not find another form of representation apart from two-dimensional paper. The basic premise for addressing the topic concerns the importance of communication performed by architecture within its context, going from a simple means of dissemination of knowledge to a powerful tool, able to progressively change the approach to the subject. Before moving to the crux of the matter, one must provide some theoretical clarification about the different stages that led to the validation of the choice of a three-dimensional model as a new, effective criterion. In architecture the dissemination of the design thinking and composition theories is usually expressed through graphics processing: the first reflection that arises from this statement is the idea of the project as a model, relating to the original concept, and as a reference for subsequent reasoning. There are different forms of "model" seen as an instrument of knowledge and communication able to explain and support the representation of architecture, whether it's a physical, virtual or abstract model, with expressive force capable of interpreting architectural intentions through the different configurations which underpinned the communication and structure of the project. Here the attention focuses on the idea of a three-dimensional model seen as operation that provides an opportunity to examine continuously the results generated from accurate data that are taken into consideration. To tackle the reconstruction of the three-dimensional model

of an architectural object we start from a traditional analysis of floor plans, elevations and sections, but the next thing to do, is to go into the substance of the understanding of the internal structure of the elements, since a correct reading of their volumetric arrangement is necessary to understand their significance. The virtual model, in this case becomes the means of validating the analysis of architecture for educational, promotional and conservation purposes. One of the most significant aspects of the digital approach towards architecture is that through direct volumetric analysis you can conduct investigations that move from the internal structure of the architectural object to the outer skin, offering the possibility of a proper planned control of the design phase, planning necessary interventions and creating a system permitting an effective exchange of information. At this point you can begin to devise the digital model as a 3D object that goes from an instrument of knowledge to a valid means of design. This becomes decisive when dealing with architectural works that have not reached us for various reasons, ranging from failure to build them to very poor conservation over time. The opportunity of digital reconstruction becomes the means of expressing a simulated reality which would be barely possible otherwise. Architecture that is no longer part of our contemporary cultural heritage finds a dignity of expression through a new and legitimate form. One of the advantages of 3D modeling is the enhanced sensory perception of architectural space going from a material conception characteristic of built architecture to a dematerialized concept, constantly evolving in form and meaning. In the field of architecture, therefore, and the increasingly widespread use of advanced digital technologies, a specific case refers to the three-dimensional modeling that offers a new life to 3D objects, and which has considerably expanded the possibilities of doing research on these issues and encouraged the opening up of these systems, which usually operate and encode simple data, so that they can turn towards the production and analysis of the objects themselves. Going into the merits of the specific approach, one immediately understands the benefits that a deliberate use of synthetically generated 3D environments has on the range of projects which have remained on paper without ever achieving material structure. Following such an approach expressed in 3D modeling, you can reconfigure the architectural space, expressing its particular volumetric integrity. Such an approach also lends itself to further in-depth studies, ranging from architectural structure to compositional and geometric aspects that are the analytical basis. The advantage of digital representation of architecture works that were never built or no longer exist is that it provides interesting possibilities to architects or anyone interested in further study to immerse themselves in a particular virtual reality, which stimulates perception through the senses until total interaction with the object is achieved.

1.1 Possible models

The following case study given as an example, concerns the design of a system for reconstruction of a Palladian villa which was probably never even intended to be built (apart from a limited section): Villa Mocenigo on the Brenta. From historical information, construction of this villa is assumed to have started in Dolo in 1564-1565, but the information is probably dubious and cannot be proved. The proposed reconstruction system uses an evaluation procedure that makes it possible to analyse this architectural "structure" through semantic meanings so that it can be used as a model for interactive browsing. Thanks to the correlated information device that validates the virtual reconstruction of the villa in question, the hypothesis becomes possible, creating and managing a simulated, reasoned use. The objective is thus to consider an actual reconstruction program which translates essentially into a two-dimensional drawing of a villa, taking into consideration the obvious difficulty of this type of working approach towards the study of the object created using three-dimensional modeling: obviously we analysed and studied a reasoned recomposition of the individual elements and of the structure as a whole. This model will involve a three-dimensional evaluation of Palladio's architectural language and rules that permit a solution with the shapes, proportions and construction of the architectural concept. We present the methodology used during the study of drawings to be compared to the "rebuilt" work, justifying and assessing the results. It is no coincidence that the subject studied using this type of analysis was the Villa Mocenigo, where Palladio's design language is particularly clear and explicit. This is developed and expressed in a more in-depth and interesting way than in the other projects for villas that were never built. In order to understand the question, it is essential to summarize and highlight the main issues in three-dimensional reconstruction: inconsistencies between the villas which were actually built and design projects of the same villas in *I Quattro Libri dell'Architettura*, a book written after construction; how to find and justify the design methods to use for interpretation and virtual reconstruction of the work which existed only on paper. The constructive approach suggests the use of digital technology to achieve a three-dimensional project and the use of virtual technology requires a new interpretation of *I Quattro Libri dell'Architettura*, a reinterpretation that offers different formal decisions to enrich and express the various design and reconstruction processes. In this case the reconstruction

procedure assumes an application of "standards" and the formation of a full prototype of all parts of the work for in-depth and comprehensive analysis. The creation of this example starts with the planimetry and elevation of the final project of the villas designed in *I Quattro Libri dell'Architettura*. The design of the work helps facilitate an understanding of the project on paper and its three-dimensional realization, using theoretical information and graphics already discussed and validated. Villa Mocenigo, whose physical construction was barely started and never completed, is the final illustration of the second of the four books. However, there is ample evidence that it was never built. Dealing with three-dimensional reconstruction of a villa of this magnitude was thus highly problematic. The difficulty lies in the transition from a two-dimensional model of villa, a drawing on paper, to a real draft outline; the intention is to give shape and volume to a drawing in order to allow a three-dimensional use. The analysis performed on the Palladian designs was a very interesting experience that led to the clarification of the various concepts learned through theoretical study and a comparison with measurements carried out on the existing Palladian heritage which has resolved many apparent graphical contradictions (wall size, proportions, height of walls, similar design solutions). Once these issues were resolved it was possible to redesign the correct plan of Villa Mocenigo based on consideration of arrangements described above. The next problem was to think about other elements available to the project in order to define the internal organisation of the villa and the plan of the second floor (remember that in drawings of Palladian villas in the second book, there are always an elevation and one plan although most projects involve at least two levels). Many difficulties arose during this phase and, taking into consideration the purpose of these operations (annotated three-dimensional reconstruction), we tried to find more relevant information to solve the problems. We should again note the continuous and exhaustive demonstration of how the integration of the traditional means of representation, implemented by innovative computing systems, facilitates the level of understanding of the rules used on paper by Palladio, resulting in an enhanced quality of the subsequent enjoyment of the heritage. Obviously in the study, the transformation of a two-dimensional to three-dimensional model is achieved through the use of modeling, detecting and identifying inconsistencies and issues hidden in the Palladian design rules outlined in the four books. The objective therefore is to detect and correct possible defects present in the paper design of the Villa Mocenigo, referring to the design in the text and then moving on to create a three-dimensional model. The ideal condition would exist if after these analyses we could have answers or create universal rules governing the transformation and reconstruction of a Palladian design in its three dimensional model. Unfortunately it is a far-fetched concept because the reconstruction process starts based on the reading and interpretation of the four books that are steeped in information about graphs that is often contradictory. Being fully aware of this difficulty, anyone who approaches these studies is led to formulate their principles and justify their assumptions; it is interesting however to draw attention to how often there are several possible solutions for a single problem that makes it almost impossible to develop a single system of solutions. This reconstruction methodology is not a reliable methodology, that is, a structural scientific method that you create and which is based on established rules before being tested and validated. It is on the contrary a procedure that is validated and empirically legitimized by rules that are framed and tested as the study of the model progresses. It is therefore by starting from Palladio's original designs that you can complete the reconstruction process. The indications from the process are therefore an updated re-reading of all the elements and current rules showing the real application and applicability of traditional Palladian rules, establishing and assigning volumes to elements of the construction (wall thickness, size of the bricks, size of the elevations, thickness of ceilings etc). In conclusion, summing up the concept and separating it into different "stages" we start from the analysis and study of Palladio's drawings on paper continuing with the suggestion of a new interpretation of the four books and the final phase consists of the implementation and evolution of the drawing in its corresponding three-dimensional form, that is in its visibly "physical" form. But the most interesting aspect that justifies the reconstruction of the Villa Mocenigo, is the possibility of carrying out an internal examination of the "place" focussing on the Palladian issue of enjoying the architectural heritage that was never completed.

Abstract

The report is aimed at describing the study carried out since 2006 by the Istituto Veneto per i Beni Culturali on the old mortars of the Crusader citadel of Acre in Israel. The investigations have been conducted in collaboration with the Israel Department of Antiquities and it has been the occasion to train up some local operators in the field of restoration by specialistic lessons delivered by Italian and Israeli teachers. More than two hundred collected samples have been studied to identify and classify their constituent materials and their related processes of degradation. The diagnostic research, together with the technical comparison and the study of the sources, contributed to define the most suitable ways of intervention. Moreover this study permitted to understand better the history of the buildings and their typological-stratigraphic classifications in a chronological sequence from the Middle Age to the Ottoman period. By the investment optimization point of view, we tried to supply the instruments necessary to define and understand the old urban fabric and to give meaningful information to the planners and to the workers involved in the conservative projects. The knowledge that this study produced will be useful to the local operators and to all the institution interested in the conservation, restoration and exploitation of the "old citadel of Acre".

Keyword: Architecture

1. Introduction

Since ancient times, the city of Akko is a meeting point between East and West, a crossroads for different cultures. The center has developed on a small cape jutting over the sea, inside a fortified wall; many urban stratifications are still recognizable and they are all related to different rulers: Egyptian, Roman, Crusader, Ottoman, British. The urban structure, developed mainly in the Middle Age, is characterized by winding roads linking districts and a few public open spaces. The maps of the nineteenth century show a compact city, with some rectangular or square buildings with large internal courtyard, generally developed on two levels. Here there were often accommodations for pilgrims on their way to the Holy Land or the Far East. It was an important commercial port of call, and it was the favorite location of Genoese, Venetians and Pisans, that still have some bazaar. The short Crusader hegemony has left visible marks in the urban structure, partly remodeled under the Ottoman reign and "sealed" and, currently, not fully explored.

Figure 1. Tunnel of the Crusader period

The historical and cultural distinctions make it so unique, that studying it certainly has a strong impact on the advancement of knowledge of the materials and techniques used in ancient times and the changes that occurred during the different dominations. The duty to preserve a broad and diversified cultural heritage also raises problems of compatibility and durability of the materials to be used for the conservation of the architecture, particularly the durability, because of the environmental conditions, marked by humidity and marine aerosol. The plasters are not only bedding or protecting materials, but they also feature waterproofing or coating and decoration. In a not so far past, they have been considered easily expendable, they were frequently removed and replaced when broken down, by ordinary interventions of maintenance. Currently they are considered an important source of information for the history of the buildings and, wherever possible, preserved as architectural heritage. The materials used in past times (both Crusader and Ottoman) have demonstrated excellent resistance to the weather, so they have limited conservative problems. The plasters recently applied, during restoration, have not been able to match the characteristics of the ancients and they have broken up within a short time after installation. The examination of the composition and technique of the ancient mortars and plasters opens an important window on the knowledge of the applied materials and methods. Then, it is fundamental to understand how to make repairs to ensure the preservation of the architectural heritage. This report presents the results obtained by studying the characteristics of various plasters of Akko, belonging to both the Crusader and Ottoman periods. The samples were collected in different locations to monitor the materials and the performed techniques with a broad and diverse series of case studies. We therefore hope that the gained knowledge may provide guidelines for the maintenance and preservation of historic buildings also by local craftsmen. The work will restart with a trial of new mortar proposals for installation in Akko.

2. Historical background

The history of Akko began during the New Kingdom, when it was tributary of Egypt, called Aak, and known by Jews as Akka. Conquered by Alexander the Great, it became Antioch Ptolemais, and then Ptolemais thanks to Tolomeo Soter; later it was a Roman colony. In the

following centuries, its already troubled history became a series of sieges and occupations, from the Arab conquest of 638 AD. The decision taken in 1009 by the caliph Hakim to destroy many churches in Palestine, including the Holy Sepulchre of Jerusalem, was the beginning of a series of religious conflicts, that lead to the Crusades, a period of bloody upheaval throughout the region. The city was conquered by the Crusaders in 1104, who called it Saint John of Acre and made it their chief port in Palestine. The urban area was divided into several neighborhoods, communities assigned to Genoa (1104), Venice (1110), and Pisa (1168), as well as to the order of the Templars (1187). The destination of the different areas, individual neighborhoods and fortifications are in a recognizable representation of Akko in the Liber Secretorum Fidelium Crucis (Venice, XIV cent.) by Marino Sanudo di Torsello. Conquered by Saladin in 1187, two years later it was besieged by Guido di Lusignano and retaken by Richard of England. Become the capital of the Latin Kingdom of Jerusalem and then an outpost of the Hospitallers, it fell back after the bloody siege of the Mamelukes in 1291. It was finally conquered in 1517 by Ottomans, who rebuilt it on the ruins of the Crusader palaces, used as foundations for new buildings. Akko underwent a further siege in 1799 by Napoleon, who wanted to foment a revolt against the Turks, but the venture failed. Then it was besieged and destroyed in 1831 by the son of the governor of Egypt. The different dominations and his being a crossroads of cultures have made Akko a venue for cultural exchanges, where Middle Eastern and Mediterranean realities have influenced each other. A Florentine traveler of the eighteenth century, noting the Ottoman city, described the architecture and construction techniques, explain that they were based on Vitruvius: knowledge and technology circulated in the Mediterranean areas, united by peculiar climatic characteristics. The differences were related to the materials, generally selected on the base of the easier supply. The manifestations of European culture from the twelfth century, the Ottomans from the sixteenth and finally the traces of the projects of Napoleon and the British rule on the buildings are still evident today. The most widely used building material is a local stone, known as Kurkar, a calcareous sandstone base with silicate material inside, typical of the coastal area, generally resistant to wear, but seriously damaged by continuous leaching. The stratification of matter is closely related to the construction techniques of the period of installation: the remains of the Crusader city are characterized by large blocks of stone with intervals of elements of smaller size; the second layer, Arabic, is made of minute stones; the third, Ottoman, by blocks of stone with sharp similar and accurate edges. The same material was also used for the composition of mortars and plasters, object of this study.

3. Samples

The samples analyzed are 40, divided into two types: 25 of finishing plaster (even if composed by multiple layers) and 15 of filling plaster or entrapment. The sampled finishing plasters are four types: waterproof (tanks, gutters / pipes), inside residential buildings, outside residential building and outside public buildings. The bedding plaster belongs to public buildings, residential monumental buildings and residential ordinary buildings. The time span of the buildings is sampled on three periods: medieval buildings (most of the buildings between 1104-1291 are Crusaders, between 1291 and 1530 Mamelukes), early Ottoman buildings (1530-1750) and later Ottoman buildings (1750-1917).

4. Analytical techniques

Thin sections were made to be analyzed by petrography, conducted with a polarizing microscope in transmitted light to identify the mineralogical components of the material and its textural characteristics. Some NORMAL regulations have been used for the analysis of the samples and their descriptions.

-10/82 Petrographic description of natural stone materials. It defines the procedures to follow for the description of the characteristics that determine the behavior of chemical, physical

and mechanical stone material, also to any comparisons between different parts of an article at the conservation status of the installed material and the corresponding material in quarry.

-12/83 Chemical-mineralogical-petrographic-morphology description of artificial stone materials. Schematic description of artificial aggregates of clasts in a matrix non-clay: it is referred to non-clay mortar matrix.

-14/83 Chemical-mineralogical-petrographic-morphology of natural stone materials. It describes the technique (to be adopted for the preparation of useful sections for the examination under a microscope in transmitted and reflected polarized light), for the characterization of stone materials and the evaluation of the effects of conservative treatments.

- 23/86 Technical terminology: definition and description of the mortars. It contains the general criteria and definitions for the plastering mortar.

- 27/88 Characterization of a mortar. The document, which sets out the general criteria and methodologies for measuring the physical characterization, mineralogical, petrographic and chemical mortars in place, consists of three parts:

1. list of parameters needed for the knowledge of a mortar;
2. methodologies to be adopted for the determination of these parameters;
3. diagram of the analytical sequence recommended for mineralogical and petrographic characterization of the mortar and its alteration products.

The estimation of the porosity of the samples was effected by image analysis in thin section.

5. Results

The summary results of the analysis of the samples of finishing and bedding plasters are listed in Table 1.

| Typology | Period | Ratio binder / inert |
|-----------------------------|---------------|-----------------------------|
| Bedding plaster | Medieval | 1/2-1/4 |
| Bedding plaster | Ottoman | 1/3-1/5 |

Table 1. Relation inert-binder of the plasters sampled in Akko. The data are averaged on the data obtained with a set of 15 samples of bedding plaster and 25 of finishing plaster.

The medieval bedding plasters have a relation binder-inert different from the Ottoman one and they are more resistant than the latter even if their composition is rather similar in both types. Even in the case of finishing plasters, there is a relation binder-inert different for the medieval period and for the Ottoman period. Particularly, in the Ottoman period there is a differentiation depending on the applications of the material. Ottoman decorative plasters for important rooms have smaller quantities of inert to be coated in very thin layers. The results obtained by the characterization, made in connection with the conservation conditions, gave three sets of samples, inside of which bedding and finishing plasters of various ages were evenly distributed: 16 were in good conditions, 13 sufficient, 5 bad. The fact that the material in conditions of insufficient conservation is lesser extent than the other, is a sign of good durability of the mixes.

| good conservation (16 samples) | | |
|--|---------------------|---------------------|
| | Crusader period | Ottoman period |
| number of samples | 9 | 7 |
| porosity 30% | 3 | 1 |

6. Discussion

The analysis of the mixtures have underlined that, despite starting from the same raw material, the techniques of realization were different during the two examined periods.

Figure 2. Sampling point 1: bedding plaster placed outside, Crusader period.

The medieval finishing and bedding plasters are generally stronger and more rigid, since the architecture of this period was much more massive, consisting of large blocks of stone. The palaces of the Knights Templar are powerful, fortresses that were to withstand sieges and assaults. Bedding plaster on outdoor walls has high porosity and grain size, and despite the strong carbonate component, generally has a good consistency. Plasters of the same type but with different location (for example, room with high humidity), have slightly different characteristics and lower porosity, and shows a medium-low state of conservation, underlining the weakness of the mixes in presence of high humidity. The city has stabilized relative humidity between 65 and 67%. Generally, amalgams placed in rooms with lower humidity are decayed, and plaster of similar type in the same environments, but situated at the top, shows a better preservation. The Crusader plaster has almost exclusively the function of protecting layer for the material below or sealing surfaces, it rarely has aesthetic purposes. The Ottoman mixtures have less rigidity and toughness, their more elastic nature should be considered in relation to the buildings on which they were placed: buildings of the Ottoman period included the increased use of elastic materials such as wood, and thinner walls than the previous period, it was therefore necessary to use less tenacious mortar.

Similarly, the plasters were often spread not only with the function of protecting layer but also with decorative aim, to embellish or cover the walls, above all inside. In this case they must have a finer granulometry to create a good basis for the decoration. The distinction between the Crusaders and the mixtures of the Ottoman period can not therefore be based on their chemical composition, but on their morphology and technique of realization. To prove the identity of the materials used in the different periods, there is the condition of preservation of the same materials that is in most cases good or sufficient. Only 5 samples show signs of deterioration such as to be judged in poor condition. Three of these are Ottomans and two Crusaders, further evidence that the two types differ only in morphology (who built them had different needs) and not for composition.

Figure 3. Sampling point 2: finishing plaster placed inside, Ottoman period.

Figure 4. (1) Image of the sample 13 as it is: Crusader bedding plaster ; (2) thin section image of the same, 40x. The sample is in good condition.

Figure 5. (1) Image of the sample 24: Ottoman finishing plaster; (2) thin section image of the same, 40x. The sample is in a state of sufficient preservation .

Further investigations may help to understand the hydraulic component in the binder, but it is known that in both periods taken into account the natural hydraulic lime or pozzuolana was not in use, and so the brick dust.

7. Conclusions

The plaster of the medieval period are strong and rigid, while the plaster from the Ottoman period are weak and flexible. The application of the plaster was made on new or reused stones. No efflorescence or saline subflorescence are present, and it was significant in the coastal environment. The absence of macroscopic salts may be linked to the same type of mixture, being able to let pass, through the porosity, compounds that might otherwise create mechanical damage.

Figure 6. Room with colored finishing plaster of the Ottoman period.

The characteristics of the different types in the two periods were not due to alteration or degradation, but to different manufacturing technologies: the massive and rigid Templar architecture required strong and rigid compounds, the Ottoman buildings, with thinner walls and wooden parts, needed compounds able to accommodate the elasticity of the structures. These are the same raw materials used in different ways to achieve different final products. The identity of composition is also confirmed by the degradation of the (few) samples of both types, indoor and outdoor, suggesting that the deterioration was due to the peculiar conditions of maintenance of the sample itself. The conservation of a higher number of Crusader mixtures (and the subsequent analysis in this study) is not due to their different composition, but to their "sealing" during the Ottoman period, that have preserved them. The Ottoman plasters, however, have been in contact for a longer time with the environment and have been considered protective layers compared to the rest of the structure, and have undergone maintenance and replacement over time. The results achieved by the polarizing microscopic observation of thin sections, may in future be supported by other evidence for a deeper understanding of the morphology and characteristics of these compounds. The knowledge gained through this survey are useful not only to understand the material history of Akko, but also to its recovery. The obtained results, in fact, will be shared with local workers for the proper preservation of ancient plasters and will be useful as guidelines for the selection of suitable and compatible materials, to experience similar environmental conditions prior to application. The experiments on mortars must determine not only their durability, but also their resistance in a marine environment, where they will be exposed to moisture, rain and salt spray. Samples of plaster are in fact tested in Venice, the Mediterranean city similar to Akko. The results allow to construct the curves of the chosen parameters (and measured monthly), and suggest the best application technique for the installation.

Abstract

In the fraction of Carbonara di Bari, once an independent common and now southern urban fringe of chief town of Puglia, remain salient traces of the oldest nucleus subjected, from nineteenth onwards, to a strong extensive building. Some design characteristics of the land of Bari are common to Mediterranean traditional - form of the urban fabric of the historic center, construction type of elevated structures and vaulted structures, thickness of walls, size, location and number of windows, etc. - but others are peculiar to the places you're going to describe. Among these, the *vicinio* represents not only a type of architecture is found in Bari Vecchia, both in the historical centers of the province, but also a lifestyle of a people accustomed to living in a land of mild climate, with winters are not particularly rigid, summers hot and windy, and persistent solar radiation in all seasons.

In this scenery took the form of historical research and detection using three-dimensional laser scanning, both aimed to the definition of the relationship between the complex massing rediscovered, to the restoration and to the subsequent reuse of the architectural heritage in a sustainable. The study showed the presence of more periods of construction and made it possible to formulate various hypotheses regarding the phases of growth of the well. The proposed reuse of the property, in compliance with the building type in question, allows to exploit the techniques and local building traditions and rediscover a way of life tied to the distant memory of places.

Parole chiave: surveys, sustainable design, restoration, reuse

The research work for the valorisation of *vicinio* in question begins with a more general recovery of the area to public and private. The commission received by a private client who intends to restore and recover it by following the building traditions and cultural character of the land of Bari. Following the spot investigation, due to the complexity of the architecture and features of the complex, it became clear the need to proceed from one side to a depth historical research document, other side of a thorough architectural survey. Therefore, the survey has allowed three-dimensional laser scanner to report correctly the two plans and to understand the genesis of structures and equipment walls. The reconstruction of complex geometries required the definition of a topographical network that has been difficult for the positioning of a considerable number of stations and target. The result obtained has allowed an accurate reconstruction of both geometry and thickness of walls, both to deepen the assumptions already made on the construction phases of the building in order to propose a recovery that that respects the calling of the places and the story they tell.

1. Historical and town-planning framework of the urban municipality of Carbonara di Bari

The urban development of Carbonara di Bari¹ is largely tied to the city of Bari and the nearby villages of Ceglie del Campo and Loseto. The present structure of the urban sinking roots in earliest times and is connected to historical events that, directly or indirectly, have helped to establish the modern structure of the town converged on Piazza Umberto I. The square, in fact, has even acquired its current radial shape during the decade of regency France, was for many centuries the place where you have done most of the city events.

1.1 Short history about the fraction of Carbonara di Bari

At the end of the eighteenth century, the surrounding countryside of Carbonara di Bari, show a landscape marked by: olive, carob and almond trees, vineyards and orchards, sown lands and finally pastures. Only with the abolition of feudalism and reintegration in the State Property of the baronial jurisdictions, however, Carbonara is transformed into a free village assisted by nobles.

In April 1799, French troops burnt down the village in response to the siege it had imposed on the population in the surrounding countryside and in the near Modugno, where he was already hoisted the tree of liberty to support the fledgling Neapolitan Republic. Carbonara, showing his loyalty to Ferdinand IV of Bourbon and therefore adverse to the Jacobins, suffered considerable destruction of the houses surrounding the main church. In August 1808, Joachim Murat was crowned King of the Two Sicilies Kingdom: opens a season of reforms which, though short, not only determines the transformations that have a direct impact on the local economy - through the sale of national property with the benefit of extending the middle-class property - but also promote the development of agriculture and, following the introduction of economic companies, the beginning of industrial foreign installations; most part of the buildings in the area are restored; is applied a new building code and start a census of housing in a cadastre.

In September 1811, decreed the "restoration and formation of vicinal and byways" of the newly formed province of Bari, while between 1824 and '30s, this process of redefinition of the internal lines of traffic also affects the new tram-car connection between Bari and Carbonara. Local administrators who look often to urban building extra moenia, hope for Carbonara that improving economic conditions and housing that involves the transformation from scratch of Piazza Umberto I, developing the area used for the threshing and so called "Piazza dell'Aja" (Threshing-floor Square), to a trapezoidal square around which to develop the built according to building regulations of Murat (Fig. 1).

On the other hand still is Piazza Umberto I, which branch off the fifteen roads along which, according to a defined radial design, thickens the built-up area: among these is the main Corso Vittorio Emanuele, while maintaining a short distance the trends north-south, connects the modern square to the oldest Carbonara's buildings date back to the XIX century, bending towards the east at Piazza Garibaldi. Therefore, even though the Italian reality is deviated by the great contemporary transformations generated by the industrial revolution in France and England, in South Italy will arrive, however, step by step, the neoclassical definition of a policy that understands the importance of a systematic series of public works that can also contribute to political stability throughout the southern region. The political up and down, then, have precisely influence on artistic, particularly in architecture, split by two main currents: in the early decades of the nineteenth century classic models become the inspiration to make room, in the second half, those Neorenaissance. These are characterized by a meticulous character design that became quickly the symbol of the aspirations and the affirmation of new and emerging business classes of bourgeois decorum. To complete this scenario, there are also reasons related to economic development and population growth and therefore the expansion of old settlements that, through the demolition of the city walls, are built along existing or new roads, following a modular grid. This process makes an important and significant part of the representation of the entire South. The teachers involved in the Academy of Naples, innovative interpreters of taste from the Napoleonic Empire, transmit it to the young students, who are also involved in Puglia. Therefore, even for Carbonara, the central square becomes the center on which engage broad that branch off symmetrically distributed from it, or from the monument, a representation of convenience and functionality of the theory of the late-eighteenth century.

From an administrative standpoint, until February of 1928, Carbonara is an autonomous municipality, on this date, through a Royal Decree, the two municipalities of Carbonara and Ceglie are suppressed, becoming a single large fraction of Bari, while in 1953 a Ministerial Decree split again the villages and in 1970 Carbonara, Ceglie and Loseto become three of the seventeen districts in which Bari is structured and, finally, in 1979 the districts are grouped into the 9th Administrative District of the city of Bari and these three fractions, from then until today, belong to the 4th.

1.2. A short essay about the modern urban transformation of the province of Bari

Early indications for the programmatic expansion of Bari to the south, or beyond the break of the railway line, appear in 1911 with the town planning of Eng. Arrigo Veccia: starting from the Murat district, is planned a urban expansion along the radial axes of growth of the traditional city, where there are already civil and

Fig. 1: Carbonara: : Piazza Umberto I of the beginning of XX century; on the background Corso Vittorio Emanuele

productive settlements.

Between the XVIII and XIX centuries, Carbonara is a suburb close around to the present Piazza Umberto I (ex Piazza Garibaldi); its structure is clearly visible in the urban cadastral map that keeps track of the properties in the city at the end of 1800 (Fig. 3): the building facades along the square and along the main radial expansion streets are mostly completed and the areas that are most built are to the north in the direction of Bari and to the south-southeast around Corso Vittorio Emanuele.

But it is with the Master Plan of the Grande Bari in Fascist time (Fig. 2), commissioned in 1930 to Architect Concezio Petrucci, that is expected growth of the city both in the east and west directions, but also and especially to the south to integrate the suburbs Carbonara, Ceglie and Loseto. In the Petrucci's masterplan for the surroundings of Carbonara and Ceglie (Fig. 4), very close to each other territorially, there is provided a unitary project of the area that involves both the demolition of portions sometimes considerable, both the construction of a substantial amount of building extensive near the two urban centers, both the intensive construction in the free space between the two municipalities; these are joined without interruption by blocks built, parks and boulevards that are modeled without following the paths of agrarian property. For Carbonara is basically confirmed the development around the main square along the radial lines that are structured in the course of the previous century; are planned several demolitions with the dual aim both to reduce the densification of the urban fabric, to make straight the streets and to create open spaces, both to facilitate - particularly in the south - the creation of wide and straight roads linking Carbonara Ceglie.

The plan of Petrucci, despite never having reached the final approval, has served to regulate the expansion of the city even after the war and, anyway, until it is approved, in 1954, the town-planning of Piacentini-Calza Bini (Fig 2). Stimulating a doubling of the population (500,000 units), the town-planning allocates extensive areas of land to the urban expansion: with the exception of the west area - not suitable for the residential use due to the presence of the cemetery and the industrial areas - the edification is planned substantially in all directions. The road system is centered on three main north-south axes and, in the south area of the railway, on three lines transverse. The Murat Centre still hosts directional and commercial structures, while the functions purely residential are located in the neighborhoods system of a crown around the city center. However, the realization of the project will be done through the systematic use of variation to the town planning scheme and of the license notwithstanding.

Fig. 2: Bari town planning: Petrucci Plan of 1938; Piacentini-Calza Bini Plan of 1954

Fig. 3: Carbonara di Bari: urban cadastral map at the end of 1800

In 1973 is adopted the town planning of Quaroni (Fig. 2), which formally can be considered a variation to the plan by Piacentini-Calza Bini, even if the city model proposed seeks to break the structure of the monocentric city in favor of a polycentric model that focuses on the reorganization and strengthening of the suburban villages, on the renewal of the nineteenth-century city center, as well as on creating a new centers of peripheral expansion. The supporting structure based on a communications system road that extends to a scale that exceeds the limits of the municipal area. Assumes particular importance the new north-south axis that, from the port, cuts the whole system of cross communications to connect Bari to its hinterland.

Fig. 4: Bari town planning – Town of Ceglie e Carbonara, architect C. Petrucci, 1938

2. Particular characteristics of the civil architecture in the Land of Bari

As has already been able to detect Sylos, the Neoclassical period and the Neorenaissance in Bari are clearly distinguishable as "*al sesto tondo si sostituisce il sesto ribassato*", noting, however, that "*a nessuna di queste costruzioni, sia del primo che del secondo periodo, mancano mai la signorile correttezza dell'insieme, l'armonica euritmia della linea, la cura e la grazia dei particolari*"². This critical position is also evident in Carbonara where, however, is also visible in the formal influence of what had been the first expansion of the nearby Bari: the buildings of the Murat Centre are on two floors or maximum on three floors including the ground floor. In particular, buildings with three floors represent the classic nineteenth-century house of Bari, with a prospect divided into three bays and about sixteen feet long, a balcony for every room and a simple but harmonious crowning cornice³ (Fig. 5).

These building types are routinely taken in the territory; the use of *dolomia* stone for decorative and architectural elements makes its appearance even in smaller countries, including Carbonara, while the common limestone, with its various gradations, is used as coating of ordinary masonry, for the ashlar of angular stone, for balconies and gables of the windows. With regard to the engineering practice, the tuff called "*zuppigno*" is used for the structure of the vaults – usually, there are barrel vaults in the service rooms, while cross vault and pavilion with lunettes in residential rooms – and of the arches, for the coating of the inside of the stone walls and for the inner walls with a single row of bricks; the tuff called "*carparo*" is especially used instead for corner pieces, for the ribs of the vaults, for frames and shelves and for the outer covering more cheaper than those made of stone. The horizontal structures, until the early twentieth century, are barrel vaults, even with lunettes, pavilion and "*a schifo*" vaults, less frequently cross vault and "*a vela*" vaults and are made using squared blocks of tuff; in a second time we can find ceilings with beams of iron and tuff or bricks vaults, and finally, from the first World War, tile-lintel floor. The thrust of the vaults, with which are also covered the second floors, is supported by very thick walls made in squared tuff.

The facades are characterized by the constant presence of balconies and by a clear majority of the wall surfaces compared to windows. The windows on the upper floors have significantly vertical relationships and are always equipped with shutters, while on the ground floor you can find openings with different shapes and sizes: small and low entrances, even with steps near the threshold, for stores and workshops; entrances "*alla mercantile*" for the passage of carts or carriages they place in small interior patios; elegant entrances often adorned with frames, decorations and columns leading to the main house on the upper floor (Fig. 6). The color of the facades, always plastered, is rather uniform and usually ranges from ocher and *beige*.

In conclusion, the nineteenth-century architecture in Bari has its own particular character, is very tidy both for its exact proportions, both for the metric relations existing between the flat surfaces and the plastic and decorative elements; the same features are also found in the other cities of inland.

Fig. 5: Bari. The Murat Centre in a picture dating from the late nineteenth century.

Fig. 6: Bari. "Bari Vecchia": vaulted structures and entrance "alla mercantile".

3. Unfinished building nineteenth-century in Corso Vittorio Emanuele

Among the buildings located in the historic center Carbonara di Bari, stands along Corso Vittorio Emanuele - the section between the squares Umberto I and Giuseppe Garibaldi - the front of a building (Fig. 7) in the bourgeois house style of nineteenth-century and follows the classic model inspired by Neorenaissance style which is mentioned in the previous paragraph.

The real historical estate is developed on two levels including the ground floor; the sober front consists of a single span, which downstairs exhibition at the center an entrance "alla mercantile" that leads into an irregularly shaped room with a barrel vault, while the upper floor has a single window surmounted by a frieze and frame and a balcony - decorated with elaborate balustrade in cast-iron - both not aligned with ground floor access. The facade is covered with plaster and on the sides is framed by two bands that in top become embossed and end with a simple and harmonious decorated band, followed, in height, by a cornice with brackets.

Fig. 7: Carbonara. The small palace in Corso Vittorio Emanuele: the facade and a detail of this by laser scanning.

Fig. 8: Carbonara. The small palace in Corso Vittorio Emanuele: rooms and vaulted structures on the first floor

The rooms on the first floor are accessible by a ladder placed in the *vicinio* and accessed by the door at the left side of the facade above described. The rooms - five in total - showing different roof systems, a clear sign of their achievement in later times: the four rooms of the nineteenth century core are covered by three vaults "a schifo" (Fig. 8) and by a barrel vault, on the contrary, the room facing west - originally probably a terrace - has covering with tile-lintel floor. From this last room, through a staircase, you enter a room with a flat roof and from there to the terrace.

The *vicinio* (Figs. 9-12) is characterized by alternating covered areas - two barrel vaults and vault "a vela", coverage very rare in such spaces, made of squared blocks of tuff - and open spaces. The ground floor rooms open out on both sides of the *vicinio* - especially in the covered areas - and show an entrance surmounted by a small opening, which is needed, obviously, to ensure a minimum of ventilation for locals that have three blind sides (Fig 10); have different shapes and sizes and are very irregular, but always covered by barrel vaults.

3.1 Considerations about the peculiarities of the building

The instrumental survey executed and the subsequent development three-dimensional of the point clouds, along with research conducted at the State Archives of Bari have served to bring out some salient features of

Fig. 9: Carbonara. Building in Corso Vittorio Emanuele: vaulted structures on the ground floor by laser scanning

Fig. 10: Carbonara. The small palace in Corso Vittorio Emanuele: rooms on the first floor by laser scanning

the architectural and allowed to advance a different hypotheses about the genesis of elevation structures and the different steps of growth of the building.

The facade shows strong asymmetries that lead to make different assumptions about the construction phases that followed each other and those who probably have never been realized. The vertical decorative elements are all symmetrical to less than a vertical band on the left side that, in the manner of parastas, uninterrupted runs nearby to the band specified above, and that at the top has a larger overhang of the other (Fig. 7). The hypothesis advanced is that of a facade designed to be tripartite, that is set of three bays as nineteenth-century buildings in Bari, but was in fact incomplete. Singular also the lack of axially between the two openings: the ground floor entrance is nearly centered on the width dimension of the facade, but not at the center compared to the inner room which gives access; a balcony and the upstairs window are decentralized both compared to the width of front both respect to the back room, but the window is aligned with the row of passages found in the rooms upstairs.

These considerations about the facade and the behind rooms, together the particular typological and structural conformation of the *vicinio* indicate that there was an older portion - difficult to date - made of ground floor rooms belonging to the same *vicinio* and rooms upstairs not exactly the same with those of existing nineteenth century building. Probably the *vicinio* was a place of passage but also a place to stop covered/uncovered that linked two parallel streets or that leading into a courtyard, as in the preceding and/or coeval examples you can find in the Bari Vecchia.

In fact, if we consider the traditional architecture of the old town of Bari, at the street level in correspondence with of the vaults a series of spaces appeared and the life went on seasonally there close, alternatively in or under adjacency of the shelter: in the hot season the vault offered meeting places away from sunlight, while, in the cold season it was possible to benefit of the direct irradiation placing oneself behind them. Later on the

Fig. 11: Carbonara. Building in Corso Vittorio Emanuele: longitudinal section from laser scanning

Fig. 12: Carbonara. Building in Corso Vittorio Emanuele: the vaulted structures which characterize the *vicinio*

vicinio, because of its proximity with the main church, it was probably damaged or partially destroyed by the burning caused by the French in 1799. After, in the first decades of the XIX century, Carbonara there was a considerable work of reconstruction and these were the years when, probably, the building was built on a pre-existent nucleus exploiting the powerful wall structures of the ground floor, which were not destroyed by the burning. The ground floor rooms became area services (deposits of tailings, shelters for animals, etc.) of the main house situated on the first floor. This historical reconstruction may be supported by a series of anomalies which it was possible to point out thanks to the three-dimensional reconstruction from laser scanner such as, for example: missed alignment and variations of thickness frequently noticed among the structures in elevation of the two floors, enlargement of one of the supports on the ground floor with a consequent reduction of the access door to the neighboring room, insertion of a flight of stairs inside a supporting structure, manholes found in some of the vaulted of the environments on the ground floor, etc.. he conditions of life happens between the two World Wars when there is an increases of the gap between the population and the number of rooms, that is because of natural events and / or natural disasters, the population impoverishes, the number of property owners stagnates but the number of tenants increases. As a consequence there is an overcrowding in some parts of the town and for some categories of users that leads to the downsizing of the housing and to the decrease of the number of rooms in it, with negative consequences of the hygienic conditions of the housing. The home becomes, in the worst cases, composed of one room on a area of only 30 square meters, with a single facing and frequently placed on the ground floor. This can be assumed for the environments placed on the ground floor of *vicinio* for two reasons: *in primis* the only plants found dated 1939 attributed to every environment category A5 (low class housing) instead of, for example, C2 (warehouse / storage) as we might suppose because of the type building; the second reason is that, within the only environment, there are toilets evident sign that the family who lived there – probably large as for tradition - was forced to live only in one room.

4. Possibility of reuse in the respect of the tradition

The *vicinio* on the ground floor and rooms on the upper floors offer different ideas for reflection to advance a proposal for reuse that values the orientation, the shape of rooms, weaving wall, the height of the rooms, etc. in the thickness of the massive walls were carved niches, fireplaces, steps that tell how the people utilized their in the past.

The draft refunctionalization is assumed that future use of the property must be compatible with the vocation of the place while respecting the rules of healthy hygiene in confined spaces (size of rooms, ability to perform proper ventilation, natural lighting requirements , etc.). Following this assumption, the *vicinio* becomes an extension of the residential property common to most homes - as indeed was done traditionally - and the

Fig. 13: Carbonara di Bari. Building in Corso Vittorio Emanuele: the vaulted structures which characterize the *vicinio*

ground floor rooms are joined in pairs to create small flats in which the division between living and sleeping areas not marked (Fig. 14). The number of partitions is reduced to a minimum: are used only to separate the toilet from the common area and have a height always less than the time to prevent conceal the complex geometry of the spaces. The walls are all plastered newly constructed, unlike existing ones will remain legible for which the wall-building in square blocks of tufa, which also shows no signs of injury or failure. The thickness of the wall is of fundamental importance to ensure the thermal inertia of seasonal and reduce power consumption for air conditioning.

Upstairs, the area of nineteenth time is valued in the same manner above described, and is scheduled reconstruction of the floor is brick and cement for structural reasons, is to ensure a better thermal insulation.

Fig. 14: Carbonara. Building in Corso Vittorio Emanuele: the project of restoration of the *vicinio* on the ground floor

¹ On 30 July 1862, the Prefect of the Province of Bari ordered to add the name of the City of Carbonara a suffix that he could identify him and the city council decided unanimously to name it Carbonara di Bari Regarding the origin of the name, instead, mention is made of different hypotheses previously reported both in published sources that in the

literature, from the one advanced by historian Antonio Bari Beatillo that extends to the derivation from the Greek words Kar (mercenaries) and bon (peasants), or the position expressed from the historic Coleman Carbonara that would attract a "coal" or "furnaces" or, finally, that reported in Bari Diplomatic Code drafted in 1195 that Carbonarium - Carbonarum - Carvonarium mean "ditch" or "ditch".

Abstract

Inside the Gardens of the Quirinal, in a rather secluded, a place is one of the oldest fountains that adorn the park, the so-called "rustic Fountain" commissioned by Ippolito d'Este in 1560 realized by Curzio Maccarone, fed now as then, Aquedotto Felice. On behalf of the office for the conservation of the artistic heritage Quirinale, a research has been structured with the aim of restoring the original form - now hidden - the monument, so they can better define the future restoration. Starting from the iconography has been possible to establish that the fountain has undergone several changes during the papacy of Paolo V - in the first decade of the seventeenth century - and Gregorio XV, which must add up the wafers produced by tartaree layers of limestone, mosses and different tree species. For these reasons the fountain shows an aspect of "organic" in stark contrast with the small tank molded on which it stands, as to make it a casus unique architectural. To meet the demands of the client has been called a "protocol" of instrumental tests such as laser scanning, thermography, digital sonic tests and endoscopy. The results of the first phase were merged within the three-dimensional model obtained by processing the scans in both the three-dimensional shape to a reduction in the skimmed "*finite elements*".

keywords: scanning laser, diagnostic, modelling, databases

1. Introduction

The knowledge needs to ascertain the state of preservation of historical artifacts according to the guidelines that govern the modern concept of conservation, as noted, require a variety of specialized analyzes. These investigations for the importance have long been the focus of intense scientific debate about the results, especially seen in the last decade, the innovative contributions provided by the electronics and informatics. This process of electro-computerization has in fact allowed to redefine the very concept of knowledge, given the current real test you can perform only theorized up until a few years earlier. In principle a framework that goes beyond the narrow scope of disciplinary architectural survey, investigations aimed at the knowledge of an artifact can be grouped within three main categories:

- I) Analysis of surface metrology (laser scanning, digital photogrammetry),
- II) Analysis of matter at shallow depth (infrared thermography, Multispectral analysis),
- III) Analysis of material-mechanical deep (sonic / impulse response, modal analysis).

Each of these investigations beyond that for which it is attached, serves the double purpose of providing a high degree of knowledge with a nearly zero rate of invasiveness may allow you to overcome many of the limitations imposed by the boundary conditions, often frequent, in sensitive scenario of investigation as to the subject of this paper.

2. The fountain of woods

In April 2011, commissioned by the Office for the conservation of artistic heritage of the Quirinale Palace, the laboratory of the Faculty of Engineering of the University of Rome CRITEVAT, has undertaken a series of investigations to determine the conservation status, and together, the "true form" of a building inside the Quirinale, in order to assist and support the preparation of the restoration project. The object of investigation, one of the oldest fountains in the garden, already mentioned in the mandates of payment for magisteria recognized by Ippolito d'Este in Curzio Maccarone in 1561, given its characteristics and nature of questions to response required a multidisciplinary approach. The research was initiated by the analysis of historical documents kept in the form of regesto by Dr. Francesco Colalucci, head of area historical research on the Quirinale Palace complex, but that does not provide a precise description of the original appearance of the building, reported several indications about the changes gradually over the centuries suffered from the fountain, thus providing the important information about the *pectus* research and clarify whether the current appearance (fig.1) corresponded to a precise determination of palimpsest the fountain in the form of a mass nature concretizia, or was the result of a superposition of layers of limestone masses of lichen.

The fountain has made two huge portions with the base a hemispherical bowl molded from which rise some elements also molded to dissipate rising to the top. These seem to be reflected with some descriptions of work performed in the middle of the eighteenth century, appear to be absorbed, rather intermeshed, by spongy masses covered with vegetation. The natural look is accentuated by the irregularity as well as also the high degree of many alveolus present. The dark gray is almost homogeneous and makes it easy to distinguish the different varieties of plants present up to the top. At the summit, where the two masses do not have discontinuities, is placed a small statue of Orus on a just sketched pedestal. An interesting aspect of the fountain is discernible in the slight shift in the axis of the artifact that leads from the prospectus of the garden in the Palace of Quirinale. In order to answer to these questions, a precise protocol of investigations has been set up, including at least one test in the major categories listed above with the aim to interpolate between them, which were in order: the laser scanner, high resolution mapping camera, thermal imaging and digital seismic tomography.

Fig. 1: Rustic fountain, the main prospect

Fig. 2: Scanning laser collated; the elimination of tree species in the editing highlights the alignment of the fountain.

3. Definition of the complex model and topological fields

First of all should be pointed out that the investigations reported in this paper were intentionally disconnected from the hardware description that made them possible, because it would require a very different focus to examine it, the one on which there has instead focused more attention was the ' usability of the results obtained. Given the inherent complexity of this investigation, the concept of usability has seemed the ideal parameter to evaluate the effectiveness of the instrumental results, as the data collected for their diversity needed to exceed the scope of the architectural survey of the discipline to move within a wider range of skills. For these reasons, priority has been the appearance of "maximizing the benefits" that were at different stages in the use of collected data (round-up) management (storage) until further processing (editing). The fountain, to be fully restored and then be fully usable in its digital form, presenting as a heterogeneous collection of architectural and natural elements, must simultaneously satisfy the requirements listed above for more simplifying where possible. For this reason, the focus of research has become, beyond the data, their interpolation. In structuring this stage it is considered the work of collecting information from the linguistic point of view, suffering from the assumption that if the "understanding" is an expression of the cultural structure of the user, "usability" and "conservation" are dependent variables of component technology (hardware) that may change to benefits (or disadvantage) of the first factor. Once defined these assumptions, were determined the bounds of the object by circumscribing the purposes to which it had to fulfill, in order to be guaranteed the usability which was the track where there is never deviated. It was therefore necessary to define how to display the amount of data registered, taking into account that these

quantities were impressive. To meet this requirement, basic "topological districts" have been defined, each of which contains a specific set of data. Before those metrics, then all the rest one after the other.

Fig. 3: Mosaicing of the fountain with the elimination (virtual) of shrubbery and trees.

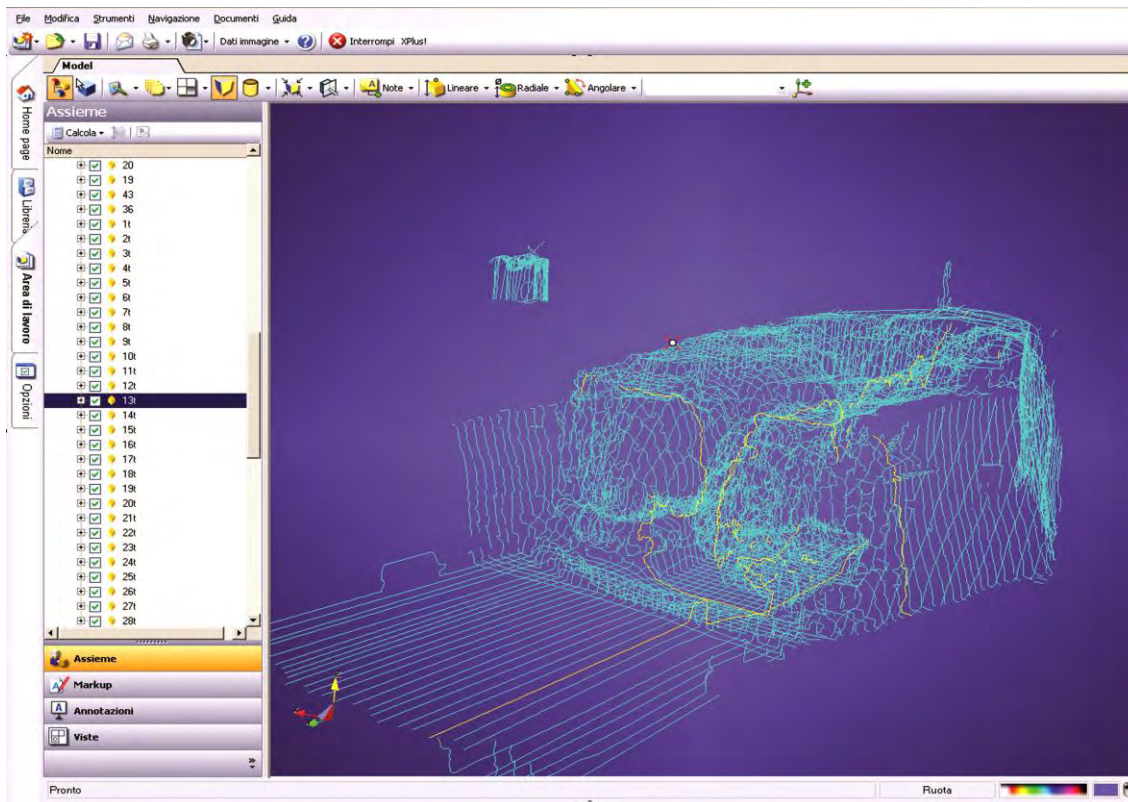

Fig. 4: Transformation of the fountain in the pseudo-finite elements, highlighting plans interested by the sonic tests.

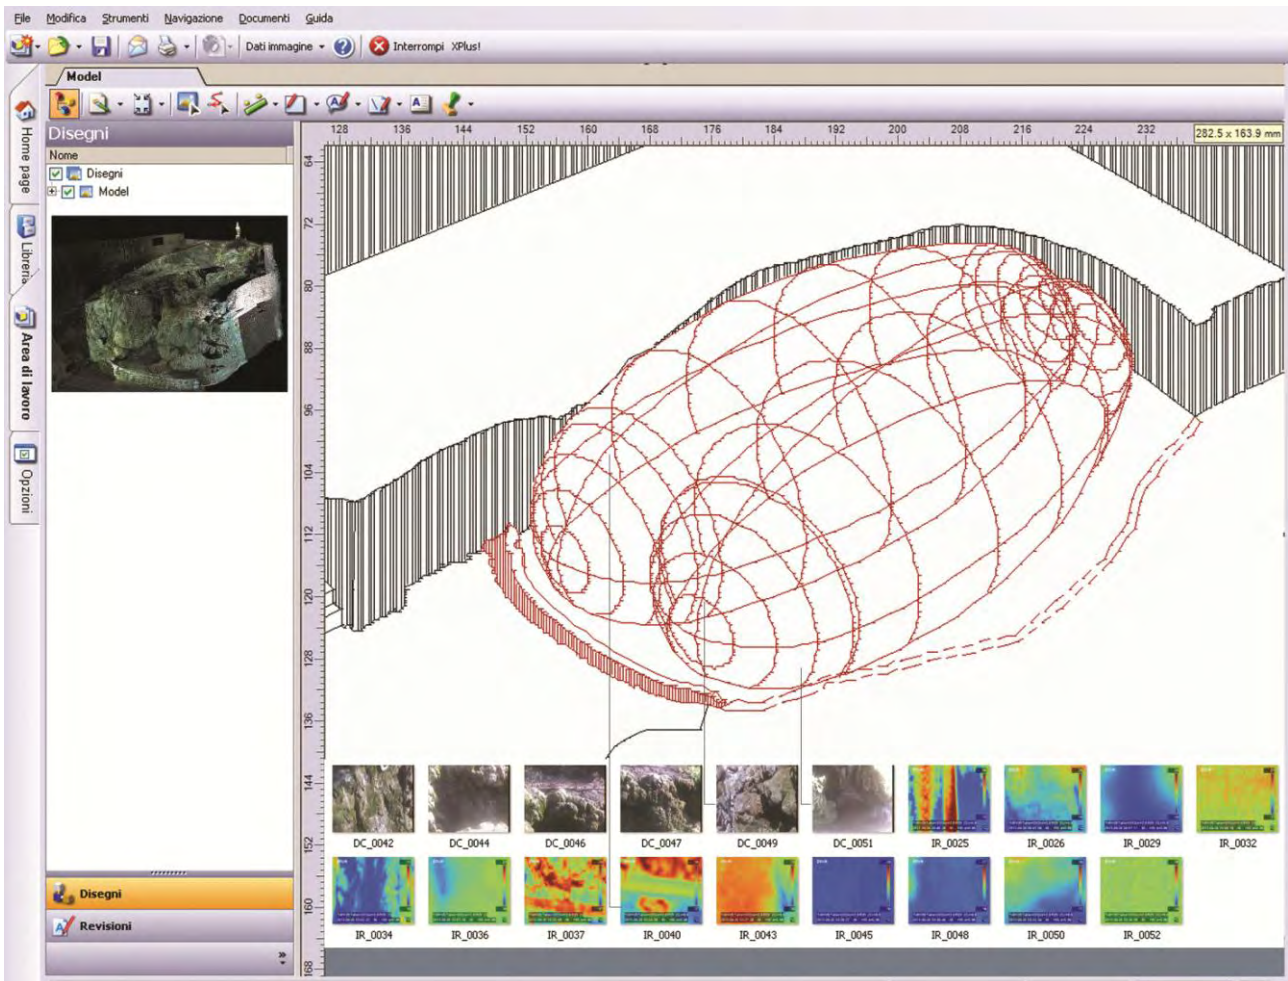

Fig. 5: Simplified model for the storage of data in three-dimensional shape with chains of thermal data.

4. Definition of Database

Once terminated the laser scanning session, made trying to avoid gray areas as much as possible, in order to eliminate any gap during the editing stage, which not infrequently take the form of anomalous surfaces, thermal mapping of the fountain was performed. The purpose of this phase was, through the understanding of the rate of release of moisture, to deeply understand the knowledge of some specific materials collected through micro-coring executed by EURESARTE company of Rome. To simplify the reading of the results, was previously calculated within predefined time intervals, the degree of exposure to the sun on the artefact, taking into account - at the time of the shooting - the solar lighting time and the portion of sky skimmed from the trees. Based on these preliminary considerations, we decided to focus the analysis in just one day, producing three separate shooting sessions, at the rate of one every three hours.

Analyzing the responses has been possible to assume a fair degree of homogeneity in thicknesses thus allowing a first approximation of mapping of limestone layers. Consecutively in this round of tests, when collated with the clouds of points, it was possible to draw the first elaborate descriptions in CAD (fig. 6.7), which have allowed us to plan accurately the sonic tests whose results are at the time of writing this paper, still under development. The maps have proved to be of great utility since it is necessary to place the sensors in a targeted manner along a direction. Given that the reverberation of the microseismic stresses produced the desired effects, it was necessary to define the precise positioning quota in order to produce an equal field superposition of effects.

Fig: 6, 7: Plan and elevation derived from laser scanner simplified calculations for the scale of representation.

The sum of the data acquired at this stage clearly showed that to obtain satisfactory results it needed a high computational power and an equally significant amount of space for storage and management. For this reason it was essential to adopt a high-end computers that could handle this amount of data (specifically, a TESLA workstation with CUDA technology), without which it would be impossible to achieve a

complete reading of the article. This workflow has, however, also made it clear that, if it has to be forced to bind necessarily data just through these kind of performing computers, the prefixed usability of the project would have failed. For this reason it was decided to build a database that was able to more easily manage the data, placing them within specific subject areas. This project called VIMuS (Virtual Interactive Multimodal System), was conceived with the interface of a model structure (Fig. 5), which reproduces the three-dimensional object using overlapping layers, it constituted itself as the paradigm of complexity in an attempt, among others, to respond with new technologies, the testimonial value of the time. The goal of this operation has been, re-reading the contemporary principles of restoration, to imagine a *modus operandi* and a computer system, which could allow the understanding that "knowledge" of a cultural heritage has value if it is possible to distinguish the ensemble made of single parts, each element that component it. Only a perusal operation, conceived from the beginning along these guidelines, might be able to return analytically the monument in its highest sense.

Obviously the hindrance of this operation, just in early development (PRE_BETA), is the difficulty of integrating the results obtained using different digital techniques of investigation. The instrumentation indeed, if by one side makes it possible to learn more about form and substance as components of an artifact, the other shows the undoubted difficulties in the process of interpolative instrumental results mainly due to differences in computer languages with which the equipment operates. Though apparently it looks exquisitely a computer matter, the interaction between the results of instrumental testing is, and remains, in *primis* a semantic problem that requires updating the technical language of architecture refund.

The experience gained in recent years indicates that the obstacle does not occur during the digitization of what you are investigating - because the operation can be understood as a *aliquid stat pro aliquo* - but in the semiotic relations of computer languages. The difficulties arise when, after the acquisition workflow of the data using the different tools, you want to merge into the metamodel the results obtained by specific software for investigative purposes, or when you try to relate and create a dialogue between their data to obtain an organic result.

5. Protocol definition of metadata

Established guidelines of the model under the aspect of "semantic", the next step was the choice of computer language that can make the best of the data obtained from tests. While remaining interest in the design of a proprietary software, in this phase – even if we are not informatic experts - has been preferred to locate a "neutral" program, with a high degree of versatility and together capable of containing the proprietary extensions software used for investigations. The importance was that the program couldn't result too complex to manage both master (the participant) and client (the user) profiles. For this reason, following a series of tests, has been selected the software SPINFIRE of 10.0 'Actify, as the most corresponding to the requirements management requests and together with a powerful list of input data. The database structure has been simplified as much as possible by dividing the content into two main areas: iconic and data, from which, with a system of pull-down menu, select all other options. Currently this system is being tested on two different types of hardware – high and low – in order to test the possibility of management. For this reason, even investigations made on other kind of artifacts using different methods of diagnostic tests, are in the implementation phase on the system; the intent is to develop even more accurately, the protocols and interfaces, input and output data.

6. Conclusions

Summarizing the above it can be said that "integration" is certainly the key word in the near future for what it is about knowledge and documentation all the more so when they are aimed at safeguarding the artistic and monumental heritage. The possibilities offered by electronics and informatics, while giving way to reaching detailed knowledge, yet are currently deficit of those opportunities for interaction and integration that are the basis of any kind of diagnostic. The experience reported here, gained on the complexity of an original and wonderful artifact which is the "Fontana rustica of Quirinale", has shown that exists and it takes the path of hypermedia and especially of multimodality, so that we can achieve a collection protocol and visualization of data, both for experts and for the most simple fans, which is just as demanding a greater completeness in the information they access to. Thanks to the editors of the various branch of research, Prof. Leonardo Paris, Giuseppe Sappa, Ettore Cardarelli, Dr. Gerardina di Filippo, Marco Mangano and finally to Luca Carloreccchio and Ludovica Cerone for the data processing.

LESS WHITE, MORE WHITE

Giovanni Maria BAGORDO,¹ Rocco VARIPAPA²

Dipartimento di Storia, Disegno e Restauro dell'Architettura, Università di Roma "Sapienza", Italia
e-mail: ⁽¹⁾ gianmariabagordo@gmail.com, ⁽²⁾ roccovaripapa@gmail.com

Abstract

It's little more than a century that architecture copes with white, the colour of the Modern Movement and of the International Style. White would seem the most natural choice for a kind of architecture that is free from decorations; it becomes a three-dimensional transposition of linear whiteness of the project: the white of the paper gains materiality and becomes frontage. But white is a colour – or would it be better to say a non-colour? – that boasts a very rooted and time-honoured use in architecture. Conventional Mediterranean houses are white, whose achromatic style isn't the result of particular graphical expression researches, but it merely fits with a practical need to limit the overheating caused by the exposition to the Southern sun. In this sense, white is *less* – absence of colour, achromaticity – and it is the colour that urges us to build a managed architecture, careful to man practical needs and to the cost limitation.

White is also the sum of all luminous radiations, white is polysemic, *more*, and it was often used for this reason – even in an improper way – to celebrate, to flaunt, to strike a sense of greatness or magnificence, becoming an *élite* colour. Is it really this one the Modern Movement lesson? Maybe the teaching of the masters of contemporary architecture should be completed with the easiness of white that unifies the Mediterranean banks, by the spontaneous recalling between towns on the hills of the islands and the waterfront of the coasts. It's only the union of resources and a shared management of goods that can guarantee to the Goods of being passed on the future generations.

Keywords: Colour, White, Modern Movement, Mediterranean Architecture

1. About white

Have already passed some centuries since Newton, with its famous experiment showed that white light is composed of the total of all light radiation, each of a specific color if taken individually.

The white is the sum of all the other colors. Claiming this, quite revolutionary, especially if, on the basis of common experience and centuries-old art of painting, he had always observed that the sum of many colors tends to black, which is precisely the opposite of what was stated by Newton.

Not by chance even in the first half of the nineteenth century, Goethe seems to be one of the fiercest opponents of Newton's theories and it took the equally famous experiments of Thomas Young to settle the issue and melt the chromatic world in the two sides of colored lights - the sum of the radiation produces white - and the pigments, those used by painters, who tend toward black mixed, or rather into an indistinct color next to a dark gray.

Since then, black and white - united by the oxymoron of achromatic colors - have risen as a symbol of the opposition of strong contrasts, so that Johannes Itten in his structural theory of color, sees in them the first and main generator of the color pair contrast of light and dark.

It is a total contrast, the one between black and white, which admits no middle way, which does not allow shades; any mixing them, in fact, produces no other whites or other blacks, but an almost infinite range of intermediate shades of gray light and shade - other achromatic color, considered neutral par excellence - that continuously connects the two extremes.

For this reason, the light/dark contrast generated by white and black becomes by extension contrasting light/shade, although it would be more appropriate to speak of light/no light, because any object in shadow does not appear black, but a darker tone of its own color.

However, the strength of this definition has led to the identification between white and light, and black and darkness is now immediate and definitive.

But this leads, again, the result of Newton's experiment: the light, as the sum of all radiation color, is white, so it should exist only one white.

But the common experience confirms that it is perceived many whites and so many attributes are associated with the term white in an attempt to identify a color resorting to common objects chromatically equivalent to it: "milky white", "creamy white", "white ice", "ivory". It even seems that the Eskimos have in their vocabulary, many different nouns to indicate the white; evidently in a place where the ice is the master – from the soft blanket of freshly fallen snow to the thick slab – the human visual sensitivity is successful to distinguish the color variations due, for example, in presence of impurities or air bubbles inside the structure of water frozen. What, then, among those mentioned above, the true white? The "ivory" – warmer and full of nuances of yellow – or the "ice", cold, surrounded by reflections in the range of blue and purple?

An example of the multiplication of the white comes from one of the great masters of Italian painting. The *Veiled woman* Raffaello Sanzio is considered to be a masterpiece in its rendering of different shades of white used to differentiate the clothes, to emphasize the parts to light, to define the shadows, in a superposition of continuous tones of white on white[1].

2. The use of white in the Mediterranean tradition: *less white...* *

And the portrait of Raphael opens the way for another important consideration: what is the relationship that is generated having to depict a white object on a white support, like the canvas or the more common drawing pad? The Modern Movement and the International Style have accustomed us to the fact that architecture devoid of ornaments should be color-white, as if color and simplified forms must necessarily coexist. The white of the façades then becomes the three-dimensional transposition of linear whiteness of the project: the white of the paper acquires materiality and becomes the facade.

But is it a conscious chromatic choice, due to the elimination of any ornament, including color, in which case the absence of chromaticity becomes a value added that is enhanced by the simultaneous presence of elements – including colored elements – present in the neighborhood of the object architecture? Or is it a surrender to an image that takes its value in the drawing and which is intended to preserve its design even in the spatial transposition? In short is it the same "blank page" terror tried by the writers, from which, rather than choose to assign a specific color to the architecture, is left as it appears defined only by the edges of the outline, those same which determines its pure form?

The white proposed by the Modern Movement is willing, therefore, a multiplicity of interpretations and takes on many meanings including semantics, just think of white as a symbol of purity, innocence, sincerity. Please bear in mind another use of white color in architecture, which has roots much deeper and far more humble.

This is the white of the Mediterranean tradition buildings, which is not the result of a chromatic specific research graphic expression, but simply coincides with the practical need to reduce the overheating due to sun exposure in the South, creating a game with white that you see opposite one another across the Mediterranean. In the modern architectural language so there is a new conflict that arises, this time, no longer by the contrast between color and no color, but directly within the same white. On the one hand, the multiplicity of values assigned by the Modern Movement and the International Style takes a white that generate a wealth of values of meaning, a white who could be called *more*; other, the centuries-old tradition of Mediterranean people, off white superstructure to restores it to its first and principal value color, back the *less* scope. It is precisely this contrast between less white and more white is to be analyzed in this contribution that, necessarily, is written for four hands to face, in an independent and dialectic manner, the two sides of the same topic.

3. White as the color of collective memory *

When in the 60s of the twentieth century, the Aga Khan turned his attention to what was to become one of the most ambitious projects of land use – the creation of the Costa Smeralda – was born the need of having to define the type of architecture that could better describe the action – by integrating into the landscape and not overturning it – and, at the same time, make it unique and instantly recognizable.

Fig. 1: Stella Maris, Porto Cervo.

Fig. 2: View of Santorini.

For this reason, between the architects invited to participate with their own ideas - and later to realize a true city plan strictly limited regarding the use of forms, materials and colors – was included Michael Busiri Vici in addition to Luigi Vietti and Jacques Couelle. At that time Busiri Vici had already distinguished himself on the Pontine coast with some architectural work that tended to incorporate architectural elements of other Mediterranean countries such as Tunisia, Morocco, Spain and Greece: core housing compact box shaped with service areas, aggregated in clusters or online, but always oriented according to the topography of the land and giving priority to the southern exposure; control from the intense summer sunlight through shadowy spaces generated by narrow streets; masonry of stone or brick, plastered with clear or white limes, to decrease in surface temperatures of the external envelope; small and sporadic openings, in addition to the front door, through which, while ensuring the lighting of the interior in both seasons, the protection is ensured by the incidence of sunlight in summer. It was, therefore, outlined his own personal style that drew its strength from the typical "Mediterranean Architecture", broken down into its basic typological forms and reassembled according to the demands of a more modern life and, above all, an environment with touristic vocation.

Without entering into the issue of stylistic work of Busiri Vici, you want to highlight here that the color, and especially the white color represents the main element that are recognized as strong points of a type of architecture so prevalent on both sides of the Mediterranean sea to be considered as part of the landscape as well as its qualifying element.

Emblematic in this sense, is the church of Stella Maris, placed as sentinel at the entrance to Porto Cervo. Its clarity, that stands out against the blue sky, makes it immediately visible, but at the same time evokes more similar images in other places, from the Greek islands to the coasts of southern Italy: those of the rock church, the sanctuary, the votive chapel, but also the ruins of the temple, located on a hillside, above a cliff, or overhanging the sea.

It's a *déjà vu* that is created and that immediately links the modern rise to the ancient architectural tradition by placing it in its continuation. The color of Stella Maris is therefore a white wanted for its denial, its absence; it is a color that, while by imposing the image of architecture, do not give it more value than those related to its specific function, in memory of what happens in similar way, unchanged for centuries, and in many other places of worship built spontaneously. So the external white also penetrates into and becomes the main decoration with few other items, such as the bronze doors or a valuable painting of El Greco. But it is also an evocative white, used to retrieve images of a collective memory that, as people of the Mediterranean coasts, we possess from birth. «And because the flow of life is never lived in a vacuum, but in the materiality of places that serve as "theater" and that therefore contribute to the sense of the lived, we can deduce that the collective memory does not exist without our own imaginary landscape. (...) Outside of the scenes that make up the imaginary landscape of our memory we are unspeakable» [11].

Thus the landscape of the Costa Smeralda loses its characteristics of modernity - and if you will, in some cases, of artificiality linked to the lack of an historical support - to acquire the same values of universal visual towns of much older tradition that dot our coastline.

The white walls of the Hotel Romazzino, or those of the residential complex of Sa Conca, near the church of Stella Maris, is the same as any other typical Mediterranean built, located midway between the green vegetation and the intense color of sky.

Fig. 3: View of Gallipoli

Fig. 4: La Valletta, Malta

4. White as the color of the absence *

And about the power of the intense Mediterranean colors speaks Cesare Brandi when he is, "a pilgrim of Apulia", surrounded by the Salento countryside: «clouds seem steeped in blood almost purple, as in Provence, and thick milk, white, blinding, curdles the pointy tops of the domes of the trulli, while the more acidic and bitter green of the vines and the dense, by cutting into slices, like a black pudding, carob trees, or opaque jade of figs, popping everywhere, in contrast, almost to extermination of the trulli»[2].

It is the domain of the sun and light, so of the white that, like milk, "curdles" and acquires its own materiality. Because, it must be remembered, without matter the architecture does not possess color, omitting, of course, the possibility of changing original colors by decorating with plaster. It is the choice of materials that determines the color of the architecture, because each material has its own color due to its chemical composition or the physical conformation of its components. So, in a poor soil, in a poor architecture, the white color is rough like stone or dense as lime.

But to dwell on the materiality of white generates a consideration: in the description of Cesare Brandi, though so rich in the palette of colors, is totally absent the blue, that deep color that characterizes summer days in the view of any area of southern Italy. An almost inexcusable absence if it was not just that white color curdled on the tip of the trulli implies the presence of a sky silhouetted against whom, and if the sky was not deep blue, white color would not be so strong.

It is clear, therefore once again, an element of absence generated from the white: the spontaneous architecture, which so much take effect from sunlight, conform in denial compared to their boundary, as if, in the landscape, they could not exist independently. So architecture becomes what is not ground - red, even purple - is not vegetation - green as vineyards or as figs, even black, like the carob trees - and is not blue like the sky and, on the coasts, like the sea.

Here then back to mind the image - at times even a little stereotype - of Greek islands, with white fishing villages densely barricaded somewhere between sky and sea, as if they were cut out shapes on a blue background. It does not matter if it's just straight Cycladic architecture - cube-shaped houses, one or two floors, densely developed alongside each other to adapt to the territory and resist high winds, where color is absent or restricted only to small details, such as doors and windows - or if it overlaps the memory of the similar Eolian architecture, also characterized by the cube as the basic modular unit, repeated for one or two floors, with an arched loggia or a pergola to the last level. It is the brightness of the colors, the white of the lime used to not overheat the rooms during the summer season, which requires the memory.

5. White as the a color of homogeneity *

So across the Mediterranean white town chase, appealed, overlap: what is the difference between the image of Gallipoli, "beautiful city" view from the sea and the entrance to the harbor of Valletta in Malta? The Mediterranean city have breathed the same history made of overlapping people and migratory flows. Cesare Brandi still observes: «Bari has its old town, and almost to the sea, fortunately remained on the sidelines, massed around the two solemn monuments which are the San Nicola and the Cathedral. At its threshold the Castle. And here you will immediately notice the contrast with the cities, as well as old, but born in the hinterland and proud to offer the space, the largest possible, in front of the cathedral or the town hall. The medieval Bari, as Molfetta, Giovinazzo, Bisceglie was born on the sea and clings the coast. From the sea is his life and his death, trade and pirate fleets of the Saracens. From this opening, at the same time a closing, it is born the barricaded character of the old city, the streets like tunnels and large dark vaults that bypass it. It seems that, before the streets, a building is made entirely of solid stone, and then drilled by strange, industrious lithophagous. Now, when I saw for the first time Bari, I could not understand this radical

Fig. 5: The Dome of the Rock and the white of Jerusalem.

Fig. 6: Jerusalem, the Souq.

dissimilarity with the cities that are supposed to resemble most: and I realized later, after visiting Jerusalem. All of a sudden in the old Jerusalem, I was in Bari»[2].

And Jerusalem, too, is a white city. White as the desert that surrounds it and which seems to draw origin; white as the stone who built it, or perhaps, as noted by Brandi, where it was excavated. Because, indeed, old buildings and streets in Jerusalem seem to develop from each other, as if it were only the arrangement of the different plans to find the m: the vertical facades of the buildings, the horizontal roadways. This is a white color that takes away the individual characteristics of each element and conforms all. The absence of an architect from the dominant personality has made the city grow in a substantially uniform; as noted by Bruno Zevi: «[Architectural] prose is largely based on the popular language impersonality in the name of collective images, living tissue. (...) The architecture becomes elusive while urban and territorial structures emerge»[13]. Thus, while the town of Jerusalem is almost homogeneous in its whiteness, all that it overlaps - and that creates a contrast - is colorful, beginning with the Dome of the Rock, blue and gold above the Wailing Wall, to the Green Army's military presence in what should be the "Holy City". There's only one place where the color, even the colors are fully integrated: it is the Souq, very vibrant, which occupies the "streets like tunnels" overridden by the "large and dark vaults," where life throbs and teems in all its forms in the swarming of many businesses located in close contact with no apparent logic. It's as if White had been crushed and broken down into its many color components which, accurately, re-emerge all at once; from this point of view, the Souq is the only place able to compensate for the unabashed candor of the city.

6. ...more white: towards the Modern Movement **

Historians seem to agree with the idea that historical process leading to the birth and subsequent growth, maturation and end of the Modern Movement is not to be easily identifiable, in contrast to the other architectural styles. However, historians identify a period that elapses between the end of the XIX and early XX centuries as the crossroads of a new idea of architecture in open break with previous tradition.

In essence, the spread of liberal ideas and the industrial revolution led to the consequential lack of confidence in Antiquity and the research of a spatial composition that is representative of that specific period. Therefore, the concept of Modern Architecture is the need to live the present time by abandoning oneself to the attempt to reproduce the forms of the past. At the same time, architects like Schinkel, Labrouste, Richardson were able to reinterpret the classic style for creating innovative products with both strong identity and unity. In this way, the duality between the past and the present was outdated in an attempt of reinterpreting the architectural principles of Antiquity in modern terms, outlining a precise guideline for the modern designer.

In this regard, according to Viollet-le-Duc, the medieval tradition was able to combine the art of building with materials and techniques of the time. Subsequently, Art Nouveau combined organic forms with new structural patterns, highlighting the perennial problem of ornament. Victor Horta was the forerunner of this new architectural idea, able to join up materials, structures and formal choices; the last ones were characterized by a dynamic supply, richly inspired by nature.

In 1895 Otto Wagner diverted from the architectural vision of Horta designing the Post Office Savings Bank in Vienna (1904-06). In order to report the presence of cladding facade, Wagner decided to emphasize the anchoring of the slabs using marble with aluminum screw caps. In this uncompromising approach, addressed pre-eminently to the exaltation of new building techniques and the new materials, Josef Hoffmann and Adolf Loos were involved. In fact, in their architectural idea, the relationship between form and function was strongly denounced especially with use of materials and building techniques.

Fig. 7: Stoclet Palace, Bruxelles 1905-1911

Fig. 8: Steiner House, Vienna 1910

6.1 In search of volumetric simplification: the divorce between decoration and function **

Hoffmann's attitude was focused primarily on a new architectural vision with no symmetrical reference. A clear example of this effect is the Stoclet Palace in Brussels, 1905-11 (fig. 7).

The distribution of internal façade emerges through towers, bay windows and other formal solutions that highlight the relationship between the shape of the volume (enhanced with essential linear moldings) and its function. Loos's approach to new architecture is, indeed, more drastic than the one undertaken by Hoffmann. In the essay *Ornament und Verbrechen* (1908), he established the divorce between the ornament and function by identifying "the ornament with the primitive eroticism and, at least implicitly, the absence of ornament with the purity and chastity."

House Steiner (fig. 8) well represents this view: the project is submitted to rigorous geometric control and the symmetry is fully expressed in the accessing ramps. Moreover, the facade has a series of openings located in not linear way on the unadorned vertical surface.

Ernst Hans Josef Gombrich, referring to Loos' identification of the ornament with barbarism and murder, believed that «there really was something prophetic in this manifesto against ornamentation. (...) Not only the idea that ornamentation of houses, furniture and furnishings items was fundamentally distasteful became a point of faith, but also it can be admitted that the formal imagination, losing its traditional expression, should be able to enjoy a new field of action»[8].

Therefore, the architect, leaving the decoration, was oriented towards pure research of formal elements, to their functional utility and to exaltation of the materials.

7. Modern Architecture in 900 and the Avanguardia **

The principles of abstract painting can be found in the modern world conception. By definition, the abstract art is the visual artistic non-figurative expression where the research for pure form happens through the use of colors and geometric shapes. The exponents of this avantgarde current were Wassily Kandinsky, Piet Mondrian and Josef Albers who influenced the development of the modern movement in the postwar period. In essence, what determines the transition from protorationalism to rationalism is the influence of Cubist painting and the Neo-plasticism that laid the foundations of question about the planimetric rigidity of the Renaissance; at the same time, the Neo-plasticism implemented a process that broke with the past. This process was represented in cubist and expressionist paintings with the depiction of exotic cultures, while in architecture was represented with the exaltation of the function considered as an inspiring muse of the form. In addition, we owe to a vanguard movements (mainly the geometrical abstract art) a new architectural concept where there aren't main facades or privileged perspective views, but where the dialogue between inner and outer space is continued. In this sense, Siegfried Giedion defines architecture as the third conception of space: «Initially, architecture of the third conception of space is based on the principle of the flat surface. Cubists were the firsts who discovered them and were followed by Mondrian and Theo van Doesburg in the Netherlands (*de Stijl*), Le Corbusier and Ozenfant in France (*Purism*) of Malevich and El Lissitzky in Russia (*Suprematism*). It was the strong emphasis on the surfaces to push them towards architecture. In this way, the idea that motivated the first single-family homes came and after the first projects of Le Corbusier, the Schroeder House in Utrecht, as well as the large areas of glass of skyscrapers by Walter Gropius and Marcel Breuer»[7].

Fig. 9: Ville Stein, Garches, 1927

Fig. 10: Ville Savoye, Poissy, 1929

8. The question about the polychrome **

A considerable interest about the debate concerning the new conception of architectural space has to be added to the discussion about the use of color in architecture. Just a few decades before (in the mid XIX century) Quatremère de Quincy, in his reconstruction of the lost statues of Athena and Zeus, used bold colors dotted with gold and ivory, therefore in sharp contrast with the neo-classicists.

John Ruskin was an enthusiastic supporter of this theory (validated by archaeological discoveries); he in fact defined the Greek temples "surrounded by a pale white as snow freezes at sunset", instead of shining of blue and purple. At the same time, the increasing confidence towards new building techniques had gradually led "new" architecture to abandon the polychrome, because it was guilty of falsifying materials and forms too.

9. In search of the simple form **

In 1918 Amédée Ozenfant and Charles-Edouard Jeanneret published the manifesto of the *Après Cubisme*, sanctioning the creation of Purism. Cubist-derived, the purists were meant to represent "objective compositions of simple elements, which are interwoven with the bottom in a unitary image without emergencies." Purism wanted to combine art with industrial production becoming itself the inspiring muse of painting.

Ozenfant, coming back to Paris after the First World War, found the ever increasing need to bring back the very existence of man in geometrical strictness and in spatial order. In October 1920, together with Le Corbusier founded the magazine "L'Esprit Nouveau" in order to spread the purist theory.

In support of the architectural purity, in an article published in the same journal Le Corbusier wrote: "The idea of form precedes the one of color. (...) The color depends entirely on the material form [...] The color is coordinated by the shape, but not the reverse".

Meanwhile, Bruno Taut became one of the most untiring supporters of color in architecture. In 1914 he built the Glaspavilion for the exhibition of the Deutscher Werkbund in Cologne, considered as a manifesto of the theory of material concreteness. The pavilion had a circular plan with a reinforced concrete base topped by a dome defined by stained glass. The question of color was subsequently furthered by Theo van Doesburg, Piet Mondrian and Gerrit Rietveld through the use of intensive combinations of primary colors and an architectural language composed of geometric shapes, intersecting planes and straight lines arranged in order to form the grids.

9.1 "The white architecture" of Le Corbusier **

During the first postwar Charles-Edouard Jeanneret choosing the pseudonym Le Corbusier, addressed concretely to the profession of architect and urban planner. In the period of time defined Purist-modernist he deeply theorized the concept of the individual house, summarizing it a few years later, in the project of Villa Stein to Garches, 1927 (fig. 3) and, subsequently, in the project of Villa Savoye to Poissy, 1929 (fig.4). In the first project, Le Corbusier expressed a strict volume, where the geometric rule regulates the whole volume. In fact, the facade was designed according to the geometric principle of the golden section, and the composition was represented through white, because it was able to emphasize, through the high brightness, the vertical surface and the contours of the black casings. Le Corbusier's decision of using white represented the sum of his purist design.

Which color makes visible, more than any other a volume invested by the rays of the sun, if not the white achromatic color resulting from the summation of full range of colors of the electromagnetic spectrum?

In fact, white, as an expression of purity, stands in sharp contrast to the falsification of forms.

Ville Savoye, however, isn't completely white. In fact, the lower portion is dark green, while in the higher volumes we find a polychromatic treatment. Ville Savoye, therefore, though it is still considered the manifesto of Modern Architecture, can be considered, paradoxically, as an expression of a sober and rational polychrome.

Fig. 11: Gwathmey Residence and Studio, New York 1967

Fig. 12: House II, Hardwick, 1969-70

9.2 Le Corbusier's polychrome architecture **

In the path towards a new architecture, the relationship between Le Corbusier and the color may appear marked by contradictions strong. Even if the purist phase seems had found its highest expression in Villa Savoye (hence the term "White Architecture"), the 30s were characterized by various studies on color. Then, it's, paradoxically, possible to argue that there are two Le Corbusier: the first, that subordinates color to the construction of pictorial space and considers the white as the only color that can bring out the geometric compositions of its architecture, the second, which proclaims, in contrast, the need of polychromy for human survival, like water and fire.

Therefore, the reflection on the color leads Le Corbusier, in a decade, to assume two positions clearly at odds. Just in the years following the Second World War he dedicated himself to a brutalist phase so called. Then, the pioneer of the "White Architecture" turned into a strong supporter of use color in architecture driven by the growing conviction into influence of color on the perception of space.

Just in 1937, Le Corbusier took a stand on the point, when he inserts a chapter titled Polychromy = Joy in a monograph. In order not to be regarded as a defender of the decoration in architecture, he calls the wallpaper "paint rolls" (an unusual term but with high impact at least for the industrial production!).

10. Chromatic architecture after World War II **

The key principles of the Modern Movement, between 1945 and 1965, became the rules for building architecture. Issues such as "naked truth" or "structural honesty" - which they obtained using white plaster and showing the true color of materials - represented the essence of modern architecture.

Despite the pervasive dogma of the modernist architects, Robert Venturi burst onto the scene in order to put an end to the simplistic vision of architecture prevailing in America. Venturi changed the motto of Mies van der Rohe's "Less is More" in "Less is Bore" to highlight the boredom generated by the modern compositions. While the position of Venturi was an attempt to overcome the modernist boredom, after forty years, a group made by five architects (Peter Eisenman, Michael Graves, Richard Meier, Charles Gwathmey, and John Heyduk (called "New York Five" or "The Whites") searched to recover the main elements of the modern movement of the '20s: Schröder House, Villa Stein and the Casa del Fascio became the role models in order to let revive forms and colors (or the color!) of New Architecture (based on rigorous and geometrical compositions), sometimes in spite of function.

During the 70s the opposition between "Grays" (as Venturi and Moore) and "Whites" (as "New York Five") wagged the architectural debate about the everlasting search of a formal truth still far from being showed.

11. Architecture White or Colour?

Therefore, "White architecture" -highly supported by Le Corbusier as an expression of the principle of modernity in the 20s- with the passing decades, became a totalizing conception of the architectural composition up to the limit of historical falsification.

Indeed, according to Le Corbusier white was expression of freshness of thought and enthusiasm for the New Architecture; it is worth in this regard, the exaltation that Le Corbusier expressed towards white facades of Gothic cathedrals; in fact, he encoded it as an authentic expression of the vitality and youthfulness of a new era in architecture. Then, for the first modern movement, the renewed conception of geometrical space - which was enhanced under the influence of light, particularly with the use of new materials and, consequently, with the new constructive techniques- must be declared through white.

Here is the modernist innovation: white is the color that identifies the progressive turning point but also the renewed confidence in architecture.

During the decades after World War II, architecture was often whitewashed in the name of a fake modernism, unable to express any concept if not purely a self-referential, dull and conformist one.

Le Corbusier's teaching was substantially distorted, sometimes to the point of creating false myths as the consideration of white as the only color for new architecture.

Other times, according to Meier, white "modern" is pure excitement of form itself, it becomes an essential part in order to understand the complex interplay of lights and shadows that are created on surfaces:

«Architecture -argued Meier- is a continuum, each generation informs the following generations. Le Corbusier's, Borromini's, Bramante's works are essential for me in order to understand the structuring of the space. What I do is different from what has been done in previous periods, but there is always a relationship with the human dimension».

Maybe the teaching of the masters of contemporary architecture should be completed with the easiness of white that unifies the Mediterranean banks, by the spontaneous recalling between towns on the hills of the islands and the waterfront of the coasts. It's only the union of resources and a shared management of goods that can guarantee to the Goods of being passed on the future generations.

Abstract

The massive presence of machines in everyday life make them a cultural symbol; the computer holds a special position within this frame: real and virtual perceptions are allowed to mingle each other, extending our material and immaterial horizons.

But is there still room for the discipline of Geometry and its creative and expressive potential in the computational era? Is the awareness of the nature and versatility of geometry still essential for the education of architects and engineers? Do its issues still concern architectural knowledge?

We believe that a geometric education tout court still implies not only a didactic of space but also the awareness of it, its prefiguration and feasibility.

These issues can be verified through the recent developments of computer as a drawing tool; however it is necessary to consider that its outputs -in spite of their realism- should differentiate themselves from reality, in order to conceive and understand it.

As a learning path to obtain less fascination for the digital tool and more efficiency in the building of architectural knowledge, we propose four training practices which allow students to understand and communicate the space by the tools of projective geometry.

Keywords: Projective geometry, representation, space prefiguration.

Introduction

Digital drawing and the consequent possibility of creating virtual realities have today replaced, almost entirely, any other kind of architectural representation, generating some paradoxical situations, where digital tools, thanks to their undeniable charm, overwhelm the final purpose, braking away from real architecture to be represented, and becoming almost a piece of art in itself. Inevitably, the “disappearance” of the manual drawing generates questions about the role of geometry, not only from a disciplinary point of view, but also from an educational one. We are of the opinion that it is still possible to reach the knowledge of the architectural space, studying geometry, and getting an effective communication of the same, through a correct representation. It is our deep conviction that the identification of the geometric genesis of an architectural space, made of complex, or simple, surfaces, can generate a clever and original representation; this leads us to believe extremely valid and still current the role of geometry as a fundamental discipline in the training of young architects and engineers. In this perspective, the digital tool becomes an instrument of the creative and expressive personal sensitivity, being just a tool and not a goal of the communication of the spacial representation. Therefore, the purpose of our paper is to outline a training process that, through the study of projective geometry – according to the needs of the perception and the representation – could allow to understand and communicate the architectural space as shown in the following four case studies

1. The virtual space of the geometrical drawing: the perspective of the 's Gravesande circle.

It is important for a young engineer and architect to study deeply all the aspects of the projective geometry [1], to move closer to a discipline that is fundamental and foundational for his training. Indeed, according to Enriques:

“La Geometria proiettiva può essere considerata come scienza astratta, e ricevere quindi interpretazioni diverse da quella intuitiva, fissando che gli elementi (punti, rette e piani) di essa, siano concetti comunque determinati, tra i quali intercedono le relazioni logiche espresse dai postulati” [2] ,

we recognize in these words the potential of theory, useful from a training point of view; by the way, a different approach to this kind of studies can drive faster the students to new ability of understanding, creating and shaping the space – a general and substantial skill to design any kind architecture. Therefore, we propose, according to the needs of perception and representation, to teach how to understand the structures of space that lie behind a geometrical drawing. Furthermore, today the digital tools can easily reconstruct the real location of geometrical entities in a virtual three-dimensional space, refining then the ability to imagine and shape the world around us: in other words, the student is asked to reflect on images taken from the repertoire of treatises about projective geometry, reconstructing the real spatial position, matrix of a planar drawing, to relocate in a virtual space the main geometrical entities, with significant results toward a solution of spatial problems. History of geometry is rich of treatises whose images can be used for this purpose. Let's take for example the construction of the perspective of a circle, that we can find in *Essai de perspective* [3] of the Dutch Willem Jacob 's Gravesande [4], exercise that offers new and clever geometrical constructions to facilitate graphic and executive procedures, to refine this kind of representation.

Fig. 1: 's Gravesande perspective of circle (left). Redrawing 's Gravesande perspective of circle (right)

Figure 1 shows this perspective [5], realized with what, today, would be called circle's homological transformation: intersecting with a set of parallel cords what we consider the overturned circle on the picture plane, and starting from the points in which these cords touch the ground line, some corresponding lines can be drawn, until they reach one point on the horizon line (image of the line at infinity of the plane which contains the circle), the vanishing point of those cords. The image of the contour of the ellipse is then identified joining the points in common between these cords and the former circle with the center O (overturned center of view and, in the same time, center of homology). Moreover, 's Gravesande adds also the construction of the axes of the ellipse, image of this circle.

Fig. 2: Settling projective entities in the virtual 3D space

Then, figure 2 shows how the projective entities, which determine exactly on the plane that perspective, are settled in the space. The conscious use of projective geometry by the architect is thus a valuable tool and an useful act to infuse scientific and intellectual support to the art of building. For this reason it is especially desirable in the training phase of a designer to deal successfully with both theory and practical examples, possibly walking in the footsteps of the great architects and painters, first to understand their process of modeling the space and second to take a personal step towards an original design.

2. Building iconographic atlases: teaching research on projective geometry

A deep understanding of drawing tools, both physical and conceptual ones, has always been the compulsory counterpart of the construction of a design-based knowledge in architectural faculties. Today, still, this begins with surveys and re-drawings of relevant architectures; their drawn output intersects *more geometrico* different scales and degrees of abstraction: traditional architectural graphics isolate and describe different issues of the analyzed *exemplum*.

The awareness of continuous switches between representational geometrical tools is one of the mainly expected outcomes in teaching architectural practices; traditional digital drawing tools built their logic on projective systems in which isometric and perspective spaces underlie bi and tri-dimensional objects.

Didactics of geometry appears to be explicit; nevertheless, the digital drawing process -with its over-determined inertia and visual fascination- often diverts first years' students from a real understanding of the represented building, thus leading to professional practices disregarding architecture for its formal logics. The pertinent economy of digital representational techniques in our experiences has shown interesting outputs: teaching staff decided to select a range of freeware CAAD softwares to be taught because of their quicker learning path and a multi-platform availability. First year's students were requested to build a personal atlas of given buildings (namely, the Art Pavilions in the Giardini di Castello, Venice) through photo-modeling digital processes. *SketchUp*, *BonZai3d*, *SharkFx* supply the students with matching-image tools, digital homological tools that allow bi-dimensional raster images to be projected onto solid and surfaces in a 3d space, thus obtaining different projective representations, notwithstanding their sort of naïve photogrammetries.

Fig. 3: Giardini di Castello, Venice: french, british, canadian and german pavilions. Territorial survey.

Chosen softwares offer a single-view 3-points perspective window, thus avoiding the multi-view logics of 3d modeling tools. An XYZ axis system can easily fit the virtual space subtended to the raster images showing the same building at different sides; the modeling process, expeditious during a first phase can be refined via scaling operation subtended to further on-site surveys.

A three-dimensional 1:1 model will lead at last to a single ISO A2 plate in which 3-d volumes are projected onto a virtual plan thus generating different plans, elevations and isometrics in a scaling range of 1:500-1:20. This last requirement push students to consider different scaling options according to different detailing degrees; to exploit the range of line weights to emphasize various issues in the architectural project; to include the physical objectivity of the paper bearing; to delineate layout issues.

These educational paths have proven to help the apprentice architect to focus on the peculiar issues of architectural disciplines, in order to build personal knowledge tools and drawn references functional to future and coherent professional practices. Moreover, students are encouraged to avoid the single-software parametric ideology in order to display a wider spectrum of architectural production.

This kind of draftsmanship obviously demanded different requirements: vector outputs, in order not to dwell upon the communicational issues underlain by each architectural image; a mensurable outcome, in which orthogonal projections derive from projective methods and perspective images, without the anamorphic processes of traditional virtual imagery; the possibility for the drawing to be reproduced, in different scales, projections and themes, in order to state and fulfill the central position of projective geometry in architectural, planning and engineering teaching. [6]

Fig. 4: Padiglione Italia, entrance hall and dome (G. Chini, 1909; G. Ponti, 1928; D. Torres, 1932)

The output metaphysic thus obtained via the over-mentioned softwares allow architectural students to get ahead of the photo-realistic issues of rendered images as well as to avoid engineering symbolism inherent in CAAD systems meant for mechanical industry. [7]

First years' apprentice architects can thus create drawing through a sort of analog fluidity; drawn outputs relate themselves to traditional architectural sketches, seen as the birthplace of morphological ideation, putting off executive refinements to a later bachelor year.

This teaching research through projective geometry strives thus for: 1- a compilation of surveys of given buildings and environments as a knowledge-producing tool; 2- an optimization of learning curves of digital representational tools that avoids misleading fascination for appealing perspective outputs; 3-the use of a wider range of representational techniques within architectural and planning practices, through gradients of literalness and abstraction.

3. Reverse procedure of the *perspectiva artificialis*: The Ovetari chapel frescoes.

The investigation of a scientific method for the representation and control of architectural space had practical applications not only in the architecture, but also in the art: the method is successfully applied not only in the most recent installations of contemporary artists, but also, and especially, in more ancient arts.

Through the analysis Andrea Mantegna's paintings (1431 -1506) [8], and in particular the study of Ovetari Chapel's cycle in Padua (1450), the students were able to reconstruct the "virtual world" represented by Mantegna in the frescos, using the inverse process of the *perspectiva artificialis*. The chapel, that was built certainly before 1372 [9], has a central room with arch and cross vault, a polygonal apse separated by the presence of another arch from the principal room, the structure is illuminated by four single-lancet windows that are located in the polygonal apse.

The testament of Antonio Biagio Ovetari, that was written on January 5, 1443, says us that his chapel have to adorn with figures narrating episodes from the lives of Saints James and Christopher – to manifest the family's social condition – as Giusto de Menabuoi and Guariento did in the main chapel and in the baptistery of the cathedral.

The cycle of frescos has been largely destroyed. An air raid on 11 March 1944, has destroyed it and part of the church of the Hermits – Padua building that receives this master-work of Renaissance painting in northern Italy – and destroying completely the apse of the church and the adjacent chapels: the *Assunta*, the *Martirio di San Cristoforo* and the *Trasporto del corpo* are the only works that have been saved from disaster, since opportunely detached from the walls at the end of the nineteenth century and moved to safer places during the war period. Small fragments, recovered from the rubble, were put in boxes, until the recent attempt of make-over and reconstruction of the entire cycle of Andrea Mantegna. In the first post-war, damaged items are returned entirely to the community changing, in part, the placement of the decorative elements. The attempt to reintroduce a spatial configuration of architectural objects in the scene, therefore lie not only on the wall paintings that have survived in excellent condition, but also on those that we do not have total information: in this case, the digital reconstruction [10] is based on pictures that was taken before the air raid of 1944, from the Graphic Arts of Amilcare Pizzi and the brothers Alinari Archives, concerning St. James life.

Fig. 5: Perspectival reconstruction of *St. James baptizing Hermogenes* and *S. James' judgement*.

In this essay we propose a method, that is applied to all panels of the wall paintings cycle, that assumes a backward path, based on the fundamental principles of perspective. It allows us to reconstruct virtually – with plans, elevations and digital models –, buildings represented in a correct perspective. From the tile *San Giacomo battezza Ermogene* and the adjacent one – in a vertical picture plane – the students were able to identify, precisely, the position of the observer's eye on the framework, its distance from the picture, the horizon line and the ground line, using the strict square grid that form the floor of the represented scene (Fig. 5). Later, on the floor restitution, are placed the three buildings that surround the scene: two porch buildings, and an arc that finds its archetypal form in the Arc of Septimius Severus in Rome.

The main front of the Arc and one of the two porch are parallel to the frame work. This layout on the scene allow to give back easily the elevations, in real form and at the scale of representation; the third building has the main face perpendicular to the framework. We proceed with the digital simulation in three dimensions of the whole scene: virtual clones of all buildings placed in the appropriate position (fig. 6-7). Thanks to this virtual reproduction it is possible to investigate the accuracy of the method applied by Mantegna in the realization of the fresco, but also verify, for example, the accuracy of the shadows represented in it: in fact, it is possible to give back the exact location – in plan, elevation and in the virtual model– the real position of light sources and reproduce them with specific programs rendering models that can visualize, more or less realistically, clones obtained with CAD system.

4. The geometrical construction of the wooden scenes: the Olympic Theatre in Vicenza

The desire to control and plan the anthropic space has deep origins, also if a real codification of the geometric rules were developed only in Renaissance; in this period the perspective allowed the scientific representation of the phenomenal space. Today these rules are still valid and, in addition, new technologies greatly facilitate the space control under many points of view; first of all they are able to enhance the capabilities of the human intellect, but they are as well useful like planning tools to design and analyze the space. After *perspectiva artificialis* demonstrated the close link between art and science, connecting the work of painters and architects to the geometrical optics [11], scholars codified slowly, more or less in a century, the Projective Geometry, which involved the theory about elements placed to infinity; in his treatise, titled *Perspectiva libri sex*, Guidobaldo del Monte, gave the first scientific proof of the existence of a vanishing point. In addition to this fundamental theoretical contribution, the last book of this treatise, dedicated to the scenery, as the title *De scaenis* suggests, provides a set of practical guidelines to establish the correct deformation to be applied to the buildings, getting an illusionary space. In this respect Filippo Camerota noted:

“La trattazione di Guidobaldo, scritta in latino con un linguaggio matematico, avrà una sorta di volgarizzamento nel libro delle scene composto da Ludovico Cigoli, che possiamo considerare la prima vera esposizione delle conoscenze teoriche e pratiche necessarie allo scenografo. Vi è spiegato l’uso dei punti di concorso, l’importanza della giusta pendenza da dare al palcoscenico, la scelta del punto di vista preferenziale, il rapporto tra distanza di osservazione ed efficacia acustica, il problema del fuori scala tra gli attori e la scena, la necessità degli spazi di servizio per i movimenti dietro le quinte, ma soprattutto il modo di procedere nella progettazione delle scene: regole geometriche, procedimenti pratici con l’uso delle corde, e strumenti per disegnare linee convergenti ai punti di fuga collocati oltre i limiti del palcoscenico” [12].

However, although no one, until that moment, had been able to pinpoint the ideal position of an observer, which regulates the construction of the whole illusionary space, some scholars sensed its strategic importance. Among them we can consider Vincenzo Scamozzi, the architect who, after the death of Andrea Palladio, designed and built the wooden scenes of the Olympic Theatre in Vicenza, applying the rules of the solid perspective (fig. 8).

The Olympic Theatre in Vicenza can be considered the first permanent and indoor theatre of the Renaissance; the wooden scenes were performed for Sophocles' *Oedipus Rex*, staged on March 3, 1585. Scamozzi designed three long streets to represent allusively Thebes, the city where the tragedy was set. The limited size of the area forced the architect to give the streets a strong perspective acceleration in order to create an illusory space deeper than the real one. Therefore, these streets are characterized by a high slope, caused by a narrowing of the cross section, which also implies the dimensional reduction of the elevation of the buildings. Of course these scenes, to keep their illusory power, should not be crossed by anyone, otherwise the contrast in scale between a man and the scene would reveal immediately the deception.

Fig. 8: Olympic Theatre in Vicenza: view of the main street (by A. Giordano)

According to Renaissance tradition, these streets in the Olympic Theatre represent a symbolic space, an ideal city (fig. 9), opposed to the real *civitas*, represented by the public [13]. The analyzes, conducted with the help of the new technologies, have allowed us to create a virtual clone of these three streets, furthermore the reverse perspectives showed that, in opposite of the claims of some scholars, we cannot definitely say that for each of these streets there is only one single solid vanishing point, but a plurality of them, all physically located beyond the back of the stage. At this point we can advance two hypotheses to justify this Scamozzi's unusual choice: perhaps the architect wanted the illusion was preserved even for an observer located in an area next to the ideal point of view, or, as it is clear analyzing a proper perspective reconstruction built from a single point of view (fig. 10), this would have led to the impossibility of making the scenes, because the projective deformation of the decorative elements, like columns, pediments, capitals, etc., would have required executive thickness too small to be realized, although using wood.

The knowledge of the rules of the projective geometry, using new technologies, have allowed us to study with "another eye" this architectural masterpiece, underlining also all the skills of Scamozzi to design the space according to his needs, as well as highlighting the limits imposed by solid perspective or by the matter used to construct the scenes.

This methodological approach of teaching the rules of the space takes inspiration from the past as tool to address the present and the future, geometry is a wonderful help for the architectural design, not only to control the formal aspects of a project but also to convey ideas and thoughts, especially if one considers that the ultimate goal of architecture is to "improve" the space as true intellectual act. New technologies and the digital programs are only tools at service of ideas and, so architects and engineers are supposed to be able to control and envisage the space through its geometric rules.

One last consideration seems appropriate, I said before that during the Renaissance, no one was able to theorize the real location of an ideal observer,

but using reverse perspective in this study case we were able to find it, in more than just one position: it is conceivable, therefore, that the rules about Projective Geometry codified by Guidobaldo del Monte are the mathematical expression of a sum of practical procedures, well known by Vincenzo Scamozzi.

The formulation of the projective geometry is ratified by the treatise, titled *Traité des propriétés projective des figure*, published by Poncelet in Paris in 1822. This discipline is therefore considered a more general extension of the former geometry: indeed, while remaining within the Euclidean space, it admits some general properties as invariants, called projective properties, including as special case also the metric properties of elementary geometry. Projective geometry calls two figures *equivalent* when they are transformed one into the other with a series of successive operations of projection and section, operations that leave unchanged those properties.

Abstract

As a result of industrial revolution, cities are faced with some problems due to rapid urbanization. Cities have become attraction centers due to the fact of rapid urbanization. Recently, the rapid increases in population and physical developments in cities have revealed some problems. It can be said that urban conservation is the biggest problem among others. Globalization process, cities' desire to become a world city, new investments for the city, intervention types and new planning techniques partially ignores the historic fabric.

Conservation concept, gained importance after the 19th century overall, comes as secondarily in the cities which are in a struggle for globalization. Providing sustainability of social values and transferring them into the next generations, and the continuity of local culture can only be achieved by supporting the history. In the developing countries such as Turkey, in order to provide Sustainability of cultural heritage primarily, it is necessary to gain conservation consciousness.

In this context, in this study, it is mentioned that conservation consciousness creation is necessary in order to transferring of cultural heritage to the next generations. Within this scope, children are the target group to create a public awareness. The importance of children relationship with the city, expansion of their city perception and their benefit to the community and their selves in the long term has been examined. . It has been emphasized the importance of children and childhood period in creating public awareness. Within this scope, An European Union Project has been examined about primary school students. The Project contains awareness studies in conservation in Uskudar, historical area of Istanbul.

Keywords: Urban conservation, children participation, children awareness, Uskudar

1. Introduction

City of Istanbul was the capital to three empires has the privileged place in terms of architecture through its extensive historical experience. All elements in this historical must be conserved by conscious responses and these important elements must not be destroyed between sudden and unearned income based urban decisions. People have taken the decisions regarding urban. The most important internal factor of non-performing urban conservation is derived from people. The conservation could be difficult because of unawareness of the people. Both people who are subject to the decision mechanism and citizens must have awareness about urban conservation. In this terms, thanks to the training of the children given by schools, families and media, they could have highest conscious towards urban and urbanization. Thus, the effect of the people factor in the conservation issue will be minimized. Children are primary purpose to transfer urban

conservation from generation to generation. This group whose number is very high in the urban is the biggest tool and target of urban conservation. The awareness of the people especially in their childhood must be raised towards urbanization and they have to be trained accordingly.

Uskudar is the oldest settlement of Istanbul and it has conserved its historical structure nowadays. In the central district where the people having low income in terms of economy are living, it is more than important the results of the cultural heritage activities of the children between 8-10 ages. The best ways to adapt the children who are stranger to their own cities to the urban are the plays and trips. The perspective of the children against the town and their environment perception are highly important. If this speculation is well-grounded, then the generations who own common cultural heritage will be most loyal indeed.

2. Urban Conservation Concept and Urban Conservation Process in Turkey

Urban conservation concept has emerged years after the development of cities and city planning. The concept has been on the process of a major development and changed since the concept first emerged. Application techniques and forms of intervention of urban conservation changed within the change of urban planning, especially in the second part of 20th century, on global scale, urban conservation demonstrated to act with a collective consciousness. The basic purpose of urban conservation is to transfer past cultural accumulations to the future. The cities are protected from city scale to monumental scale, tangible values to intangible values.

Conservation, in simple terms, is a concept emerged in the last 200 years of urban planning system. It started with conservation of single buildings, after this subject, conservation of urban environment has developed; nowadays it has been started conservation of intangible past heritage discussion. Transferring all values of past into the future generations under the name of common heritage has been a task in common responsibility of whole society in 20th century. Urban conservation tools and types are different from each other around the world though they have same purpose. According to countries' culture and value to be protected, new urban conservation tools and types have been emerged. Conservation actions applied in somewhere may not be applied in another region. Urban conservation includes common purpose internationally merely it contains different actions.

Until 1930's across the world it had been traditional approach to cities. Important theoreticians such as Ebenezer Howard, Henri Le Febvre, Le Corbusier had developed new alternatives to resolve problem of cities and modernization. Within this period, in 1923, with the proclamation of the republic, reconsidering the cities and planning process has been started. As the beginning point of this planning process; Henry Prost, invited Istanbul, planned city of Istanbul and made first decisions about Historical Peninsula which is historical city center of Istanbul. Although planning movements had started with Prost Plan, it has not transit to comprehensive planning until 1980's.

In 1858, it has been found the traces of conservation in the 133th article of punitive law. With this article of the law, it had been provided the people who will destroy monumental and sacred buildings (Mumcu, 1969). With the proclamation of the republic, in 1924, Muhafaza-i Asar-ı Atika Commission was established as an institution taking on a consultant task about monuments (Kuban, 2004). Jansen planned including first conservation approach in Ankara in 1932. Ankara inner part of a fortress and it's around was shrouded in this plan (Gulersoy, 1991).

It has been seen that main core of city center was not interfered in the plan in 1940s. By the 1960s, the government restricted rights on ancient monuments belonging private people. Constitution of 1961 has brought conservation obligation for buildings and monuments which have historical and cultural value. In 1972, ancient monuments law had been gone in effect. This new law was brought the opportunity to analyze larger areas in terms of urban and archeological under historical site conservation (Kuban, 2004). Between 1973 and 1974, it had been put emphasize on subjects such as record keeping, museum studies and works about these subjects started. In 1983, Bosphorus Law has been prohibited any kind of new construction except restoration of historical buildings in Bosphorus conservation area.

Istanbul wants to be a world city has been entered in the process of globalization. Within the globalization context, urban planning and conservation approach have been changed. All social and economic effects of globalization process have been seen in the cities, especially in the city centers that has been started the need for urban conservation more than before (Tosun, 2008). In the global scale, cities have entered into competitive projects and these big projects have been started to be prepared to compete with each other. These projects are subject to represent their cities, spread out their culture and economical development. At this point, the most affected areas of these cities are their historical city centers due to the fact that

uncontrolled developments, rant focus interferences, lack of awareness and also lack of conservation awareness.

3. Conservation Problems

It has hampered the existing urban conservation problems regarding urban conservation. Conservation problems can be examined by dividing those two. The first one is physical problems arising from the location of the structure, ground specifications, design problems, failure material and bad labor could generate the unprotectable structures (Ahunbay, 2004).

Other conservation problems are external causes indeed. Human being is the primary external reasons among them. The wars, heavy traffic, uncontrolled population rising, nonstrategic and unequal country and regional plans, unplanned urbanization, income focused approaches and responses, lack of awareness are the most basic conservation problems created by the human being. On the other hand, among those problems, the most important one is the lack of conservation awareness belonged of the people. The conservation awareness is very relevant to the urban awareness. People could not reach to conservation awareness without having urban awareness. The urban awareness means to understand and live the city, culture of the city, as well as to feel that they belong in the city and to disperse homogenously in the city without being a group, to feel the changes and development in the city, to feel responsibility for all kinds of negative and positive situations and to be participatory every sense.

It is very difficult to compose urban and protection awareness adventitiously. People who come from rural area to urban or different groups in the towns want to sustain their own cultures and to live as before. It takes very long time to break these rules. Although people want to change these, habits coming from childhood, the lessons learned, the first environment that has perceived are the most important element of oppression. At this point, it is more than important that the new generation should be educated by the urban awareness, to recognize and be aware where they are living and their awareness should be raised and their consciousness should be promoted accordingly. The contributions of family, culture, media and educations are very important to recognize the place where the children are living.

4. Children and Participation in Urban Conservation

Thanks to the training that is very important tool to compose and develop the awareness of urbanism, then, the adjective of citizen, adaptation of urban history and cultural identity and sense of belonging, mobilizing the urbanism dynamics by means of social culture, the right and duties of urbanism could be provided. Within the scope of "Urban Awareness", three basic approaches that have been foreseen for the children are as follows:

- To realize historical and cultural values of the city.
- To perform the physical, cultural and social transformation of the city.
- To protect the city by feeling the sense of belonging in the city

In addition, the effect of the media could not be underestimated. There is no doubt that spot films, discussion programs, the cartoon books, children's coloring book and story books have affected the urban perception of children significantly (Urbanization Council, 2009, Urban Awareness , Culture and Training Commission Report, Ankara-Nisan 2009, Turkish Republic Ministry of Public Works).

On the other hand, the participation in the broader sense is to plan the people's relevant subjects and to play an active role during the decision making process. This process is mostly involved stages such as defining the problem, collecting the relevant data regarding the subject and analyzing as well as providing the participation of the various age groups into the decision making process and developing the alternative decisions in this way, deciding unanimously for the best decision and implementing the decision unanimously (Driskell, 2002). Children participation in city planning has been popular among many cities in the process of planning. Children ideas are implemented into plans and planning policies in some cities and some international organizations such as UNICEF believes that providing friendly and sustainable cities by advancing children participation is one of the best ways (Francis and Lorenzo, 2002).

Children participation have provided bringing children in their own areas to the cities and at the same time raising public awareness. The children must be taken into the account of social category in their participation to the planning process and the public awareness must be raised accordingly. The most common initiatives are Children's/Young People's Council and Participation in Planning Urban Spaces among the possible participation types of the children in the changing process of the cities. The council that has very important training value to train the children as active citizen presents the reformist form of the children participation in the social life (Alparone and Risotto, 2001).

The social environment namely individuals composed of structural environment are the milestones of this environment. The individuals who are the user of the cities have directed the spatial organization of their own cities so that their participation in the planning process are more than important in this sense. Each individual have right to speak regarding their own cities and to direct the town accordingly. In the meantime, children could develop their own environments where they live.

Councilors focus on transformation of the urban environment in quality of life. The purpose of the children participation can be listed as the following (Alparone and Risotto, 2001).

- To observe the environmental conditions and to promote life environment and education applications.
- To develop the sense of belongings and community participation
- Organization of the benefited services.
- Programs for the development of third World Countries and environmental rehabilitation

5. Participatory Model in Conservation of Cultural Heritage – Uskudar

Istanbul is intercontinental city and the city has been situated onto two continents; European part and Asian Part. The city firstly established in historical peninsula which is located in Fatih district, in European part. Uskudar is one of the historical districts of Istanbul located in Asian part.

Before the conquest of Istanbul, Uskudar was small Anatolian town which has important location. After conquest of Istanbul by Ottoman Empire, Uskudar had been had quick development and began to have urban fabric. From past to present, the district has been always a city centre, residential areas and Classical Ottoman neighborhood with it's unique historical fabric/pattern including important mosques, madrassas, fountains, turkish baths and caravansary from the wiew of architecture. Mimar Sinan who is the most important Architects has important monuments in Uskudar such as Mihrimah Sultan Mosque, Selimiye Mosque, Old Valide Mosque and Şemsi Ahmet Paşa Mosque. Besides the district have other important monuments such as Kız Kulesi, III. Ahmet Fountain, Valide-Atik Mosque, Cinili Mosque, Cinili Bath, Mimar Sinan Bazaar, Selimiye military post and etc.

Since May 2010, Model in Conservation of Cultural Heritage has been applied by Istanbul Branch of Archaeologists Society within the scope of Civil Society Dialog Istanbul 2010 European Culture Capital City Donation Program during one year. The partnerships of the project are Concorzio, ABN A&N Network Sociale Perguie, Italy, Antigone Thessalonica, Greece. The participants of the project are Istanbul University, Department of Prehistory and Atlas Bulletin which is monthly geographic and discovery bulletin.

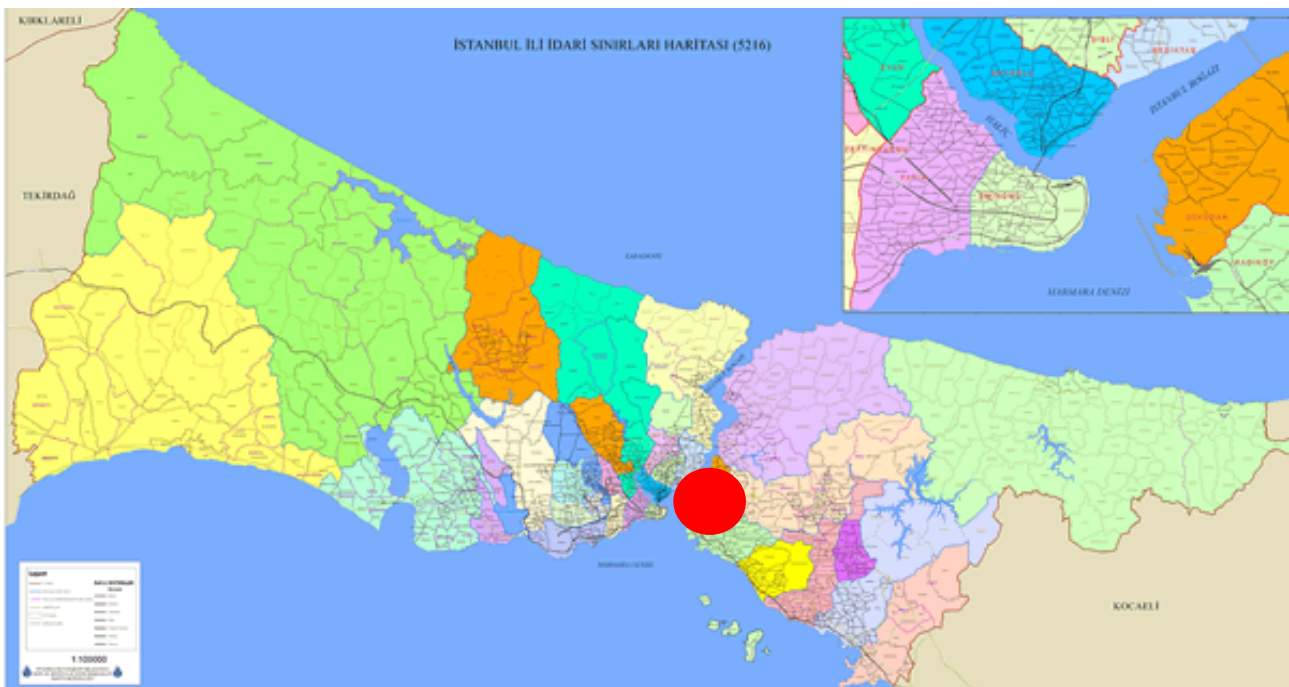

Fig. 1: Location of Uskudar in Istanbul (<http://www.ibb.gov.tr>)

The aim of the project is to compose a conservation model by raising awareness towards cultural heritage of the people living in the Uskudar and organizing information activities as well as reviewing current cultural assets of the region through local volunteers and transforming information and notifications to the relevant offices on the internet addresses to be formed. The most important specification of the project is to protect children indeed.

The targets of the Project can be listed as the following:

- Providing formal training techniques and training of trainers about Uskudar to 25 Archeologists, city planners, architects and art historians,
- Carrying out information activities related to Uskudar cultural heritage to approximately 500 students,
- Reaching local volunteers by organizing meetings together with civil society foundations and local people in Uskudar district,
- In order to conserve the cultural heritage, the complaints have been taken, current and participatory monitoring processes have been monitored by web sites.
- In order to conserve the cultural heritage, to encourage the local volunteers and people to establish a system and to develop the monitoring process through the web site to be established.
- Three seminars shall be organized in different contexts where the Cultural Heritage will be main subject.

The volunteers who will train the students have organized weekly meetings and participated in the project development process. They have been informed about Uskudar architecture by means of Uskudar visits. In order to share the best experience in the implementation of the project and to develop the organizational capacity, preliminary review visits have carried out in August and September to the Antigone (Thessaloniki, Greece) and Consorzio ABN A&B Network Social (Perugia, Italy) organizations that are the project partners. During the visits, the best examples have seen in each two city. In addition, the meetings have organized towards participatory conservation and cultural management together with the experts and project application calendar and the context of the activities have discussed with partner organizations.

Afterwards, in December 2010, the meeting was held by the participation of district mukhtars, volunteers, academicians, civil society organizations, public foundations and associations and partner organizations on December 2010.

The project has been carried out by the training of the volunteers. The relevant trainings about culture and cultural heritage concept, history of Istanbul and Uskudar, Children Training, Physiology and communication trainings with the children have been performed to volunteers who will be trainers.

Training has provided for three hours in the project that has aimed at participation of the primary school students. At the beginning of the first lesson, a game was played by a small ball prepared by the volunteers. The volunteer having ball has explained his/her name, occupation and why he/she is there for the children and he/she threwed the ball to other volunteer. When five volunteer finished the name play, they have trown the ball to the students and they have started to learn their names. Thus, the children have started to get used to the teacher whom they have not known in this three hours. Immediately after play of name, a presentation was organized about what is the meaning of culture, cultural heritage as well as tangible and intangible heritage concepts and these have prepared by experts by using the children style interactively.

Children have divided into groups composed of five children in the second lesson and a card was distributed to the groups including one of the pictures of Uskudar's historical structures to each group. The children were asked to tell about that structure to their friends and a time of five minutes was given to the children and they have studied how to express those by using the body language. Afterwards, groups have stimulated their studies together with others. The friends in the other groups tried to find out that study. By means of this game, it was attempted to develop their visual memories and it was targeted to enable them to learn about the name of the studies.

Second game is a map game. Children are divided into different groups and they have three dimensional maps that show Istanbul Historical Peninsula and Uskudar. They attempt to settle the architectural arts in different money types and to put them into the map and thus, they could pay attention to the distance of the arts by taking into the consideration of Istanbul and its location.

The last game of the second lesson is the memory game. Visually, important buildings of Uskudar that have processed to the cards visually have put into the package. The package has mixed and lined up as closed. Childrens have respectively opened two cards among others, closed ones and they have attempted to find the same cards accordingly. Children will speak up as if " I found out Mihrimah Sultan Mosques among others or I could not find the pair of Maiden's Tower. Thus, the awareness could be raised both visually and namely.

In the last lessons, volunteer elder brothers and sisters asks them “where they will go if unknown friend or distant relative come to Istanbul and what they will talk about and where they will suggest them to see. Tell them by using poster and pictures”. After giving them paint, picture paper, old bulletins, scissor and binder, we could learn about what they have procured, which architectural arts they have been wondering, which protective elements they have been affected accordingly. After collecting posters, the children will be asked who will do protection and all children will be voiced we are.

6. Result

There are some problems in the implementation of urban conservation in Turkey. These problems occurred in urban scale and structural scale could make the conservation difficult in a sense. However, the solution of all these problems could be solved by the projects and implementations in the favor of public benefit. The urban management has the potential to solve most of the problems by means of participatory policies. It must be carried out in accordance with the adaption for the public benefit. At this point, the public has most important task for public is . to carry the urban awareness and conserve the area where they are living. If each individual has sense of responsibility towards their living area, those places could be conserved and integrated against future.

At this point, the habits coming from childhood and lessons learned have become basic leader of the person. Providing the integrity with the urban and to endear them to their living places must be main responsibilities of the urban managers and families. Social policies to be applied towards the children in the city and the project organization that will strengthen their relations with the city, the consultancy services against the children in the town and their roles for the socialization must be defined. The urban management must have main responsibilities to help the children who have economic and social different to benefit from the urban possibilities in the equal base. Because, every children are equal.

The most important things for the children are children parks and green areas, when taking into the consideration of urban protection and planning vehicles. Another place must be designed for the children in the physical area. Children should go out and play in safe. The urban actors must prepare more realistic projects and the projects must be carried out towards the world of awareness. It will be more than important to establish the relations of the children with the city. Most of children are living together with their families without basic urban services. The children of the families who have problems with the air pollution and unplanned urbanization (particularly low income groups in the economic sense) could be grown up as antisocial. The urban management must have basic duties to transfer the negative situations to the positive situations. Thus, the individuals must be grown up who affect the urban not to isolated. Since the beginning of primary schools of the children, the awareness of the environment is more than important. Children know the trees, flowers and parks. However, when we are talking about the cultural heritage, they feel themselves strange to this concept.

The most important questions in the minds of the children that establish the figure of city are that if the city is sleeping, hungry, if the city has hand or arms, internal organ, if it is thirsty, if the city goes somewhere. Children have been grown up without knowing about the city although they have seen the concept of environment in the story book, some cartoons. Generally, until the adult period, individuals who could not go out alone could discover the urban at 14-15 ages. Families and schools are responsible to help children to meet them with the urban, to introduce them cultural values. Hence, the lessons should be included about town to the curriculum and each child should learn about their responsibilities about their environment, street and district accordingly. If the children do not learn about environment and if they do not have any awareness towards environment, these questions will have funny town description on their mind. They attempt to learn about the town by asking these questions. However, this definition comes from outside. The best awareness could be obtained when the children go outside.

The basic factor is to familiarize the children with the city is the game. There are some basic element for children to love their living area such as street games, friends etc. Traditional games are the basic factor of intangible cultural heritage and most of them could be lost timely. When children play in the street, these could be experienced. On the other hand, playing is involved with the relations of the children with the environment and their neighbors. If the children play in the street with his/her friends, he/she will love his/her living area, home and he/she loves the air, nature and save his/her memory. When he/she grows up, his/her sense of belonging will be developed and the feeling of protection will be promoted. Because, conservation is love.

Istanbul is the biggest city of turkey in terms economic and social aspects with its 13 million population. Approximately 30% of this population is composed of children between 0-15 age group. This big and

historical city that has such kind of young population must be known by the public. Although new approaches have been brought to the relations of the children with the city, the sufficient activities could not be still carried out in national and international sense.

The results of the project in Uskudar have revealed by the posters that have been done at the end of the lessons and satisfaction survey fulfilled by the students at the end of the lesson. The concepts on the memory of the children and architectural arts and other relevant questions how they find their teachers have taken part accordingly. The maiden's tower among the architectural arts on the memory of children is the most attractive one. The reason is that the Maiden's tower is located in the middle of Bosphorus and it is very popular by legendary story of beautiful princess.

In this sense, it can be said as a result of the project as the followings;

- Children in Uskudar are mostly curious about Istanbul and their attentions are very high as well,
- They have listened very carefully about each sentence of the presentation and they have raised creative questions.
- Particularly in the game of sculpture, they have animated the architecture arts enthusiastically.

The most important area where the children have contact with the city is public places such as the streets and squares where they are playing. The prioritized areas where the urban awareness could be provided for children are the areas where the easiest communication could be provided indeed. Thanks to the mental perceptions of the children that are open in the learning process of the children, various methods could be provided to raise their awareness in early ages. The sense of protection should be provided for the children through the games during pre-schools and primary schools. The application models must be developed in participation for children.

Abstract

At a time when resources are increasingly scarce and we have become increasingly aware of the need to save resources without sacrificing comfort or beauty, it is useful to look not only around us but also to the past and find inspiration from historic models.

We strongly believe that architecture is a product of creativity, imagination and invention, born out of the relations that are established during the thinking process between what is known, that is longed for and the notion of harmony and proportion inherent to the creator.

In this study we will examine the traditional houses of the East, with special attention to Japanese and Chinese buildings. Since the peoples of the Orient, out of necessity and economy of means, for centuries have created a way of life and an aesthetic philosophy based on harmony and proportion, where less is more.

Our research is based upon ten years of documental analysis of the mayor treaties on figurative arts realized in the western and the eastern world in the last 2000 years and on a continuum of published material on that subject.

With our project, we intend to foster academic reflection on the importance of harmony and proportion, present in the Memory and the Cultural Identity of places, as elements that will encourage and develop avenues for development of an architectural language in the current context of sustainable construction.

Keywords: Harmony, Proportion, Traditional Oriental Houses

Harmony and Proportion in Traditional Oriental Houses – Where Less is More

At a time when resources are increasingly scarce and we have more awareness of the need to save means without jeopardizing either comfort, or beauty, it is useful to look not only around us but also to the past and find inspiration from historic models.

The design and materialization of shelter is one of the earliest and most representative manifestations of the activities of men.

The diversity of architectural pieces is the result of specific needs that the various spaces are designed to meet. These needs however are not just of utilitarian nature.

Utility may be the factor that arouses the need for construction, however, the way the response to this need is given, the materials used, the technical means available, reflect the social, political and economic development of the societies in which they arise.

According to Rafael Echaide, together material production, science and art, architecture is in its complexity, a characteristic reflection of a given historical moment, of the society that gave it its reason to be. [1] And in the words of Pereira "their particular conditions of production as well as the political structure and social system act in parallel to the functional, technical and ideological factors, resulting in an architectural space." [2]

However, despite the many factors which are taken into consideration in architectural composition, the utility of the space and its suitability to the needs that gave rise to it should never be forgotten. The existence of architectural space would not make sense if it had no utility. It is in space that architecture is fulfilled.

Bruno Zevi says about this: "[...] the most important is to establish that everything does not have interior space is not architecture." [3]

When space starts to be seized, closed, shaped and structured by the elements of form, architecture begins to exist. Space therefore represents the primary element. However it would be unsatisfactory to define the essence of architecture only as its space, it would be like drowning right from the start the purpose of our investigation.

Society, by requiring concrete spaces at specific times, raises the problem while trying at the same time, by architecture and through architecture, to solve this problem either by building spaces, or by forcing man to adapt to the existing space.

However space is not exhausted in its relationship with man, it extends beyond time, evolving and growing with man.

To speak of time as the fourth dimension in architecture means understanding the historical evolution of architecture throughout the centuries and all the factors that comprise it. The predominance of one or another factor generates the different spatial conceptions. In the words of Isabel Santa Rita, "the conscience of time always departs from a past experience, some of them very vague, that inevitably enter the human mind. I would even say the very texture of life. Today's time is the sum of many other times. What we experience today is the result of many thousands of experiences lived by ourselves and by others." [4]

The reflection presented here is an attempt, albeit theoretical, to understand the representation of existential space, experiential time and of what stems from its relationship with the man-made architectural objects. This is however much progress might influence us, it is important to know where we came from, so we know where to go. Following this reasoning, architecture also served for centuries as a means of transportation of symbolic cargo associated with aesthetic, socio-cultural, economic, social, political, economic, technical-scientific, etc. references of every age and of each culture.

The application of attributes such as shape, volume, light, shadow, colour, texture, ornaments and use of materials, allow us to articulate the basic special relationship between man and space, between space and its surroundings. These are the relationships that allow us to differentiate the various architectural expressions.

If in the West, man's relationship with space is traditionally the most prized in the East it is the harmonization of architectural space with nature that assumes greater importance.

In this sense, the big difference between Eastern and Western architecture is the role that nature plays in architectural space: the architectural space in the West is a man's attempt to dominate nature, in the East it is a kind of idealized place, where apparently nature dominates.

This particularity and specialty of architecture in the East, follows both a desire and a need to compose the three dimensions of space, which justify the existence of architecture, but also to enter in this composition space, form and material, thus establishing the connection of harmony and proportion of architectural design with the surroundings.

It is for these reasons that today, when faced with the need to find models that allow better management of the environment; we turn to oriental architecture.

Despite the great diversity of architectural styles that we encounter in the East, we find that the transversal theme is the quest to establish the perfect balance between functionality, utility, durability, beauty and harmony with its immediate environment, nature and universe.

In China's case, the layout of an architectural space, like the other arts, "derives from a traditional philosophy, developed as a synthesis of the constant opposition in Taoist philosophy, between *Tao* and *Qi*, or the tension between the intangible (metaphysics) and the tangible (physical). In this fundamental pair of concepts, *Qi* refers to all the things in nature that can be perceived by the senses, while *Tao* is the origin from which all things are generated." [5]

That is, the *Tao* represents the search for harmony with the natural forces, the demand for the cosmic rhythm of life, the great syntheses in their pre-established schemes of objects, beings, of things of the

universe and the agreement of sounds, colours, body parts, elements of the cosmos that form the basic structure of Chinese culture and thought.

In order to complete one of the fundamental ideals of Confucius is that nature and the universe must be in harmony and this should also extend to humans. In Confucianism, *Tao* symbolizes harmony prevailing in the universe, that is, the good and balanced relationship between all things. This harmony is the model for the whole society. The individual must therefore live in harmony with all that surrounds him and this can be achieved if his interior is in harmony with the *Tao*. In a simplistic way *Tao* can be defined as the order of things according to natural law, the instinctive process that manifests itself from the ongoing transformations of the Universe [6], the balance of *yin* and *yang*.

This way of thinking and being will be reflected in all facets of artistic expression, thus resulting in a broad diversification of style and technique.

Thus, the Chinese aesthetic is a result of a confluence of principles that are structured around the contemplation of this spontaneous process of nature, where man is part and interact so that their own artistic creation represents the path of contemplation and reflection, the understanding of the cycles of nature, of order, and of the primordial chaos, to achieve a state of balance and harmony.

To the Chinese, a balanced and harmonious architectural space represents the culmination of the merger of the Confucian concept of art as a human creation following the model of nature and the Taoist faith in the superiority of the natural world as an art form.

This thought led to the construction of a stock of symbols, present in all aspects of Chinese life, culture and art, including in architectural design, where all elements play both aesthetic and symbolic roles. [7]

In addition to the Taoist and Confucian teachings, there is still to take into account the concepts of *Feng Shui* in order to interpret correctly an eastern space. *Feng Shui* is a mixed discipline between science and mysticism. It is a theory that encompasses many disciplines, from reading a place, through geomancy, metaphysics and reading cosmological influences, to psychology. It is a science that is applied to the natural and built environments. It is also the art of planning, locate, orient and build, so that the architectural objects set balance and harmony with the physical shape of the terrain, climatic conditions, geographical location and the persons to whom the building is intended. [8]

The concepts of *Feng Shui* and the mystical concept of Taoism are usually present in the composition and the construction of Chinese architecture, whether of common houses or of religious and imperial structures (Fig. 1).

The use of certain numbers, cardinal points, volume, light, shadow, colour, texture and ornaments in traditional Chinese architecture reflects the belief in a kind of immanence, where the nature of something can be contained completely in its own shape.

To support this assertion, simply enter a compartment of a Chinese house, whatever it might be, living room, dining room, bedrooms or even a garden. It will almost always present itself with great simplicity as a place where all elements, materials, colours, light, shadow, textures and ornaments were meticulously designed.

It should be noted here that, in addition to awareness on the need for economy of means, for the Chinese, according to the theories of *Feng Shui*, excess furniture and / or objects may represent obstacles that prevent the *Qi* energy from flowing and covering the entire interior space.

Good balanced use of resources and conscious awareness of the need for economy of means, causes Chinese dwelling space to be devoid of superfluous, i.e., it has only the essential elements of use, which often play simultaneously a utilitarian and decorative role (Fig. 2)

In Japan, despite sharing many of the philosophical principles of China architecture takes on a more intimate expression.

Most traditional buildings, whether of temples and palaces or of humble dwellings, are characterized by heavy roofs and by the dense shade they project.

These roofs are the result of the need to protect the building materials, more fragile than those of China due to the need to minimize the devastating effects of the frequent earthquakes, from the gusts of wind and rain.

The interior of the houses receive, due to the advance of the porch, low light. The transformation into a virtue of this factor, that probably elsewhere, especially in the West, would be considered a disadvantage, is a distinguishing characteristic of Japanese architecture (Fig. 3).

According to Junichiro Tanizaki, "the beauty of a Japanese division, produced only by the variation on the degree of opacity of the shadow, waives any accessories." [9]

The spaces themselves are stripped of any superfluous elements and the few objects found there, the colours and the materials used at the walls are arranged to produce the most dramatic effect possible in the middle of the play of light and shadow.

An example is the *toko no ma* (Fig. 4). This niche, usually present in a major division wall perpendicular to the garden, plays a key role in the decoration of a traditional home. Here is an object is displayed, it can be

an object of art or a floral arrangement. According Tenazaki however, the primary function of that object "is not decorative in itself, since it is more like adding to a shadow a dimension in the sense of depth." [10] Also in Japanese dwellings living in harmony with nature is of utmost importance. This relationship is usually established through the gardens. However, as the interiors of homes, in the gardens the type of nature that is invoked is minimalist, stylized and idealized. It is this artistically manipulated nature, which is seen from the inside of the dwelling. This view of the garden often plays the role of the decoration of the space - it is a living picture (Fig. 5).

The relationship between space/shape and space/material in oriental architecture is the result of a culmination of experiences, feelings and emotions that characterize the eastern people.

As Westerners, we do not share those memories. However we can look, enjoy and draw inspiration from the simplicity of oriental architectural objects. We can, as many have done, recognize the beauty, balance, harmony and proportion that an eastern space, where less is more, transmits and learn to apply this lesson.

The role of drawing in regeneration of the paths of memory. The site of Caponapoli

Teresa DELLA CORTE

Department of Architectural and Environmental Design, Faculty of Architecture, University of Naples
"Federico II", Naples, Italy
teresa.dellacorte@unina.it

Abstract

The research aims to start a survey on the site of S. Aniello in Caponapoli an ancient settlement that was situated around the highest point of the city in which there was the acropolis of *Neapolis*.

The reading-oriented adopt a structuralist method; in parallel with a process of progressive studies in depth, it operates a 'disassembly' of stratification making knowable the meaning of the existent, spatial and temporal, 'contaminations' that are transcribable in a *corpus* of representations, which are suited to highlight the regenerative critical states and potentialities of the studied area.

The traditional drawing is already an augmented reality that - as accepting an upgrade process - express itself much more through the modern possibilities which are offered by the information technology. In the new features of solid modeling reality is represented by structures-simulacra where the virtual navigation simulated space is permitted; infinite bidimensional aspects and significant 'cuts' can be extracted from the *continuum* of the model; they investigate and reveal the architecture in the same way of an anatomic dissection. Similarly, the latest technologies for the 3D data acquisition (like photogrammetry and the laser scanning), are able to change over from the physical object to its digital representation. They are strongly innovating the processes of reading and revision of the external data, making possible the extraction of complex formal parameters.

The creation of the simulated reality - as the area of Caponapoli - is extremely useful for the strongly stratified sites, which require operations of integration between memory and contemporaneity.

Keywords: augmented reality, stratification, contaminations, virtual section, regeneration.

1. Drawing as 'augmented' reality

Urban archaeology applications to the historic centres are increasingly extraordinary occasions to know the multi-layered urban sites, which are characterized by complex and articulate urban-architectonic palimpsests.

In great and small cities (for example, London, Milano, Roma, Lecce) have been conducted many experiences which have demonstrated that historical cities are richer and more complex archaeological contexts than the traditional open-pit sites; historical cities are archaeological sites which are hidden under our feet, under the asphalt or the flagstones of streets and squares where we walk every day, and sometimes even under our houses. In these archaeological sites, diachronic architectural vicissitudes, which have been created by the sequence of cultures and interventions, intersect in a single space: for example, the recent finds which were discovered in Napoli on the occasion of the excavations undertaken in the construction of the subway, or the delightful site of Rione Terra (Pozzuoli).

The methodological choices and the definition of the "working tools" have a fundamental importance, because there's the exigency of creating knowledge structures for identifying an intervention hierarchy for the historic cities.

The preservation of the preexistences and their integration with the contemporary needs require devices able to interpret and to represent the complexity of the sites. These devices have to enlighten on the various interrelations, superimpositions, stratifications and reciprocal interferences between the sedimented parts, in order to take possession of the global significance of the place.

The architectural drawing is traditionally the partial and specific result of the subsequent stages of a site surveying. And then it's the final synthesis (or the gnoseological summary) of all the previous cognitive and interpretative operations which allow the representation. The drawing is the oriented simulacrum of the reality, in which continuum the most appropriate data discretization and selection are operated. The drawing is "the architect's real sight" [1], it's intrinsically able to reveal aspects and properties which aren't immediately visible in the 'natural' image of the studied object.

The survey of the whole historic city (or of a part of it, for example a block) requires the adoption of a structuralist method, just because there's a variety of aspects that may be found. In parallel with a process of progressive studies in depth, it's necessary to do a kind of 'disassembly' of the area, in order to attain the meaning of every part which contributes to the making of the whole. Consequently, the whole is tidied up, finding its rules of combination and transformation; these rules are transcribable in a *corpus* of significant representations, which are suited to highlight the regenerative critical states and potentialities of the studied area.

"Structural man takes the real, decomposes it, then recomposes it; this appears to be little enough. Yet, from another point of view, this "little enough" is decisive: for between the two objects, or the two tenses, of structuralist activity, there occurs something new, and what is new is nothing less than the generally intelligible: the simulacrum is intellect added to object, and this addition has an anthropological value, in that it is man himself, his history, his situation, his freedom and the very resistance which nature offers to his mind" [2].

Therefore drawing is a text which is parallel to reality; it's more suited to our cognitive appropriation than the experience of reality itself. In its role of interpretative action, drawing is an operation of adaptation (a critical and not diminutive adaptation) of reality; at the same time it's able to enlarge the reality, because drawing can highlight both the evident elements and the elements of the invisible world which "is formed not only by what can be seen, but also by what isn't [usually] highlighted in the field of view" [3].

In this sense, drawing is always been an 'enlarged' reality.

This fundamental peculiarity expresses itself much more through the modern possibilities which are offered by the information technology, as accepting an upgrade process. There's been an improvement of the virtual reality applications in architecture and other contiguous disciplines (firstly, the archaeology). After the first popular-didactic results (ideal reconstructions of buildings or lost cities), this improvement has produced an extraordinary modernization of the methods for studying the buildings and the sites. At the present time, it's not only a revolutionary support for the phases of data sampling and for their restitution and representation, but it also has a great importance in the process that identifies and structures the

Illustration 1: Zenithal aerial image of urban context of S. Aniello a Caponapoli.

connections between the outcomes of the enquiries and their relation with the project hypothesis. The new features of solid modeling allow the complexity management; reality is represented by structures-simulacra which are organized in layers where the virtual navigation of the accessible and practicable simulated space is permitted. Static and dynamic views, infinite two-dimensional aspects and significant 'cuts' can be extracted from the *continuum* of the model; they investigate and reveal the architecture in the same way of an anatomic dissection.

The possibility of a simultaneous visualization of this aspects produces a great figurativeness. It makes the modern concept of representation able to reveal criticalities and potentialities of the historic sites, and suggests their regenerative possibilities. Therefore it's an irreplaceable tool for sounding and knowledge.

Similarly, the latest technologies for the 3D data acquisition (like photogrammetry and laser scanning), which are used singularly or complementing each other, are able to change over from the physical object to its digital representation. They are strongly innovating the processes of reading and revision of the external data, making possible the extraction of simple information (like linear measurements, thicknesses, or diameters), and also of more complex formal parameters (like sections or best-fit surfaces), through the *reverse modeling* process.

Drawing has a revealing role, which is amplified by the present and future sceneries of *Augmented Reality*. Through the superimposition of one or more informative layers on the physically perceptible world, these sceneries multiply the amount of simultaneously available information concerning a particular real context. Therefore, they are useful future tools for the processes of knowledge and valuation of the impact on the highly complex urban areas.

The simple act of drawing already gives a sense of amplification of the reality. Even in the case of relatively simple objects, the act of trying to draw verifies that "the objects become more visible (even more real) when they are converted in a system of signs which are put on a two-dimensional support; so, they offer themselves to a comprehension that incorporate a memory (and this is a not secondary quality)" [4].

2. Caponapoli. Space-time interpenetrations and contaminations

The 'simulated' reality is able to duplicate the real context; it reveals the various aspects of the place and makes them visually comparable. All of these aspects are significant; but if they are taken singularly, they are insufficient to reach a critical knowledge which could generate and orient the intervention.

The creation of the simulated reality is extremely useful for the strongly stratified sites, which require operations of integration between memory and contemporaneity.

This is the case of Caponapoli, an ancient settlement that was situated around the highest point of the city in which there was the ancient acropolis of Neapolis. This area is one of the most sensitive to variation of times and situations; in the course of centuries, its important natural position – this area was defended by the ancient deep valleys (which correspond to via Foria and via Costantinopoli at the present time) – and the historical events of the whole city have determined many complex transformations and space-time

Illustration 2: Close aerial image of the urban context of S. Aniello a Caponapoli.

Illustration 3: Road transversal section of difference in level (about 17 m); from piazzetta S. Andrea delle Dame to salita Stella.

interpenetrations, which are revealed by various archaeological finds and by the complex consistency of the present built-up area.

Beyond the decorous alignment of 19th-century buildings downstream, and the apparent composure of the streets upstream, the built-up area is a very intricate three-dimensional net, which is constituted by interventions and superimpositions, alterations and erasures, stratified levels which are accessible through unexpected horizontal and vertical routes...; the texture of joints and interferences is seen as 'splitted into two', in particular in the points of discontinuity, where it is hardly readable.

This ideal structure of relations is permeated by a sense of spatial and temporal 'contamination', which is connoted by multiple values; in particular, there is a double value, which is referable to the meaning of the latin word *tactum*. This word has two very different (but always interactive) senses: the negative acceptance of 'contagion' or 'infection' (it is particularly associable with the improper or irresponsible interventions which enveloped the precious preexistence of the area of Caponapoli in the course of time) and the positive acceptance of 'interaction' or 'hybridization', which is very attached to the cognitive value that is assigned by the contemporary culture to the concept of multiplicity [5].

3. The story of the stratifications

The numerous archaeological finds place the origins of the site about the V century B.C.. Even if most of these finds are still divided or not visible (like under the clinic of medical semeiotics, in S. Aniello alley and near Maria Longo stairs), they show themselves in various points of the hill (for example, in Villa Chiara, near the transept of the S. Aniello church and under the floor level of the homonymous church); Roman walls of the Augustan Age in *opus reticulatum* were discovered here, at the same time as Greek walls of the III and IV centuries B.C., early Middle Ages tombs, traces of the apse of an early Christian chapel, and a series of finds which are probably pertinent to a rural sacellum and are datable about VI century B.C., before the foundation of Neapolis.

The present site is intensely steeped in history and myth (according to an ancient tradition, the bowels of the

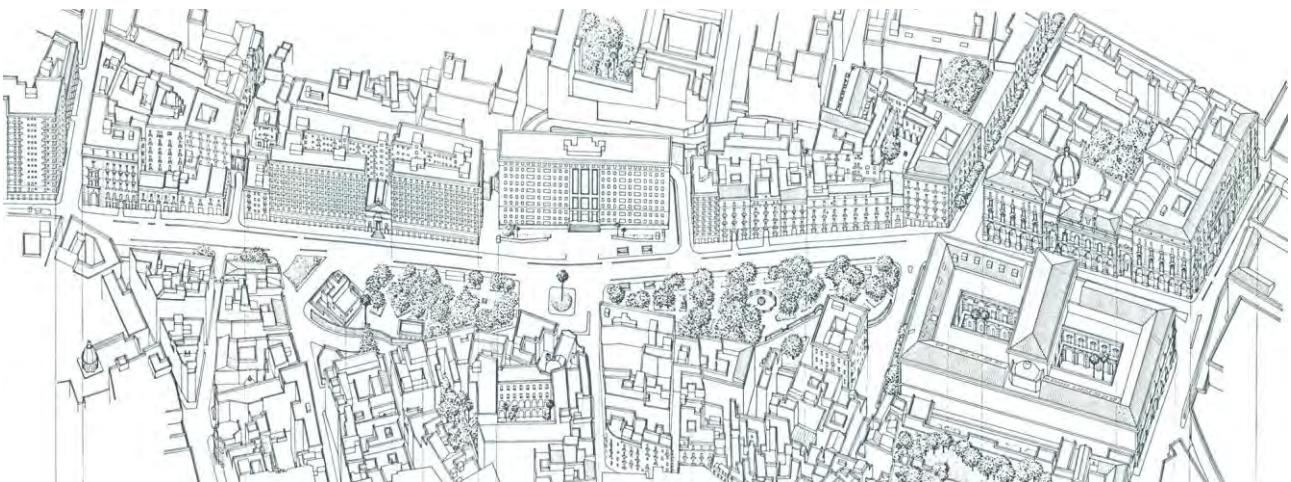

Illustration 4: Axonometric view of the study area in the context of piazza Cavour.

Illustration 5: Elevation of urban front of S. A Caponapoli, in piazza Cavour.

hill give hospitality to a supposed sepulchre of the siren Partenope [6]). It springs from the enlargement of the ancient S. Agnello church (IX century); this church rose on the previous chapel that was dedicated to S. Maria Intercede (VI century).

The present nave of the church was built during the Renaissance, in accordance with a Latin cruise scheme where the ancient church serves as a transept; it is an integral part of a religious complex which was subsequently supplemented by a monastery, a cloister and some residences. In 1809, after the abolition of the monastic order of S. Aniello, the monastery premises were sold to doctor Cosmo de Orazij, who englobed them in the structures of his new palace; this building is situated at the intersection between the directrices of Foria and Costantinopoli street, and it absorbed the garden of the ancient claustral space.

In the same period, the persistent structures of the ancient monastic citadel were hidden and compressed also by the large alignment of the buildings around Cavour square. Cavour square leans its volumes against the strong difference of altitude still today, and it contributed towards determining the sensation of occlusion which connotes the studied area. This sensation relegate the area to a sad condition of carelessness and decay, which is caused by many flaws in the relation between the fronts of these buildings and the ancient structures of the conventual complex.

In the sixties of the last century, a modern building was built along S. Aniello alley. This building put itself between the remaining buildings of the convent, between the esonartecce of the Renaissance church and the south side of de Orazij palace; it dominates the slope of S. Aniello alley (this slope was previously arranged as a pedestrian way with a flight of steps) with a powerful rhythm on the facade. The apparent polish of the composition of this facade is reversed on the opposite side, where the new ferro concrete structures are indiscriminately inserted into the preexistent structures of the monastery.

It's the drawing of the city of Naples, given to us by historical cartography that, comparing the view of Alessandro Baratta (1670), the map of the Duke of Noja (1775) and the map of Luigi Marchese (1861), makes clearly readable a lot of these transformations; particularly, still in 1861, it's attested the presence of a pedestrian route which hugged the longitudinal extrados of the transept, from S. Aniello square, near to the

Illustration 6: The garden of the ancient claustral space of S. Aniello a Caponapoli's convent.

side entrance of the church, arriving at the cloister. This route, reported also by the Duke of Noja, is already guessed in the view of Baratta; instead, the map of Schiavoni (1880) doesn't report it: anyway, this map also omits the empty space of the cloister, which is the only surviving element of all the stratification at the present time, so the dating of the obstruction of this route is indeterminate.

4. Contagion or infection

The site of S. Aniello has been the protagonist of a complex stratification, which bred a 'laddered' space. This space was completely transfigured, in its original values, by a lot of spontaneous and inadequate interventions which have compromised its historic and environmental value, and the uniqueness of its cultural identity. Sadly, this also happens where the 'plot' seems to become more clear, like in the cloister of S. Aniello in Caponapoli, with the garden, the well and ancient plants: in fact, the remains of the cloistered walls, with their round arches in piperno, are strongly damaged not only by improper insertions of other buildings in the course of the time, but also by a diffuse anthropic and material decay. The cloister is relegated to a condition of isolation, which is very different from the original condition of spiritual retreat: the two surviving sides of the arcade (the southern and the western sides) are no more accessible from the new contiguous buildings, while the use of the garden is reserved for a level of de Orazij palace, whose eastern structures of the facade incorporate the arches of the original cloister, ruining the depth of the arcade on that side; the ancient pedestrian route connecting the entrance and the transept of the church is also completely obstructed.

The whole site, and in particular the space of the cloister, are consequently 'closed' compared with the great integrative potentialities of the area: upstream, with the net of relations of the ancient centre; downstream, with the height of Cavour square and the cultural and communicative flows which are included in the square (archaeological museum, subways, ...). Actually, the strong difference of altitude (about 17 meters) between S. Aniello church and the present Cavour square is the main cause of the problematic stratification and not only physical isolation of the area.

An unexpected vertical connection between the two altitudes already exists (it's a private connection consisting of an adventurous system of stairs which starts from the building overlooking Cavour square and throws itself on largo S. Aniello), but the improvement and the protection of one of the more stratified areas of Naples would be assured by the integrated refunctionalization of some of the existing buildings and the creation of a public connection between the two altitudes.

A strategical point for the creation of a vertical connection is near to the seat of the missing Costantinopoli Gate; it would be a new entrance of the routes of the ancient centre, and it would take possession of the existing space of connection between de Orazij palace and the contiguous building.

5. Positive interaction or crossbreeding

Drawing (in particular, the architectonic representation with the modern systems of modeling) is very important for materializing and turning the knowledge of the sites towards the present processes of urban

Illustration 7: The current state of the cloister of S. Aniello a Caponapoli.

regeneration. Lately, the revitalization of the area of Caponapoli seems to begin with the reclaiming of the homonymous church. Within the initiative promoted by the bishop's Court of Naples for reversing the neglect and the decay of the great historic and architectonic patrimony formed by the closed or unused churches (transforming them in social catalyzers useful for the production of culture and knowledge), the church has been reopened to the public, after a very long time of closure and spoliations, and it has been assigned to social and cultural activities in addition to the religious activity.

The long process of interventions and restorations, begun in the sixties of the last century, required archaeological surveys which showed exceptionally the whole history of the city, from the time of the foundation to present days. The large works of excavation under the church proceeded parallelly to the coeval Italian discussion about the methods and the aims of the urban archaeology and the diffusion of the stratigraphical methods. The new methodologies based on the Harris' theories found the archaeological excavation on its accurate survey, because they consider the excavation as part of the knowledge process. The tidy activity of the stratigraphical method follows a structuralist approach and realizes a physical disassembly of the existing stratification; moreover, it associates an accurate and systematic data research with this disassembly. This activity is based on the concept of "stratigraphical unity", which is the definition of every trace left by every single human or natural action in the archaeological stratification of a site. It is able to infinitely multiply the amount of information which can be made up from an excavation [7]. Consequently, this activity requires the use of present representative instruments which will make possible the scientific management and the simultaneous control of the data, therefore the global knowledge of the site.

The very refined restoration work of the church, directed by Ugo Carughi [8], is inspired by a principle of simultaneity too; this work operated in the body of the nave, and inserted a glass footbridge around the central void that permits the sight of the Greek, Roman and early Medieval archaeological finds. The footbridge is below the floor level of the church, so the descent is like a descent into the void and it's possible to synchronically perceive all the ages, which are "from different times but in the same place".

The extraordinary charm of this perceptive condition springs from the dialectical presence of the various 'levels' of the stratification, of the various additions and modifications which sedimented themselves in the course of the centuries and are now simultaneously understandable.

This is the 'positive interaction' or space-time permeability, the dual aspect of the sense of 'contamination' which characterizes the area of S. Aniello. This interaction is referable to the conception of 'reality' as it is seen by the contemporary culture, whereas the intensification of the possibilities of information about the more various aspects of reality made this very idea of reality less and less conceivable. At the present time, far from the reassuring scientific formulations of the nineteenth century which considered reality as a rational cause-and-effect system, this multiform idea of reality is obtained from its numerous, contemporaneous images or interpretations.

6. A section of the time: the cursory scan of the virtual model

A similar transparency of relations always characterizes the fabrics of the living historic cities, in particular the densely stratified areas like the area which generates the complex identity of the studied site.

Illustration 8: The current state of the arcade of cloister.

Stopping the elusive mixtures which reveal and enhance the knowledge of the places, through the comparison of the various aspects (in accordance with the Renaissance Albertian principle for which every knowledge is obtained "*per comparatione*"), is the present duty of representation and its interpretative, methodological, technical instruments based on the modern *hard sciences*. Still now, the use of the section plane is an essential instrument for the acquisition and the transmission of the knowledge of an architectural site.

The architect entrusts section plane with its need to reveal the various sequential planes of a building, to scan them with appropriate vertical, horizontal cuts in order to bring back the unity of the building.

It's a close anatomical examination where the graphic sign "is able to separate the objects with unbeatable surgical precision (incisiveness)" [9]. Section plane is the scalpel of the architecture which all along connects the cut of the buildings with their intersection with ground and underground (the underground is almost always considered the place of memories and the identity place). In this case the anatomic metaphor is very close to the body of architecture, which is subjected to a progressive updating of the representative potentialities of CAD modeling and visualization; current human body scanning is a parallel process which is directly comparable to the new representation techniques, because they are similar to the axial tomography method or the magnetic resonance. In particular they allow moving the section plane over the model (like a ray of a scanner) [10], and stopping it in the most critical positions, always obtaining a two-dimensional section without distortions. A virtual section isn't a limitation, a separation; it's the place where synchronous relations and contaminations interact: between inside and outside, above ground and underground, nearness and distance, memory and contemporaneity, preexistence and transformation.

The virtual section is also the converging point of a double duality which is integral to the three-dimensional model. The first duality is the compresence of inductive and deductive logic: infinite sections can be extrapolated from the model, but the data of at least one of them are necessary for the construction of this very model. The second duality detects another interesting antinomy: on the one hand, the section discretizes the continuum of the investigated material object, breaking down it and making up one of the piece individually; on the other hand, its peculiarity of reading the relations between the parts and its dependence on the position of a cursor plane make it an instrument for investigation and global knowledge. This instrument fluctuates between the reductionist and structuralist scientific method (the opposite pole of the Strauss' theory) and integrates them [11].

The correlation and the combined visualization of the various sections and views which can be obtained from the virtual model, allow the constant control of the order of the elements which are present in the investigated context. They allow a global knowledge which was rarely obtained by traditional drawing.

The model is very dynamic, because there's the possibility to animate the sections in order to simulate a route into the model. In addition, dynamicity is mainly generated by its peculiar capacity to sound every entangled body *sub specie sectionis*. It's useful to understand the passages, the exchanges of height, the stratification of these bodies, in order to reveal criticalities and potentialities of the historic city; so, representation projects itself into a concrete planning dimension.

Illustration 9: The interior of the nave of the church after the restoration and during excavation work.

Illustration 10: From top to bottom and left to right, historical maps of Caponapoli and current image of ancient path site that lapped the transept of the church .

Abstract

The Spanish domination has affected the Sardinia from the fourteenth to the eighteenth century. The traces for such a prolonged stay can not be summarized in a few, though of great value, buildings published in the literature. There is a huge underwater heritage, in the so-called "minor contexts", unexplored, but not lacking in importance and historical significance. It is absent, even in the best-known cases, spatial and geometric analysis based on the finding of the building: the published studies have in fact a purely historical character, almost completely ignoring the technical-constructive and geometrical space.

Here we report the first results of a research project in which the documentation has been made, mainly graphics, such as to illustrate every part of the buildings surveyed, with the ultimate aim to promote knowledge and thereby safeguard. Each phase of the project has faced several methodological and technological issues, from data to their management and organization for consultation. The method of investigation is highly technical. The results will promptly publish and useful, because it meant in terms of compatibility with current and common dissemination platforms, such as Google or similar. The end result will make available the data collected and processed into 3D models complete with data sheets, directly on the interface as "Sardinia 3D" or Google Earth.

Keywords: late gothic architecture, 3D modeling, web diffusion, survey, cultural heritage, Sardinia

1. Description of project

Study and conservation of the historical architectural heritage combined with a proper promotion of the territory could be a starting point for development, in a perspective of sustainability and conservation of specific local differences. The information currently available on most historical architecture located on the Sardinian territory are highly technical and accessible, but not structured for a functional diffusion. There are two fundamental issues that revolve around the problem, the preservation of the object and the operations related to restoration and the use and enjoyment of the object in relationship with promotional operations. In the first case, although there have been considerable advances in acquiring data for the urban historian who led the preparation of "recovery manuals" is still not a systematic survey of historical architecture.

In the second case we can see how the dissemination of information on historical and artistic heritage of Sardinia is still very weak. Sites as "Sardegna Cultura" and "Sardegna digital library" offer only few, scant information on the buildings they describe. A user of the Web, especially if foreign, is likely to try a lot of high-level information on-line: often want to see interactive visualizations of the monuments, that invite him to visit the monument from real. For each village are also usually shown a few buildings of interest, neglecting some emergencies very important from the point of view of history and architecture, but still completely unknown. The point of contact between the two aspects of the problem is the historical and graphics documentation

that can be used, with appropriate variants, as a starting point for both the restoration project and the promotion of monuments.

The project of research is therefore to revise the documentation system of architectural heritage in order to standardize and integrate existing data and draw a graphic documentation that support not only the technical aspects of design but also the diffusion of information on the web. Interactive 3D models, easily implemented with low-cost photogrammetric survey (photo modeling), can be built using software distributed for free (ex. Google Sketch Up). This models can be uploaded to the web quickly and easily, and viewed by any user. They represent an instant communication and are used not only in the documentation of cultural heritage but also in many other areas. The historical and architectural information so collected and compiled will form a portfolio of the village studied, which will be published and will be spent at the international level in order to carry out such a promotion from the perspective of cultural tourism.

1.1 Main stages of the work

The first phase of the work is to provide a general survey of the area to find the most historically significant architectures. The project focuses on religious and civil buildings, or parts of them, unknown to the existing specific literature. In particular, attention will fall on rural churches and smaller ones embedded in the historical center of the villages, which is not given any importance in the current books on architecture, but are a huge cultural heritage for the island's villages, yet completely unknown. Churches, preserved almost entirely, allow to obtain a series of reasoning related to shape and geometry, especially on vaults and ornate decorations carved on the main architectural and structural elements that compose them. The same importance is devoted to the study of civil architecture, studying the location, type, texture and through the survey and the graphic rendering. Where possible, it is useful to study details of facade and interior elements that allow for stylistic comparisons, to identify the geometric dimensions of buildings in order to discover the design method used by the builders.

The method used is drawing, survey and three-dimensional modeling, in order to produce graphic and photographic documentation. Survey method is highly technological and immediately accessible, because it is already thought in terms of compatibility with the current and common diffusion platforms, such as Google or similar. The final result will be to have the availability of data collected directly on a 3D interface as Sardinia 3D or Google Earth, where approaching with the cursor in the affected area will see all the buildings surveyed in that territory; moreover, the three-dimensional model appears, for every building fully intact. This system will facilitate the widest diffusion around the world of the architectural culture of villages studied.

2. The village of Busachi and architectures studied

In collaboration with the cultural association of *Collegiu* sited in Busachi we carried out the research project in question, aimed at promoting the culture of the village. Busachi is a small village located on the left bank of Tirso river, in a small natural amphitheater near the artificial lake Omodeo. Busachi was, since the medieval period, the capital of the region of Barigadu, in which also actually insist. The village is divided into three historic districts: *Busache'e susu* (Busachi above), which would coincide with the oldest part, *Busache'e Josso* (Busachi below) and *Campu Majore* (Major Field) [1].

In the first quarter we can find, the parish church of San Antonio; in the second one we can find the church of San Bernardino. The first, dated from the early '600, has a rectangular floor plan with three naves covered with barrel vault with lancet arcs. The presbytery is characterized by a stellar vault. The architectural features of the interior of the building identified it as a late Gothic architecture. The facade was made in a subsequent period. The church of San Bernardino has not a certain date, but some historians speculate that it was also built between the late 1500's and early '600, although an inscription on the facade bears the date 1779. The plant is in the shape of a Latin cross with barrel broken vault, divided into three parts by lancet arches.[2]

Within a strong territorial identity were then grafted styles of overseas art, mostly from the western coasts of Spain, ruler of the island for 400 years. In this way has been created an hybrids style that produced a new original and fascinating architecture still visible in these areas of Sardinia inland.

Two interesting examples, both built by the work of Girolamo Torresani, Marquis of Sedilo and Earl of Busachi, are, the monastery of the Sixteenth century, called *Collegiu*, and the church of *Conventu*. In 1577 the noble made the foundation of the College of the Society of Jesus in Busachi, with intent to promote, through the presence of pastoral care, basic education, both in Busachi and in neighboring villages. The choice of the Jesuits by Torresani was not random because of their beneficial presence in Sardinia in two colleges located in the cities of Sassari and Cagliari.

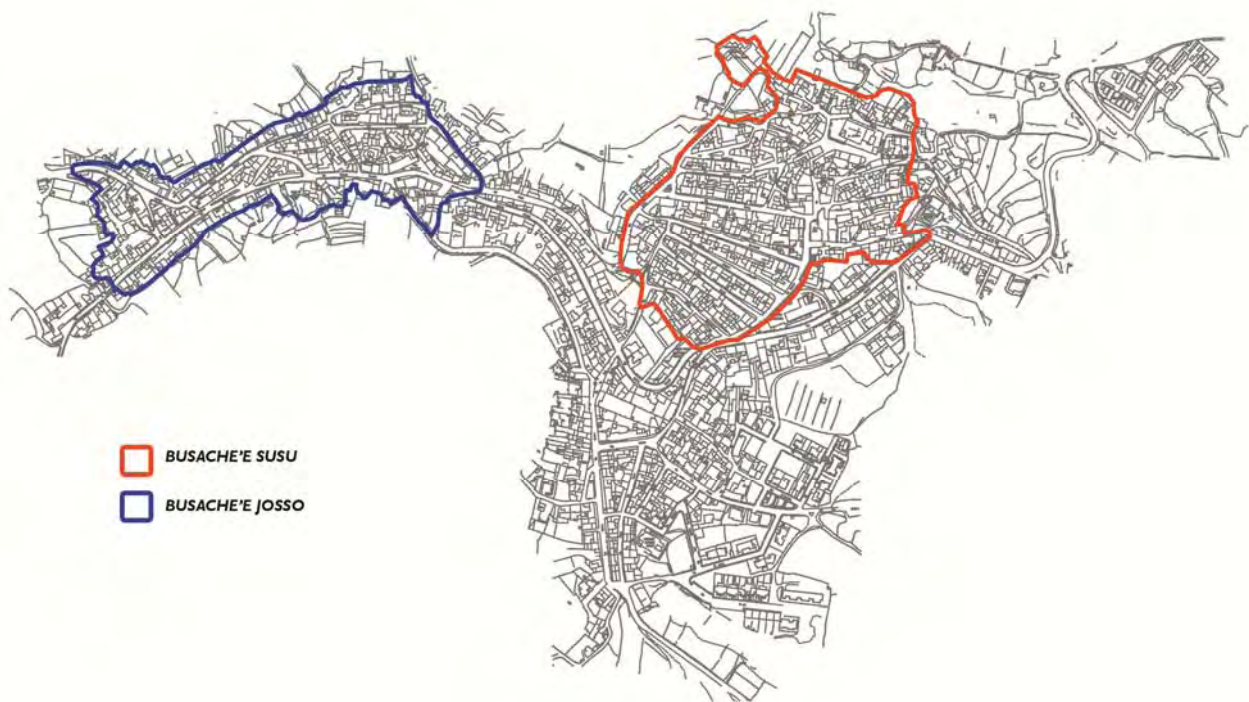

Fig. 1: The village of Busachi.

For this initiative Torresani donated many real assets including the building Palazzo of Busachi with the surrounding buildings, a chapel, yard, garden, barn, kiln, grinding wheel, and even the prison. The Jesuits stood for a few time in these places and they were followed by the Friars Minor of the Provincia di St. Maria delle Grazie, the only one in Sardinia. This monastery has long life, about 246 years. The company deals with the construction of the novitiate, on *Collegiu* and the church of Nostra Signora, whose vault is completed in 1730.[4]

The complex is similar to others made by the Jesuits in Sardinia in the same period [6]. It included the cloister, the monks' cells and the church. Today after a recent restoration has preserved almost intact the cloisters and cells, while are traces of the foundations and the apse of the church, which is experiencing a strong state of degradation. The church has a typical system of Jesuit churches of this period, while the late-Gothic cloister, presents the character as some other buildings on the island and the country itself.

Another important architectural evidence of this period is the structure called *Cunventu*, located in the main square of the village, entrusted to the Dominicans, and then also inexplicably abandoned. Built in 1571, included a large complex of which now remains only the church of San Domenico, that is a little gem of - Spanish art in Sardinian. Deconsecrated and left to decay, after careful restoration, now houses a collection of ethnographic objects and the Museum of Costume and linen. The building is an interesting example of the influence of Catalan and, despite being of modest size, it houses all the features of architectural and decorative repertoire of this cultural trend. The plant is rectangular, with a single nave, and a side chapel with ribbed vault full of ornaments carved directly on the stone of the major elements such as columns and arches angular, jagged ledges, niches with columns surmounted by a tympanum. The facade is simple and straightforward with flat top and canopy, which today remains only the ring, and the crest of the Torresani above the main entrance. On the left is a square bell tower. The nave is covered with a gable roof supported by four stone round-headed arches. Directly from the nave you can access to the bell tower, through a stone stair.[8]

This is one of the recurrent cases in the island where there is a blend of decorative elements typically Catalan and the classical Renaissance style, which leads to an interesting architectural composite style.

Fig. 2: Church of San Antonio; Church of San Domenico (*Cunventu*).

Fig. 3: Church of San Domenico (*Cunventu*); Church of San Bernardino.

Fig. 4: Church of Nostra Signora delle Grazie e Collegiu.

3. The rural village of Santa Susanna

The rural village of Santa Susanna is located about 5 km from Busachi and probably stands on the site of an abandoned medieval village known as *Moddamene* [1]. Are accessed through a portal with typical features of Spanish architecture. Through a fraught road, you can reach the hill on which stands the church of Santa Susanna, consecrated by the Bishop of Terralba in 1349.

The original church is medieval, but has undergone several changes and additions over time to take the form we now appreciate. All around the building there are the religious building called *muristenes*, made, in the nineteenth century, as in other parts of the island [7]. In the past this little buildings offered a shelter for the pilgrims for festivals and fairs. The building has a single nave without transept, with the main facade oriented to the west and a south side entrance. To the main entrance there is a porch with three lancet arcs. Also the side door is characterized by a medieval porch supported by columns resting on stone parapet. The façade is gabled with a belfry on the top. Above the portal there are three majolica paterae. The interiors suggest a possible temporal evolution of the building: the nave is covered with a gabled wooden structure with the presence of stone arches that divide it into three parts. This part should be the oldest of the church. The presbytery is also preceded by a round-headed stone arch with beams of stone finely molded as late Gothic school teach. In this part there is a barrel vault characterized by classical decorations that prove a most recent building. On the back wall there is a niche formed in the thickness of the wall, in which there is the wooden statue of the saint Susanna; below there is also an altar of stones with moldings.

The presbytery is also finely decorated with tempera both in the vault and in the walls. The painting tells the story of Santa Susanna, is not signed but is dated 1753, and is attributed by some scholars to the painter Gragorio Aru come from Fonni, a descendant of an ancient Genoese family and active in Busachi in those years, along with his father Pietro Antonio.[5]

Fig. 5: The rural village of Santa Susanna.

Fig. 6: Church of Santa Susanna.

4. Interactive representation methods: procedure, potentialities and limitations

In an attempt to provide a description of the area in the most simple and immediate way, we used the method provided by Google Earth (available free on the web) that lets you share pictures, models, and other information, of handy and immediate use [3].

Google Earth allows browsing bird's-eye level or ground level, with the ability to enable Street View mode. This mode provides images of the buildings as if you really journeying along the constructed space. In either mode, you can insert a placeholder identifying a location using longitude and latitude coordinates.

For each placeholder you can enter detailed information, images and references to websites outside Google Earth in order to supplement and enrich the existing information. In the case of Busachi, we start from a situation of poor documentation. In fact, at present, in Google Earth you can fly over the area, or use street view, but there are no textual information related to places in the town. The supply of images, added by

users of the Web via Panoramio sharing tool, is more rich. 3D models of the most important buildings are completely absent. The information collected during the survey was organized into a system of data, charts and drawings, designed to the immediate dissemination. We experimented the system of dissemination of geographic data in Google Earth, creating a series of descriptive headings for each building documented in the research. The tools provided by the platform, allowing you to enter information, images and models of all kinds directly on the satellite image of the area. In addition, the Sardinian Region has implemented a similar program (compatible with Google Earth) based on the same principles that allows interactive viewing of the regional territory mapped and modeled in three dimensions with color orthophoto map extensively detailed. Here we will outline the approach used to describe the area by the means provided by Google Earth. First of all, we proceeded to rationalize the available data, meaning these: textual data, photographic images, and 3D models of the buildings. Each type of data has been grouped into different folders. These same folders are also created in Places of Google Earth. Still in Place, we create folders for the placeholders of the places to be represented. Directly in Google Earth we added the placeholders. Each placeholder, marked on the building, was customized adding features and descriptive notes in the space for the records of the caption. These operations were carried out with ease by drawing directly on the 3D viewer of Google Earth and real-time checking the correctness of the information entered. For the inclusion of three-dimensional models, we followed a specific procedure dictated by the interaction between Google Earth and Google Sketch Up. The two programs are completely compatible, and while the former allows the visualization of virtual environments, the second allows the creation. The use of the latter is extremely intuitive, both as regards the creation of models, both for what concerns the sharing of them in Google Earth. For the creation of models we performed a direct survey of control measures, coupled to a photographic survey for the photo-modeling. In this way it was possible to model the basic volumes, sufficiently adherent to the real in terms of size, orientation and position on the ground. The modeling did not go far beyond the definition of these volumes and spatial relationships between them, in fact, the complexity is not a useful data to share on the web. The model should contain the least possible number of surfaces and must reduce the complexity to a minimum because it is functional to the interactive description.

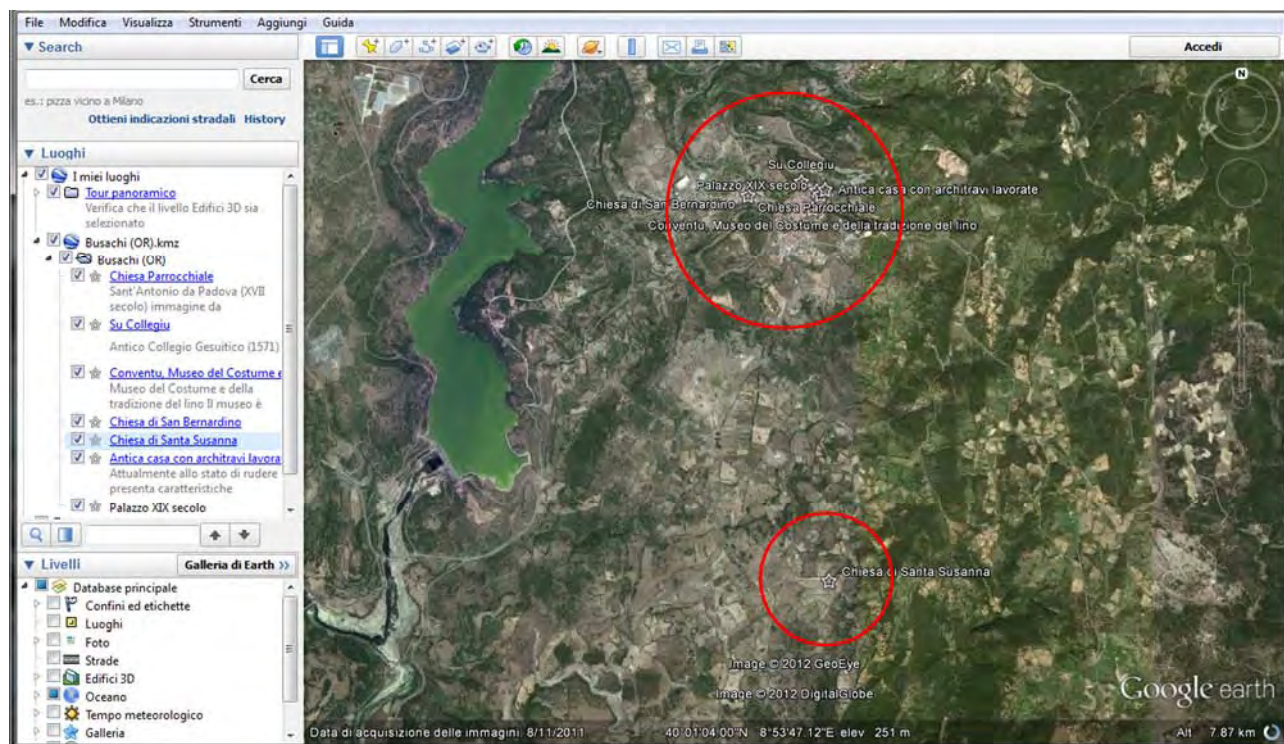

Fig. 7: Busachi and Santa Susanna: placeholders

Fig. 8: Santa Susanna, phases of modeling: photo modeling and georeferencing of the model

Fig. 9: Views of the model in Google Earth

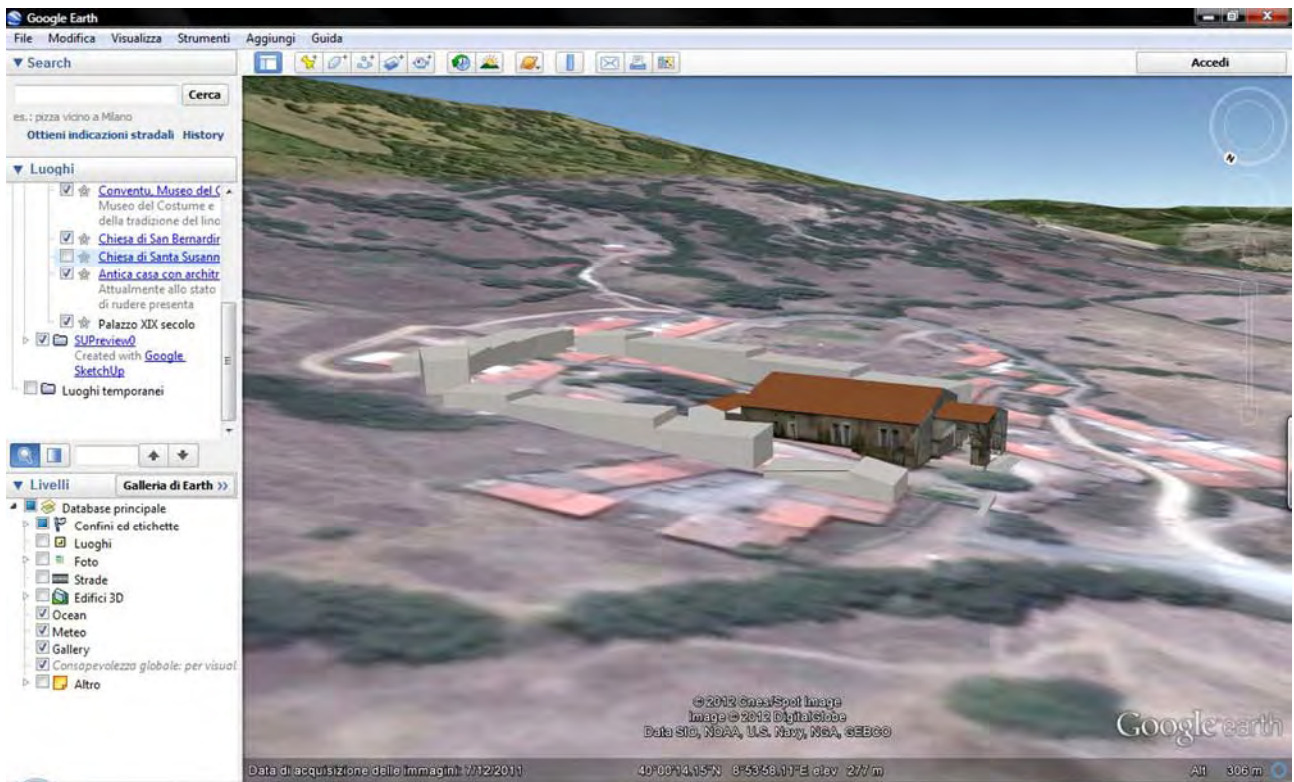

Fig. 10: Views of the model in Google Earth

The basic model has been built using specific software for the photo-modeling, and then was imported into Sketch Up to build a simplified diagram and covered with images as textures mapping, that supplement the lack of detail of the model. Another very important change was the repositioning of the model in the correct orientation according to cardinal points. This operation is necessary to make easier the correct georeferencing of the model.

The georeferencing procedure of models has followed the simple instructions provided by the Google Sketch Up online guide; using tools in the toolbar to interact with Google Earth, we have captured images of the terrain on which to place the models. Once settled over the land, the models were automatically exported on Google Earth.

All the operations described above were performed by operating on a local server, without sharing the results outside the local network, simply to test the functionality of the medium. At any time, however, these models, the cartographic processing and the information provided may be shared with all users of the web. Moreover, any changes made to the virtual system could be implemented in real time by all users.

It is necessary to do some practical considerations regarding the usefulness of modeling operation in comparison with the powerful tool of Street view. The two display systems architecture, are both valid but provide information of different nature. Street view allows immediate display, but is not always available for all buildings. In the specific case of Busachi, monumental buildings are located in positions distant from the streets and therefore, street view documents a small portion of them.

Both Santa Susanna and *Collegiu* are emblematic examples, in fact in the first case it is possible to appreciate only a part of the complex church-surrounding buildings, in the second case it is possible to see only the entrance gate. A 3D model allows overcoming these limitations, adding a volumetric description of the buildings, and completing the representation of the entire monument only partially visible through photographic images (albeit provided by many different angles).

5. Final considerations

The analysis led to the following considerations regarding the land and buildings in it. If, on the one hand, a work of documentation was needed for proper cataloging and documentation of historical architecture, it was the inspiration, the opportunity to review in depth the history of the center and highlight the main features. The starting operation has been to rationalize the available information by arranging them to be functional for insertion into a simple consultation system that is already well established and widely used by thousands of users. The streamlining and simplification of the information has still not led to a impoverishment of the research. In fact, within the interactive descriptions displayed in Google there is an external link that provides more information and details accompanied by documented verified references. At the same time, the 3D models provide an immediate way of understanding of the space and monument, and also can be downloaded and viewed out of context. We experiment that: careful use of simple 3D modeling, and the inclusion of text with references to external links, allows increasing considerably the knowledge, offering information on the center studied. While browsing in Google Earth, the information included in the tags refer to other resources already available on the web relating to places described. As an example we can cite: YouTube videos uploaded by users, or entries on Wikipedia. In this way a user finds concentrated directly in the descriptive tag, the information that can be found scattered on the web and he should seek using a specific search. The interactive visualization allows any user, even those not accustomed to the traditional cartographic representations, to evaluate, in an immediate way, the interrelationships between population centers and the relationship of these with: access roads, internal paths, the topography of the area. Such tool, then, albeit with the limitations offered by the low precision due to the ease of use of the instrument, allows to describe in a simple preliminary draft of proposed land use to a wide audience that can evaluate the effects in a real time.

Abstract

Functionalism the first, after the International Style, and, finally, the Post-modernism are the main stages of a crisis, the twentieth century, which produced a crisis of values in the merged globalism consumerism of the third millennium. A crisis arises mainly covering the put on a show of contemporary architecture that has lost its main objectives related to the hospitality of the different forms of living necessary for human life. In this perspective, the need for a return to simplicity must have as a goal for the ethical and aesthetic society of the third millennium: a society characterized by a constant voltage to the rampant consumerism that leads to a vulgar approval of commercial products and cultural ones. Simplicity as a value could be the best antidote to the apparent paradoxes produced by densification of consumption -energy, materials, images, territories- in a globalized society. In the continuous fluctuations of the main themes that characterize the contemporary debate duality -built/constructed, tradition/innovation, local/global, tectonic/deconstructed- the return to the concept of simple architecture could help to find that path that leads to his virtuous graphic and theoretical foundation in order to restore the original meaning and significance to the art of building the natural and artificial area's of our tomorrow

Parole chiave: semplicità, rationality, design

1. The design of simplicity

Functionalism for first, after the International Style, and, finally, the Post-modernism are the main stages of a crisis, the twentieth century, which produced a crisis of values in the merged globalism consumerism of the third millennium. A crisis stems mainly covering the spettacolaize a significant part of contemporary architectural culture that seems to have lost the search of his real objectives in society or those related to the hospitality of the different forms of living necessary for human life. A dwelling which, to be respectful of the natural environment, needs to relate to reevaluation of basic concepts that, taken together, could support the notion of conceptual simplicity of restoring the dignity held in the past. One could easily evolve into an essential elementary able to fight the contemporary architectural complexity that, in most cases, becomes a consistant novelty seeking, an end in itself, unable to protect the relationship with the place, natural or artificial, in which the new architecture is placed. Even the contemporary representation, through the so called virtual design, participated in this escape from reality to documentation and knowledge of natural and artificial contexts to arrive at a hyperreal figurative dimension and, in most cases, dreamlike, surreal and metaphysical. The concept of simplicity has suffered during the recent revolution in digital graphics, an ideal that has resulted in a depletion vulgarization and trivialization of architectural drawing. A trivialization mainly covering the stems spettacolaize of contemporary architectural culture that, through the copious production of virtual self referenced images, ends up losing the main goal of its task or one connected to the staging of

projects whose objective is the hospitality of the different functions necessary to human life: that working from home, from the social to the political, cultural than religious. Not only. Contemporary architecture has not been able to build even a new drawing shared cultural. Conversely, disruption of the different languages through the subjective search for isms figurative custom, started a whirlwind chatter representative based on the spectacular potential of the virtual image provided by the increasingly sophisticated Computer Aided Design. Transforming potential use, in most cases, the status of the innovative system for representing computer as a tool to serve the project (as a translation aid to help, aid, assistance and aid) to the nutrient sap varied contemporary creative process. In this context it should be noted that there is a trend for a distancing from revolution in computer design. Far from it. This is attributed to the more specific and disciplinary Computer Aided Architectural Design, CAAD, its rightful role as organizer and integrator of all technologies oriented to the management of the design with other metodologie. The current proliferation of computer design leads to a trivial use of its real potential, a negative reverberating chief concern of those characters held, always, from the fundamentals of architecture and its representation. Creativity against reason, subjectivity against objectivity, against the image representation, the virtual versus the real, the excess against the measure, against the concave convex orthogonal, the immateriality against materiality, the exception against the rule: these are the antithesis of the cultural representation describing a revolution involutive contemporary design that has marginalized, increasingly, the tradition of drawing from architecture principles that, historically, had guaranteed the modification of the territory in relation to it and not against it. The representativeness of the characters identity contexts of settlement, for example, achieved through the use of local materials, local traditional building techniques, careful listening context of geography and topography situale has now become almost a given completely irrelevant in the processes of transformation of global society. The concept of representativeness is dissolved in the immateriality of the communicative nature of virtual images. In this perspective, the need for a return to the simplicity of the design must have as a goal for the ethical and aesthetic society of the third millennium: a society characterized by a constant voltage to the unbridled consumption that leads to a vulgar approval of commercial products and those cultural. Simplicity as a value could be the best antidote to the produced by densification of consumption - energy, materials, images, territories - in a globalized society. In the continuous fluctuations between the major themes that characterize the contemporary debate duality: constructed/erected, tradition/innovation, local/global, tectonic/deconstructed - the return to the concept of simplicity could help the architectural representation to find that path that leads to his virtuous graphic and theoretical foundation in order to restore the original meaning and to the art of designing and constructing the natural landscape and artificial life within which it develops human life. The identification of conceptual categories related to the idea of simplicity is, in this sense, an attempt to emphasize the need for a critical reappraisal of the purpose and primary objectives for which the architecture, through design, was made by always essential, indeed inherent, to living man. A requirement that, for the complexity of contemporary life, needs to relate to two critical form, son the one hand, to improve the quality of living conditions on earth and, secondly, to preserve the natural environment and artificial contexts of functional loads too oversized for the relative, specific and not unlimited, capacity for absorption. If is true that the living man on earth needs to function is equally true that the functions must inhabit the world by defending human needs, especially by modern man who consumes, unreasonably, naturalness. Emphasize the need for simplicity, instead of adding of removing, in the actions of man in global society means, in essence, try to take a road that constitutes as little as an added value both in quantity and in terms of quality sustainable development based on resource saving rather than wasting them are in need of a substantial intellectual investment knowledge and understanding as the only true factor responsible for the coupling of a new economy. In this perspective some thematic concepts should reactualized to be replicated in the global society as the principles needed for urgent reconfiguration of its structure and some consumer exempla architecture of the past recur, however, such models can explain the profound coherence between its configurative structure, their social utility and the way they fit in a natural or artificial settlement based on rules derived from the geographical or architectural history of one or the other. To this end if, on the one hand, the depth thematic categories of issues related to the concept of simplicity, - as the unity, practicality, and rationality, the rhythmicity represents a first attempt to "simplify critical" towards those cultural positions based on "critical simplification" of the other, the use of a description of an architectural model as that of the original design of the "Albergo dei Poveri" in Naples allows you to check the quality of simplicity even in an extreme case as that of utopian century building. Concepts and architectural models that, taken together, can help formulate a new hypothesis of modification sustainable land as opposed to the current transformation of unsustainable places of our living.

2. The design of the unitary

Pitagora, linking the square to the one and all, basically posed the problem of unity. No other geometric figure presents the characteristics of specificity and generality as clear as synthetic: the square, in fact, is the union of four segments, dimensionally equal to each other, placed, each of these, two other perpendicular and parallel to the third system geometrical shape which, in architecture, corresponds to the system trilitic that is to that elementary structure composed of two pillars and perpendicular to a lintel brought which, in turn, is parallel to the ground line. The square also provides, as the sum of its four corners of ninety degrees, the total of three hundred sixty degrees in geometry that corresponds to the complete revolution of a body around its own axis. The square, finally, contains within it two diagonals where the measure is given by the root of the sum of the squares of the two sides which, in the case of unit size of the latter, is equal to the root of two. The overturning of the diagonal root of two, on one side of the square base, generates a rectangular shape formed by a side of unit size and by another measuring instead root of two. In this way the square with unitary side stands as the basic module for the concatenation of proportional figures, the so called dynamic rectangles, obtained by successive reversals of their own diagonal or by applying, from time to time, to the rectangles generated the known relationship Pythagorean. The philosopher of Samo (570-490 BC) had also revealed, the square, the inner order of the combinations for the odd and even numbers had in fact initiated the possibility of a reflection of compositional order based on measurability and objectivity and rationality of geometric unitary matrix. Monodimensionality, parallelism, centrality, specificity and angular dimensioning diagonals are characteristics that reinforce the idea of unity expressed by a simple that is set, since ancient times, all reasoning behind wanting to deal with a rational concept of beauty. For Platone a student of Socrates and teacher of Aristotle - the square called the conceptual path of those who having climbed the reason why the thing known and come to the first idea of this universal necessity, become the last link of his reflection. The scientific formulations of Euclide (Third Century BC) and Tolomeo Claudio (AD II), they determined, then fortunate composition of the matrix geometric square shape. In this sense, the ability to offer a mirror image with respect to the axis of symmetry horizontal, vertical and diagonal as well as the predisposition to synthesize through four points, or break down through four lines, or defined as a real two-dimensional surface enclosed by four sides have contributed to giving the geometric shape of the aura and feel of the modulator coveted status has always sought unity in the architecture of the past, both the remote and what is next. The unity of the square is different from that of the circle just because of his inherent willingness to be broken down into something different or more elementary than, for example, the circle is not given. If the circle can represent the unity of the latter is in fact only given as a dowry abstract to the square,

on the contrary, the unity is attributed as the practical value that can provide operations that refer, as recalled by Pitagora, so as to drive generality. And this kind of unity of interest noted in the square, or, by extension, the architecture in order to understand and clarify meanings, qualities and values. To relate the parts between them and between them and the whole, giving applicants dimensional values, comparing the elements of continuity and discontinuity, inquiring into the rhythm and the syncopation; relate to areas of similar architectural features (plan, elevation) compared an axis of symmetry perfectly specular or through appropriately tailored asymmetric equilibria: these are the main options to be investigated when the architecture through the proportional paths, looking through a reference in the simplicity of the unitary category. Many architectures of the past have been confronted with issues related to the square seen as a typology but not topological architecture: conceptual place within which the world of ideas has researched the topic of the unity in order to relate it to that of the truth as primary source of simplicity and beauty. The interplay between the concept of unity and the shape of a square seen as an index of the geometric primitive concept of simplicity should not be considered as a design constraint to proactivity. The design possibilities inherent in an architectural practice that can restore the broken dialogue with a centuries-old tradition in fact be considered unlimited. The “Albergo dei Poveri” in Naples is the architectural representation of this potential. The unity can also use convenience, paying homage to the ancient concept of utility now supplanted by the vernacular of functionality.

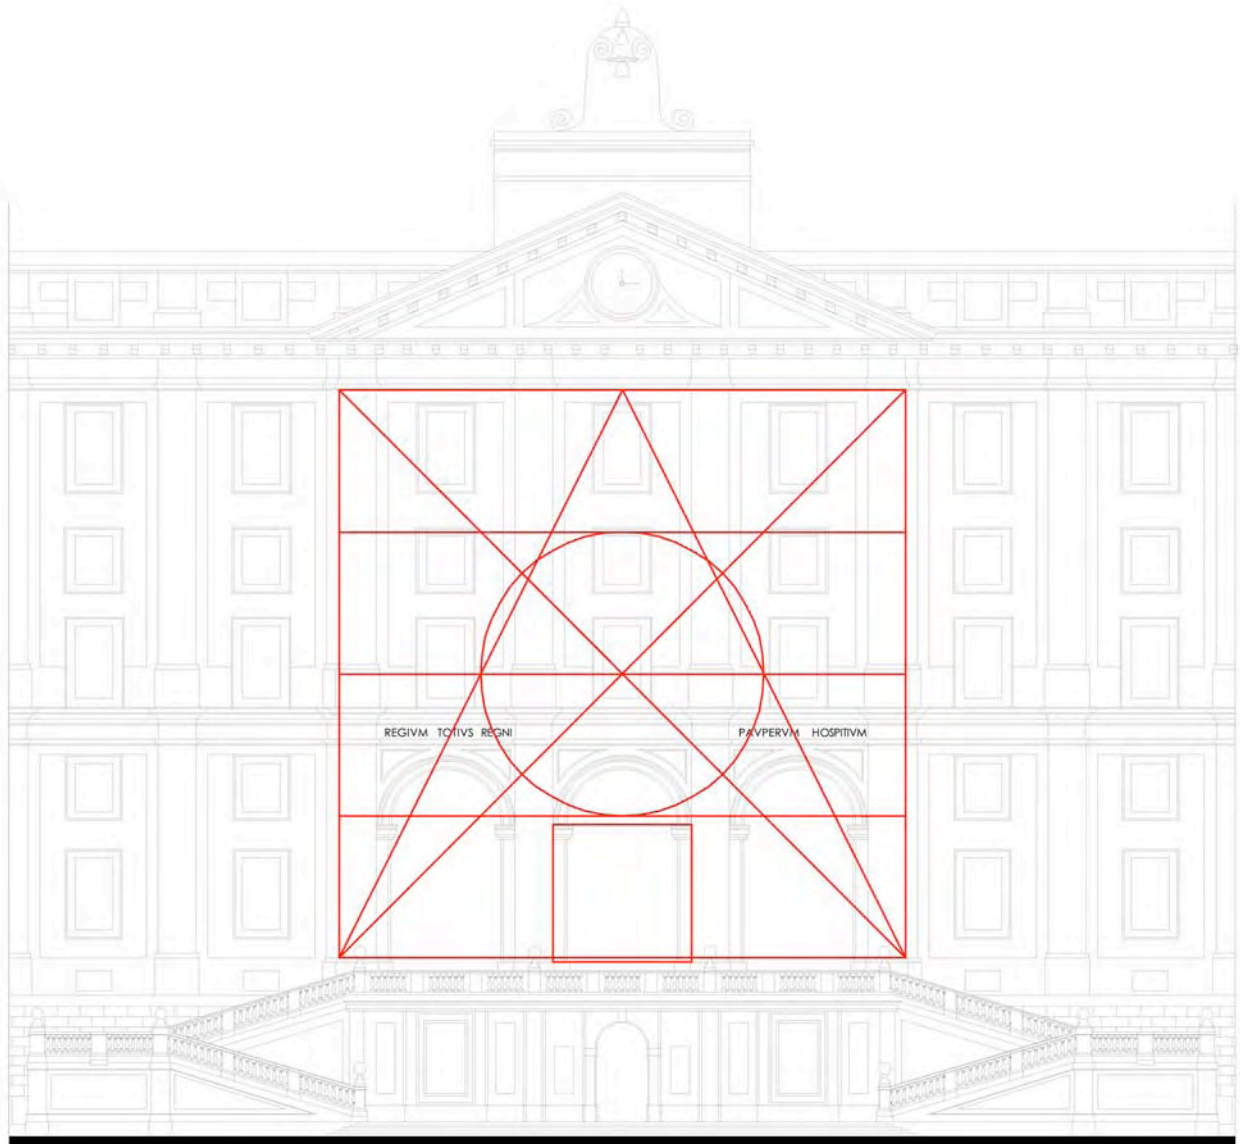

Fig. 3: Albergo dei Poveri, tracks proportional

3. The design of the practicality

The practicality is the feature that in things, in general, and in the architecture, in particular, denotes the adherence to reality of the requirements to be met. The convenience function that dowry should be able to facilitate, through appropriate forms and types, the relationship between man and architecture. Not always because the livability of the architecture is a requirement offered, as something arising from spontaneous design, to its users. Very often alleged creativity formal complexity and articulating distribution architecture to make a constructive infused with practicality. Typological archetypes of the enclosure and labyrinth represent the opposing concrete realizations of a simple and practical attitude on one side and the other complex and artificial. In the enclosure in fact, a place bounded by four walls perpendicular to each other two by two, the practicality of built manifests itself in full in the clear and precise division between an open space natural, the *cháos* outside and insecure, and a space delimited artificial, the *kósmos* internal and secure. In the back inside, much like the outside, it still constitutes as tame nature, however hostile and inhospitable. Here the ultimate goal, the function that underlies the intricate texture of types, is creating a sense of disorientation, bewilderment, which is accompanied, usually, to a state of bewilderment from which the user tries to escape. Far from the imperturbable cosmic orientation provided by the simple perimeter fence, with the clear identification of a functional stay inside, gives the viewer a state of calm and balance. In ancient Christian symbolism many iconographic representations relating to paradise or paradise lost to use the type of the sacred enclosure and, conversely, frightening maze to depict hell with its various groups and scary. Disturbing that group, referring to the contemporary, are reflected in the design exercises without any engagement with the reality of the place and, unfortunately, the real functional needs of a globalized society that would need everything except the current breakdown of the basic principles of architectural order: It 's necessary to prove greater distrust of the current state of electronic distortions and fantasies of architects and artists too prone to wander endlessly through the maze of images. A propensity, the latter, widespread that, a project, tends to favor the spectacle of images rather than the representation of the actual content of architecture. The weakening of the contents, therefore, is reflected especially functional programs and, therefore, in recurrent lack of practicality of use and management of the new architecture capable of producing, in most cases an indefinite space and empty . Plight, the latter capable of photographing with pitiless clarity the cultural drift of contemporary design that paradoxically, as of their character identity, pursues the quest for the instability, deformity, or the complication of all that is opposed practicality. The practicality, then, is that point of balance that the architecture of simplicity should find with his own typological nature, so that something less or something more would need to configure the features common on one side and irrational complexity the other, or as not meeting the specific needs and the needless complication of programs seen as inconsistent with the practicality natural gift of good architecture. Of course, practicality is not a functional quality easy to reach but a dowry punishable by a patient process of aging can satisfy representative, describing and interpreting the same time, both the reasons that the human architecture.

Fig. 4: Albergo dei Poveri, tracks proportional

Fig. 5: Albergo dei Poveri, tracks proportional and texture.

4. The design of rhythmicity

The rhythm is, for simplicity, the ability to deploy with one or more parts of the architecture of the recurrent elements that combine to mark the time and linguistic structural architecture according to a hierarchy of easily identifiable. The rhythm is connected to the lines through the base of other figures or those items that beat the time of an architectural composition. In classical architecture would lead to the rhythm of the colonnade of the temple greek joke: the column was provided by a module is represented by the diameter of the same columns that structured the four sides of the archetype classical architecture. The rhythmicity should not be viewed or detected only in the presence of solid elements which are, for example, the columns of the temple Greek or pillars of the Roman structures but also through the presence of voids and openings of the architecture, whether they are doorways or windows, porches or arcs. The rhythmicity is expressed not only from right to left and vice versa, but also from the bottom to the top of an architecture. This rhythmic succession, in most cases of classical architecture, is realized through the use of string courses, cornices or eaves and attics crowns: factors that highlight their presence with the existence of another order rhythmic not linear character but superficial. Rhythmic vertical scans are mainly dominated by rectangles which, as we know from the geometry, may be gold or dynamic depending on the size of the largest dimension is provided by the length of the diagonal or the length of the diagonal of the half portion upper edge of a square shape assumed as a module base generator. All options, those that refer to the grammatical sense of the architecture or the mode of articulation of facts and figures with the volumetric mass of the building. The rhythm of classical architecture, in analogy to musical composition, is always based on repetition, in varying shapes and sizes, of certain elements that, taken together, are combined according to regular patterns and symmetrical: the arrangement of structures in plant or the alternation of full and empty on the table, the concatenation planimetric indoor spaces in their differentiation between served and serving spaces or overlapping of structural elements with decorations in relief in the underlying design of the facades are the primary canvases on which the plot is woven through rhythmic architectural elements such as pillars, columns, dividing walls, windows, pilasters, pilasters, cornices and string courses. The contemporary rhythm suggests, conversely, solutions like morphology and differentiated language in which the concepts of temporality, closely related to the measurability, are clearly readable in an architectural order due to these codes based on the regular repetition of the classical canons, or, conversely chosen from which emerges, according to an emphasis spectacolize, complete dissonance with respect to the principles established through the enactment of scores irregular and asymmetrical: on the one hand, once again, the rational architecture connected to the legacy of the past and on the other hand, the architecture as a work of art, even transgressive, willing to accept in its form, its type and its language characters deconstructed, fragmented and heterogeneous expressed by globalized society.

Fig. 6: Albergo dei Poveri, tracks proportional

Fig. 7: Albergo dei Poveri, tracks proportional and texture.

5. The design of rationality

The rationality of simplicity should be interpreted, in an era of consumerism and dissipative condition as the present one, which stands for logical and reasonable. More architecture is capable of expressing rationality, the more its aesthetic value is high and related to the real needs of our contemporary use which requires careful and resources sensibly, from water to those energy as well as from those of matter to those food. Even contemporary architecture is pervaded by an agonizing desire for consumption and use of various materials, the more complex spatial configurations, the most advanced technologies. This architectural badly intoxicated that is combined with static and solid sense of beauty expressed by most of the monuments of the past a past that was violently deconstructed, fragmented, fragmented in favor of an open conflict with the essential and immutable conventions into architecture had more income collected and refurbished over the centuries. Deliberately illogical, disproportionate, and broken many dynamic contemporary architecture ride the wave that permeates the hectic life and the unbridled activities of our society, no more western or eastern, northern or southern but not simply global. Return to confront a project that will oppose this outrageous essentially means asking a question of convenience as well as logical reasoning: what is suitable to accept unconditionally the vicious circle? As it is convenient to wean the project the exercise of reasoning? As it is convenient to abdicate to the superpower of everything is possible? The answer, strictly speaking, is one: it is not convenient. Specifically architectural concept of beauty without rationality is not too convenient: if only for the intrinsic that allows the reasoning of what is logical and, because rationality is an exercise involving the reflexivity as we know, is the result of thought. Locate a path of logic in the architecture means addressing the issue of the necessary objectivity and rationality necessary to design and architectural design to avoid falling into the trap of subjectivity and creativity: a tempting trap, helped to proliferate in contemporary society from the need global marketing of the architectural image, or an image ready to spread through the network, to a world of diverse users, approved and unable to tune to a culture based on the logic of the choices on their potential rather than spectacular. The consumer society seems to need only architecture capable to send messages to the background, either, to the captivating advertising images of the latest generation cars or plebiscitary impending need for new political and economic empires of the Middle and Far East. Not of a traditional logic, contextual and management of the architectural megastructures part of the Third Millennium, with their waste, apocalyptic tribal feast of our planet, this is an uncomfortable truth to which the wise and ancient architecture rationality should not succumb. Introducing the category of rationality in the design drawing into architecture means reintroducing the beauty logic generated by the harmony of the parts and the parts with the whole: it is all relative to what is inside a single architecture and all that is represented by host and multiple environmental contexts of the different architectures.

6. The simplicity design in the “*Albergo dei Poveri*” in Naples

Groped to find a picture of simplicity in an architectural model such as that represented by the design of the original design of the “*Albergo dei Poveri*”, prepared by Ferdinando Fuga in 1752, an exercise could be misleading if the conceptual category was not sought in the different thematic aspects that characterize the identity of its own: the square, index of unity, the fence, typological space of the inner courts, the rhythm, linguistic properties of the prospectuses and, finally, rationality is understood as characteristic of eighteenth-century building representing its identity, in together, transliterations of issues related to architectural simplicity. The “*Albergo dei Poveri*” is a building that offers, thanks to its morphological type and decorative-structural interpretation of the simplicity inherent in different categories, from time to time, the size, language, and the intimate proportions. As for the simplicity filtered through the category of greatness it can be argued that the “*Albergo dei Poveri*” is an architecture on a human scale. Its main prerogative type morphology is, unquestionably, the large size which, alone, contributes to the eighteenth century building architecture is abnormal in relation to other elements with which it communicates to the monumental urban scale and is related to tissue residential surrounding it. Infact, this exceptional greatness is not intended as a limit for either the building itself or to the city boundary, but as a resource primarily for its ability to establish itself as a measuring element of the natural hill behind it as it appears clearly represented in his original configuration, the face of the map of the Duca di Noja, in addition to the urban proactiveness demonstrated by the subsequent structure of the front part of the city's main architecture adopted which vertex from which radiate a system of road features trident shaped, and finally to the ability to make cohesive around its architectural mass of a system of housing is heterogeneous and fragmented and is neat and compact: these are the main features of a building, through the large, able to communicate visually with the landscape, with the city and the surrounding buildings. The ability of the “*Albergo dei Poveri*” to arise, even from simple perceptual point

of view, as the undisputed director of the architectural urban context of membership is, in essence, a mode of simplicity expressed through the theme of great size. As the size of the language is also an aesthetic category proportion with visible directly to the concept of simplicity. The determination of expression and simplicity figurative Ferdinando Fuga, components highlighted in the design of the exterior elevations and interior of the "*Albergo dei Poveri*", have aesthetic qualities to find in a reflection of types, and formal linguistics devoted to relate the new logic rationalist of architecture in the age of enlightenment. The linear sequence of openings on the main facade of the "*Albergo dei Poveri*", in spite of limited rhythmic variations of the decorative, provide an architectural object limited, albeit large, the idea of simplicity enriched by the modular architecture of the system generally. Similarly, not so much the succession as the linguistic uniformity of treatment found in internal reports of the courts of the "*Albergo dei Poveri*" is closely related to the possibility of providing a uniform size, then finished the architectural space right in his order that the extrinsic its perfection, and consequently its simplicity understood as synonymous with beauty. Also obtained a beauty, it is worth emphasizing, in accordance with the laws relating to the harmonious proportions of the buildings. In this sense, the "*Albergo dei Poveri*" meets a set of criteria to be able to develop harmoniously the traditional design of the exterior elevations as well as domestic courts. The short side fact, the eastern and western ones, are characterized by a square shaped plant onto which, for each court, four of which an interior elevations, the north, linguistically and structurally differs from the other three measures, instead of simple rectangular windows, framed between pilasters and cornices, of a triple vertical succession of arches replaced by massive pillars. Well canvases prospectus is dimensionally defined, in its various component parts, a triple series of tracks proportional enhance the aesthetic qualities. This analysis was performed on both the interstory height, or between entablature and cornice, is about the size of the pillar system, in its total height, and the partial, limited to that significant parts of the moldings of the pillars. As regards the first proportional system it was noted that the dimensions of the height of interplane are based on a succession of climb of rectangles that dynamic, the first to the third level, are the result according to a sequence $\sqrt{5}$, $\sqrt{4}$, $\sqrt{3}$. The second internal system proportional to the first, constituting the height of the whole arc pillars from the base of its eaves, the key proposes a vertical succession of climb of the arcs defined by a sequence of $\sqrt{4}$, $\sqrt{3}$, $\sqrt{2}$. The third system of proportional representation makes explicit the constant presence of a rectangle $\sqrt{2}$ traceable, according to different methods, the system arched pillars. The presence of traces proportional able to harmonize the internal surfaces of the short side of the "*Albergo dei Poveri*" are also found in the remaining three statements, or those defined by a simple and elegant orthogonal warp composed of vertical pilasters and cornices are placed in horizontal rectangular windows of variable size. Even for these statements of the wishbone western neighbor of the botanical garden that has built all three levels of the original prospectus was a bold graphical analysis and interdimensional and the heights, both on the size of the areas located between the windows host cornices and pilasters, and is then proportional to the size of the windows confirmed the upward succession, from bottom to top, the second harmonic of rectangles $\sqrt{5}$, $\sqrt{4}$ and $\sqrt{3}$, so found in prospectuses as well as the south eastern side of the court and Western Europe, eighteenth century building. As regards the dimensioning of the panes host the windows can be seen at the first level and second level the presence of second harmonic rectangles $\sqrt{3}$, for the third level of $\sqrt{2}$. Finally, it very interesting the sizing of windows whose height measurement, net perimeter of the moldings, is equal to the measure of the width of the box in which is housed. The square that inscribes the window gives rise to dynamic rectangles according to the square root of, able to define the heights of the boxes, laterally, superiorly by the pilasters and moldings of the cornices defining the outside placement of interior floors. The uniformity of the internal walls of the short side of the "*Albergo dei Poveri*" and the rhythmic succession of the elements of this plot is enriched proportional superimposed together and connected to each other and even between the linguistic structure of the grammar that defines the overall architectural design and measures of statements in question. Further confirmation of this grouping proportional between the parts and the whole is the presence of square grids that define the size of internal tables: each side of the short side is in fact visible forms through the identification of three squares each incorporated it as a basis five of the fifteen bays constitute an individual and as high elevations the size of three levels, the trampling of the court until the last ledge. As for the sizing of the eighteenth century interiors of the building was visible the actual use by Ferdinando Fuga is proportional paths in buildings and in both the longitudinal and transverse scaling in the central court. Compared to this last part of the eighteenth century architectural complex building inspection was conducted on both the remnants of the unfinished church and is on the same graphic reconstruction of the original design and final. The graphic reconstruction of the section circular chart of the transept aisles located between the four diagonals for the guests and the central middle intended for outside public also helped to identify this portion of the building the presence of tracks proportional again just on the figure the square and its development into a golden rectangle. The with of the transept is sized on the same measure that defines the height of the same until the tax rate of the hemispheric dome lowered. The diagonal of the

imaginary square so constructed coincide with the set of arches that mark the passage between the transept and the central X shaped four aisles designed to accommodate the guest of the four classes of the poor: men, women, children, girls. The golden rectangle, which is obtained from the square base provides the total height of the transept, culminating in a lantern covered with a hemispherical head. This modular system is embedded in a sovrasistema geometry defined by a square that has the basis for measuring the height and width of the central court. The diagonals of the square intersect the amount of the tax of that lantern. Such a square, in turn, is embedded in another that defines and gives a rythmn the succession of the short side in their longitudinal proportioning based on the shape of the square is also used for the sizing of the body of the factory building eighteenth century. It was noted fact that the measure of the width of the building is equal to the height of the three main floors of the building (ground floor, first floor and second floor) and that the golden rectangle is obtained from the square base that defined originally, the overall height of the building. Taken together, the original design of the “*Albergo dei Poveri*” demonstrates membership - through the unity, practicality, and rationality of rhythm - to the family of architectures based on the concept of simplicity while explaining its inner complexity. Retry final that the less may be considered, in most cases, more than the more.

Less versus More: Ethics and Origins of Decoration in Architecture

Alexandra AI QUINTAS

E-mail aquintas@fa.utl.pt

Abstract

Mies van der Rohe has paraphrased through his architectural work “less being more” and introduced a minimal use of decoration in his own projects. Decoration had been previously questioned by Adolf Loos according to his writings as well as his architectural production.

Nevertheless, can we consider decoration as being totally eradicated from *Miesian* architecture? What about materiality and the inherent properties such as color, textures, brilliance, refraction, transparency or reflections? There is no such thing as “less” in the architectural production of Mies or even the Modern Movement.

We have to go deeper into the tradition of academic architectural teaching in Germany to establish the importance of Gottfried Semper and his concepts, namely the ones he summarized in the work *The Four Elements of Architecture* (1851). His constructs have reformed the whole idea of decoration, leading to an origin situated in some ancestral cultures.

Can we possibly assert that “less” can be “more” when wall decoration derives from patterns used in tents and primitive shelter structures? Nowadays, contemporary architecture, through the works of Herzog & De Meuron, Rem Koolhaas or Jean Nouvel, proceeds, satisfying human necessity by texturing surfaces, transfiguring spatialities, and nurturing the human gaze, eager for harmony and delight.

Keywords: architecture, ornament, gesamtkunstwerk, bekleidung.

The immense and cross-cut theme of 20th century architecture has been the question of the process of transformation and that of the degree of abstraction. It has also been debated the segregated by Loos theme of ornament. Ornament that more than constituting a simple decoration, integrates the language of design and a certain genealogy of shapes. “Less” ornament would imply a loss in meaning.

Art as a whole is a concept derived from an ideal that maintains a relation with an organic analogy, according to which, architecture could work as an organism, where the organs pertain to the whole in a perfect integrated system, as if the constitutive matter of architecture would be unique.

Matter tends to flow out of the frame, expanding horizontally, not detaining itself from unfolding its folds both in length and extension. Wölfflin has referred that a multiplication of lines in width would act as a “conquest for the informal”, giving as examples such as the Gothic style with strong structural elements and light partition elements and the Baroque. This latter accentuates matter [1]. Deleuze defines Minimal Art as some kind of layered reality allowing to fold and unfold, these two as constant operations valid in the Baroque period as in today’s context.

Decoration has been a facet that was discussed by theoreticians such as Ruskin, Morris, O. Wagner and Adolf Loos. According to the first, it pertained to the domain of Architecture and was close to the relation of forms in Nature, while to the second it constituted a form of appropriation and relation with the spaces, developed with quality. This occurred in a period when the Industrial Revolution generated a massive and unqualified production of objects.

Mies van der Rohe has been paraphrased throughout his architectural work with the expression of “less being more” and introduced a minimal use of decoration in his own projects. Decoration had been previously questioned by Loos, according to many of his writings, as well as his architectural production.

Loos was absolutely sure that the question of ornament or decoration in architecture pertained to an attitude close to that of the then so-called primitive cultures or to a childish frame of mind.

Nevertheless, he had a prolific production of writings and he even contradicted himself, from time to time, relying on Persian carpets or tapestries to complete the furnishing of his villas, conceived under the *raumplan* layout. Therefore, in the different levels that contributed to define the various spaces in which the inhabiting social functions would be performed, were ornamented with decorative stones and the carpets included in the furnishing would provide for some comfort in the spaces concerned.

Nevertheless, can we consider decoration as being totally eradicated from *Miesian* architecture? What about materiality and the inherent properties such as color, textures, brilliance, refraction, transparency or reflections? To be completely accurate, there is no such thing as “less” in the architectural production of Mies or even the Modern Movement.

It is obvious that the *Barcelona Pavilion* (1929), along with its walls with polished onyx was not deprived from ostentation in the use of materials. The texture and color of these surfaces had a formal rhetoric of their own. Evidently these resulted very detached from the Art Nouveau period or even the formal wealth associated with the interiors produced under Arts Deco [2] taste in various programs such as residential Villas, Hotels, Office-buildings, Restaurants, Theatres, Packet-boats, railway carriages.

Fig. 1: Mies Van der Rohe, Barcelona Pavilion, 1929.

Of course we need to go deeper into the tradition of academic architectural teaching in Germany to establish the huge importance of Gottfried Semper and his concepts on the interpretation of the origin of ornament in architecture.

This Architect and Academic summarized many aspects of his convictions in his work *The Four Elements of Architecture* (first published in 1851). He established a genealogy for the element of the partition in architecture and elaborated an explanation on the origin of decorative mural elements.

One of the four elements was the *enclosure* and its origin was defined by the activity of *weaving*. According to the fact that basic structures like fences or pens were woven sticks or strings of vegetal fibers, the most basic form of a spatial divider still seen in use in parts of the world today is the fabric screen. The partition implied the function and only when it needed to bear load and have structural function the material aspect of it transcended the fabric.

His constructs have reformed the whole idea of decoration, leading to an origin of it that can be located near the shelters of some ancestral cultures. Can we possibly assert that “less” can be “more” when wall decoration derives from patterns used in tents and primitive shelter structures?

We should not forget the importance of the Polychromy question, raised in the twenties of the 19th century that constituted a “querelle” very popular among the archeologists and architects of the period. Moreover, the excavations that were done at the time, tended to confirm the suspicions, according to which, ancient Greek architecture was originally painted with pigments and the model developed in the Renaissance period of an architecture characterized by an immaculate whiteness, was far from true.

The overwhelming excess of ornament that was inundating the architecture in the 19th century, as a result of the stylistic revivals, along with the eclectic formal solutions in architecture, finally resulted in a rejection of such abundance.

Architects turned themselves into concerns related to an ethical attitude derived from new tectonic technologies, such as the use of concrete in the structural frame and the economic need to provide society with an architecture destined to other social classes but the bourgeoisie. “Less” would imply “more.”

The *Gesamtkunstwerk* originated in the work of R. Wagner that instituted the Opera as a convergence to a whole of different arts like architecture, scenography, music, singing, dance, performance, costumes. It

continued as an ideal in Expressionist Architecture and the first period of the Bauhaus production and pedagogy (Weimar, 1919-1923).

An architecture less elaborated in terms of decoration would bring a richer one in terms of spatiality and the stress would be put on the spatial organization, along with the scale and dimensions of the different areas destined to the various functions. The human shelter became a "Machine à habiter."

The "Machine à habiter" brought a functionalist concept that would be later generalized and developed until its last consequences throughout the architectural production of the architects of the CIAM and even later the International Style.

Fig. 2 Le Corbusier, La Tourette Monastery, 1956-60.

Le Corbusier in his villas from the 20's, the *Unité d'Habitation* de Marseille, the administration buildings at Chandigarh or the monastery de *La Tourette*, that is, in the span of his own productive life, did dedicate a considerable part of his reflection to the aesthetical aspects of architecture. He used panels with bas-relief, murals and surfaces painted with color, establishing contrasts with concrete walls and other materials. This attitude would contradict the principle of the minimal use of resources in the treatment of architecture.

Fig. 3, 4: Luis Barragán's house and studio, 1948.

Even if the Modern Movement stressed the importance of the predominance of natural colors of materials, Luis Barragán emerged as an example of reaction to this common practice, with the symbolical and transcendental use of color in many of his works.

Mies brought to the United States, a material sobriety that would impose itself and generate a "style" that would last until the sixties and the first signs of the post-modern awareness in the seventies. "Less" seemed to be an option and it did not relate, in any aspect, to a context of economic restraint as the west was easily recovering from the post-war aftermath.

After the work of critics such as Charles Jencks and the theoretical landmarks by Robert Venturi, one was introduced to a sort of "Wild West", with a lack of restraints and references, where everything was allowed. We were dealing with a strong reaction to the postulates that had been driving architecture to such austerity that everyone was starting to reject. Both the agents of architectural production and reception was eager for "more", independently of what it meant, stood for, or the inherent implications.

The phenomenological approach since the work of Husserl draws the attention to the importance of the experiences lived in the first person to the vision of the work of art. The way according to which "I" see

something or the way I feel observed that makes me become subject-object, as a reflection of the “other” is decisive in the analysis of the work of art.

The materials that constitute a kind of membranes to architecture, the spatial limits defining the appearance, contribute, along with the chromatic or textural properties, or even the effects created by the incidence of light to a sort of spatial transfiguration.

The concept of *Bekleidung*, first set by Semper, is still in evidence nowadays in architecture for technology allows for the exploration of an epithelial organic metaphor. The skin of buildings receives an imprint that is very detached from the early strategies of decoration. In fact, it results more like a tattoo; something that belongs to the organic nature of the surface of the building.

Fig. 5 Herzog & De Meuron, Brandenburg University library, 1998, 2001-2004.

Fig. 6: Herzog & De Meuron, Ricola production an storage building, 1992-1993.

Contemporary architecture, through the works of Herzog & De Meuron, Koolhaas or Nouvel, proceeds in the process of displaying façades or spaces with decorative applied effects, satisfying the human “necessity” by texturing surfaces, transfiguring appearances, and nurturing the human gaze, still eager for harmony and delight.[3]

Many of the “clothing” applied to the works of Herzog & De Meuron transmit a language of their own, through color. Many of the buildings by Herzog & De Meuron present a certain laconism, an austerity close to that of Aldo Rossi’s.

When Wölfflin proposed a global and synthesized reading of the History of Art, from visual categories, he was establishing the basis for the work of art to cease being a representation and become abstraction.[4] The avant-garde artists in the beginning of the 20th century believed to be contributing to a fluid History of Art, in continuous motion, which end seemed to consist in different representations of Nature.

Against everything that would seem natural, abstraction would consist more in an end than in a beginning. Establishing a huge turning point, the end of the 20th century was dealing with the search for the origin. Some philosophers like Nietzsche, first, and later Heidegger, established that a new beginning was implicit in this later period of History, both believing that culture needed to find new starting points.

Artists were astonished to find the unspeakable in the simple presence of the simple, anonymous things of everyday life. They tried to recreate this experience in Conceptual Art, Minimal Art and Earthworks, which stand for a certain anxiety motivated for this search for an origin.

Frontiers between the arts, since some decades now, have evolved to become more and more tenuous and artistic experiences tended to a search of the origin. New media, like the light and the space have allowed for the work of Robert Irwin and James Turrell. Matta-Clark has approached the exploration of the limits of space, intervening in ruins.

Fig. 7, 8: James Turrell installations.

Jean Nouvel, Rem Koolhaas, Peter Zumthor and Herzog & De Meuron use a palette of textures like tattoos imprinted in the skin of the buildings.

Art has been traversing a period that seems to be ruled by a paradox. This resides, according to Yves Michaud, in the fact that the triumph of beauty and aesthetics is being cultivated in a world more and more stripped of works of art, objects with an “aura”. The more aesthetical the world is, the less there are real works of art and art tends to volatilize.[5]

Fig. 9: Peter Zumthor, Kolomba Museum, Cologne, 2007.

The scene of the international architecture has produced examples of great relevance, with significant incidence in the recuperation of the cosmetic [6] character of the arts.

The constant cultural democratization, present in leisure activities, in tourism have contributed to transform museums in commercial terms; they became the malls of art.

This consummation of the industrial production of the works is accelerating the disappearance of the work of art. The world is “rarefied” for being necessary to preserve the reputation of art, of its illusory character, with the motivation of a certain still existing nostalgia.[7]

The relations between production and reception of the work of art are nowadays submitted to huge transformations, determined by a globalized world and suffering mutations in the social structures.

Also the production and reception of Architecture as an autonomous discipline, has been, by its specificities, subject to modifications, even though it is an art with a status of utility.

The critique to Richard Wagner’s concept of *Gesamtkunstwerk* has been, according to Peter Eisenman, initiated in 1888 with an article by his friend Nietzsche, entitled “Nietzsche against Wagner”, even he had at first admired the modernity introduced in the Opera genre by the Musician. *Gesamtkunstwerk* can be assimilated to a synthesis of the real with the virtual, or the duality established by Apolo and Dionisos.[8]

Eisenman also states that Frank Lloyd Wright was the first, in the beginning of the 20th century to assess that Architecture is the mother of all Arts. Nowadays the prevalent among the architects idea of wholeness, will have a literal character and signify the simultaneous interpenetration of the concepts of function, aesthetics, place and symbolism.

Therefore, the central question seems to be, in accordance to Peter Eisenman, that of the autonomy of architecture, as a discipline. That concept is necessary to keep the integrity and diversity, and is emphasized when it becomes self-referential in a closed system, then considered as another form of totality.

As a discipline, Architecture should not colonize other discourses but use them to contribute to her own opening. *Gesamtkunstwerk* can assume different forms in harmony with the new features of art, becoming increasingly immaterial.

ONLY A HUGE STONE-WALL

Michele Giovanni CAJA,¹ Maria Pompeiana IAROSSE²

School of Civil Architecture, DPA-Dipartimento di Progettazione dell'Architettura, Politecnico di Milano, Italy
e-mails: michele.caja@polimi.it, piarossi@polimi.it

Abstract

"A huge stone-wall, with windows cut out of it. And that is that. You see with how few means you can make architecture – and what an architecture!" With these words Ludwig Mies van der Rohe expressed his enthusiasm for Palazzo Pitti during his Italian travel in 1908, recognizing in the building his value as a paradigm out of the time, able to confront itself, even for its elementary construction, with the dimension of the contemporary city and architecture.

This contribution represents the first outcome of a research which, sharing the Miesian judgment, assumes the architectural re-drawing and relief as tools of knowledge and typological reconstruction of the Italian *palazzo* in its different variations and declinations.

An analysis focused to research the richness and variety present inside the selected examples (53 examples in 9 cities), but also to show their actuality as possible models in relation to the contemporary project's practice.

The theme is investigated under different points of view and through various comparative analyzes, with the aim to underline more general characters connected to the relation with the city, the architectural and spatial plan, the composition, the choices about construction and language.

From this methodological setting-out descend both the adopted representation codes and the primarily handbook's character of the reached results, exemplified in synoptic tables which classify the examples in relation to the problematical cases, which emerge from time to time: building type/placement inside the block, planimetric articulation/vertical distribution, building type/access system, ecc..

Parole chiave: *Palazzo*, Typology, Housing, Handbook, Representation.

1. Il palazzo come tema

Nel 1908 Mies van der Rohe, nel corso del viaggio compiuto in Italia, così manifestava il suo entusiasmo di fronte alla facciata di Palazzo Pitti *"uno degli edifici più forti (...) soltanto immensi muri di pietra con le loro finestre incise (...) con mezzi così semplici si può fare architettura!"* [1], riconoscendo all'edificio il valore di paradigma sovratemporale, capace di misurarsi, proprio per la sua elementarietà costruttiva, anche con la dimensione della città e dell'architettura contemporanea.

Condividendo l'adesione miesiana e con l'intento di comprendere più a fondo la lezione contenuta proprio in quelle pietre, è stata avviata la ricerca tutt'ora in atto, di cui vengono qui presentati i primi esiti.

Si tratta di un'analisi condotta su una cinquantina di esempi noti di palazzi urbani situati in nove città storiche italiane e realizzati in epoca rinascimentale e oltre. La scelta di considerare il palazzo come tema d'indagine non è casuale, né tantomeno dettata da ragioni di ordine storico-critico o puramente tipo-morfologico. Nasce piuttosto in relazione al dibattito attuale sull'architettura di nuovi modelli residenziali per la città europea. Un dibattito vivo soprattutto in Germania e in particolare a Berlino, dove la questione della ricostruzione critica della città attuata negli ultimi vent'anni si è concentrata proprio sul tema della casa e del palazzo all'interno di isolati parcellizzati. Il palazzo viene qui inteso sia come modello contemporaneo per abitare la città storica, che come modello storico, riletto dal punto di vista urbano e tipologico e "ricostruito" a partire dalle condizioni attuali dell'abitare contemporaneo [2].

Inteso in questo senso il tema del palazzo viene qui affrontato da diversi punti di vista, quali:

- urbano: l'idea di città che sottende: compatta, a isolati parcellizzati;
- morfologico: il rapporto tra impianto volumetrico, spazi interni (corti e giardini) e lotto;
- tipologico: i suoi caratteri autonomi rispetto ad altre forme di residenza (la casa gotica, il castello, la residenza collettiva, ecc.);
- compositivo: la gerarchia delle facciate, il carattere rappresentativo, il linguaggio classico.

1.1 Il palazzo come modello urbano

A partire da queste considerazioni, che intendono sondare le potenzialità insite in una tipologia storica rispetto all'attualità dell'abitare contemporaneo, il palazzo si rivela come modello paradigmatico anche rispetto alle questioni di carattere urbano, cioè all'idea di città che esso sottende. Nel dibattito attuale sulle diverse idee di città oggi praticabili – che oscillano tra l'idea di città compatta ripresa dal modello della città storica, e l'idea di città aperta introdotta dal Moderno [3] – il palazzo urbano mantiene una sua autonomia e identità. Si propone come modello attuale di residenza in città [4] all'interno di un'indagine in corso sulla legittimità e validità di tipologie storiche per la città attuale (si pensi a recenti esperienze in Germania, che hanno dato nuova vita a tipi come la *villa urbana* o la *casa gotica*) [5].

Il tipo del palazzo urbano, come analizzato nella ricerca, si connota in base a due principi ad esso associati:

- una tipologia di spazi urbani fondata sull'idea di spazio formalizzato e concluso (strada, piazza, corte) rispetto a uno aperto e continuo;
- forme insediative basate sul principio dell'edificazione perimetrale all'isolato.

Da qui emergono tipi diversi di palazzi associabili a modelli concreti quali:

- il palazzo *parcellizzato*: variabile in funzione dell'entità di parcelle occupate all'interno di un isolato: dall'accorpamento di due o più parcelle e case adiacenti (Palazzo Rucellai)
- il palazzo *isolato*: quando si identifica con un intero isolato (Palazzo Farnese);
- Il palazzo come *parte di città*: in quanto modello autonomo ripetibile, può essere ripetuto a definire una parte unitaria di città (Strada Nuova, Genova)
- il palazzo come *fuori scala*: quando la sua dimensione è tale da renderlo comparabile con quelle di una reggia o di un residenza extraurbana (Palazzo Pitti);

1.2 Attualità del palazzo

Il palazzo sta vivendo una rinascita in alcune esperienze recenti, che tendono a vagliarne le potenzialità rispetto a logiche sia urbane che compositive. Proprio in rapporto al tema dell'isolato, e alla idea di città compatta con spazi definiti di strade e piazze che esso sottende, il palazzo si propone come tipo particolarmente interessante in quanto a cavallo tra la scala della casa individuale (la casa gotica, la villa urbana) e la grande casa collettiva (dai grandi isolati unitari a corte della riforma architettonica degli inizi del Novecento all'uso diffuso delle case in linea dei quartieri del Moderno). Seguendo il principio del montaggio e del collage la combinazione di frammenti o parti di palazzi riconferma d'altra parte una ricerca sulla *tenuta* dell'isolato come principio insediativo ancora attuale.

Tra i casi attuali che impiegano il palazzo come modello si ricordano:

- l'isolato sulla Schützenstrasse a Berlino di Aldo Rossi: un progetto-pilota per molti altri isolati berlinesi della *ricostruzione critica*, si propone come caso esemplare per la composizione alternata di frammenti di palazzi o di citazioni di modelli storici decontestualizzati: il frammento di Palazzo Farnese monta e sposta in facciata un comparto del loggiato della corte interna del modello romano [6].
- l'isolato della Cassa di Risparmio di Firenze di Giorgio Grassi: la ricerca di un isolato unitario a corte allude alla grande scala urbana di Palazzo Pitti e alla facciata in rilievo di Palazzo Rucellai, rivelando le aspirazioni alla costruzione di un'unità volumetrico-architettonica, nonostante la suddivisione in parti imposte dal piano urbano preesistente [7].
- la ricostruzione in corso dei palazzi palladiani di Potsdam: nella contemporanea ricerca tedesca sul tema della *ricostruzione critica* della città e dell'architettura storica [8], il caso attuale della politica urbana di Potsdam, rivolto alla riproposizione di alcuni palazzi storici, già copie di palazzi palladiani realizzati nel Settecento, propone il palazzo come copia ricostruita in facciata divenendo *copia di una copia* palladiana (Palazzo am Neuen Markt 5) [9].

1.3 Questioni aperte e obiettivi della ricerca

A partire da questi casi, ma se ne potrebbero fare altri che ragionano sul palazzo come modello urbano, restano aperte le ragioni del tema di lavoro prescelto, che riguardano in particolare l'indagine su palazzi

storici considerati come possibili modelli di residenza nella costruzione della città contemporanea.

Consapevoli di lecite questioni che un approccio di questo tipo solleva, quali:

- Il palazzo è o non è un tipo?
- Se può essere definito dal punto di vista tipologico, quali sono i suoi elementi d'individualizzazione?
- Quale rapporto vi è tra il palazzo, la casa individuale e l'abitazione plurifamiliare?
- Rappresenta il palazzo un tentativo di conferire un carattere monumentale alla residenza (una linea di ricerca che va dai palazzi rinascimentali fino a esperienze del Novecento, si pensi ai grandi Höfe viennesi o alle corti di Amburgo)?
- E' lecito oggi impiegare il tipo del palazzo o, più in generale, rifarsi a tipi storici per la costruzione della città contemporanea?

Senza volere, o potere, dare risposta univoca a queste domande, l'analisi si rivolge a individuare le parti proprie dei diversi palazzi attraverso il ridisegno critico, che mira innanzitutto a ricostruire l'individualità dei singoli manufatti architettonici, evitando il rischio di cadere in schematizzazioni astratte o concettuali. I palazzi vengono qui studiati come modelli veri e propri, non come semplici tipi riconducibili a principi generali astratti (il tipo a corte, a blocco, ecc.). Proprio per comprenderne la ricchezza, ma anche per mostrare, rispetto alla tendenza riduzionista e astratta di molta architettura contemporanea, quanto questi modelli abbiano ancora da insegnarci, sia dal punto di vista spaziale che architettonico.

Un ulteriore livello dell'analisi è poi quello di indagarne il rapporto con la città e con le parti costituenti il palazzo rispetto ai suoi elementi principali:

- il cortile o il giardino interno come spazio libero semipubblico incluso;
- l'androne come elemento di mediazione tra la strada ed il cortile;
- le scale come elementi architettonici e non semplicemente distributivi;
- la facciata come elemento rappresentativo e urbano.

1.4 La facciata del palazzo: tre diverse forme di riduzione

Il tema della facciata si propone come caso paradigmatico del rapporto tra il carattere rappresentativo del palazzo e la progressiva riduzione attuata dall'architettura contemporanea. E' possibile qui, portando il discorso nell'ambito del linguaggio, riferirsi a tre casi di riduzione, che hanno portato dalla facciata muraria decorata alla struttura a telaio di travi e pilastri. Tre forme di astrazione formale, tra loro lontane nel tempo, che rappresentano modi diversi di intendere il tema della facciata, riferita qui al caso particolare del palazzo. L. B. Alberti riprende dall'architettura romana la *muratura* come fondamento costruttivo dell'architettura [10] e il *decoro* come elemento rappresentativo del carattere di un edificio. Il decoro, come lo intendeva Alberti in Palazzo Rucellai, non è semplice ornamento, ma strumento atto a rappresentare il carattere pubblico dell'edificio. Riprendendo il sistema degli ordini sovrapposti del Colosseo e di altri teatri romani, e applicandolo alle facciate delle case retrostanti, conferisce ad esse una inedita rappresentatività e monumentalità urbana.

Se tale procedimento definisce il carattere dell'edificio e ne sottolinea il ruolo pubblico rispetto al carattere civile dell'edilizia residenziale medievale, il modo in cui questo avviene risolve in termini architettonici il tema della facciata di un palazzo. La ripresa degli ordini sovrapposti viene effettuata in *stiacciato*, secondo la tecnica del bassorilievo donatelliano, riducendo le semicolonne a semplici lesene piatte e gli architravi a fasce marcapiano poco aggettanti. Elementi *araldici*, utilizzati come citazioni evocative di un ordine qui ridotto a semplice struttura di ripartizione in superficie della facciata. Avrà inizio da qui la lunga serie di facciate urbane, impaginate da un ordine sempre più astratto e geometrico, riscontrabile anche in contemporanee esperienze. Vedi l'uso di lesene, paraste e fasce marcapiano sovrapposte in modo da evitare la fuga a vista, in molti edifici urbani realizzati a Berlino dagli anni '90 da Hans Kollhoff, Petra e Paul Kahlfeldt, Walter Noebel e altri.

La critica di Adolf Loos ai palazzi realizzati sul Ring di Vienna alla fine dell'Ottocento si rivolge soprattutto all'uso improprio dell'ornamento, che diviene un *delitto* in quanto espressione inadeguata rispetto allo spirito dell'epoca, un'epoca che "preferirebbe che le facciate delle case fossero lisce da cima a fondo". Gli elementi storicisti delle facciate non sono elementi integranti della struttura muraria della facciata, come nei modelli originali dei palazzi italiani, ma sono ad essa semplicemente applicati. "Perché questi palazzi rinascimentali e barocchi non sono neppure fatti con il materiale con cui sembrano costruiti. Ora vorrebbero sembrare di pietra, come i palazzi romani o toscani, ora di stucco, come le costruzioni barocche viennesi. Non sono né l'una cosa né l'altra: i loro dettagli ornamentali, le loro mensole, le loro ghirlande di fiori, i cartocci e i dentelli sono tutti in cemento e attaccati sopra" [11].

Non il fatto di impiegare elementi storici, dunque, quanto il *come* questi vengano impiegati in senso ornamentale, anti-costruttivo, è oggetto della critica di Loos. Compito dell'architetto, per Loos, è quello di trovare le "forme che sono strettamente legate alla natura stessa di un determinato materiale" e giungere a "un nuovo linguaggio formale per il nuovo materiale. Tutto il resto è imitazione."

La critica all'ornamento in Loos si fonda sulla consapevolezza che l'architettura non è più intesa come arte del costruire, ma è "scaduta ad arte grafica". L'architettura nega così la ragione costruttiva ricercata dagli "antichi maestri" e traduce la profondità della sua facciata su un piano bidimensionale. Da qui la difficoltà a rappresentare l'architettura del passato, come quella di Palazzo Pitti, "l'architettura più straordinaria", dato che "l'architettura autentica" non può "essere resa con efficacia sul piano" [12].

Che il padre dell'odierno minimalismo, di quel *less is more* divenuto quasi un motto di un'intera epoca ed emblema in negativo di quella successiva (dal *less is bore* di Robert Venturi [13] al *Titanic* di Stanley Tigerman [14], il fotomontaggio in cui la Crown Hall di Mies affonda in mezzo al lago Michigan), rimanesse così fortemente impressionato dall'architettura dei palazzi rinascimentali italiani è cosa meno nota. Di fatto il suo interesse per la storia, anche se tradotta in forme costruttive adeguate allo spirito dell'epoca, sarà un elemento costante dei suoi interessi, come ancora nel 1959 ribadiva, dicendo di avere "*imparato il massimo da vecchi edifici*" [15].

Anche se in forme contemporanee, alcuni dei suoi primi progetti degli anni Venti a Berlino sembrano riflettere dal punto di vista urbano il carattere proprio degli ammirati palazzi della città storica italiana. Nella loro compattezza volumetrica e nella loro condizione di edifici monolitici isolati essi emergono come dei veri e propri *fuori scala* all'interno della caotica struttura urbana ottocentesca. Essi presentano la medesima semplificazione volumetrica degli esempi storici, anche se la consistenza materica della facciata in pietra, non più necessaria dal punto di vista costruttivo, viene qui tradotta in pura struttura, privata di qualsiasi rivestimento, e ridotta a pura architettura "pelle e ossa" [16].

Una riduzione radicale, che comporta non solo l'omissione dell'ordine classico, ma anche dell'involucro murario, non più necessario da un punto di vista costruttivo. Come scrive Mies nel '24: "*Dato che trovo assurdo ricoprire con la pietra lo scheletro in acciaio dell'edificio, gli ho dato una pelle di vetro*" [17]. La muratura lapidea dei palazzi storici viene sostituita da una *pelle* in vetro, che lascia intravedere la struttura retrostante dell'edificio, le sue ossa. L'architettura viene così spogliata non solo del suo *apparato decorativo* (l'ordine classico), ma anche della sua *carne* (la muratura). Viene così negata qualsiasi gerarchia alle facciate, implicita nei palazzi rinascimentali (la rappresentività del fronte principale, la semplificazione e il carattere domestico dei fronti secondari) e l'edificio, ridotto in senso puramente volumetrico, resta neutrale rispetto al luogo in cui si pone.

Loos e Mies, due maestri della riduzione, mostrano atteggiamenti simili, anche se differenti rispetto al rapporto tra architettura storica e riduzione formale. Il riferimento comune a Palazzo Pitti indica come essi siano fortemente attratti dalla massività lapidea della sua facciata, ma anche dalla sua semplicità e unitarietà volumetrica. Nonostante che l'introduzione delle nuove tecniche costruttive del cemento armato e delle strutture metalliche abbia comportato la perdita del muro come elemento portante, questo esempio italiano viene ammirato come fosse un modello, sia dal punto di vista urbano che architettonico. Ma se Loos (e con lui Hilberseimer) spoglia l'involucro murario dell'edificio da tutti quegli elementi che risultano essere solo ornamenti applicati, Mies persegue una riduzione che libera la struttura dal suo apparato murario. Da una parte l'architettura ritrova l'essenza della massa muraria, la sua massività atemporale, che dall'epoca romana a quella rinascimentale ha costituito il carattere primo dell'architettura – da cui la ben nota aspirazione di Loos a costruire come "avrebbero costruito gli antichi Romani" [18] e la ricerca delle "forme durature nel tempo" di Hilberseimer [19] –, dall'altra coincide con la sua struttura, intesa come ordine tettonico di elementi portati e portanti, secondo l'insegnamento schinkeliano [20].

1.5 Astrazione ed evocazione degli elementi classici

Da qui, si può dire, scaturiscono alcuni filoni della ricerca attuale in bilico tra classico e razionale, tra volontà riduzionista e impiego astratto di elementi classici, usati nella composizione delle facciate in senso evocativo a rappresentare una continuità con l'architettura della storia. Dopo la volontà di *razionalizzazione* del Moderno, dopo il minimalismo e il riduzionismo concettuale degli ultimi decenni, questi sforzi si spiegano come tentativi di superare i limiti di un'architettura ridotta a pura stereometria o struttura costruttiva. Emergono da qui linee di ricerche differenti, ma simili nel tentativo di riappropriarsi del carattere rappresentativo dell'architettura e superare quel *minimum* espressivo, divenuto dogma per intere generazioni di architetti e ancora diffusamente praticato. Da una parte, la rievocazione degli elementi storici attraverso pratiche come quella della *citazione* o dell'*omissione* ha improntato alcune ricerche già a partire dagli anni '60 e '70, che hanno portato avanti una revisione critica del razionalismo ricercandone una continuità con la storia. Dall'altra la concezione dell'architettura come costruzione ripropone, in certe posizioni attuali, l'aspirazione al carattere rappresentativo della costruzione come riferimento astratto al classico [21]. E poi, più dichiaratamente, quelle esperienze in cui il riferimento al classico si fa più diretto, laddove la volontà evocativa si trasforma in vero e proprio sforzo di ricostruire la profondità (e non la planarità, seguendo Loos) dell'architettura storica. La facciata diviene in questo senso il campo principale di sperimentazione di un ritrovato rapporto compositivo in profondità degli elementi che la compongono.

Quali siano questi elementi e come impiegarli resta il tema principale d'indagine di queste ricerche sia in ambito architettonico che in quello dell'analisi teorico-compositiva. Superato il divieto di riferirsi al mondo formale degli elementi classici, conseguente all'abuso provocatorio e ludico che ne ha fatto la stagione del postmoderno e dal successivo annuncio della *fine del classico* [22], il classico rivela oggi una sua rinnovata attualità, anche per l'idea di città che sottintende e a cui dà forma, dimostrando che esso "riguarda sempre non solo il passato, ma il presente e una visione del futuro" [23].

2. Problemi metodologici.

La volontà di affrontare il tema del palazzo urbano con intenti specificamente progettuali e non filologici o storici, ha orientato la ricerca verso metodologie d'indagine ed esiti volutamente manualistici.

Tuttavia, in architettura, la tradizione della classificazione quale fondamento teorico ed operativo al progetto rimonta ad un esempio illustre e d'ineguagliabile chiarezza, costituito dal secentesco *Maniere de bien bastir* di Pierre Le Muet [24].

Tale opera consiste nel *recueil* di 20 esempi di case unifamiliari, ciascuna rappresentata mediante piante,

prospetti e sezioni.

La sequenza degli esempi è regolata dall'incremento della misura della testata su strada del lotto edificabile, dando luogo ad una casistica di 13 *places* (parcelle tipo), con consistenza superficiale crescente da un minimo di 27 mq agli 850 mq (giardino escluso) della più estesa, così da coprire l'intera varietà del *parcellaire* parigino.

Si tratta dunque di un vero manuale operativo, poiché a ciascuna *place*, corrisponde la soluzione edificatoria ed abitativa ritenuta più adeguata, unitamente alle sue possibili varianti.

La risposta tipologica viene modulata al variare della consistenza dell'unità fondiaria di partenza; i primi nove esempi sono infatti ascrivibili al tipo della casa a blocco in profondità, caratteristico della tradizione costruttiva ed abitativa della città gotico-mercantile; i successivi nove esempi sono invece case a corte, definite nella declinazione costruttiva e linguistica dell'*hôtel particulier*, le cui varianti sono sviluppate fino all'undicesima *place*. Quest'ultima, caratterizzata da estensione superficiale di mq 725, rappresenta il limite ammissibile per l'unità fondiaria urbana, oltre il quale la risposta formale proposta è quella del *pavillon* e della *maison de plaisance aux champs* descritte dagli ultimi due esempi.

L'impianto classificatorio di Le Muet restituisce così, nella varietà ed unitarietà del suo insieme, l'immagine lontana di un mondo di forme certe, entro cui ad una determinata disponibilità di superficie corrispondeva una precisa possibilità di articolazione funzionale e distributiva, fondata su una definita idea di città, su un sapere costruttivo lungamente sperimentato e, infine, su un sistema di elementi linguistici e stilistici condivisi. In un mondo siffatto – assai distante dalle condizioni della contemporaneità – il piano di divisione particellare del suolo svolgeva il ruolo di telaio, entro cui la molteplicità delle condizioni sociali e delle potenzialità economiche presenti nella città trovava corrispondenza di rappresentazione in una varietà finita, ancorché riccamente variegata, di risposte formali, distributive, economiche e rappresentative.

Analogamente, altri e più recenti esempi di manuali hanno mostrato la capacità di un singolo aspetto del fare architettonico, assunto quale criterio dell'organizzazione classificatoria, di divenire una chiave di lettura capace di riassumere rispetto a sé tutti gli altri e diversi aspetti dell'architettura.

Valenza tassonomica similare viene ad esempio assegnata da E. Neufert [25] alle attività quotidiane essenziali, il cui svolgimento governa, nella filosofia della definizione dell'*Existenzminimum*, il dimensionamento dei luoghi e delle parti della casa ad esso deputati o, perfino, dei singoli manufatti o elementi d'arredo.

Questa condizione di equilibrio ed intima interconnessione fra i diversi aspetti del costruire, caratteristica dei tradizionali manuali d'architettura, appare oggi irrimediabilmente perduta e se, da un canto, il parcellario urbano, privo di ogni regola di modulazione della sua scansione, appare piuttosto come una pelle così frequentemente e diversamente tatuata da poter narrare solo una storia intricata di conflittualità, dall'altro il mondo delle forme architettoniche appare ipotecato da intenti comunicativi, aspettative d'immagine e volontà di eloquenza della forma ormai del tutto separati dall'atto costruttivo in sé.

Non è dunque più possibile adottare un unico angolo visuale rispetto a cui analizzare le possibili risposte al problema dell'abitazione urbana, tale da riassumere l'ampio e, talora, contraddittorio ventaglio degli aspetti del fare architettonico.

Con la consapevolezza di non poter perciò più far riferimento ad un unico criterio di classificazione, nella ricerca qui in esame si è scelto di ordinare gli esempi di palazzi studiati secondo un principio del tutto convenzionale, raggruppandoli per città e, all'interno di ciascuna città, secondo un ordine alfabetico riferibile all'identificazione proprietaria con cui gli edifici sono correntemente conosciuti.

L'adozione di un criterio volutamente astratto e neutrale, analogo alla convenzionalità caratterizzante l'adozione per l'*Encyclopédie* dell'ordine alfabetico, ha permesso di assumere il tema architettonico del palazzo senza che alcun aspetto singolare (urbano, morfo-tipologico, costruttivo, stilistico, ecc.), risultasse prevalente rispetto agli altri e nell'intero ventaglio delle sue implicazioni.

Queste ultime sono state indagate mediante un procedimento articolato in due successive operazioni analitiche:

- descrizione standardizzata di ciascun esempio;
- composizione di specifici abachi di comparazione.

3. La descrizione degli esempi

L'obiettivo di costruire una raccolta di esempi di palazzi capaci di svolgere il ruolo di modelli operativi per la progettazione dell'*housing* urbano pone in primo luogo la necessità di mettere a fuoco una modalità di

rappresentazione omogenea per tutti i casi prescelti e, soprattutto, in considerazione del principio di neutralità adottato per la classificazione, capace di farne emergere affinità e differenze e di porsi in tal modo come strumento efficace ai fini della comparabilità degli esempi tra loro.

Con tale intento analitico, il più efficace strumento è risultato essere ancora il tradizionale sistema di rappresentazione basato sulle sezioni e proiezioni ortogonali.

Infatti, tale modalità di descrizione grafica presenta il vantaggio di non essere influenzata dal punto di proiezione che, per il fatto stesso di essere collocato all'infinito, introduce un principio di astrazione che consente di prescindere dal contesto specifico e dagli aspetti più contingenti, per far emergere quegli aspetti dotati di un grado di generalità tale da consentire la possibilità di risperimentare l'esempio di volta in volta proposto, estrapolandolo dalle condizioni locali o temporali che pur hanno contribuito a determinarne la genesi.

Tale ricerca del punto di equilibrio tra condizioni individuali specifiche e contenuto di generalità riflette la tensione tra convenzione e realismo che ha sempre caratterizzato il disegno d'architettura, il quale nell'intervallo tra queste due opposte polarità ha per lungo tempo sviluppato le proprie potenzialità conoscitive.

3.1. La scelta dei codici grafici tra convenzione e realismo

Il problema generale della rappresentazione architettonica si è sempre incentrato sulla necessità di fissare i modi di relazione tra la realtà fisica del manufatto – già esistente, nel caso del rilievo, o in via di definizione nell'iter progettuale – ed il modello preposto alla sua descrizione, guidato da un dispositivo "convenzionato", cioè costituito dal linguaggio destinato a descriverlo accettato e condiviso e, per questo, dotato di un grado di generalità tale da consentirne la reiterazione in applicazione ad altri oggetti analoghi.

Tale dispositivo è stato nel tempo codificato dai diversi metodi proiettivi posti a fondamento scientifico della più tradizionale accezione del disegno che i più recenti sistemi di rappresentazione digitale sembrano soppiantare, nella fascinazione iperrealistica del *rendering*, entro cui il progettista (o comunque il produttore dell'immagine) coincide con il fruitore del manufatto.

Codesta condizione d'appartenenza dell'osservatore allo spazio rappresentato distanzia enormemente i nuovi dispositivi di rappresentazione immersiva dai metodi di rappresentazione tradizionali e, perfino, dal più mimetico di essi – la prospettiva –, la quale presuppone la prossimità, ma, insieme, l'imprescindibile separazione tra lo spazio osservato e quello entro cui si situa l'osservatore, il cui confine è marcato proprio dal quadro prospettico che, come l'arco scenico nel teatro all'italiana, demarca il confine tra i due mondi contigui, ma comunque separati.

La proiettività ortogonale mongiana afferma invece un principio di astrazione rigidissimo, in cui la distanza infinita del punto di proiezione improprio sembra aspirare ad una sorta di volontà di visione assoluta, ad una descrizione delle cose e dei luoghi che, depurata dalle aberrazioni e distorsioni proprie della proiettività conica dell'occhio umano, risulti coincidere non con ciò che si vede, ma con lo schema logico, prima ancora che spaziale, di quelle stesse cose o luoghi e, dunque, quasi una rappresentazione del mondo *sub specie aeternitatis*.

Paradossalmente, proprio un sistema di rappresentazione fondato su un principio così raffinemente astratto dal punto di vista della *ratio* geometrica costituisce lo strumento abituale, compreso ed impiegato da qualsivoglia utente e per la descrizione di qualunque fenomeno in cui la descrizione dello spazio abbia una qualche rilevanza (dalle mappe per i turisti alla pianta della stanza per l'acquisto della nuova credenza).

Il fatto è che il sistema delle proiezioni ortogonali, al di là del principio astratto su cui si fonda, presenta il vantaggio di consentire l'immediato apprezzamento metrico, la commensurabilità tra la realtà e ciò che è rappresentato e dei contenuti rappresentati tra loro, caratteristica che costituisce un requisito prezioso quando il fine della rappresentazione sia dichiaratamente tassonomico come nella manualistica.

Questo principio di commensurabilità tra la realtà e la sua rappresentazione mongiana, nel disegno d'architettura tradizionale era affidato alla sola mediazione aritmetica del fattore di riduzione, che per lungo tempo, ne ha garantito il valore conoscitivo e le capacità analitiche.

Invece, la disciplina sembra oggi oscillare con disagio, propendendo talora verso l'iperrealismo virtuale e talora apparendo invece propensa ad abbracciare incondizionatamente la smaterializzante sostituzione della nuvola di punti 3D alla descrizione grafica di un manufatto.

Per contro, si registra in ambito tecnico una sempre più accentuata prevalenza del grado di convenzionalizzazione, attraverso il moltiplicarsi delle tabelle UNI alle scale alte (quali quelle territoriali ed urbanistiche) o molto basse, impiegate nel disegno esecutivo.

3.2. La scelta delle scale di rappresentazione

Sembra indispensabile ritrovare anche nel mondo del disegno digitale quella capacità di lettura critica, che nella tradizione della rappresentazione cartacea la scelta di una determinata scala riusciva a garantire.

Nel lavoro svolto sui palazzi, perciò, al coefficiente di riduzione scalare è stato affidato il compito di mediare tra realtà e sua rappresentazione, fungendo da valvola di regolazione della quantità di dati ed informazioni di volta in volta introdotti nella rappresentazione, così come avveniva nel tradizionale disegno d'architettura, in cui l'adozione di un determinato rapporto di riduzione scalare coincideva con l'individuazione della finalità conoscitiva della specifica tavola, rendendo operante un criterio di astrazione dalla molteplicità del reale di quegli elementi – e solo di quelli – ritenuti capaci di svelare sistemi di relazioni significativi.

Le tavole tradizionali si comportavano, infatti, come carte geografiche tematiche, poiché la possibilità di rappresentare graficamente solo determinate famiglie di elementi era implicita nell'adozione di un certo rapporto di riduzione scalare. Una sorta di saggio senso della misura nell'introdurre dati ed informazioni era, in definitiva, imposto dalla soglia ammissibile alla miniaturizzazione grafica del dettaglio.

Oggi, invece, la diffusione poco consapevole di Autocad (che induce a far erroneamente coincidere la massa dei dati numerici inseriti con il file di stampa della singola tavola) unitamente alla elevata precisione grafica dei mezzi di stampa digitale, rischiano di spegnere la capacità di operare una selezione critica fra i fatti, che va consapevolmente recuperata.

A tal fine, nel corso del lavoro fin qui svolto sui palazzi, si è ritenuto utile riflettere sulle potenzialità conoscitive peculiari di ciascun rapporto di scala, per ritrovare il senso dell'operazione di selezione ed astrazione dei dati ed in tale modo sottrarsi con fermezza alla "vertigine del dettaglio", da cui si è costantemente cercato di preservare questo studio.

L'intento di far emergere i differenti possibili modi di declinazione della relazione con lo spazio urbano circostante – isolato, strada o piazza- ha perciò dato luogo ad una rappresentazione unificata degli esempi, a scala 1/2000 e con vista zenitale, volutamente scarna e priva di qualunque elemento di arricchimento grafico estraneo alla questione in esame.

Allo stesso modo, l'indagine sul palazzo, inteso come modello insediativo riproponibile, ha determinato una seconda modalità di rappresentazione degli esempi, orientata verso una finalità analitica tipologica.

Ciò ha indotto ad individuare fattori di riduzione scalare compresi tra l'1/200, adottato per i palazzetti di modesta consistenza superficiale (come la Casa degli Omenoni a Milano, in cui la differenziazione rispetto alle preesistenti *case da nobili* è affidata alla sola accentuazione del carattere di rappresentatività [26]) e il coefficiente di 1/750 adottato per i casi di dilatazione dimensionale fino alla coincidenza dell'edificio con l'isolato urbano (come nell'esempio di Palazzo Farnese a Roma o Palazzo Marino a Milano).

L'individuazione di tale intervallo di scale di rappresentazione come strumento ed ambito dell'analisi morfotipologica ha indotto ad espungere dalla rappresentazione tutte quelle informazioni non rilevanti rispetto all'obiettivo conoscitivo prefissato. Per esempio, non sono stati rappresentati i serramenti e sono state omesse le notazioni materiche (come l'esatta orditure dei mattoni o della pietra), se prive di rilevanza dal punto di vista della precisazione tipologica.

Fig. 2: Palazzo Marino, Milano: prospetto su piazza della Scala.

Una terza rappresentazione è stata poi predisposta alle scale più basse per descrivere i particolari linguistici e costruttivi, scelti in base alla loro rilevanza nella connotazione dei caratteri di riproponibilità dell'esempio di volta in volta prescelto.

Tale intento strettamente conoscitivo ed analitico è stato ulteriormente potenziato obbligando gli strumenti della rappresentazione ad assumere un *habitus* rigidamente autoptico.

Ciò ha subordinato a precise ipotesi interpretative la scelta dei punti per i quali far passare i piani secanti, orizzontali e verticali, da cui sono stati generati le piante ai diversi livelli e gli alzati, formulando uno specifico piano di sezionamento.

Nella sezione orizzontale, ad esempio, particolare cura è stata posta nella scelta della quota del primo piano secante, assumendo quale criterio analitico privilegiato il rapporto tra il suolo su cui ciascun palazzo insiste e la descrizione dei suoi caratteri distributivi e tipologici.

Con riferimento al sezionamento verticale, invece, la collocazione dei piani di taglio è stata finalizzata a far emergere gli aspetti connotanti il tema del palazzo e distintivi rispetto alla casa *tout court*, ravvisabili nella rappresentatività caratterizzante la costruzione sia dei fronti urbani e sia di quelli prospicienti lo spazio inedito – giardino o corte – incluso.

Per raggiungere tale obiettivo, l'applicazione della teoria delle ombre nella descrizione degli alzati si è rilevata di particolare utilità, fungendo da sistema rivelatore sia dei principi compositivi classici regolanti l'alternanza di pieni e vuoti e sia dell'intento di monumentalizzazione, perseguito attraverso l'enfaticizzazione linguistica e plastica di taluni elementi distributivi e costruttivi, come scale o cornicioni.

4. Principi di comparazione

L'adozione di specifici filtri di tematizzazione analitica ha consentito di avviare la composizione di alcuni abachi, ciascuno dei quali consente di comprendere come la specifica relazione istituita di volta in volta tra due aspetti o chiavi di lettura adottate dall'analisi urbana abbia contribuito ad arricchire il ventaglio di potenzialità espressive sedimentate nelle molteplici sperimentazioni del tema del palazzo [27].

L'applicazione dei filtri tematici, al momento, è stata sperimentata con riferimento solo ad alcune variabili definite; tuttavia essa potrebbe estendersi fino a comprendere dagli aspetti geografici e territoriali fino alla tassonomia dei singoli particolari costruttivi e costituire non solo il punto di estrema precisazione della conoscenza analitica dell'architettura della città e del territorio, ma porsi altresì come fondamento normativo, certo e sperimentato, alla prassi progettuale nel suo insieme.

Di particolare interesse sono risultati gli abachi che hanno messo a confronto gli aspetti urbani e quelli tipologici e, fra essi, la griglia che studia l'interazione fra le condizioni ubicative e le declinazioni tipologiche, determinando una modulazione del tipo edilizio, dalla soluzione del blocco elementare accostato entro la cortina stradale alle variazioni entro il tipo a corte (semplice e multiplo), per approdare nuovamente al tipo a blocco, dilatato alla scala del paesaggio ed articolato in linea nella soluzione di Palazzo Pitti.

Ulteriore approfondimento di tale casistica di esempi è pure costituito dall'abaco che indaga le variazioni linguistiche adottate per i portali di accesso in rapporto all'ubicazione rispetto agli elementi urbani (su strada, d'angolo, su piazza).

L'abaco rappresenta perciò uno strumento d'indagine prezioso, capace di far emergere collegamenti, affinità e differenze all'interno di una casistica di esempi solo apparentemente disparati e per questo non riproponibili, laddove invece l'approfondimento della lettura comparativa suggerisce la possibilità di riconoscere di volta in volta l'appropriatezza della risposta architettonica ad un problema progettuale analogo.

Un fondamento metodologico, questo, che consentirebbe il superamento nei fatti della logica vincolistica insita nel piano regolatore ottocentesco – e da cui non sono del tutto esenti neppure i nuovi strumenti di governo del territorio – per affermare invece un sistema normativo basato sul ricorso ad esempi positivi e modelli operativi entro cui collocare la ricerca nell'ambito dell'*housing*.

5. Appendice

I paragrafi 1 (1.1-1.4) sono a cura di Michele Caja; i paragrafi 2, 3, 4 sono a cura di Maria Pompeiana Iarossi. Le elaborazioni grafiche qui presentate sono state eseguite da S. Bon, C. Bosisio, C. Meli e S. Ubiglia sotto la guida degli architetti I. Brambilla, S. Zaroulas e con il coordinamento grafico di S. Lattuada.

Forms and archetypes of the Nabataean façades at Petra

Giuseppe MAZZACUVA,¹

⁽¹⁾ Dipartimento Architettura ed Analisi della Città Mediterranea, Facoltà di Architettura, Università Mediterranea di Reggio Calabria, Italia
giuseppe.mazzacuva@unirc.it

Abstract

The city of Petra in Jordan is an archaeological heritage of great cultural and scientific value for humanity. More than 800 rupestrian tombs in the Wadi Mousa valley testify the great Nabataean architectural production.

The classification and dating of these unique architecture carved into the rock has attracted particular interest into researchers of the last century.

The study identifies the composition and style rules of Nabataean façades through the acquisition of a repertoire of knowledge and accurate graphical analysis.

The monumentality and complexity of the rock-cut facades contrasts with the geometric simplicity of the burial chambers inside.

In reference to a significant number of tombs, it was made a linear process of comparison among different types of tombs found in Petra in order to create a morphological abaco of the Nabataean architectures.

In addition, the development of a digital 3D model of the structures considered allowed the exploration and decomposition of the architectural shell and of its surfaces through countless sections and axonometric views. A fundamental operation for the reconstruction and preservation of these monumental architectural works subjected to a slow degradation by the action of time and weather.

1. Introduction

The monumental tombs of the city of Petra are the testimony of a great civilizations of the past, permeated by numerous cultural contaminations from the Hellenistic and Oriental world. This cultural diversity is done by a variety of styles and features (quality) translated into architectural results of great originality, in the constant search of an artistic expression of local identity.

The executive techniques of Petra's tombs reveal a unique method for the definition of the architectural elements in the sheer walls of Wadi Musa Valley, through a removal operation of the stone and proceeding to carve the components from top to bottom.

The drawings allow to investigate the designing and morphologic characteristics of the Nabataean funerary architecture through a linear process of cataloguing and dissection of architectural artefact in its distinctive features.

The tombs investigated were included within precise typological reference categories established on the basis of the main stylistic and formal characteristics of the external decorations.

This approach has allowed to identify recurring elements in the Nabataean production defining a grid of comparison to understand the stylistic and chronological evolution of the types on the site.

The direct knowledge of the Valley of Wadi Musa and Petra tombs, was directed to the acquisition of a broad repertoire of analytical information, where dimensional and formal aspects were synthetically investigated by tools of architectural survey and techniques of digital representation.

The two-dimensional representations obtained from the survey, are the necessary basis for the subsequent philological interpretation of the monument through a three-dimensional reconstruction of the original form. The 3d reconstruction models[14], finally, synthesize the complex critical analysis applied on the funerary architecture of Petra, providing additional levels of interactive and exploratory investigation within a dynamic multi-sensorial space.

1.1 Petra: the city of the dead

The large number of the rock tombs makes of Petra an huge necropolis.

Following the path from the site towards the inside, appear, in the first instance, the excellent funerary and sacred works excavated in the rock and then, reaching the Centre of the Valley, you can admire the remains of the old city, which the social and political life of the Nabataean Kingdom carried out.

The steep walls on the border slopes of the Valley are suitable for carving and excavation of funerary frames. It is not a coincidence that the beautiful rocky façades were along the path of access to the Valley. In the royal tombs meets a wonderful sacred street.

The largest tombs, in extent and number, are located near to the great Theatre, along the outer Siq and at the sides of Gebel al Khubta; but, there are other minor groups of tombs disseminated in the whole area.

At the rich system of funerary structures joint other religious monuments, including churches, convivial rooms and sacrificial altars.

The Nabataean tombs are dug and carved throughout of the rocky fronts of the Mountain. These rock structures have an internal room obtained from the subtraction of stone material for the external frames, made by the processing of the rocky surface through carving operations and sculpture.

Inside space, in the most of the analyzed cases, appears essential and regular: generally, the plants are quadrangular and enclosed by burial niches or graves in the floor or in the side walls. The tomb can be composed by a single room or, in some cases, by secondary smaller burial rooms sideways placed (associated or autonomous).

The inside burial room is entirely collocated within the rocky mass, while the embossed façade puts out and sometimes it seems to come off keeping, however, a link with the rock array. Typologies are identified on basis of the location and at the type of tombs found inside of the sepulchers.

The exterior façade of the tombs is the expression of the artistic and cultural wealth of the Nabataean people. In most of the examples found, it is enriched with precious sculptural elements and stylistic features inspired to Eastern and Hellenistic art.

The cataloguing of Nabataean rock monuments bases on the examination of façades and it considers as parameters of comparison the different artistic and architectural characters present in the same compositions.

Fig. 1, 2: Khasneh and Ed-Deir.

Fig. 3, 4, 5, 6: The Petra's tombs: Theater necropolis, Palace Tomb, Silk tomb and Pylon Tombs.

1.2 The stylistic characters of Nabataean façades

The Nabataean, in artistic and architectural field, assimilated the main tendencies coming from the Hellenistic and Eastern world. First, through the trading interchanges in the Mediterranean Sea, and then, about the presence on the Arab territory of the Greek and Roman dominations; while, from the Arab culture, thanks to the social and commercial intercommunions with the regions of Northern Africa and Arabia.

The stylistic, Eastern and Hellenistic treats mingle in the wide Nabataean building repertory, undergoing a considerable evolution that adapts to a renewed style "Nabataean".

Naturally, inside of this complex component system perceive some originality or formal variations of local mold in funerary monuments.

The most recurrent element of the original production in architectural works of Petra is the Nabataean capital[15]. It inspires in its peculiarities to the profiles of the main classical architectural orders coming up again in a basic and rough-hewed form.

In addition to the local capitals, in the Nabataean artefacts, it can detect the valuable Corinthians examples coming from the rich Alexandrian repertory. This type find it, above all, in excellent examples of Nabataean architectural production (Khasneh).

The column in the Nabataean façades assumes a decorative mean and it doesn't perform any static function. The architectural order in the tombs of Petra presents considerable variations, the backups can be made from columns, , pillars, pilasters, half – pillars etc.

We often find the main side pillars coupled with the quarter column with capital or with two separated sections, or two quarters of column (ed-Deir) joint with its capitals.

The pillar with a quarter of column, it is a characteristic element of the Nabataean tombs in the first century B.C..

Fig. 7: Abaco of the architectural elements.

In the façades with superposed orders, the higher order backups, sometimes, they are not aligned with the ones below, because it does not perform any static function, but only decorative.

The main order, composed by high support and an articulated entablature, it describes the entrance portal: a conjunction element between the outside and inside space of the Tomb.

The numerous variations of portals found in Nabataean tombs shows great ability of the Nabataean people to combine the decorative elements of different array.

In the Petra façades, the pillars of the main order support a wide entablature (of classical matrix in the examples of the 1st century B.C. and 1st century A.D.) with a single or double architrave, frieze (smooth or Doric type) followed by a series of moulded frame.

The main entablature of more complex tombs (Royal tombs) can support one or more overlapping orders, formed by dwarf pillars with another entablature that concludes in a triangular pediment or an attic.

The culmination of the façades is a fundamental element for the classification of the Nabataean tombs, in which the most important studies on this subject refer it.

In the façades of the oriental array (Pylon tombs), there is a wide use of Assyrian battlements carved in an attic. The row of crowsteps can be single or double. The evolution of this decorative form sees the mutation of small crowsteps in two sets of five steps (step tombs) addressed and included in an attic. This is a feature inherited from the Mesopotamian world[19]. In these types the transition between the lower and upper part of the façade occurs through a cable frame.

The expression of the Hellenistic and Roman influence perceives in classical façades (Nabataean and Roman). The so-called "Gable Tombs" crowned by large triangular pediments, often overcome by acroters.

Another of the most significant elements of Nabataean architecture is the broken tympan, from the Ptolemaic models[17].

The reason of the broken pediment with *tholos* (ed-Deir, Khasneh, Corinthian Tomb) is an imitation of the architecture of Alexandria, although the basic models are of Hellenistic array.

The façades of Petra tombs, seemingly of classical setting, show the architectural solutions, very scenographic (almost Baroque style), with an important sculptural plasticity of its elements.

The Nabataean architecture is, therefore, the result of the assembly of different style elements based on a component reinterpretation in original way.

1.3 Executive technique

The construction process of Nabataean works depends on the topographical and geological characters of the territory and by technological expertises of the Nabataean people.

The vast territory of Petra Valley is surrounded by massive rock formations of sandstone, in which there are the numerous rock structures of the town.

The sandstone becomes the primary element of all Nabataean buildings, both for its workability and abundance within the same site. It was used in high buildings below form of blocks, while, to derive the sacred and funeral buildings was sculpted and carved.

The beautiful carved façades in the rock, from the Nabataean people, followed an effective method of processing and extraction of the stone. Many hypotheses were done respective to the possible techniques of construction used to this people to construct their colossal works, but the most reliable seems to be the realization of vertical surface by an excavation for following horizontal rows.

The procedure below provides two phases of execution.

In a wall of a cliff delineates the profile will be broken through the removal of sandstone blocks, starting from the top. The blocks are extracted with the use of wedges in a regular way, according to horizontal rows, as in a pit occurs, and then thrown down on the ground to be reused in other constructions[18].

After creating a flat surface placed in vertical cliff, it proceeds to the stage of defining the architectural frames and inside spaces. Starting from the top, there is a succession of horizontal levels up to the base. The first level on top defines a plan of support for the Nabataean workers, who work the architectural surface according to a project based on precise geometrical and dimensional rules. As the extraction of blocks follows, the Nabataean work the rock defining the features of the façade in its details and mouldings using cutting and engraving tools.

This technique doesn't allow mistakes in the planning inside aspects, because it is derived directly from the rock, beginning to the crown level (the project was drawn up on paper) and not from ground attack. The proportional relationships are, above all, between the architectural components to have a precise correspondence and a harmonious balance.

Besides, the static problems of structures are resolved by the Nabataean engineers through the perfect

Fig. 8: Executive sequence for the construction of a Nabataean tomb.

distribution of the forces that emerge within the rock mass and not on the outside architectural elements: it involves also reduced dimensions of the burial chambers.

The emptying of the inner room begins to the parallel level at the architrave of the entrance door. The blocks are taken in a perpendicular way at the vertical plane and transported outside by some tunnels and passages created for this reason.

As evidence of this building technique of the Nabataean tombs can see, in the Centre of Petra, the Incomplete Tomb: a particular tomb under construction, where it can still identify the different phases of execution about outside frames and inner room.

2. The Petra's tombs: the three-dimensional modeling [14]

The operation of the three-dimensional reconstruction of the fronts and interiors, selected in a group of tombs in the Wadi Musa's Valley, it is necessary for the completion of research and analysis process put in place. The possibility to have some determined volumetrically forms in a virtual space allows to monitor and exploring the subject above many points, and so, getting interesting morphological and geometrical information. Besides, the method provides an incredible amount of data, which they are very important for the dimensional and chronological investigations of the Petra's monuments.

The three-dimensional reconstruction of the Nabataean artefacts originated from a series of two-dimensional, numerical and graphic processing, that it provides a valid scientific support for the decoding of the formal parameters of the real object. The knowledge of artifacts was realized through the use of tools of the representation.

For understanding the formal connections between architecture and territory developed it a process of critical analysis through from life drawing. While, the monitoring of the architectural forms and the metric data's acquisition foretold important campaigns of direct survey checking and integrating some data of the photogrammetric survey.

The metric data was processed with a software for the vector-based drawing (AutoCAD), defining a set of two-dimensional representations (plans, elevations, sections) of the monuments survey.

The orthogonal designs drawn up, lay out, the geometric lines of the architectural object as a result of an overlap between the photogrammetric images, the direct survey data and the graphic interpretation of the architectural elements according to some stylistic rules.

The photogrammetric applications have provided a large number of images of straightened planes, where we can detect the features of the façades of Petra, with his gaps and deficiencies had to the degradation of the surface. The interpretation of these parametric data, by a process of geometrical and morphological analysis that allows, according to the forms of classical architecture, to define an useful repertory for the three-dimensional reconstruction of the artifacts.

The set of two-dimensional documents, derived from survey, has provided the number of points, profiles, plans for 3D reconstruction of the architectural object.

The operation of the solid modeling occurred with a software for the vector data processing (AutoCAD) and the points management and surfaces that make up the object (3d Studio max).

Each architecture, to rebuild in three-dimensions, were drawn the main profiles that make up the horizontal and vertical planes. The choice of the appropriate modeling technic was based on metric information possessed, and it was fundamental for the search.

For the characteristics of the selected buildings, it prefers a representation of solid kind, where the concrete

Fig. 9: Three-dimensional modeling of a Nabataean column.

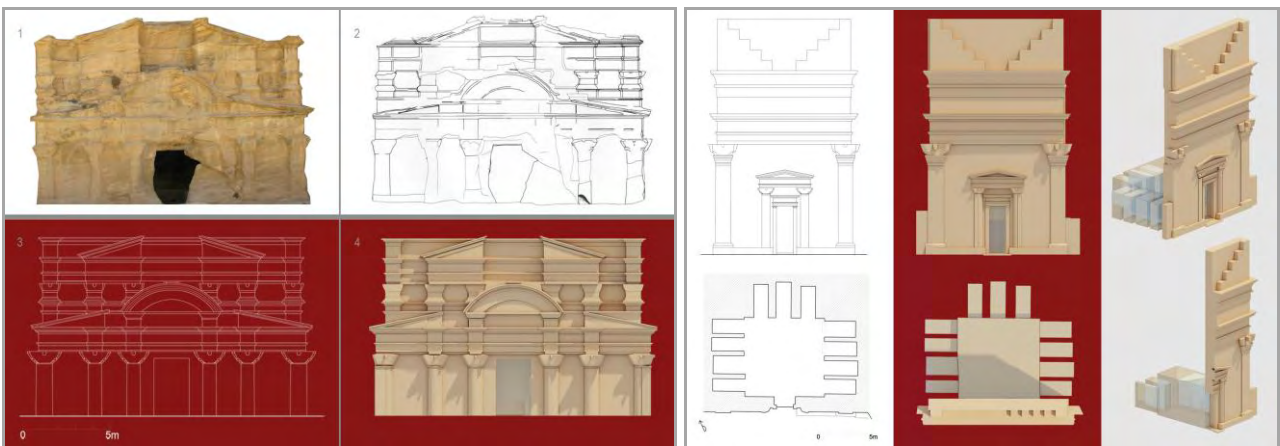

Fig. 10, 11: Bab el Siq Triclinium – Uneishu tomb: photogrammetric survey, geometric survey and rendering images.

form of the rocky mass and sculpted shapes is enclosed within its geometric borders; besides, it allows to apply effectively actions of subtraction and addition of volumes to make tangible the excavation process (subtraction) of rocky material from the full volumetric mass to generate an empty space inside. The subtraction's concept is the word-key in the Nabataean tombs project, where the full stone block is emptied inside, through subtraction of the corresponding positive geometric shape, but getting the negative part. Outside, the rocky front is carved for the architectural framework's definition of the façade. As if it was printed ideally into the vertical plane of rock a negative cast of the mouldings and decorations to obtain the positive image. This concept can be expressed in a comprehensive three-dimensional virtual representations that reproduce the dynamics of this important executive technique.

The fundamental operation for the three-dimensional reconstruction of Petra's monuments was that to identify the shared profiles between the different elements and drawing the geometric outlines of the basic

architectural units combining the characteristic points of each volume or surface. But even more important, in the specific case of rock fronts was the digital transposition in vector lines of the mouldings. In the most important examples of Nabataean architecture, these, perform a fundamental role to resolve the transitions between the plans and to articulate geometrically the rocky surface in organic way. They are the main components of architectural order set up in the proportional and formal rules.

For the reconstruction of the ed-Deir façade, rich of decorative details and involved mouldings, was adopted the best strategy to select the points and to decode the compositive rules of the architectural elements. The creation of the façade's model composes in some parts: rebuilding in a first phase, the vertical wall of rock from the profile of the plant and then shaping each individual architectural component divided by categories (columns, mouldings, openings, niches, crowning, decorations). Every detailed profile of items was treated previously by the 2-D processed repertory in AutoCAD and decoded through the codes of representation.

So, the mouldings both architectural orders of the ed-Deir were rebuilt for extrusion of its descriptive profile along a trajectory formed by a polygonal and horizontal line that follows the plant perimeter of the object. As regards the part of the crowning, formed by different types of shapes, some different modelling commands were applied to. The central part of the *tholos* was created by the *revolution* of its geometric profile around a central axis; while, for the two side broken tympanis had to progress by the extrusion operations changing the orientation of the coordinate system in connection with the different reference planes.

The extrusion faces or closed architectural profiles can occur along a defined trajectory, or along an axis of horizontally or vertically symmetry based on figures provided by the survey.

The relative forms to pillars, columns and walls have been divided in horizontal profiles to extrude along a vertical axis with metric defined parameters. In the specific case of the columns could apply the command *revolution* to generate the solid, rotating the whole profile of the column around an axis of the vertical symmetry. The column was divided into two parts: the stem with the base and the capital. The Nabataean capital presents in its profile the different sections which define the geometric shape. The "loft" command allowed from a good number of horizontal sections of the capital, the generation of the corresponding solid.

One of the most complex forms of Petra façades is the entablature, a collection of moulded items collocated on a perpendicular plane. For the modelling, of such entity, was created a corresponding profile by the characteristic outlines of the sequence of mouldings, from which it could extrude a three-dimensional body along an horizontal trajectory that follows the perimeter of the front. The complexity of concave, convex and linear lines of the moulding was built, geometrically, in the space. In immediate way, the sections of the wall of facade along its vertical were shaped.

The interior space of the tombs presents in the essential geometries based on regular surfaces and main points. The excavated space transposition occurred in two distinct phases, but interdependent. In a first step, it progressed in the plant modelling defining its topology with the creation of a full solid that incorporates every border areas, or the inner walls that represent the junction point between the stone block and empty space. The plant's solid (B) inserted into another larger volume (A), comparable to the mass of stone; through a subtraction operation between two elements (B-A) has been called the vacuum of the burial chamber. Connections between the façade and the interior carved space of the Nabataean tombs was represented, effectively, in axonometric wireframe images, numerous cutaways and deconstructions of the

Fig. 12: *Sextius Florentinus* : axonometric analysis.

geometric components. The cutaways axonometric have used the horizontal and vertical cutting planes to highlight the inner parts of the building envelope. This representation forms a good tool to describe the spatiality of the incorporated hollow into the rock.

The sequence of graphic produced images for each case-study reproduces analytically the decoding process of the architectural forms according to the precise geometric rulers.

The wireframe representation shows in close up the carved façade and in transparency the internal geometries. Instead, the second axonometric image uses a vertical and horizontal section of the inside architectural artifact, showing the negative outline of the plant impresses in stone and connections with the external frames. Finally, the axonometric representation of the whole volume of the plant in positive, it expresses the geometric regularity of the internal space configuration. These images arranged in sequence, constitute, a valid repertory of graphic analysis for understanding the formal dynamics of the Nabataean tombs examined.

The return of the architectural models has predicted the creation of rendering images to convey adequately the joints of the rebuilt forms. Besides the rendering for feature lines, previously described in the operations of axonometric analysis, the numerous renderings of volumes used to simulate the environmental and material characteristics of stone architecture have been executed. The rendering images were obtained from the mathematical models, previously processed by AutoCAD and imported in the software 3d Studio max; where, thanks to the rendering engine *v-ray*, it gets some immediate descriptive images of the Nabataean tombs. At the three-dimensional models was applied a monochromatic (ochre) material similar to one of the lighter shades of sandstone. Inside the scene was inserted a *v-ray* sun light with an inclination about 45° to simulate the diffuse light of the Sun. In the basic parameters of the rendering engine was selected the GI (Global illumination) algorithm, to capture above the direct sunlight also the indirect light reflected from surfaces, recreating a more realistic lighting of the scene. In each three-dimensional model of selected tombs were produced the different rendering images of axonometric, perspective and two-dimensional projections. The visual impact is significant, because it allows to take the accuracy of the architectural details and the complex play of light and shadows, which it affects the surfaces of the carved façade. In addition, the application of transparent materials at these volumes underlines the light contrast between the interior space (indirect lighting) and external surfaces, directly exposed to light.

The rendered images, effectively, communicate the plasticity of architectural frames present in Petra's monuments; obviously, these representations interpret a virtual reality of the rock architectures, through processes of geometric reconstruction of architectural components that allow to integrate discontinuities or gaps of the surfaces and volumes discovered in their actual form.

The 3D prototypes of the Petra's tombs and their digital representations provide, therefore, an important file of descriptive information of the morphological, dimensional, geometric and material characters, of the building envelope carved in the rock. The system of digital information will be used for purposes of virtual tourism through exploitation of three-dimensional numerical models able to reproduce faithfully, the architectural works present in the Petra's Valley. An interactive path that includes also the display of a DEM of the whole mountainous territory of Wadi Musa, shaping the surfaces of the steep rocky walls on the basis of the vector maps and satellite images. A passage that goes through the Siq and leads to the Khasneh and at the excellent rock façades of Nabataean people, allowing a virtual navigation outside and inside of architectural frames, it continues until to reach at the great expanse of Roman ruins, where the remains and traces of the buildings recompose reproducing some scenographic images of the old area.

3. Conclusion

This study on the tombs of Petra is aimed at providing further scientific developments in architectural and archaeological field, providing an effective graphical method for the interpretation of the design process of Nabataean architecture.

The 3d modelling of the Nabataean tombs collocates, therefore, inside to the experimental activities for analysis and conservation of the cultural heritages that have the main purpose of formulating some possible cataloguing systems and data processing, using the latest tools in the field of digital documentation and studying some alternative or complementary representation forms to the traditional ones.

The presented study is the basis for a methodological process of digital representation and interpretation of the Petra's archaeological heritage, defining the different keys to the reading on the basis of the communication and diffusion through the use of software and multimedia applications.

Abstract

Since the beginning, man has attempted to make restoration invisible, and then more subtly, less distracting from the artifacts as reassembled. Glass used as fill, both structurally and as interpretive surface, allows us to come tantalizingly close to the theoretical goal. A seamless membrane defining historic enclosure (where missing) it can protect as a vitrine while providing the armature to suspend the artifacts in their earlier positions. If carefully managed it can mediate the environment within to provide passive conservation. Glass can be stronger than wood and many masonry materials and thus can become a prosthesis to complete a structural member within its original dimensions allowing it to be placed back into service using carbon fiber where tension connections are necessary. Laminated glass not only provides redundancy for structural considerations but multiplies the myriad of coating options as well as the ability to imbed OLED arrays allowing computer imaging support of interactive interpretation. When faced with necessity and no other good solution, the authors undertook the appropriate design, structural analysis and physical failure testing to verify the prior statements for an actual project, gaining the support of Rob Cassetti at Corning Museum of Glass. Full scale installations in Plexiglas and plywood to protect some weather sensitive areas were installed demonstrating constructability and visual effect. We feel that this research should not die with our project.

Keywords: structural glass, carbon fibre, historic ruin, Menokin.

1. Introduction

Fig. 1,2: Menokin during mid-20th century at left; and in 2010 at right.

Fig 3: Menokin reassembled with glass providing the structure and fill (Computer rendering by Declan Nevin)

The recipe in hindsight is quite simple. Take one Apple Cube and cut it to the ragged profile of the ruin. Adjust the fins to the thickness of the ruin walls and to positions on either side of openings. Hang structural glass shelves between the fins to support belt courses, floors, doors, and windows. By the way, do not make any places that cannot be reached for cleaning.

Getting there was a bit more difficult. John Lee and Charles Phillips have collaborated for decades. While working to stabilize the ruin at Menokin it became apparent that even though a superstructure had been built, it was so high that it was not protecting the remains, including wooden floors and timbers from rain – then the sun would come out and it was a terrific parasol. Obviously the ruin needed to be enclosed to

Fig. 4,5: Looking up through the Apple Cube Store, 5th Ave. NY, USA; Menokin 3D CAD build out.

Fig. 6,7: The Harry Ransom Center, The University of Texas, USA; Original model of Menokin shown to Tim Macfarlane.

preserve a number of the materials. The superstructure was so minimally structured that it would not allow enclosure. In addition it was considered a visual blight that distracted from interpretation of the site. After lengthy consideration as to where to place the walls of the enclosure [if the walls are too close to the structure then it cannot be reasonably observed from inside the structure – if the walls are reasonably far from the original walls then the enclosure on the site overwhelms the site interpretation.] we realized that from an interpretative point of view matching the original walls was the only place where the enclosure would not be a detriment. Matching the original walls could add to the interpretation by connecting elements and visually providing the building mass.

Phillips as an architect, conservator and perpetual student of museology was often intrigued by the interpretive power of The Harry Ransom Center at the University of Texas which utilizes architectural glass to describe the sort of archival material that is contained in their collection. The Byzantine Chapel in Houston Texas, by François Minel incorporating frosted glass panels to provide the original spatial organization for rescued frescos also provided inspiration into the capabilities of glass. Ads were starting to come out for LCD glass in monochromatic colour; but it was the Apple Cube that connected mental image with reality. Tim Macfarlane was the lead engineer for the Apple Cube glass. Phillips, Lee, and conservator Ellen Hagsten arranged to meet Macfarlane for Breakfast at the 45th Annual (2006) Seminar on Glass at Corning, New York where he was a primary speaker. Breakfast turned into four hours; Tim joined the team and carried the model on stage when he spoke.

This paper is limited to our work directly associated with development of the glass house and associated glass prosthesis concepts. The direction of years of archaeology and documentation of the unpacking process, determination of the original framing plan and matching all of the timber artefacts to the plan, sorting the artefacts removed before the collapse which had been at moved at least twice before being piled

Fig. 8,9: 2005 Photo and 3D position documentation of artefact removal during unpacking the ruin; 2007 Sorting the interior trim removed before 1968 collapse (one room shown minus base and cornice).

into the artefact store room on site [along the way interiors of two other houses joined the disorganized stacks] cannot be dealt with here. We also will largely ignore the stabilization and conservation of the masonry and plaster remains. However it does need to be mentioned by way of context that Menokin was the home Francis Lightfoot Lee, who was one of the 56 signers of the our Declaration of Independence. As such this ruin of a well designed Georgian Cottage is of national significance.

2.0 Glass Fill

Philosophies of work on cultural properties have long advocated that one not attempt to falsify the record by confusing the old and the new work. At the same time infill must reconcile the losses and allow the artefact to be perceived as it was created allowing for reasonable aging. This often moves toward reducing the visual contribution of the fill. This can some times be accomplished by allowing the substrate to show in the missing areas if it is not too visually strong that it competes with the intact portions. Glass as a fill can even provide the structure when that is missing. It becomes not just feasible but compelling to accept a philosophy of allowing the artefact to be visible in the entirety of its remains while subtly implying the missing components. There is never any question of what is real artefact and what is not. The savings of interpretive time and space explaining what is and what is not, is emence. The visible building is a compelling concept. It allows us create an exhibit of this building as an artefact. It allows us to stabilize and store all of the miscellaneous parts and pieces that have been salvaged in their appropriate three-dimensional locations so that strange markings—evidence—on one piece can be related to apparent damage on other pieces, or a symmetrical location can be found on another piece. At the individual object level, these things are close to impossible to deal with—one cannot find the forest for the trees.

The arrival of Macfarlane really opened the team's eyes to the potential of glass. At that first breakfast he suggested that the glass skin be carried on structural glass fins rather than a metal armature and immediately saw the potential to use glass as a prosthesis for damaged structural artefacts, allowing them to be placed back into service. Under the worst case, the artefact could be suspended between two beams of glass, but as we talked it became apparent that in most cases the glass could be connected to the artefact and carry the original dimensions of the member across to its intended bearing point or other connection. We had been thinking of large sheets of glass as floor where the original boards were long since rotted. Macfarlane pointed out that since the glass was stronger than the original wood and since most of the floors were splined, we could use three layers of laminated glass where the central layer was not as wide as the top and bottom creating the groove for the spline. By using a tinted acrylic spline it would be visible within the floor and interpret the original construction. Since in most cases we could determine the varying widths of the random width floor boards they could just as easily be made the correct widths as they would be cut out by computer.

Several rules of thumb:

1. If glass is laminated with three or more layers, all of the layers can be fractured and the assembly will still carry the design load.
2. Standard glass sheets are about 5 times stronger than wood. This means that a glass beam 1/5 as wide as a wooden element will carry about the same load. 1/4 provides an additional factor of safety and if two laminated beams are spaced so that their outside faces are aligned with the outside faces of the wooden element, the composite provides the visual dimensions of the original with slightly more than two times the strength of the original. [dimensional compatibility and redundancy – a great combination]

Fig.10,11: Basic forces in a simple beam; Glass beam of two laminated faces with blocks between.

Fig. 12,13: Beam with completely deteriorated area at a mortise; Exploded view with a loose casting to fill the missing portion – if tightly assembled, in theory it only needs a tension connection at the bottom to function. See Fig. 14-17.

3. Standard construction epoxy adhering carbon fibre tape to the face of wooden elements fails within the wood itself; typically at the point where the epoxy ceases to penetrate. This means that high-tech adhesive systems are not necessary to exceed the strength of the original wooden system.
4. No book or computer simulation can tell how a specific deteriorated then conserved artefact fitted with a prosthesis will actually perform. Therefore All members returned to service must be tested individually, and as assemblies where appropriate, to a factor of safety beyond expected loading, in a rig that mimics the attachment that it will have in service. This is not testing to failure, but rather verification that anticipated capacities have been achieved.

Fig. 14,15,16,17: Loose blocks epoxied to a 1.5in. carbon fibre tape in various arrangements from bent causing the blocks to spread and become quite flexible, to very rigid as the blocks come into contact and meet compressive forces. The stick spanning the chair and table will easily support a 200lb. person – the table is likely the weakest element. The three sticks at the right are: at the top a series of blocks with a tape below; the center stick has a 1.5in tape inserted into a saw cut; the bottom stick has the tape fully covering the face. With the tape on the side opposite the force, each will resist more strongly than a plain stick without the tape. Note: the loose blocks do not even need to be attached to the tape toward the center of the span – The tape requires a sound connection to the end blocks only. Attachment to several at the ends helps distribute the adhesive bond strength. A mechanical attachment to the end blocks would relieve the need for any adhesive.

Fig. 18,19: Two views of the initial concept model for the glass prosthesis. The fragment of old wood is not from Menokin and salvaged from an urban trash container. It happened to have an angled top face and thus the top of the prosthesis was beveled at the point of contact. This would not likely occur in actual usage but obviously can be accommodated. The Prosthesis in the model is acrylic.

We went back to the basics; asking what do we really need for this element of the structure to do? Where are the forces and what are their magnitudes? We know that the original configuration was working quite well until the roof was allowed to leak. Therefore if we can work back toward the original configuration that should be adequate. Trust but verify. Most engineering texts and computer simulations are a poor approximation of real life. We are designing for real life not for some mythical computer simulation. Since we cannot look up the critical values for a deteriorated element we are forced into a testing program that will determine element by element what its actual resistance to force is.

Many of the beams and joists have had one or both ends rotted to non-existence. Some have pockets of rot that likewise, no longer exist even as the equivalent of frass. Some are little more than a veneer surface. The realization that a series of loose parts connected by a tension component such as a carbon fibre tape can carry more load than a single element of the same material and overall dimensions without the tape, was very liberating.

The primary point is that one can treat a deteriorated beam that developed serious rot at several major mortise locations 4 to 5 feet apart and is now in 4 major pieces and missing the mortises and put it back into service. There need not be any major armature outside of the piece or major loss of fabric from cutting away material for splices. The new and the old are always apparent, but now one can see where the structure goes and what it was intended to attach to and how the assembly worked. First the individual pieces that made up the element must be consolidated so as to be handled without loss and to be able to resist compression. Then loose castings must be made of the missing mortise portions [no loss of fabric] and if one end is missing several feet then an end transition for a prosthesis must also be cast. The prosthesis

Fig. 20, 21: The initial jigs were quick, crude, but effective. The force gage was old and out of calibration but provided a good comparative analysis.

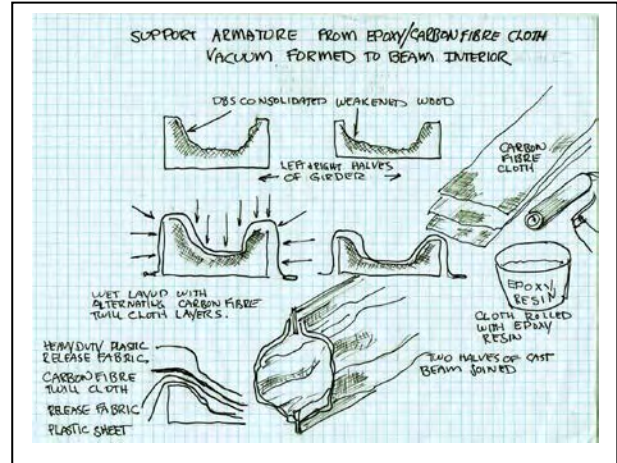

Fig. 22, 23: As the project progressed we got a little more sophisticated. This rig on the left is testing shear in torsion between the wood arm and the carbon fibre faced block seen just below the brim of the hat. The drawings on the right show the steps to making a carbon fibre core for a timber with a rotted center. Note the core will be filled with foam to reduce buckling.

fabricated to dimension and finally two or more carbon fibre tension members must be attached between the end of the prosthesis and the other original end. Test the beam for the necessary loads and put it back in place having lost very little of the information contained in its skin. Joists are just narrow beams with few mortises.

It would be nice to have an easy method to drill longitudinal holes that would essentially allow post-tensioning of the assembly with no visible skin loss. That is something for future research. We also looked at the possibility of creating a woven tube of very open design similar to a Chinese finger locking device like the ones we had when we were children, where one sticks a finger in each end of the woven tube and then the tube shrinks and tightens as one tries to remove the fingers. This wrapped around the assembled original parts and missing pieces would make it whole again while being completely reversible.

Fig. 24, 25, 26, 27: Show the steps described in figure 23.

Fig. 28, 29: Macfarlane and Phillips conferring about details for the East wall enclosure. As with most projects that involve unique detailing, it is best to do much of it on site. The right view shows the Plexiglas enclosure in place before the shading film detailing was applied. Although the glare provides a presence for the glass skin it does not visually overpower the original structure. It does temporarily mask the interior which aids in understanding the form of the building.

Fig. 30, 31: When not standing where the glare is brightest, one can see the plywood fins. At the right the cast concrete bases for the fins are easily visible – a more elegant solution can be found. There is a sheet of plastic between the concrete and the historic masonry as a bond breaker. Interpretively this relationship with the glare also allows one to see the interior makeup of the building and how it goes together (form/detail).

We were faced with a problem of temporarily protecting the wooden floors and plaster in the North East Quadrant. Rain was blowing in and we could not wait until the whole glass house was funded. After rejecting the initial suggestions of a tarp, which would be difficult to control in a wind and probably dangerous; not to mention ugly. Then rejecting a plywood wall which would be comparatively expensive and just as ugly as the tarp; we proposed an equally expensive option using this as an opportunity to mockup the glass house concept and get some constructability knowledge about actually getting things into place. It is one thing to draw the fins in place, but how do you get them into place? How do you control a large fin without knocking down the ruin in the process? How close do you cut the contour (We chose 1/2in. – it worked) of the only fin that must embrace a portion of the wall where the outside half thickness collapsed leaving the interior half still holding up the second floor? Needless to say we learned a quite a bit.

We chose to use MDO plywood over a 1.5 in thick wood frame for the fins. This was 2.25 inches thick while the glass was intended to be only 2in. but the wood was readily cut and manipulated on site. For similar reasons of on site adjustment we chose Plexiglas over true glass. Actually from a structural standpoint the real glass would have been a better choice and its rigidity would have made some of the end connections less of a problem. This being a temporary construction the cost difference was also in the favor of using the alternate materials.

The costs were minute however when compared to the current interpretive value and the ability of this mockup to sell the final product. A gain it is one thing to talk about the visual impact and a computer rendering looks awfully good but a full scale portion in place is stunning and hard to argue with.

The interpretive value of the glass is immediately apparent. The ghosted in window stones and sashes could even be less pronounced but even as it is, the understanding of the building that it conveys is tremendous. Without the frosting how many visitors realized that the straight sections of the broken edge of the wall were actually the edge of the window stones? It takes much less imagination now to start to connect the elements to the missing corners and imagine the house complete; either as original or as envisioned in glass. What opportunities would be available, what exhibits could one develop with the ability to change the image on the glass? Make it display whatever can be created on a computer screen and then animated? This is a house of Georgian design and it was based on Classical proportions. What if, as one described the descriptive geometry of the façade, the construction lines appeared there in the glass? Menokin is located in the small rural community of Warsaw, one hour from Richmond the Capital of Virginia and about two hours from Washington, DC. Why not invite the town and surrounding neighbors to a picnic on the grounds and when

Fig. 32, 33: These views show the appearance of the shading film detail from the exterior and the interior.

the sun sets, show a movie like “Star Wars” on a portion of the front façade? In terms of sparking the imagination The Corning Glass Company has published a video on YouTube that may surprise you. Actually they have recently released an update: “A Day Made of Glass 2.” They are both worth watching. How would you use glass as infill? We hope this paper opens the door to more inventive uses of glass in heritage conservation and thank Hugh Miller, Richard Wolbers, Rob Cassetti and Peter Drobny for their kind support.

The visual description of the piedmont landscape in the historical iconography: from *Theatrum Sabaudiae* to landscape painters of eighteenth-nineteenth century

Maria Paola MARABOTTO

Facoltà di Architettura, Università degli Studi di Catania, Italia
mp.marabotto@gmail.com, maria.marabotto@polimi.it

Abstract

This study proposes the Piedmont landscape overview and comparison of some iconographic images, from *Theatrum Sabaudiae* (1682) to the views of artists, painters and engravers of the eighteenth-nineteenth century. The comparison of similar representations of the same city or part of a territory has highlighted the diachronic changes of different places and the landscape that contains them.

The landscape, understood as an expression mediated between territory and attendance anthropisation, was analyzed through the study of graphic documents of the city of Turin and the surrounding area made by Italian and foreign artists who passed through the Piedmont during their travels in Italy.

The paintings by Bernardo Bellotto (1721-1780) made for kings and princes of the House of Savoy now exhibited at the Galleria Sabauda of Turin and drawings by William Turner at the Tate Gallery in London kept describing, with different languages, different aspects of the same place. Therefore it is important to the comprehensive interpretation of the territory starting from the understanding of the changes of settlement, economic and social *topos* of using heterogeneous fields of investigation, which show the change of land use under the most varied aspects.

The critical comparison of the iconography of a particular historical period, realized through the present study, is one of the possible research areas, integrated with other, leads to true Knowledge of a place.

Keywords: historical iconography, landscape, Piedmont, perspective views

The visual description of the piedmont landscape in the historical iconography

The territory is a space defined by a set of physical characteristics that appeal to principles or ecological, institutional or economic or cultural. When people acquire knowledge of this individuality land where they live, they play those processes of construction which, with their sediment and interbreed, they produced the landscape. Land and landscape are categories highly interconnected in a single, larger historical design. They are a set of tracks, historical stratification of elements, culture and signs.

The landscape is understood as an expression mediated between the community and attendance anthropisation, as the relationship that develops between the built and natural elements, through historical, political, and cultural production that affect the transformation of the environment by man. Understanding this relationship is the basis of any knowledge of the area and allows you to identify the dynamics of change in which you insert the control of the further transformation processes.

The rural buildings, civil, religious, cultures, channels, paths, road networks, making up the signs of human presence on the territory, lose, on a regional scale, the significance of that unit and become elements of a comprehensive set of objects homogeneous built into the landscape. Their definition is tied to the prime

factors of colonization of the territory and its organization, as the conquest, settlement, exploitation, production, control the defense and civil and political administration; through each of them one can reconstruct the history of transformation of the landscape.

Are part of the landscape many relevant factors such as the coastal areas, rivers and lakes, mountains, parks, reserves and forests. But there are other landscape situations, particularly those related to human settlement of the land as agricultural landscapes, the signs of the roads, the geography of city centers, and all those elements that are subject to frequent changes.

Just because these items are considered significant and important in the complex system of relationships between humans and the environment, it is important to make an integrated interpretation of the territory, starting from the need to understand the dynamics of settlement, economic and social topos, linked to natural resources that have influenced the choice of a site. To do this it is important to use diverse fields of inquiry useful as indicators of change and land use under the most varied aspects.

Fig. 1: Bernardo Bellotto, *The Ancient Bridge over the Po in Turin 1745*. Torino, Galleria Sabauda.

The study has investigated the Piedmont landscape through the review and comparison of some iconographic images, starting from the engravings of the *Theatrum Sabaudiae* (1682) - one of the most important documents for the knowledge of the Piedmont region in the late XVII century - to the views of artists, painters and engravers of the eighteenth-nineteenth century.

The *corpus* of one hundred thirty-four engraved plates that make up the *Theatrum Sabaudiae* covers different types of representations including orthogonal projections - plans, elevations, sections - axonometric, perspective, views and a bird's-eye perspective. And between subjects also very different: his court offices, military, civic and religious monuments, pleasure villas, hunting lodges and castles, fortification systems, ports and fortresses, monasteries, abbeys and views of the capital and major cities of the duchy. The great variety of subjects involved the use of different methods of representation at different scales, ranging from

urban scale to the geographical scale and reach to the architectural scale. Of one hundred thirty-four sixty-five incisions are drawings of cities and fall within the category of urban iconography which has as its purpose the "portrait of the city" that celebrates the city itself. This political and ideological intent requires that the urban image is captured in its full extension for which you choose privileged viewpoints able to make the shape urbis in all its spectacular potential.

Fig. 2: Bernardo Bellotto, *View of Turin from the Royal Gardens*, 1745. Torino, Galleria Sabauda.

Considering the period in which these representations have been realized, taking into account the technical and scientific culture of the time, we can say that the perspective view and the profile can be made with an observation *vivum* to the city, often supported by the use of proper instrumentation. The plan and bird's-eye view but are not the result of a real visual experience, but the result of a process of abstraction. In particular, the bird's eye view of itself as an alteration of the urban structure, obtained through a geometric procedure that is obtained through simulation of the flight that had not, at that time, real feedback. This was often performed as an axonometric foreshortened, a representation which exerted great fascination on the viewer and that is why they emerged as the most popular type of show for the urban images. The point of view very high offers the possibility of recreating urban space so that it is viable and recognizable in all its parts and provides an image of the city as a whole and with a good reliability topography.

The *Theatrum Sabaudiae* represents one of the most important works for the knowledge of the Piedmont region in the late seventeenth century. It was intended as a photograph of anthropogenic and natural area that offers a depiction of the political aspirations of the House of Savoy.

The critical comparison involved some engravings in the *Theatrum* representing the city of Turin and a few paintings and drawings of a later period. At the *Galleria Sabauda* of Turin are preserved two oil paintings by Giacomo Bellotto, Canaletto's nephew, the painter who lived between 1721 and 1780, which represent two views of Turin: *View of Turin from the Royal Gardens* and *The Ancient Bridge over the Po in Turin*, made in 1745. Commissioned by Carlo Emanuele III and unusual cutting decentralized to them was assigned the spread of the new image of modern European capital, the king of Savoy wanted to offer the city of Turin, together with the beginning of major modernization work of the Royal Palace.

The first view was compared with the table eight in the first volume of the *Theatrum Sabaudiae* which represents the reverse of the painting of Bellotto. The incision, made a drawing of Giovanni Tommaso Borgonio in 1665-1666, representing the *Bastion Verde* including the facade of the Palazzo Reale to the gardens with bastions seen from the south instead of north as the painting. The difference between the two different techniques of representation highlights different characteristics. The sign of the incisions is essential, of great clarity and effectiveness, and waiving of naturalistic landscape painting with a concrete and without force result. The picture that emerges is clean and inspiring solemnity thanks to an effect of optical expansion that expands the existing and part of the vision real simple projects.

Fig. 3: *Turin, Bastion Verde*. *Theatrum Sabaudiae*, Amsterdam, 1682, vol.I. Engraved a design by Giovanni Tommaso Borgonio, 1665-1666.

Painting by Bellotto the clear light brings out the imposing facade of the Palazzo Reale to the garden, while quick and brilliant brush strokes describe the details of the laundry hanging in the sun and the workers on the scaffolding of the bastion. The artist's interest is always double so as to depict the monumental architecture is that the suburban areas. The large size of the canvas along with the point of view at the top and the open view, contributes to the construction of large and airy image that anticipates the views of Dresden, Vienna and Warsaw were made following the author.

In landscape painting the basics are the documentation of the places, the artifice of the embodiment, the composition selected. But the constant element of the view is the perspective, even before the topographic fidelity. The view can be "*taken from the places*" that is exact, natural, but also "*invented*" that is of whim or fancy, but it is important the correct representation of the buildings, with their planes, edges, and the views expressed accurately; a chronicle of architecture as solid geometry and the theory of shadows. The purpose

of likelihood perspective is to stimulate the sense of space which must be reflected in a broad overview of the architectural centerpiece of our representation.

The time difference between the two representations shows a different urban setting. The engraving shows buildings around the royal gardens - the sleeve of the Royal Library with the Military Academy - and the ramparts graphically represented with a sign-linear, no-frills with the tower in the ravelin less impressive than that represented in the framework of Bellotto. As part of the venetian painter, left, check the roofs, including the Royal Palace and the cathedral, a polygonal dome of the Chapel of Sacra Sindone by distinctive design, hand engraving of Borgonio not present because they do not yet taken the time. The landscape outside the moat is not treated in the engraving of the *Theatrum* probably why it was necessary to give as much prominence as possible to the residence of the Savoy and its gardens. In view of Bernardo Bellotto space over the moat is defined and described, and the view extends over the next bastion in the background until you see the hills and the Alps.

Fig. 4: Turin, Piazza Castello Theatrum Sabaudiae, Amsterdam, 1682, vol.I. Engraved a design by Giovanni Tommaso Borgonio, 1674.

The panel five in the first volume of the *Theatrum Sabaudiae* represents Piazza Castello view from the south. Engraved by de Hooge Romyn designed by Giovanni Tommaso Borgonio and dated 1684, shows the square at a time of lively city life; on the big rectangular space, carriages, horses and people during at an event. The square is surrounded by the imposing buildings of representation that still crown the perimeter of the urban. A medieval castle on the right without the current Baroque façade of the Palazzo Madama, attached to the Royal Library by the Gallery no longer exists. On the left the long facades with wide porches on the ground floor and the Royal Palace in the background with the front yard separated by a fence with a large square with arches and a central door with three tiers. A similar representation of the square, over the previous incision, is a painting by Antonio Tempesta (1555-1630) kept at the Galleria Sabauda entitled

Competition in Castle Square in Turin. The square is seen from the south to the Royal Palace and central point of view very high place that produces a central perspective of great scenic effect. The buildings that overlook the urban space are still present today, although modified in prospectuses. The medieval castle has two towers on the façade now incorporated in the baroque facade of the Palazzo Madama; the fence that divides the square from the courtyard of the Palazzo Reale does not have the door with three floors and facade of the palace of the King is resolved geometrically differently. In the painting the prospectus is solved with three vertical partitions with the central part which has a more dignified façade crowned by a cornice with statues. In the engraving of the *Theatrum* the facade of the building is equal to that of today, with regular course and two towers at the ends of the building that will rise above the roof of the downtown area. In the two representations do not include the dome of the Chapel of Guarini and designed the bell tower of the Cathedral on the left image.

Fig. 5: Antonio Tempesta, *Competition in Castle Square*, fine XVI secolo. Torino, Galleria Sabauda.

The end result of representations is that of a precise determination of the dynasty, which makes great reality of the territory, enhancing wealth, population density, urban centers, factories, defensive structures, to underline its aspirations of power in Europe.

Research has completed a comprehensive interpretation of urban land through the comparison of iconographic images, starting from the understanding of settlement dynamics and using disparate research fields, which are useful as indicators of change in use of urban spaces. The critical comparison of the iconography of a particular historical period is one of the possible research areas, integrated with other, leads to true Knowledge of a place.

Fig. 6: Joseph Mallord William Turner, *Turin, The Castle Squar*. From *Turin, Como, Lugarno, Maggiore Sketchbook*, 1819. London, Tate Gallery.

Density changes in the redevelopment of the urban spaces

Carlo Alessandro MANZO

Facoltà di Architettura “Luigi Vanvitelli”, Seconda Università di Napoli
Dipartimento “Cultura del Progetto”
e.mail: carloalessandro.manzo@fastwebnet.it

Abstract

Density control and ground-modelling are important factors to work out the redevelopment of urban spaces, both in the old cities and in the new urban settlements. Their smart use can help to carry out solutions within a good environmental sustainability first of all opposing to the waste of lands in the metropolitan territories. In order to improve private and public spaces of the contemporary city, we must study the best strategy to change the town-central areas, sometime reducing existent built volumes (or parts of them), sometime increasing the density in case of suitable places, any way to gain open spaces and green areas. The urban projects criteria I will deal with, use ground-shaping techniques to achieve essential solutions increasing green areas, and to answer to environmental sustainability and energy saving needs. These projects, designed for different urban contexts, create some “hypogean” modern architectures, (aimed to get underground useful spaces for utilities), trying to get some advantages: efficient solutions insulating buildings by thermic variations, protected spaces close to the new utilities, and safeguards of green areas creating grass-lands and roof-gardens over the new spaces. In order to investigate these problems the paper will exemplify the architectural designs for Vanvitelli residential area (Caserta), for Tor Bella Monaca social housing (Roma) and for a small square built in Cesa (Caserta).

Key words: redevelopment, urban design, density

1. The density in the social housing redevelopment

Here I will speak about few architectural designs, made up in different urban contexts, underlining the problem of density and volumetric evidence in the singular place of the city. The density control is really an important factor to work out the redevelopment of urban spaces, both in the old cities and in the new urban settlements. Its smart use, maybe helped with ground-modelling techniques, can help to carry out solutions within a good environmental sustainability, first of all opposing to the waste of lands in the metropolitan territories. If we consider the needs to improve private and public spaces of the contemporary city, we must study the best strategy to change the town-central areas, sometime reducing existent built volumes (or parts of them), sometime increasing the density in case of suitable places, any way to gain open spaces and green areas. These urban projects use ground-shaping techniques to achieve essential solutions increasing green areas, and improving the environmental sustainability and the energy saving needs. Within the different composition proceedings, I tried also to create some “hypogean” modern architectures, (aimed to get underground useful spaces for utilities), not only to achieve a good architecture, but also to gain some advantages: efficient solutions insulating buildings by thermic variations, protected spaces close to the new utilities, and safeguards of green areas creating grass-lands and roof-gardens over the new spaces.

The redevelopment of public residential neighborhoods has been tackled in recent years with different levels of transformation depending on the approach to urban planning. On the one hand, there is a tendency in Europe to demolish buildings, motivated by a rethinking of the very idea of the large neighborhood, which is criticized for the lack of individuality and the high density of its distinctive features (towers, vertical residential units, etc.), quite apart from any architectural considerations. In the contrary direction, there is a will of restoration which, beyond economic and social reasons and population density, seeks to prevent the demolition work from

cancelling an important part of the rationalist experience. In terms of the techniques and the composition, the approach to restoration is motivated by criteria of environmental sustainability and efficient land use. Indeed, various schools of thought on residential architecture are repropounding compact designs with concentrated densities. These represent convincing reasons against the indiscriminate demolition proposals by means of which the supposed drive towards renewal often masks interests in property speculation (as in the recent case of Tor Bella Monaca in Rome). In terms of the quality of the urban layout and the architecture, many public residential neighbourhoods were built in Italy during the post-war period by important architects represent a heritage of historicized works of the modern city which should lead us to consider them as a resource for future urban transformations. A selective approach to restoration should safeguard the identity and character of this architecture, while offering a critical reinterpretation of outdated aspects.

In order to address this issue properly, it is important to bring specializations together within a unitary approach to architectural design. This is important for ensuring that the various components of structural and technological refurbishment, and environmental sustainability, are incorporated within a truly architectural perspective that also lays emphasis on the urban context. Even if the renewal of these recently built settlements is considered as “modern restoration”, any proposed transformation should interpret the original features following the compositional approach behind the original work. This idea of *critical continuity* should not be restricted to mimesis and restoration but should consider the possibility of pursuing alternative paths and achieving unexpected results. In order to investigate these problems the paper will exemplify the architectural designs for Vanvitelli residential area (Caserta), for Tor Bella Monaca social housing (Roma) and for a small square built in Cesa (Caserta).

2. The densification in the IACP area “Luigi Vanvitelli” in Caserta

In the Prin-research (National Research Project involving departments of the Universities of Rome, of the Second University of Napoli, and departments from the universities of Palermo and L’Aquila) we selected a significant sample area for testing the densification criteria to redevelop the area. Considerable importance was given to the “structuring” role of the system of free spaces and courtyards which, in different ways, demonstrate the persistence of pieces of countryside which are inserted between the houses. The interweaving between green spaces and building is one of the innovative compositional principles of the modern city, and this has convinced us to focus on “courtyards” as the organizational core of the redevelopment of districts and as a central place for the services and productive activities. The various possibilities for intervention include the techniques of land modeling which incorporate the new spaces in underground structures, reducing the occupation of courtyards and increasing the surfaces of green areas. A key factor is given to productive green space with the aim of assessing, through measurable experiences, the recent popularity of urban vegetable plots and gardens.

In the IACP Ina-Casa “Luigi Vanvitelli” residential area in Caserta, (designed in 1963 by a team led by Mario Fiorentino) made up of rows of buildings and tower blocks, an important role is played by the structure of free spaces made up of a system of courtyards arranged around a large central courtyard-garden. The intensive building activity that is saturating the rural areas gives a special emphasis to the size and quality of the free spaces of the district compared to the widespread fragmentation of buildings.

The main themes for modernizing the settlement concern the addition of services to the district and the upgrading of access to the houses.

The criteria of densification have been adopted by inserting within the large courtyard several buildings that meet both the domestic nature of the district and the requirements of an urban scale. Thus the large courtyard-garden contains new buildings without contradicting the unitary character of the collective space.

The additions are precious objects, linked to paths, barriers and excavations. They create new discontinuous profiles which break up the view of the continuity of the large walls of the buildings. In the “a pilotis” groundfloor area of the Vanvitelli district, densification involves the inclusion of small volumes designed to act as *social-rooms or shops*. In order to resolve the problems of access to the houses, new structures are created for the lifts which are directly grafted onto the balconies of the individual houses, creating new entrances to the residential units. This solution expands the balconies with *brise-soleil* and vertical gardens, creating a discontinuous design which partly breaks up the structure of the original facades without hiding them.

2. Ground-modelling in a Tor Bella Monaca residential court, Rome.

An interesting example is the Tor Bella Monaca district, a large settlement of over 25,000 inhabitants built in Rome in the eighties. In contrast to the design of Leon Krier presented by the council administration of Rome which plans for demolition and rebuilding, various Italian university departments have developed studies and proposals for redevelopment.

Despite certain weak points, Tor Bella Monaca has a clear structure “divided into distinct parts”, a significant number of free spaces and a carefully structured typological composition of houses which (when suitably refurbished and joined to low houses) can play an important role in the relationship between the metropolis and the surrounding countryside. The mixture of functions and typologies (lines, courtyards and tower blocks) enables an effective relationship between land, open spaces, infrastructure and buildings which, in the city council design, was entrusted solely to the building-road relationship. Indeed, the Krier’s design, supported by the council administration, proposes a densely inhabited residential district of a nineteenth century mould with an emphasis on single function residential units, despite the problems of sustainability and extensive consumption of the Roman countryside.

Instead, by following a perspective based on redevelopment, it is possible to count on the fact that currently almost 40% of the open spaces of Tor Bella Monaca do not have a definite purpose and can be used – using the criteria described above and without further consumption of the countryside – for a range of purposes such as private offices, shops and craft centres, and services. It is therefore possible to density and build on built-up space. With the construction of spaces for work activities and private services, using the experience of project financing; services on a scale with the urban sector (library/media centre, multiplex cinema, etc...); services on a scale suited to the district (for the elderly, children etc.), residences for different users (students, temporary workers, co-housing, etc...), it is also possible to “redesign” current public residences with different sizes of accommodation and services.

In the “redants” system designed by Barucci and Passarelli in the R5 sector, the proposed transformation criteria concern both the rationalization of existing housing in residential courtyards, and the inclusion of structures for the service industry in courtyards facing in the direction of the city. To overcome the problems of the weak points in the sector (the presence of housing on the ground floor overlooking the street, the lack of differentiation of the residential types and the lack of low houses), the priorities of the programme concerning the change of density were so identified:

- Reinforcement of the features and quality of the urban layout creating green corridors.
- Varying the range of residential types by introducing, in the large courtyards facing the countryside, terraced houses with gardens and houses with patios.
- Replacing the accommodation in the lower floors of the courtyards with service industry functions.
- “Targeted” demolition of the residences in low buildings, replacing them with tertiary sector activities or public services.

4. The rebuilding of a small square in Cesa

The architectural design for the rebuilding of a small square in Cesa (CE) starts from the need of replace the old power station, now out-of-date. It regards a triangular space on a trivial wide stretch, located in the entrance point on the way to the town-centre. Till now this space had been built with the 4 meters high block of the former power station, on which was fixed a Madonna Statue, very important for the local believers. The requirement program asks for a new power station with a plan of m 3,00 x 5,60, in a partial basement room but with minimum 1.50 meter free upper the ground level. Considering the small dimension of the suitable area, we used this new technical building to separate the main traffic street from the pedestrian place, usable for walking or resting. This small space with stone benches is reachable by a slope *path* along the power box side. The new pedestrian system allows to walk inside the new square reducing the basements dimensions on the roads.

-In this urban project the new power box is composed in a big stone wall, closing two sides of the space in order to form a small terrace higher than street, protected from the traffic, and in the same time to give an unitary solution well characterized for the passer-by. The wall covering has a “texture” alternating smooth and *bushammered* surfaces. For the benches and the floors we used the same Trani materials, but the basements are paved with dark gray *piperno* stones.

The continuous design, both on the top and on the wall, is broken off with the fountain green marble slabs, well visible in the night for the lightened falling water.

The Madonna image is located in a remarkable but not central position, coherent with the theme of stone wall recint, facing to the benches of the small new square. She is covered with a thin structure in white and blue marble. This solution underlines that the statue place belongs to the whole walls system.

Abstract

To control the environmental conditions, people of many part of the world have chosen the way of reconciliation with nature. The effects of such approach are seen in different climates in different forms. Among all these approaches, the mechanical methods employed for generating energy are the samples that reflect human wisdom and intelligence in utilizing the environment facilities. Windmills are one the most exclusive items that convert uncontrollable powers of the nature to useful energies. The origin of them must be searched for in the east, and especially Iran. The remains of a unique form of this invention, which dates back to around 2000 years ago, can be found in the eastern regions of Iran, i.e. South of Khorassan and Sistan & Baluchestan. These structures as one of the most outstanding native buildings stand against the wind and their tall structure reflects the glory of the civilization of their producers and as Seifollah Bakharzi said: "They move around science axis".

Deserting windmills due to the invasion of modern technology on one hand and starting destroying and renovation of adjacent contexts on the other hand, gradually pales the connection of these structures with the city and accelerates their destruction. The writers believe that knowing windmills is a way to understanding the deep link between economics, culture and local knowledge of the people who have chosen the harsh nature for their residence.

In the present paper, the writers intend to present a precise interpretation of a range of Iranian windmills located in Nashtifan, near Iran-Afghanistan border through field study, analyze them and show a clear picture of the different aspects of such constructions, including their architectural and mechanical features, and their cultural position in the life of this secluded area. The writers emphasize the significance of global attention to this valuable site as one of the first origins of using wind energy. To do so, after a review on the history and evolution of Iranian windmill, and showing their position in the customs and traditions of the people in this region, the different parts of a windmill will be discussed and analyzed in two parts: Mechanical, and architectural structure. This will be done through maps and 3D models. At the end some suggestions will be proposed to renovate windmills and return these structures back to the living cycle of local society. In this regard some measures will be surveyed like establishing museum site to attract tourists and running the windmills to generate electricity for local community.

Key words: Windmills, Local technology, Local community, Local economy

Preface

The time human used the wind energy is not completely clear; but a many researchers say it was Iranians who controlled wind energy to move the mill.

Iranian windmills has spread through Eastern part of Iran specially in south part of Khorasan and Sistan. They are the symbol of Iranian wisdom in controlling wind energy and changing it to useful forms of energy. As we will discuss afterward, Iranians found a simple but wise structure which was based on environmental facilities through centuries that is a mixture of mechanical science and architectural art.

Now, our role for preserving this valuable memorial of our ancestors which with no doubt is the result of hundred years of effort and experience should be emphasized.

Through this article, we want to emphasize on importance of more researches by exact and documentary introduction to Iranian windmills with a comparative approach from a new point of view. So with a review on history and the changing process of windmills and looking at the special type of climate of eastern part of Iran as the main factor of windmill formation, we will have a look at different parts of windmills.

In spite of two dimension diagrams, three dimension details of windmills based on exact checking will be presented. After ward in order to find out the differences between Iranian windmills and European types, in a part of article, we will have an introduction to the structure and manual of European windmills. At the end, the importance of a review in wind turbines from the two points of view will be reviewed.

Figure 1. View of wind mills in Nashtifan village in Khaf area. (Source: Internet)

History and changing process of Iranian windmill

Some researchers believe that the wind mills came into use 200 B.C (Balkhi, 1974) Ebne khaldoun^[1] believes that the windmills in Sistan were in use before Arab rush to this land. The first source which you can find something about wind mills is an old Indian book named Arthosatra of kantili in which windmills invention goes back to 3400 years ago which it means 1400 BC and in that book was mentioned that windmills were used to move up water. (Farshad 1997, P.99)

Windmills as source of energy in Greek and Roman civilizations were unknown. The documents after Islam have clearer information about windmills which were used for grinding grains and moving water up.

The oldest written document in which you can find the word windmill is Masoudi history in that there is a dialogue between Aboulolo, the Iranian slave, and Omar, the khalif of Muslims. Aboulolo implied his ability in making a windmill (Masoudi, 1986, P. 677)

The writer of Sistan hisroy^[2] writes: ... and the other thing is that they build windmills to be worked by wind and they make flour out of wheat, but in other cities there is a need for animals or water to grind the grains. They also have built a kind of wheel to get out the water from well for their gardens and farms ... and they get several uses out of wind ... (anonymous, 2002)

These all present the long life of using wind energy by the wind mills. Ansari Dameshq^[3] has drawn the oldest drawing of the windmill structure in Sistan. In this book, he has drawn many pictures of the visited sight-seeings and wonders by himself. Using them, now we are able to get informed of their structure. The structure that he has drawn is not the same as what you can see today, in fact the main structure is the opposite of what exists today. Turbines of windmills in that time and probably before that were at the bottom and the stone mill was at the top and it has been a model of watermill in which the turbine was moved by wind instead of water. (Modarres Razavi- ...)

Figure 2. The windmill structure related to Ansari Dameshghi time. (Source: Nokhbe Aldahr book)

120 day winds as the main factor of Iranian windmill formation

Structure of wind mills can be seen just in some parts of Iran because its Function depends on strong, continuous and long time winds, so you can have them only in places where you can find wind so strong that it can move the heavy and huge mills. Sistan and Khaf in Zozan fields have a type of wind called 120 day wind and this caused the wind energy to be used by natives and windmill was invented a long time ago in this land.

This wind start point is from the heights of Pamir and north of Afghanistan that first comes to Iranian and Afghan borders and the strong flow of that is in Sistan. Some reports say that the start point is in western part of Herat. It starts in early of May and continues to September and even October for this reason it is called 120 day wind.

Wind flow in Sistan continues in all seasons in Sistan and the most Cases are in summer. From September afterward the weather is more calm. Based on statistics at weather for casting station in Khaf (the nearest station to wind mill area) in recent 3 years (2007 – 2009) the highest average monthly speed of wind was for mordad which was 23 meter per second and the lowest one was for Aban which was 11 meter per second. In this area which is under the influence of 120 day winds, wind blows in more than half of the months of the year by an angle between 50 to 70 degrees, and in other months 170 and 320 degree winds are quite common.

Mechanical system and architectural structure of wind mills ^[4] :

Before taking a look at how Iranian windmills work, we should know about different parts and some idioms and words related to them. Below you can find the very important ones their plan and picture.

Mechanical system ^[5]:

1. Kharpol: To control the vertical axis in upper part a wooden axis is used with a diameter of 30 centimeters and about 4 meters long which stands on the side walls that the main axis of wind mill comes in the inner whole of the wall.
2. Tirpol: A wooden axis with 35 centimeters in diameter, in a round Shape contains 3 connected parts of pine wood. The turbin connects to it.
3. Bahoo: They are woods, 175 centimeters long and around 7 centimeters in diameter that connects the turbine to Tirpol.
4. Par: woods 15 to 20 centimeters wide and around 1 centimeter in diameter around 6 meters long that in each turbine 4 to 5 of them are connected to each other by Bahoo. Because of their resistance against wind the interchange the energy for wind mill.
5. Tavareh: It is a metal bow-tie like around 36 to 50 centimeters long which its width in the narrowest part (in the middle) is about 6 to 7 centimeters and the thickest part is 7 to 12 centimeters. Its diameter in the narrowest part is 2 centimeters and the thickest part is 12 centimeters this metal piece comes inside the

whole of upper stone mill and by the thick and metallic shaft which is at the end of Tir pol, it is run around and the windmill is run.

Figure 3. Section of a windmill in Nashtifan village. (Source: Writer)

6. Moushteh wood: A conical wood, 40 to 50 centimeters high and at least 3 to 4 centimeter in diameter and 13 to 15 centimeters in maximum by which the interval space between the stone mills can be changed so the grind size can be determined.

7. Leakage: A wood around 15 in diameter and 60 long in which from its whole inside wheat from supplier is moved to stone mill.

8. Lak lakeh: A wood 40 to 50 long and 5 centimeters in diameter which is connected to leakage from one end and the other is free on stone mill; by its vibration wheat comes into leakage entrance.

9. Daneh kesh: woods 2 canter in diameter and 10 to 12 centimeters long which is connected to the walls of wheat supplier by a string. Using optional numbers of them in leakage, the amount of wheat comes into stone mill can be determined and by its vibration wheat step comes into leakage.

10. Wind gate: It is a canal 50 centimeters wide and long that leads wind from the back of windmill to a place inside it and used for blowing wind into wheat and cleaning it.

Figure 4. Wind gate position on interior and exterior walls. (Source: Writer)

11. Stone mill: It is a consist of two pieces of upper lower part they are around 35 centimeters thick and weigh around 900 kilo grams. The upper part is not fixed while the lower part is fixed and it has a whole around 20 centimeters in diameter in center called Galougah from their friction wheat changes into flour.

Architectural Features:

One of the specifications of windmills is the mixture of mechanical science and architectural art and structure which is a native innovation and a masterpiece. The structure has a simple but wise structure. It has two different separate parts. They are the upper part and lower part. This structure has been made of the simplest material which was available at the time means Kahgel that is a mixture of mud and the wheat or barred dried plant . It shows the original native Iranian architecture that uses native constructing material and has simplicity and self sufficiency in the structure. Windmills create a beautiful sight seeing specially when they are built next to each other like the windmills in Nashtifan village. They are a result of smooth changing on soil which creates a symphony Between form and constructural material with environment. Nobody can forget the view of wooden turbines stand high in sky and challenge the wind.

Having Kahgel and mud break in their construction is a remarkable point in the structure of windmills because an important issue is the vibration caused by rotating of the turbine and the pressure created when wind touches the turbine. Using flexible and formed structure constructed by mud and break can tolerate them all well.

The upper part:

It is actually the out part of structure which has 3 walls about 4 meters high that stand on the roof of windmill.

Side walls: Two walls 50 to 60 centimeters in wide that start with the width of 4.5 at the bottom and end to 3.5 meter at top which control the upper part of windmill main axis (Tirpol).The step like form of side walls not only bring the stability for walls but also makes it possible to climb up the windmill for maintenance and service.

Back wall: This wall which confronts wind and is in eastern side is 35-40 centimeters wide and controls the confrontation of wind and turbine so there is a slot at the end northern part about 100 to 120 centimeters. It creates a force of wind flow as high as the wall height to turbines and the mill works. For more stability, the slot has been stitched by woods 10 centimeters in diameter.

The lower part:

This part makes a room for grinding activities and is about 9.5 meters long, 4.5 meters wide and 4 meters high. The occupied space is about 30 square meters. It has been made of mud and break too. In first section, activities such as storing wheat, and separating stuff from wheat by wind flow was led inside from the slot has been done and in second section the stone mill and wheat supplier (parkhoo) were located in this section, Tirpol connects to the upper store mill through a slot 60 centimeters wide in the roof.

Figure 7. A wind mill in Nashtifan. (Source: Writer)

Figure 8. Section of a wind mill in Nashtifan. (Source: Writer)

V. Position of wind mills:

Time interval for using windmills regarding the blowing time of 120 day winds is from spring to early in fall about 5 months of year because only at this time wind is strong enough to rotate the windmill turbine. It is interesting that it is exactly the time of harvest. Mostly, windmills were built in group and in a line that has different reasons:

- 1- Tilting windmill together causes unity and more resistance.
- 2- They made a business place for dealing wheat.
- 3- Because any structures before windmills reduces speed of wind the back yard land was specified to the graves yard.
- 4- On the other hand for the maximum use of wind speed a high land was a better place for them. So such a land had several windmills.

Figure 9. Windmill position. (Source: Writer)

History and changing process of European windmill:

In this section, for having a clearer picture of differences between Iranian and European windmills we will take a look at short history and changing process of them.

Based on documents, windmills were used in eastern part of Iran for the first time; but about how they went to Europe, there are different ideas that mention some of them:

1. It is said that vertical axis windmills went to Europe through Al-Andalus (Lynn White Jr. 1962) at the time of Muslim government. (Some historians like Lynn White Jr. hasn't accepted it.)
2. Some historians as Miceal Johonton believe that this science went to Europe through Byzantine Empire. (Lucas, 2006) Late medieval some similar cases like Iranian windmills were found in Greece, and Kandia, Crete.
3. Windmills went from east to west through Crusades.

However, the debate about whether the European vertical-shaft windmill evolved from the Islamic horizontal-shaft windmill or was an independent development remains unresolved. (Lucas, 2006) The oldest documents for existence of horizontal axis windmills are related early years of 12 A.D. Lynn White Jr. presents the first Document of windmill existence in Europe in 1185 in Weedley Yorkshire. (Lynn White Jr. 1962)The first windmills had a vertical pole that the whole windmill was rotating around it to be on wind path. This feature, considering different wind direction was a necessity. At the end of thirteenth century, windmill towers were built that instead of whole structure rotation only the wooden cap part was rotating, in 1745 the fantail, a small windmill mounted at right angles to the main sails, invited by Edmond lee that lead the turbines in wind direction. During 1772 to 1789, to improve windmill function various turbines were invented, finally in 1807, an engineer from Norfolk named William Cubitt invented a new generation of windmills that is the basis form of automatic windmills and so the permanent supervision over wind mills was stopped. ^[0]

Figure 10.A comparative picture of two windmills in Iran and Europe. (Source: Internet)

Comparative view over Iranian and European windmills

To clarify the basic differences between Iranian windmills and European types we will have a comparison here:

1. Iranian types rotate around a vertical axis while European ones have a horizontal axis.
2. Iranian types were lower than 10 meters high while European ones were more than twice of Iranian type high.
3. Iranian types were built in row and in a complex so they occupied less room while European ones were built in long distance intervals to optimized wind energy wage.
4. Iranian models the power transformed to the stone mill directly using the main axis but the European model this was done by gears.
5. In Iranian types because of having a fixed slot for wind entrance only in certain directions it was possible to have the proper function although because the turbines were located in a room with 3 walls it was possible to have a good function in spite of changing wind direction in a limited changing direction interval.
6. Unlike European type in Iranian models by changing of wind you don't need a rotating wind mill structure so you lose less energy.

Figure 11. A Comparative picture of mechanical system in European and Iranian windmill. (Source: Internet & Writer)

Conclusion:

Generally speaking, wind machines are divided into two groups based on their rotation axis: 1- vertical axis turbines 2- horizontal axis turbines. This direction can be found in historical Iranian and European windmills clearly.

Although from common and public point of view wind turbines are high towers with 4 wings rotating around a horizontal axis, but in today researches both types are considered important because each type is proper for a special climate and has its own economical and executive problems related to the location.

Having in mind what we discussed through these pages, it can easily be understood that the turbines are used these days to interchange wind energy to electricity and other forms of energy widely, is a science that goes back long ago in time, now the question is what is the importance of looking back in basics of this science.

Two different points of view should be considered:

The rational advantages of native technology used in Iranian windmill: Having documents for the integrative process of Iranian windmills during history and through centuries but this integrity process has been slowed down or stopped in recent centuries; while western engineers used wind turbines in producing of electricity by developing of this science in a way that this science has been exported to different parts of the world. But the question comes here into mind that weather these types of turbines produced in west is proper for windy climate of Iran and specially Eastern parts like Khorasan and Sistan. It should be asked, whether it is not the time for using the modern science to develop the native technology. If it is acceptable that the difference in Iranian and European windmills is in their rotation axis because of differences in Sistan climate and low lands of Europe, should not this be regarded today?

Vertical axis windmills are based on a long time experience as long as thousand years of history and it was their proper style for Iranian climate that caused them stand high through centuries and come to present time. So it seems necessary for Iranians to have a scientific and exact study over their specifications which is based on local features and characteristics to design new turbines proper for Iran climate (specially in Sistan and southern part of Khorasan where is the best location in Iran to make use of wind energy based on statistics). Another reason for having this technology in this part of Iran that makes it economical is scattered population and being far from industrial cities which makes transforming energy very expensive for this area.

2- Native technology as a cultural symbol: In spite at advantages for vertical axis windmills for unique condition of Iran climate, it is very important to keep in mind that this is a valuable memorial and a cultural symbol which can be preserved in two ways:

2.1. Reconstructing the remains windmills and changing them into public museums to introduce this birth place of windmills in the world.

2.2. Using them in a modern form and improving them by new technologies (for reducing waste energy by friction reduction, increasing in height or turbine width or decreasing in moving pieces weight and so on) while we preserve the harmonic structure and form with the local features.

Notes

1. The famous Arab historian and writer of Ebn Khaldoun history book.
2. This book was written by more than one person, maybe two or three one after the other wrote the book. Mohammad Taghi Bahar writes about it in this way: "The writer of Sistan history was Molana Shamsedin Mohammad Mavali that wrote the book in 448 in Tajodin Abolfazl time and Mahmud Ben Yousef Esfahani again rewrite it in brief between 465 to 725.
3. Shamsedin Abo Abdollah Mohammad Ebne Taleb Ansari Dameshgi Soufi was one of genius people of his time. He was informed about many fields of science and wrote some books. He was born in 645 and passed away in 727.
4. All maps, diagrams and 3d models drawn in this article related to Khaf windmills of Nashtifan village has been done by writers and students of Mashhad architecture college in 2009 named Morteza Aliabadi, Mehdi tabatabayee Yazdi, Sadegh Hashmi, Ehsan GHasemi .

Abstract

Starting from the concept of sustainable use of natural resources, cross-cutting theme in the research carried out by the authors, we propose a reflection on the enhancement practice of waste associated with the anthropization phenomena of a place. The combination of waste - resource while is not a new concept it's, from the environmental point of view, highly relevant and, therefore, there is a need to approach the problem in a systemic way promoting the diffusion of innovative technologies that can maximize the input of the "resources" in new vital, productive and designing circuits. It is evident, therefore, the necessity to set strategies of sustainable waste management through its recycle and reuse in order to contribute to the safeguard and conservation of such a resource. More specifically, from the systemization of critical issues observed to building and landscape scale with respect to the main human activities, the living, the authors suggest a synthesis framework about best practices for the recovery, reuse and recycling in the Architecture project (in particular: waste landscape, C&D materials, storm water, urban gardens) framing this approach in a logic of technological and design opportunities. Even at national and international level, in order to comply with the directions contained in the various Framework Directives, there are numerous initiatives oriented both to the reduction of waste production and to the promotion of innovative strategies by working directly on the sustainability of construction.

Key words: waste landscape, building waste, storm water, urban gardens

1. Waste landscapes: abandoning / integration characters (Francesca Muzzillo)

Two contrasting characters are contained in a "waste landscape". They make us become more aware of how human behavior can easily result in a danger. But at the same time we know that wastes are in a certain sense inherent in urban processes. We should therefore better work to change their intrinsic values, instead of trying to eliminate them.

Alan Berger says: "Contemporary modes of industrial production, driven by economical and consumerist influences, contribute to urbanization and the formation of waste landscapes – meaning actual waste (such as municipal solid waste, sewage, scrap metal, etc.), wasted places (such as huge parking lots, retail malls, etc.). The terms urban sprawl and the rhetorics of pro- and anti-urban sprawl advocates all but obsolescence under the realization that there is no growth without waste and that urban growth and drop go hand in hand, and always have, not because of anything human, or indeed even pertaining to life, but due to physics itself. Complex processes must export waste to their boundaries in order to maintain and grow. This is the lesson that designers of the built environment should learn from nonequilibrium thermodynamics" [1].

From this point of view in a recent exhibition in Rome the concept of recycle has been investigated in every possible meaning of the word with reference to architecture: in each case recycling is considered for its capability of creating innovative practice [2]. This is an opportunity also for young designers and with this reference in the mind students could also make experimentations into their academic works. [3].

Indeed, the term “waste landscape” is new and what it exactly means is not completely defined, but, speaking of “waste landscape”, we essentially include an idea of marginalized places in which the designer wants to operate in order to make an improvement. This improvement not necessarily corresponds to an effort to bring the places back to the origins, but, even with contemporary and innovative shapes, the projects go in the direction of a primordial simple relationship with nature.

“By shaping these typically marginalized places in an ecologically revealing way, we can begin to unveil and recognize the destructive effects of our consumptive lifestyles. But more importantly, we can create spaces that inspire people to contemplate and recognize the value of environmental quality as well as the development of strategies that enhance ecological function. As places that facilitate meaningful human interaction and activity focused on recycling, waste and reuse operations can galvanize a group of people around a common cause. They can help facilitate the paradigm shift from mindless consumption to thoughtful conservation. There is immense potential for waste places to act as local rallying points – spaces that remind us that there is such a thing as enough” [4].

No doubt that creating a new sense of place for the identity of a community is one of the most important characteristics of the design process for waste landscape architecture. But it is also, perhaps, the most difficult characteristic to restore. It is difficult suggesting a new identity which can merge again to become the core of a place. So a careful research of community values is fundamental, not only as regards the compositional features but also with reference to “common images” in perceptual, sociological and mental sense. A project should depend on the continuous interaction between architecture and social perception of damaged places, which is never fixed. In fact, it is possible to notice the continuously changeable presence of external elements, contributing to the identification of a place in a mobile relation between natural elements and life of people. It follows that we should search solutions which are at once sociological and perceptual. Obviously the way in which the natural elements are perceived depends more on the morphological and material aggregation than on sociological elements. And the consideration of vegetation and water as constructive materials encourages to value natural materials with a special attention to their possibility of being flexible. Different mutable prevailing conditions are given by the nature itself of natural components, which are dynamic into aggregation. The entrance of the light, water, air and vegetation, forced by internal directions, respects the core of the place.

Now, how should we operate during the design process through data gathering, evaluation of alternatives, schematic design and design development, focusing on the idea that the flexibility should be the guideline for new sustainable integrations of wastes?

Probably it is on the borders of a waste landscape that we could conveniently operate. The borders between the internal areas and the external ones of a waste landscape are permeable in these arches for the connections between the outside and the inside, in order to find single parts joined together with flowing relations. The idea of Recycling for regenerating a place is the most apt process to create relations among economic, aesthetic, social values into a dynamic ecosystem.

produce beautiful landscapes that reduce maintenance costs and protect the environment.

Overall it is evident that, especially when industrial processes have radically changed the physical appearances of places, whatever a design process could pursue, it is signed by a common denominator: it is an idea of “reduction”, taking account of reduced water, nourishment, costs and energy.

2. Construction and demolition waste: towards a “recycling society” (Caterina Frettoloso)

The theme of rehabilitation of the existing built heritage in an energy and environmental key puts designers interesting challenges related not only to the issues concerning the specific character of the design solutions to be adopted, but also to the delicate problem of construction and demolition (C&D) waste disposal. Such waste consists mostly of inert materials and then, in smaller amounts, of metals, plastics, wood, glass, often “scrap” processing of construction sites, and above all, a large variety of small and big building components from buildings to be demolished.

From the perspective of the control and reduction of the ecological footprint of the building and demolishing activity (even in case of renovation) there is a need, on the one hand, of a selective approach to the demolition phases, on the other hand the adoption of controlled ways of waste recovery associated with such transformation processes.

This recovery can be aimed at re-use and/or recycling, depending on specific considerations related mainly to building material characteristics of waste, construction site logistics and available resources. It is important

to note that recovery operations must be designed in a flexible space-time point of view, that is C&D waste can and should be placed in any building process, regardless of the construction they come from.

In 2008 approximately 860 million tons of waste in the construction industry were produced in Europe, about 33% of the overall waste production in Europe (Source: Eurostat). In the same year the Framework Directive 2008/98/EC was enacted with the hope that it would have produced "a change of mind in the way one considers the waste – from unwanted weight to precious resource – [contributing] to transform Europe into a "recycling Society" [5]. Article 11 (b), in fact, is worded as follows: "by 2020, preparing for re-use, recycling and other material recovery, including filling operations which use waste to replace other materials, non-hazardous construction and demolition waste, (...), will be increased at least at 70% by weight".

These are the ambitious goals, but up to now, with the exception of virtuous countries such as the Netherlands, which has a percentage of 100% of recycled C&D waste, for the year 2008, closely followed by the United Kingdom, the Czech Republic and Germany (with amounts ranging from 79% to 37%), Italy occupies lower ranking places just with 9% [6].

Yet the advantages linked with a rational approach to C&D waste management are now a common heritage of knowledge and concern mainly:

- a) reduction of waste disposal landfill sites;
- b) saving of natural resources, through the integrated use of both natural and recycled aggregates;
- c) new opportunities in economic terms related to the market of recycled aggregates.

On the other hand, the not so clear distinction between recycled and waste material (an aspect also faced in the Directive mentioned above), as well as the relatively low cost of C&D waste disposal landfill sites, at least in Italy, and other considerations related to both the cultural specificities of each place and the building techniques used that not always facilitate the selective divestment of the construction, are combined to hinder the diffusion of practices aimed at rational and sustainable criteria.

2.1 Comparing experiences

In Italy, besides environmental legislation increasingly oriented to a performance approach, the issue about C&D waste is dealt in an operating way in Protocollo ITACA, already in the version of 2004. The evaluation on "environmental burdens" finds "the construction site solid waste management" as one of the three categories of requirements to be observed in the construction/rehabilitation of a building of quality. The requirement consists in reducing both the construction and demolition waste and the consumption of non-renewable raw materials and, from a wider point of view, promoting an eco-friendly management of the waste; the performance indicator to be used is the "relationship between the weight of waste which is not sent to landfills and overall weight of solid waste (%)" [7].

Meaningful experiences in Italy in such a sense are found already in the late 1990s, in harmony with the "innovative" content introduced by Ronchi Decree (05/02/97 - n. 22) even though today it is not possible to track meaningful feedback between regulatory framework and operational practices. Among the projects of public-private partnerships, the Program Agreement promoted by the Province of Bologna and in force since 2002 is an interesting example. The project goal consists in "promoting an efficient, effective, economical and transparent management of C&D residues, based on the cooperation of all public and private stakeholders involved in the waste cycle. The Program Agreement includes a whole of actions that Subscribers undertake to implement all phases of the waste cycle in order to minimize hazards, reduce the quantity and increase recovery and recycling; [specifying] the modalities and procedures taken for the proper execution of certain steps particularly meaningful for construction and demolition waste management"[8].

Recently, Emilia Romagna was the main character of a project on the production of recycled aggregates from inert waste, entitled SARMa (Sustainable Aggregates Resource Management), a project co-financed by the European Union within the projects for the South East Europe (SEE). "The project aims at studying the sustainable aggregates management, and, among other activities on legislation, planning and control of aggregates resource, foresees specific close examinations on the evolution of inert waste recycling. Among the main aims of the project, there is the one to define the Sustainable Supply Mix (SSM), represented by a mixture of natural aggregates, recycled aggregates, sub-products of mining and earth and rock excavation, in order to maximize the benefits provided by using aggregates from various sources, including unconventional sources" [9].

Even at European level, in order to comply with the directions contained in the Framework Directive there are numerous initiatives oriented, on the one hand to the reduction of C&D waste production, on the other hand to the promotion of a market, not only of recycled aggregates, but also of building components to be re-used. Such an aim is pursued also by working directly on the sustainability of construction testing, for example, technologies and construction techniques that consider, among many variables, disposal and its relative ways of demolition.

An example of extreme interest, especially for its technical - operational aspect, is the experience made in Boston for the construction of the Big Dig, the motorway route which crosses the city for a long stretch going ahead with an underground tunnel. The construction of this tunnel, which has presented a series of problems relating to both engineering and geological and archaeological aspects, creating a huge amount of infrastructural steel and concrete material, has given the chance to make an interesting planning experiment. The design and the subsequent construction of the Big Dig House by the Single Speed Design architects, addresses the delicate need to recover/re-use the waste materials, "creating a prototype repeatable anywhere that had the intent to open a new course for building waste recycling also in quality-driven architecture. (...) The structural system of this house of about 300 square meters consists of steel and concrete discarded from Boston's Big Dig and uses more than 30 tons of recovered materials. The project proposes above all a protocol of material reassembly that can constitute a pattern of prefabricated production of components made of material from recovered building material " [10].

3. An innovative system for water reuse: the "green street" (Rossella Franchino)

It is evident, therefore, the necessity to set strategies of sustainable water management through its recycle and reuse in order to contribute to the safeguard and conservation of such a resource. Within the rational water management in urbanized territories the recovery and reuse of rainwater is particularly interesting.

In the urban context the continuous increasing of impermeable surfaces has often determined great problems of erosions and flooding besides altering the hydrologic natural water cycle damaging the balance among precipitation, evaporation, groundwater recharge and surface outflow. It is evident that it is imposed, therefore, a change of attitude in the water management in urbanized territories that must follow the natural cycle. The actions to be made for a sustainable management, therefore, are those ones to re-waterproof the ground, allow the infiltration of rainwater as much as possible and recover them in order to reuse them.

In order to check outflows and infiltrations of the meteoric water in the ground, both permeable paving and street gutter can be used, as well as infiltration basin, French drainage basin and rain gardens.

The rainwater collection for their following reuse can happen either with simple collecting systems exploiting ground pendency and permeable surface, or with more complex water collecting systems from impermeable surfaces such as roofs of buildings, paved surfaces, etc.

In the water reuse cycle, the building represents the central element of the network: it is able, in fact, to join the resource use exigencies with the same reuse ones, in an optic of sustainable environment.

A system for recovering and re-using rainwater for buildings is set up in such a way as to allow for the collection of water from roofs, terraces and pavement gutters and to re-use it, after appropriate treatment, for various uses such as: WC flushes, car washes, washing exterior pavement areas, watering kitchen gardens, lawn and green-area irrigation, air-conditioners and heat pumps, reintegration water for anti-incendiary use and even for some electrical appliances like washing machines, appropriately fitted.

The system involves several phases, the first of which is collection. All impermeable surfaces are suitable as areas for collecting rainwater. Obviously, the greater the area for collection, the greater the amount of rainwater that can be collected for re-use.

The next phase is that of filtration. A filter is fitted that permits the removal of those elements which deteriorate the quality of the water in the water-tanks. After this, storage is required for the water in holding-tanks. Some of these are fitted with a system that slows and regulates input flow in order to prevent the disturbance of sediment that collects on the bottom. The tanks can be positioned below ground outside the building or in basement spaces or storage spaces inside the building. Those tanks which are placed outside have the advantage of being hidden from sight and protected from accidental damage while, those placed inside have the advantage of not requiring any tampering with the external system for their positioning and therefore eliminating the risk of damage to the main system apparatus. Furthermore, it is preferable to place the latter in a vertical position so as to reduce the amount of space they occupy and to position them in parallel in order to increase capacity. The tank contains a pump, which through a control unit passes the water into the recovery plant.

Within the sustainable water management of urbanized territories a particularly interesting case study, that can be considered as a virtuous example of "water management", that is planning of systems that exploit rain as a resource is that one of Portland city in Oregon.

In 2007 this city structured and carried out an innovative project of sustainable rain water management according to the general concept of "water management." The rainwater disconnected from the sewerage has been collected locally, treated with natural systems and partly reused and partly subsequently reintroduced in the groundwater. It was carried out a real "diversified water collection" through systems of garden roofs, filtering gardens, green streets, diffused in the whole city. Practically most of the impermeable surfaces have been replaced by permeable layouts endowed with vegetation and able to absorb and filter

water and in some cases to store it, too. The point of strength of such a project is the so-called "green streets", that are the elements allowing collection and reuse of rainwater, but they are also more because truly they improve the liveability of the districts and they add green spaces to the city. The system consists of a net of green bands along streets and pavements endowed with permeability so that they allow the rain water collection in established collecting areas where natural treatments happen before their entry in the groundwater. Besides, naturalistic engineering technologies are used to check water outflows.

Such "green streets" sensitively reduce meteoric water runoff, demolishing together with the quantity of rain that reaches the surface from the street and subsequently the final receptor bodies of water, also the pollutants that rain takes from the street mantle.

Moreover, the municipality of Portland tried to carry out other "green streets", besides those ones already built, and planning new districts and carry out the rehabilitation of the existing districts in the viewpoint of a sustainable rainwater management also allocating incentives and foreseeing free technical advice to the residents who want to carry out either a garden on their own roof or a rain garden in front of their own residence. According to the data 2011 of Portland Bureau of Environmental Services, the "green streets" allowed the recovery of 140 million litres of rainwater and their expansion would allow to reach 30 million litres per year.

4. The urban gardens as a synonym for waste recycling, recovery and reduction (Fosca Tortorelli)

We usually think of urban gardens as a way to occupy areas of the city, in order to fill with something alive, beautiful and useful spaces that are left free from building material, by choice or by chance. But perhaps our way of thinking the city – the city at the center and the surrounding countryside in the background – is no longer realistic. However, what the American urban historian Richard Ingersoll writes in *Sprawltown* may as well be true: According to him, almost without notice, the city has disappeared and has been replaced by the "sprawl", a periurban area characterized by shopping centers, highways, parking lots, houses, and empty spaces. In such a sprawl, the citizen has become a sort of tourist, belonging less and less to his place, which he uses mainly through consumption. Thus, Ingersoll dismantles the city's old image and makes of agriculture, along with urban gardens, the tool for citizens to get back their space and role. The countryside has gone back "inside" [11].

In these years, cities are organized on the basis of criteria that are increasingly demanding speed and space. It is the American model which has won and has been copied around the world, even in poor countries which could not really afford it. Sprawling cities seem uncoordinated, even when they are the result of planning, and make us feel disoriented. The territories have been robbed and injured by an overdose of infrastructure, and unfortunately such a way of placing urban functions is environmentally unfit and cause of great waste. The idea of a urban garden is always positive, because it is an expression of creativity and sometimes a need, although it is not possible to contribute positively to the urban system with a "spontaneous" or "anarchic" garden.

People should think of urban gardens from two viewpoints: the natural and the social. The spontaneous garden almost never contributes to the spontaneous birth of a social network while through a collective and coordinated management of urban gardens the two functions are always preserved..

The social garden is in itself a form of participatory management of space. However, if you do social activities and exchanges are not present, then social gardens will end up becoming lots, which are intensively cultivated and close to one another. Many municipalities give to urban gardens' management a landscaped approach. Leveraging on the assumption that the landscape is a public good, they emphasize how the activities of urban farmers are not aimed only to the noble purpose of self-production of good fresh, seasonal and natural food. In many cases it has been possible to overcome the tendency towards intrinsic closure, instilling in urban farmers the pride arising from the recognition of their work as a social mission aimed to build a better city.

In order to promote and keep this social function alive, activities are organized in these open gardens, which emphasize the nature of collective goods, such as meetings, social dinners, tastings, lectures on botanics, and so on.

A good example is the case of the small English town of Todmorden, located near the center of the United Kingdom, where all began thanks to the initiative of Pam Warhurst, who, cultivating fruit and vegetable in the garden of his house, decided to put signs in order to invite by-passers to come and collect what they wanted.

After a few months, a movement of people ready to help Pam started to develop. In this way, gardens, lawns and vacant lots started to be reconverted in public places, where agricultural products would be available to all citizens. This led to the birth of a community legally constituted and called "Incredible Edible"[12].

All members decided to re-evaluate the active role one can play in making the way of living the city more sustainable. In this way, residents can do their shopping and eat fresh seasonal products. The overall goal is even more ambitious: becoming a self-sufficient city by 2018. But beyond this there is also the aim to create a conscious movement, engaged in the construction of sustainable local economy.

Other factors connected with such an urban agricultural practice are important, since they highlight how waste and all that is related to the activity itself can undergo a transformation and be characterised by a sustainable use.

Up to today, project and management philosophy has given life to a strategy involving the revitalization of inner parts of the city, organising such spaces into urban gardens units.

An efficient regulation of such urban gardens units will have to inform the request and supply modality, with the expectation that vegetable waste will be transformed into compost.

The assignees will deliver in appropriate places vegetal material coming from each urban garden, in small pieces and in groups, with pre-arranged shifts decided by the members of each urban gardens units. They will provide whatever is necessary for the transformation of the substance into natural fertilizer or final compost.

In some Italian cases, one could realise that through such a *modus operandi* "a good urban garden" contributes significantly to the reduction of waste production, to low cost production of a fertilizer useful in order to keep the fertility of cultivated fields, and to a reduction of chemical fertilization and weeding.

Another recent example is that of Genova[13], which in collaboration with Italia Nostra, Coldiretti Liguria, Agricultural Institute "Marsano" and Amiu, has given birth to "innovative urban gardens", an initiative within the Smart City project. They are lots with a wider surface compared to urban gardens, which are preferably assigned to associations or groups in order to promote environmental education, develop projects to reclaim local traditions as well as traditions from the ancient 'cultivar', integrating them by using new methodologies. It's interesting to analyse the dual aim pursued by the initiative; the chosen urban areas are subtracted to urban blight (deterioration) and neglected; environmentally friendly agricultural practices are carried out, preserving biodiversity and contributing to the collection of waste and the development of composting, reducing the use of agrochemical products (fertilizers and pesticides), with the use of organic and integrated farming systems.

It is remarkable that in such areas itineraries related to environmental education for school and for anyone who could be interested have been organised. To become assignee of an urban garden is sufficient that the citizen participates to the public municipal announcement. In this way, the assignee may cultivate the land entrusted to him and get a production of flowers, fruits and vegetables for themselves and their families.

Research, experimentation and social dimension of the residential building in Naples between the end of 19th century and the beginning of 20th.

Maria Rosaria DELL'AMICO

Facoltà di Architettura, Seconda Università di Napoli, Italia
mariarosaria.dellamico@virgilio.it

Abstract

In the context of the urban and architectural changes in Naples after the dramatic 18th century's cholera infection, the topic of housing became a new researching field aiming at the adaptation of the design-based zoning constraints to the social changing needs.

On the basis of the influences of the great Exhibitions, the trade practice of architects and engineers who took part in the carrying out of the wide programme of the urban Renewal and Extension of Naples was characterized by the original planning approach based on the research for a social dimension of architecture, giving a contribution to the definition of the formal aspects of a folkloristic and bourgeois Naples.

The technical administration of the Municipality developed few housing philanthropic and cooperative initiatives and proposals, the new housing typologies were elaborated by experts belonging to the Renewal Company who played a fundamental role in the planning of the buildings. The housing policy adopted by the Company was oriented towards a differentiated building offer, according to the different social classes and housing typologies which, joining quality targets and urban decorum to the property market standards, gave to Naples the role of promising building laboratory to experiment building typologies.

Key words: Residential Buildings, Naples, Renewal, Typologies, Property Market Policy.

After the joining to the new unified Country and without its role of capital, Naples was living a deep political change and an economic change but, at the same time, rich in art, urban changes, strong architectural interventions which underlined the development of the contemporary city. Since 1860 we have recorded a great urban and building continuum between the interventions of the pre-Unitarian Government and the new Municipality, managed by architects and engineers dating to Bourbon period (among whom Antonio Niccolini, Stefano Gasse, Luigi Malesci, Gaetano Genovese, Orazio Angelini, Francesco Saponieri, Enrico Alvino, Luigi Giura) who faced the topics of rebuilding and joining the western outskirts, used by middle class housing, to the eastern one, housing industrial settlements and working areas, and the "modernization" of the city-centre to improve the living conditions of poor people [1]. Important rules were given by Garibaldi's provisional Government that, expropriating and expanding the outskirts (building a bourgeois district in Chiaia) and restoring the city-centre (the district of the Duomo), promoted the creation of the first popular borough in order to offer housing to lower classes: «a Government risen by people and living for people, aiming at satisfying this one, trying to give it healthy, comfortable, cheap houses» [2]. Confirming the continuum in the projects and plans of Bourbon line, the post-unitarian rules couldn't join the urban changes to the economic and industrial development of the town and proposed the introduction of a new economic strategy linked to the value of lands and buildings and given to privates or house sales companies [3]. The different economies of the lands gave rise to a new distribution of social classes that modified the 18th century's urban asset characterized by the presence of a "vertical" stratification in the same places and

buildings [4]. The urban architectural interventions in the first twenty years before the unification of Italy were about the building of a joining way between Museo and Port'Alba, in the areas where there was the edification of Accademia delle Belle Arti of Alvino and, later, the Galleria Principe of Naples (1876-83) by Breglia and De Novellis; the last part of Corso Maria Teresa, joining western and eastern area; dei Fossi street, today Corso Garibaldi, joining the railway station to Casanova bridge and Marina square; lastly they started the sea reclamation works of the area belonging to Chiaia, from Chiatamone to Mergellina, where they projected middle class residential settlements [5]. However, as it was an urban policy mainly free of an urban global vision and a coordinating action, they made a partial restoration not considering the problem of an overwhelming and bad socio-sanitary conditions of the central districts of the sections of Porto, Pendino, Mercato and Vicaria where there was a concentration of poor people. From a theoretic point of view the situation has greatly been studied since 1861 by Marino Turchi – Full Professor of health education, city councilor and chairman of a philanthropic association involved in the building of workers' houses – who produced a document essential to the knowledge of the tragic sanitary situation of Naples. The decadence of the capital could be associated to the social urban economic problems, consequently, professor Turchi underlined the necessity to check the sewer system and the water network, the building rules, the opening of new streets and the building of new buildings in the most degraded areas [6]. Mr Turchi underlined the worst living conditions among people of lower classes and proposed, without a technical solution, to use the urban reshape planned to rebuild the loop line between the station and the city-centre to clear up the lower districts, so changing the old urban asset [7]. According to such information and the international urban trends based on Haussman's model in Paris, the common urban topic to transform the existing asset was to project a stretching road line corresponding to the double target of improving the link between the railway station and the city-centre and to clear up the lower districts [8].

Despite the two competitions the Municipality had published in 1862 and 1871, witnessing the training level of experts about the foreign models, it was only in 1884 that the municipality was obliged to present a program of urban restoration, known as Renewal, when there was a new epidemic of cholera, the eighth after 1836 which affected the lower districts spreading out all over the city [9].

As it was an expensive intervention it was necessary to get an economic support by the Government which promulgated, after a long legal administrative iter, a special law supported by the foreign minister, Stanislao Mancini, Mayor of the city, Nicola Amore, Agostino Depretis, oncen Prime Minister, and by Prefetto Sanseverino, published on Jan. 15th 1885, n. 2892 [10]. Such a law pointed all the areas which could be considered useful at a sanitary building revival of the city which the Municipality owned by extraordinary intervention tools, among which special laws useful at expropriating demolishing buildings [11]. It was the first time Italy faced such a huge programme to reorganize a big city on rational and modern basis through a strategy which considered the sanitary renewal a key point to redefine and specialize the components of the urban environment [12]. The key points of the intervention were in the creation of a modern sewage system and a supply of drinking water, the demolition of the warehouses, the widening of the road network and the enlargement of the eastern city side, from strada Arenaccia to the surroundings of muro finanziere, by realizing the new working industrial district. According to such criteria Adolfo Giambarda, on October 18th 1884 presented to the Mayor Nicola Amore a general project on the base of another project dating back to 1871, dealing with the opening of a main road from the station to the crossing of via Medina and via S. Bartolomeo where they could create an octagonal square joined to via Toledo. Sixteen orthogonal roads towards the "straight stretch" plus other parallel roads should define a variegated texture modifying the existing urban tissue. To enlarge the structure they proposed to prolong the north side of Corso Garibaldi to piazza Ottocalli, before the "Albergo dei poveri", and the realization of a working district around three streets rising from the Reclusorio till the Arenaccia. To reduce the density of the central areas and housing evacuated people from the area they wanted to clear up, they envisaged the building of new districts on the outskirts at: Arenaccia, Ottocalli, Ponti Rossi, Miradois, Materdei, Vomero, Arenella, Belvedere, Principe Amedeo, Santa Brigida and Santa Lucia where they thought to open a coastal road [13]. The proposal of the Municipality about the enlargement was approved by the law 25th July 1885, also to the industrial popular middle classes. As regards the projects presented to the Municipality by the well-known professionals they named a speciality commission divided in three sub-commissions aiming at analyzing the problems about the sewage system, the redevelop of the low districts and the new buildings [14]. According to the survey of the Commission they decided to give the project of the work to the engineer Giambarda who modified the path of the straight stretch (where there were 14 instead of 16 roads of a width of 12 or 10 m) reducing it till Piazza Borsa where it branches off in two roads (via Depretis & via Guglielmo Sanfelice) to reach Piazza Municipio and via Medina while at the crossroad of via Duomo it lets in an octagonal square (piazza Nicola Amore) [15]. The straight stretch was the main axis of a new system of relationships between the centre and the outskirts: at east, next to the future industrial area, the artery linked the centre to the new intensive

districts for the working classes; at west, through a pre-existing road system it joined the middle and high class districts. The plan was definitely approved on July 22nd 1886 and the Municipality decided to put a commissioner in charge of getting the three main interventions: the expropriation of the lands and new buildings; the subdivision of the area in many different concessions and to conclude new buildings before demolishing the old firms and to build many cheap houses to grant housing to lower classes [16].

As regards the residential building, the involvement of the Municipality paid attention to people needs, identifying new typologies of cheap houses – not only in the east part of the city but also at Materdei, S. Efremo and Margherita di Savoia – through new criteria about «modern building devices and sanitary rules», a special need many researchers (among whom Turchi) previously asked promoting a philanthropic association aiming at improving poor and workers' living conditions and the Municipality too emanated a concourse to study the best types of cheap houses, on May 18th 1887 [17].

Reading the report of the Municipality dating back to 1888 about the development of such a project we understand that some of the proposals were based on the most modern national and international experiences, so that they could be “imposed” as prototypes to new private Associations aiming at building cheap houses [18]. As regards the choice of new cheap housings, the Municipality makes reference to European advertisements about popular houses, e.g. É. Muller & É. Cacheux's book *Les Habitations ouvrières en tous pays*, Paris 1879 and the two volumes by the German association in favor of the social policy *Die Wohnungsnoth der ärmeren Klassen in deutschen Großstädten und Vorschläge zu deren Abhülfe, Gutachten und Berichte herausgegeben* 1886, about the problem of the residential building in Germany, England and France under the socio-economic building point of view, making reference to a wide important bibliography and the building drawings looking like those ones in Rome, in Testaccio district, and in Naples on “S. Efremo Vecchio's hill”. In order to monitor the conformity during the realization the Municipality asked for a special commission made up of three to five councillors. Moreover they monitored the uniformity of the building typology «according to the area they rose up and the coordination to the facades of the four main squares and the straight stretch which should be harmonized and decorated» [19].

The Municipality thought to solve the housing problems through a simple imposition to the builders of building typologies, creating rules about the esthetic of the facades, optimizing areal and light standards but without any limit to the rent prices, so deleting the benefits for poor people by 1885's law consequently creating a speculation. As we know the working phase of such a restoring plan was limited by economic interests of not-local important financial societies which had been attracted by the chance to get economic benefits in Naples. Consequently, there was the arrival of many Italian and European experienced researchers who gave a great contribution to the modern architectural production in Naples. The professionalism of people who have long been involved in the writing of the building projects was characterized by a new planning approach based on the research for a social dimension of architecture, so presenting a new graduate-professional the “social engineer” capable of reorganizing urban social and building problems and the dynamics of house sales so joining reality and utopia, sustainable economic settlements [20].

On October 20th 1888 the Municipality assigned the restoration works to «Società pel Risanamento di Napoli» by a 25-year agreement, a consortium of banks and northern building enterprises whose capitals were given by the Società Generale di Credito Mobiliare Italiano, by Banca Generale and Banca Subalpina di Milano, by Società Generale Immobiliare dei Lavori di Utilità Pubblica, by Banca di Torino and F.lli Marsaglia enterprise [21]. The new Company developed new modern housing models which, joining quality targets and urban decorum to the requests of the house sale market, gave to the big building site of Naples the role of laboratory to experiment building typologies [22].

The study of new types of housing was started by such a Company before its constitution when, in September 1888, the engineer Lodovico Martinoli, next general manager of the recovery plans and manager of the railway station of Sardinia, who studied the typology of residential housing in Naples [23], assigned to the engineer Piero Paolo Quaglia from Lombardy the writing of different housing typologies to get the approval of the banks involved in the financial aspects of the building work and, later, to define the terms of the contract work with the Municipality of Naples [24]. Once they got the assent of the graphs and the building work assignment, the Company checked the expropriations and the demolition of the buildings, the planning of the elegant buildings all along Corso Umberto I, corso Garibaldi and the main squares; popular and cheap houses between piazza Carlo III, via Arenaccia and part of the districts of Loreto and S. Antonio Abate, or the districts called “della Maddalena”, San Cosmo's, the old English cemetery, Arenaccia and Cavalcatioio [25]. The company instituted an Office of Art, later incorporated in the Ufficio Tecnico, whose management was given to Quaglia, aiming at planning both popular building housing and elegant «modern buildings not subordinated to other cities' ...always been up-to-dated about any kind of progress both in Italy and outside» [26]. Piero Paolo Quaglia became the main character in such a complex building Company

where he played an important role in solving architectural aspects of the Restoring plan [27]. He was particularly appreciated by Roman financial international building sectors and this influenced his appointment as head of technical studies of the Restoring Company. Strong relationships with the main representatives of the banks, among whom the Senator Antonio Allievi, director of "Banca Generale di Roma", allowed him a study tour in Europe subsidized by "Cassa di risparmio di Lombardia" «so that he was one among many artists who perfectly knew the building problems others faced in Austria, Germany and France to avoid in Rome and in the new Italy» [28]. The engineer has known Naples since 1885 very well, because, on behalf of Deserti & Fantoni building company of Rome, he elaborated some important urban and architectural projects, never carried out, such as: the drainage of Santa Brigida district, the new gallery Umberto I, a hotel in piazza Municipio, Rione Carità, the new district Santa Lucia [29].

Quaglia's main collaborator was the architect Vincenzo Benvenuti from Foligno (1858-1904), former partner since 1885 at "Studio di architettura" of Rome, they both participated in the building of the new Parliament in Rome and the restoration of piazza Carità and Rione Monteoliveto in Naples where, by the use of courtyard houses, they anticipated project solutions developed for the Company of the Renewal [30]. Apart from Benvenuti the project group of the Company is made up of interesting people, engaged as "drawers", among whom Urbano Neri, architect of Rome, Quaglia's collaborator in restoring the building of the Parliament, piazza Colonna in Rome and, in 1892, the building of the prefect's office in Benevento. In Rome he independently realized a proposal for the urban plan and the building of the Ponte Vittorio Emanuele on Tevere [31].

Stanislao De Mata, engineer of Naples who was born in 1872, was engaged by the Company in 1889 to deal with the lie of the buildings, the roads, the areas of Porto-Mandracchio, in Pietro Colletta street, in Depretis street, in Alessandro Poerio street, all along the straight stretch. He planned many buildings and terraced houses in Vomero, the corner building between via dei Mille and via San Pasquale (lotto XII), twin buildings along via Crispi, before the former Loreto Mare and planned the renewal of the city of Potenza in 1914 [32]. The Company entrusted the elaboration of new proposals about the "experimenting" plan of Renewal to external experts among whom the architects De Paschinis, Guerra and Comencini [34]. The last one (1849-1924) arrived in Naples in 1884 as technician of Società Veneta, and the Municipality engaged him to transform piazza Municipio and Maschio Angioino. He restored some of "palazzi umbertini", planned the "*des Londres* and Santa Lucia" hotels inspired to the new floral trend, and many restoring urban interventions in the western part of Naples [35].

The main role in organizing the Company was played by the engineer Giuseppe Florio from Naples who was asked to manage the building works. In 1885, together with the engineers Francesco Carrelli and Gennaro Sommella, he was the author of the project of the urban plan of Pozzuoli; during his working activity he elaborated the water-supply of the Serino, carried out the Teatro di Corato, the bathing establishment of bagni d'Ischia, the hotel of Telese and the big project for the new old people's home Misericordia in Casamicciola [36].

The engineer Ettore Vitale (1844-1935) from Naples was particularly important in managing the Company, he was elected chairman in 1901; since 1890 he has planned many residential buildings at Sirignano district (Caravita palace), Vasto district, Corso Vittorio Emanuele (Monsolini palace), via Duomo, via dei Mille (Betocchi palace), via Crispi, piazza Vittoria (De Senna palace) and Posillipo (Villa Maria). He managed the renewal of Ospedale degli Incurabili and Palazzo Corigliano in San Domenico square; he planned industrial buildings in via Arenaccia (Lancellotti plant), Ponti Rossi (Wenner factory 1905), the building of commercial warehouse in Corso Garibaldi and the hotel Londra in piazza Municipio. He managed the plumbing system of Regi Lagni, Caserta and Taranto, the railway Rocchetta-Avellino, the harbor station of Molo angioino, the quay of Santa Lucia and the dry dock in the port of Palermo; he took part in the competition to solve the problem of the sewage system of Naples in an innovative way; together with a group of bankers and businessmen he created a company called "Ghiacciaie e Nevriere napoletane" whose he planned the headquarter in Naples at corso Novara 7, and in Libya and in Eritrea [37].

Attilio Rota, manager of the renewal work, was the chief engineer of a group of local inspectors who monitored the building and the test of many buildings [38]. In 1884 he planned, together with Luigi Scoppa, a new district at Ponti Rossi consecrated to the small manufacturer activities, the so-called "*arti rumorose e incomode*", housing workers in order to renew the city centre [39].

The industrial engineer Eduardo Talamo (Cava dei Tirreni 1858- Roma 1916)'s activity was very important, in 1904 he managed the Istituto Romano dei Beni Stabili created by the Banca d'Italia about a planned management of the real estate contributing to the residential building reform and the renewal of Rome as capital [40]. Senator Pasquale Atenolfi's nephew, chairman of the Renewal Company from 1893 to 98, Talamo managed the expropriations and the building about the renewal works and elaborated building typologies that Quaglia considered negative [41]. In 1887 together with Gustavo Scielzo, he planned a

stretching of via Caracciolo till Capo Posillipo and was the tester of Galleria Umberto I built between 1887 and 1890 by Esquilino business firm and Deserti & Fantoni company according to engineer Emanuele Rocco's plan [42]. In 1897 after the Banca d'Italia got lands in the new western district of Chiaia, consequently the opening of via Filangieri, via dei Mille and the stretching of via San Pasquale a Chiaia till parco Margherita, the engineer was engaged by such a bank to liquidate the estate. In order to enhance the estate policy and to increase the estate profitability, Talamo planned a division of the original 15 parcels in 44 plots of land, characterized by the presence of buildings such as: small villas and small blocks of flats [43]. The planning solution looked like a modern bourgeois district and aimed at joining the urban and architectural developments of Naples to the National and European ones.

The engineer Vincenzo Veccia, external collaborator of the Banca d'Italia, author of many building surveys ordered by the Renewal Company and currently saved in the historical archive of the Banca d'Italia, was noteworthy [44].

The housing policy adopted by the Company was oriented towards a differentiated offer of the buildings, planned according to social classes and building typologies: the building plan satisfied local needs: from a family with many children ("*ticket famiglia*") type to a lonely person's, we believe no other Italian town has so many air, light typologies [45]. As regards the architectural middle class building the planning interest aimed at a better esthetic façade and to comforts: these housing typologies, from the simplest to the most decorated and comfortable, (any details missing in the old typologies) will become refined centers [46]. In the new urban areas of the pre-existing tissue were built blocks of buildings showing an homogeneous urban area through the reiteration of courtyard typologies which adapted to variable solutions and to dimensional changes, they granted a rational distribution of the entrances, halls, courtyards and stairs.

The new building typologies elaborated by the Company were classified in four solutions on the base of the bonds of the law of the Municipality and planned having store at the ground floor and flats on the first one. The first typology, planned on small rectangular shapes (16x25 meters), was characterized by the block-shape without courtyard but with a central stairway. On the ground floor there were the shops having a main entrance on the road, in front of which there were the flats. Around the stairway there were six flats avoiding internal long dark corridors and external disadvantaging ballatoio (long balcony leading onto a number of flats, usually overlooking a court yard) but without wasting stair area [47]. Each flat did not have corridors but rooms, kitchen and a hidden external lavatory, avoiding the typologies of Milan or Turin, where there were too comforts and were adapted to clerks or graduate professionals [48]. As Quaglia said: «a house planned for a family must have: bedrooms, kitchen, loggetta, lavatory, water supply, that is the independent housing» [49]. Such a kind of building, never realized by the Company as it was little profitable, became the base building module planned on bigger plots of land. As regards the large and long rectangular shape areas they adopted a second building typology according to the axis of the courtyard and dividing the two building parts through three rooms corresponding to the width of the courtyard.

On quadrangular shape plots of lands (30x40 m) they planned the third building block typology with a central square courtyard including "diamond-shape" stairs. From such a typology we get the so-called pluri-courtyard buildings of Loreto and Arenaccia districts.

The fourth typology - never realized - aimed at big rectangular areas (35x50m), was made up of four courtyards risen from the joining of five rectangular blocks, each of them having a central square stair around which rose the building housing blocks.

If on one hand the dichotomy between the social and economic aspects imposed different housing typologies, based on different social needs, on the other, the market and economy reasons aimed at reaching the same qualitative standards. The popular building typological solutions were repeated and experimented with the same logic in the wealthy middle-class housing typologies, even if with important changes as regards the number of housings and the ornamental elements of the facades. The housing equipments too changed according to the building areas resulting in widespread building solutions: «among the group of big factories next to the railway station there are very simple civil factories, divided in small districts, a little bit more elaborated than economic houses...as well as the factories that are being risen next to piazza Carlo III in Foria, opposite to Grande Albergo dei Poveri [...] A better building category before the square of the railway station, called piazza Unità d'Italia, wider and larger if compared to the previous one. The same effect is reached by the new corso Garibaldi leading to via Foria opposite the just mentioned Grande Ospizio dei Poveri. [...] A more civil category of factories is on the right and on the left of the new big Arteria del Rettifilo, called Corso Re d'Italia» [50].

The comparison between the residential typologies elaborated by the technicians of the Company of the Renewal and the buildings in Berlin, London and Paris allows us to trace new restoring models satisfying an interesting urban policy to compare national and European surveys [51].

The experimentation about the location of the buildings, the shapes and the methods pointed towards social and architectural models inspired to “Familisterio of J. B Godin” according to the Proudhonian model [52]. Since 1890’s we have had a heated debate about the building typologies, as Giustino Fiocca’s building of the Filatropica alla Sanità was soon thought being obsolete [53]. In 1880 the engineer Giulio Melisurgo considered obsolete the barrack-typology spreading over in Naples while the optimum was the Anglo-Saxon comfortable typology [54]. However the “isolated houses” were ideal but unrealizable. Piero Paolo Quaglia was aware and after a direct survey in Austria, France and Germany, he realized a capitalistic building system based on different social classes. In fact, in the building courtyard typology of Loreto district and the eastern area we can notice an analogy with the popular houses of Berlin, built by the architect Theodor Goecke (1850–1919) [55]. Other analogies are made evident in the Italian examples of the courtyard houses in Florence built between 1849 and 1851 planned by the engineer Enrico Guidotti (1821-1903) [56].

So experts were up-to-date about the most innovative housing typologies to be aware of a modern model of city, but they were also influenced by economic benefits so altering the original Renewal plan. The problem was clearly explained by Quaglia in a letter to the Company: «Anyone knows how patient I am and how much interest I’ve in studying and solving problems in order to get a profitable factory, even if renouncing the advantages architects like, such as: wide courtyards, developing stairs; on the contrary I have always studied the most useful solutions in contrast with the building code, dividing walls, height differences, oblique light, in order to gain and use the most of benefits from the factories» [57].

The carrying out of the plan was slow and the economic collapse of the Italian banking system in 1893 involved the Company of the Renewal in the bankruptcy. Changes in contract works of 1888, changes in the building code, interruptions of the building works were constant; there were so many accusations and slanders that they needed special laws about the financial supports of the Government and the Banca d’Italia whose support was necessary to conclude the plan after the postwar period [58]. The Renewal and Enlargement works were not limited to the mere solutions of the economic quarrels: the Banca d’Italia sold back the so numerous acquired goods as Giolitti promoted in 1893 and such a difficult situation caused the institution of the Ispettorato Tecnico Generale, managed by engineers, who had to deal with the management and the increasing in value of buildings aiming to sell them [59]. The Bank, together with the Company of the Renewal, the Banco di Napoli and the Municipality, worked at completing the unfinished buildings as established in order to get a major benefit, a minimum loss, and a main role to finish the works both in the central areas and in the developing ones [60].

The critical analysis of a rich survey saved at the archive of Rome of the Banca d’Italia allowed the knowledge of unknown technicians, engineers and architects, working at the Office of Art of the Banca d’Italia during the years of the Renewal: Nicola Facini, manager of the Department of general offices, Romolo Remiddi, in 1885 he was the manager of the Renewal Works, *pontine* swamps; Laschi Sigismondo, supporting engineer; Biagio Accolti Gil (1872-1940) of noble origins from Naples, technical author of the Banca d’Italia in Trieste and Reggio Calabria; Paolo Cortese, special employer; Angelo Ugo Beretta; Giuseppe Tarra; Rodolfo Buzzi; Pietro Rey and De Vincentiis Edoardo, engineers of Office of Art; Pietro Dell’Olio, manager of selling office; Ruggiero Simoncelli, inspector; Luigi Antico, Luigi Dall’Ongaro, Gennaro Astolfi, Efisio Piana, Guido Corsi, Umberto Taticchi, Luigi Lagomaggiore, Adolfo Amendola, Antonio Cottini, Tancredi Chionio, Cesare Monti, Giovanni Jacometti, Gioppi di Turckheim [61].

The new buildings carried out on the base of the building Renewal code were estimated according to detailed iconographic surveys, when the *Consiglio Superiore* of the Bank sold them. They documented the results of a building process managed by the *Istituto romano* in order to avoid the interruption of the “beneficial and brave program” of the Renewal Company which could damage the image of the city. Concluding, starting from the needs consequent the 1884’s cholera and the new market laws, the Plan of Renewal and Enlargement was the occasion to relaunch Naples, even if sometimes in an anachronistic way if compared to European and National essays, thanks to the presence of experts who tried to interpret and improve the city according to modern urban rational architectural values.

Less Architecture.

Some world cases and their relationship with paradigms of Modernism

Francesco COSTANZO

Dipartimento di Cultura del Progetto, Facoltà di Architettura "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Aversa, Italy

francesco.costanzo@unina2.it; francescocostanzo@gmx.net

Abstract

New geopolitical phase, with coexistence of great emerging nations and geographical areas of decadence and decay, induced the affirmation of an alternative architectural tendency respect to iconic and dominant one, a tendency that exemplarily represents an application of the concept of less that is an attitude for acting in economical and material limited conditions.

This contribution wants to show some cases of this tendency in different geographical areas of South America, Africa, some Asiatic areas, some European degraded areas, and wants to highlight in which way, starting from operative conditions of less, New-Rationalism has adopted a compositional modus that unites construction and language, redefining architecture in its essential data.

These experiences, that some critics call New Contextualism, represent a new ecology, cultural and necessary datum of today, using what is present and available in situ.

These cases show that architectural composition has been renewed looking at ways to recombine local materials and architectural elements, determining new meanings and values through sophisticated compositional rules that are globally established by the best architectural discipline. This is the composition of simple stereo-metric forms and it finds the centrality of construction. In fact, as happened for Le Corbusier with his studies for African architectures, and as happens today for Mumbay Studio in India, forms and construction techniques are synthetic but achieve a high expressive value, determining compositional quality of architecture.

Key-words: Rationalism, *Utilitas*, Paradigm, Elements, Construction

1. Introduction

This paper about *less architecture* tends to highlight the theme of utility in architectural project. It has re-emerged in the last years codifying *utilitas* concept by Vitruvio, which absorbs and assumes contemporary characters. We must clarify three points that influenced this cultural process.

The first point is about the emptying of architectural themes. During last years there has been a tendency characterized by technical experimentation and iconicity, in which architectures are oriented towards the external space. They are thought starting from their communicative dimension – this condition assumed a priority role – and they are realized through a rhetoric of coating, skin and envelope or through spatial hyperboles in which technique and constructive advances are shown – in an interior speech.

This facts are somehow connected with global neo-colonialism. It developed in different geographic areas with different forms and weights, in a constant demonstrative aspiration. The effect produced by this phenomenon is that the construction aim is increasingly distant from real needs, and it's impossible to understand effective program, architectural theme and architecture's purpose. Iper-capitalistic iconicity's logic is independent of relationship with reality, architecture's reason is less and so a reason's architecture is impossible, an architecture springing from a research about architecture's sense, from relationship between

architecture and its reasons. Moreover, in this general scenario, the designer architect perceives the infeasibility of his work, the irrelevance of his actions on the reality.

The second point is the fact that architects and architectural theorists distanced themselves from the worst cultural premises connected with financial economy's logic.

The third point is that the better components of architectural world don't deal with developed geographical areas, where financial logic has established itself, but they search geographical and cultural contexts where architectural needs are clear: construction of a small school, a small hospital, a small social space, houses responding to specific urges. Designers working in these places have clear programs, as Italian and European architects had during post-war reconstruction and through them, they realized valuable architectures.

The main issue is that in these experiences there is a connection between particular facts – local constructive techniques, project site's importance represented by inductive aspects of material culture and history as theorized data, but also the culture setting in participative processes – and a general fact we define a “universal” fact – the use of intelligent and sophisticated compositional techniques that architects learned in the best architectural schools of the world. There is the meeting between autochthonous culture's conditions and refined aspects of architectural composition. These techniques are globally diffused and they are consolidated by modern paradigms, that nowadays – with a right temporal distance (that purified the interpretation of modern architectures from critical biases) – reveal their didactic and demonstrative value.

This practice is original and shows the architecture's role and compositional research's value in architectural schools. This approach is distant from Bernard Rudofsky's premises for exhibition “Architecture without architects” held at Mo.Ma in New York in 1964. In Rudofsky's thesis the history of architecture and the time's role were failing. Instead, the time always gives particular conditions to be taken to advance.

2. Mumbai Studio

One of the most emblematic examples is represented by Mumbai Studio. These Indian architects are known because they participated at XII Venice Biennale of Architecture. They realized a mounting in which their work was presented showing materials used in their buildings. In this way they underlined a re-compositional intent, an assemblage, produced by a methodical position and influenced by a choice starting from necessity of using exclusively existing materials. This position is defined by real possibilities – the effective availability of materials – and by availability of resources.

Projects by Mumbai Studio highlight a precise design approach. Utsav House in Satirje, the Indian region of Maharashtra, is an enclosure-building set on the ground adapting itself to slight height differences and exalting the ground's conditions. This architecture completes itself in situ, as the authors Bijoy Jain and Jeevaraam Suthar stated, because of two reasons. The first issue is a compositional issue: during building's construction is possible to realize corrections, starting from observation of interior circumscribed space and of external landscape selected by architectures set against the enclosure. The second issue is a constructive issue: the building is completed through discussion with workers, collecting and choosing materials. They are limited resources that designer must quantify and must eke out.

y

Fig. 1: Mumbai Studio, Utsav House, Satirje (India), plan

Fig. 2: Mumbai Studio, Tara House, Kashid (India), plan

This project reveals a precise and clear idea about architecture. It is composed through Semper's four elements as shown by Mies Van Der Rohe. In this case, the elements are: slender wooden pillars, concrete walls – often coated, as Mies often used to do – floors or basalt bases, thin coverings leaning on wooden beams. This compositional choice, using distinct elements, has a selective nature, within possible compositional registers. This choice is established before project's beginning and assumes a strategic aspect because it is about the construction with non-conspicuous resources and about a open method accepting in progress variations induced by progressive adjustments, refinements, suggestions and solicitations. This paratactic composition presupposes a clear definition of elements and it allows variations. This fact is not possible in holistic project, a project entrusting its fate and success to its shape. Shape presumes its rightness and it owes the success to its rightness. This "rigid" project is connected to a figural rightness but also to a predetermined constitutive method that doesn't allow variations because they could undermine design premises. Paratactic composition is sophisticated. For example we can think about isolation of elements – produced by clear individuation principles -, about corrections and breakings of enclosure as fundamental figure, about "will of form" conditioning building's closing elements – they demonstrate the craftsmanship of their making, that is the link with metal forging culture -.

Composition considers rhythms, geometries, procedures not simply referable to Indian architectural experience (autochthonous), but clearly connected with other cultures, with other significant experiences forming cultured anthology of architectural history. This fact is very evident in Tara House realized in Indian town of Kashid. In this architecture we can observe the great attention in building house's osmotic enclosure and the assumption of modern tradition. Diaphragm's precision: a wall built with thin wooden sticks allowing light to enter with modulation regulated by architecture. A clear device for a well-known image, for an experience that we know: La Tourette's corridors (promenades) are characterized by aureus rhythm of vertical elements established by Le Corbusier. Photos of this building-paradigm have influenced architects' imaginative world and their education. This light mitigation space, with vertical elements in backlight, exalts the presence of vertical elements and their bright distance.

3. Anna Heringer

Work by Anna Heringer – Austrian thinker and architect working in Linz University of Art, Industrial Design and Architecture – represents some relevant points of less architecture.

Our intent isn't the highlighting of her activist attitude and of her work's humanitarian sense, or her attention in calibrating projects in relationship with craft constructive techniques. Our intent is to underline the relationship between these projects and the goal to define and defend the rural world's identity. This attitude hides the desire for an identity independent of urban and western models.

The first two projects analyzed were built in Bangladesh, the most densely populated developing Country of the world, that become independent of Pakistan in Seventies and assumed a democratic Constitution only in 1991. In this Country, we must premise, there are important urban concentrations generated by exodus from rural villages that still held an important cultural and economic role. Presented projects want to build perspectives – considered architecture's limits – showing villages' identity value and the possibility of creating a correspondence between architecture and traditional lifestyles to contrast the abandonment of these villages.

Fig. 5: A. Heringer, METI, Rudrapur (Bangladesh), external view

Fig. 6: A. Heringer, METI, Rudrapur (Bangladesh), first floor plan and ground floor plan

Fig. 7: A. Heringer, METI, Rudrapur (Bangladesh), transversal section

METI project (Modern Education and Training Institute) in Rudrapur, in northern Bangladesh, is a two levels primary school and was built in six months, between 2005 and 2006. The materials used in this building are: earthbound materials such as loam and straw, and lighter elements like bamboo sticks and nylon lashing. This project – as underlined by Jury of The Aga Khan Award for Architecture 10th Circe – is not repeatable in its forms, in its constructive solutions, because it is connected with local conditions, but the approach is repeatable.

Heringer's projects look for constructive and climatic solution surpassing traditional buildings' advantages, in which bearing walls delimitate spaces with low climatic fluctuations. In Heringer's idea, architecture's constitution provides places characterized by great spatial value, inedited spaces demonstrating modern opportunities for development of traditional architecture.

In Meti project there is a volume delimited by bamboo diaphragms, a great covered attic. It is a sedentary place, the light inlet is mitigated. Diaphragms' consistency and the possibility of opening them, regulate ventilation. Wind and shadow rooms, inhabited in hottest months of the year, consider covering as a shelter and develop this idea to determine new human experiences. This superstructure re-defines covering's role – starting from reflections about roofs by Le Corbusier, developed during his African voyages, arriving to codification of roof garden and living roof, and establishing new possible roles for covering in modern architecture -. Heringer doesn't let roof surface as indeterminate space, but she defines it as elective place measured by repetition of bamboo poles and beams. This rhythm is visible from the outside and contributes to define architectural character. All the elements, ground floor solid volumes and elective volume on the roof, define a Bangladesh typical "poetic of living". We must consider the condition of the hollow space contained in school's volume – interpreted as small house. It is a tunnel close to schoolroom in which young students dedicate themselves to individual activities. This space is poetical and evocative.

Paul Finch, in an article written for Architectural Review, speaks about desire for modernity expressed by developing Countries. This aspiration produces negative consequences in economy and culture, importing foreign models always expensive and inefficient.

"All too often, aspirations towards modernity in developing countries have malign economic and cultural effects where construction is concerned. Traditional materials and techniques are abandoned in favour of the import of expensive and sometimes energy-inefficient materials and products, benefiting only manufacturers in more advanced economies. The outcome can at worst be the imposition of alien buildings, forms and materials which don't last long and are difficult to maintain. Their only merit is to look new for a time. By contrast, this joyful project, in a poor rural area of Bangladesh (said to be the world's most densely populated country), shows that new and refreshing local identity can be achieved by exploiting the immediate and the readily available (...)."

(Paul Finch, Architectural Review, UK)

Fig. 8: A. Heringer, METI, Rudrapur (Bangladesh), attic

Fig. 9: A. Heringer, METI, Rudrapur (Bangladesh), tunnel for individual activities

Fig. 10: A. Heringer, DESI, Rudrapur (India) external view

Fig. 11: A. Heringer and BASEHabitat, home for disable children, Orangefarm (South Africa), external view

Second project is DESI (Dipshikha Electrical Skill Improvement) in Rudrapur, a small school built in earthbound materials and bamboo. It shows the possibility of guaranteeing to poor families and middle class that modernity doesn't consist in west life-style but in advance of tradition starting from existing elements. Heringer observes that poverty induces a sustainable tradition, instead progress looking to the West imposes a change of materials used and technologies – depending on technological control (air conditioning, for example) - that are less sustainable than the traditional ones. Project adopts pavilion-system because it refers itself to aggregative modes of traditional buildings in Bangladesh. They are detached buildings – corresponding to different functions – often characterized by a courtyard. The break-up of the building and the articulation of detached elements respond to constructive simplification reasons. Windows system on facades doesn't respond to a simple compositional variation, but tends to calibrate natural ventilation system. Building, as underlined by the author, tries to reach a perfect balance of high and low technologies because it connects a traditional constructive idea with an advanced energetic system (solar panels for energetic self-sufficiency and for hot water production).

Third project, realized in 2005, is an ambulatory for children with disabilities and it is situated in Orangefarm, near Johannesburg (South Africa). Project was promoted by prof. Roland Gnaiger with Anna Heringer – for Linz University – and it is included in research program BASEHabitat. Small architecture is built in earth, concrete blocks, clay, straw, timber, grass mats and it was realized by architecture students from Linz and Orangefarm community. Project – providing absolute energetic autonomy – develops the idea of ventilated roof. Diaphragms are made in earth and horizontal wooden elements and interpret a precise constructive idea showing linguistic possibilities granted by this technique.

4. TAM Associates

Work by Italian office TAM Associates is about hospitals and ambulatories for ONG Emergency. These buildings are situated in Sudan and in neighboring countries. They tend to realize medical cooperation between different countries (often in political hostility) with an eminent political character. In this way, the idea of health assistance as right is introduced.

Fig. 12: TAM, Container medical compound (Emergency), Soba (Sudan), external view of cafeteria and common spaces

Fig. 13: TAM, Container medical compound (Emergency), Soba (Sudan), external view of residential volumes

All the projects by TAM Associates express a particular idea of less architecture starting from different themes: reutilization of waste materials, adoption of simple constructive technologies – from earthbound wall to frame system with wooden elements or reduced to necessary shape and mass.

In Soba, near Khartoum (Sudan), Container Medical Compound for the Salam Centre – a complex consisting of small houses and a cafeteria for people coming from different countries and working in Emergency “Salam” Central Hospital in Khartoum – provides reutilization of ninety 20 feet (6 meters) containers. Module is repeated with some breaks – collective spaces – and it is adapted using caulk panels and realizing diaphragms to protect volumes from direct solar light. A second skin is separated from masses and it is wisely designed: covering is detached from modular volumes to become a ventilated roof and a sunscreen system builds verandah spaces for houses. These devices give unity to repetition, conclusion to sequence composition revealing a will of form for a simply modular architecture. Empty slots – voids – contributes to composition. Elements definition is a sophisticated compositional procedure: bearing in mind modern paradigms’ lesson – especially cultured modernity pursued by Italian architect Franco Albini – every element is well-defined and its shape clarifies its constructive role. Sunscreen system is didactic because it separates white metal frame from bamboo diaphragm. Similar principles are adopted in projects for nine pediatric clinics around Nyala in Darfur and in Cardiac Centre “Salam” in Khartoum (reference specialist centre for satellite clinics). In particular we can observe that centre, overlooking Nile river, has a complex program: guesthouses, service buildings, administration pavilions and buildings for medical activities.

In these projects is always present the idea of characterizing some spaces – in particular connective and collective spaces – starting from rhythm and structural elements’ condition. In this way less architecture realizes itself: structural necessity is equipped with expressive power. In fact pillars and beams are designed following the idea of maximum material economy. Pillars often are formed by two vertical poles with punctual rigid junctions and beams often are vierendeel beams – separating elements in strain from compressed elements -. These composite elements – always isolated and so clearly recognizable – reach a formal richness and concur to define character of covered spaces. These places evocate sedentary condition and they respond to clear no-time actions: they define a shelter before they respond to a function.

Fig. 14: TAM, Cardiac Centre “Salam” (Emergency), Khartoum (Sudan), view of external arcade

Fig. 15: Franco Albini, Exhibition of ancient goldsmith at IV Triennale in Milan, Milan (Italy), 1936, view of main room

Fig. 16: TAM, Cardiac Centre "Salam" (Emergency), Khartoum (Sudan), view of external spaces
Fig. 17: TAM, Pediatric Clinic (Emergency), Nyala (Sudan), view of external arcade

5. Conclusion

In this sense, project described in this paper clarify their participation in a common discourse: they realize themselves starting from a spatial plainness in which different elements give a characterization following a constructive and compositional idea of pithiness and laconism. Here we realize that less architecture is rational architecture. In the way these architectures evocate historical spaces and re-found local constructive knowledge, we find mature lesson of modern paradigms.

The sad story of Carditello

Riccardo SERRAGLIO

Dipartimento di Cultura del Progetto, Facoltà di Architettura “Luigi Vanvitelli”, Seconda Università degli Studi di Napoli, Aversa, Italia
riccardo.serraglio@unina2.it

Abstract

The Royal Estate of Carditello, former fiefdom of the Earl of Acerra, located in the rural territory between San Tammaro and Capua, in an area which is bounded by Regi Lagni canal to the south and Volturno river to the north, was acquired by Charles of Bourbon in 1744 to settle a stud farm in the buildings once used as stables by the prince of Caramanico. In the 80's Ferdinand IV decided to build a royal palace and to add around it a modern farm, entrusting the planning to Francesco Collecini, his special architect. Elaborating a just existing model, once experimented in San Leucio, he conceived a complex where royal residence and output buildings were in close contact.

The construction of new buildings began in March 1782 and the royal possession has been often enlarged till 1816 getting nearby forests and parks. The magnificent palace built in the centre of the large landed estate is the melting pot of roads conceptually similar to Luigi Vanvitelli's, the same he used for the royal palace of Caserta, and which is linked to the different rural buildings of the estate.

After the end of the Bourbon reign the estate was divided and at the moment the royal palace which is one of the most interesting architectural 18th century building - according to the critics - is managed by a local government which has recently decided for an auction sale. In the recent past such building has been damaged and forgotten, moreover it has recently been stolen especially in its memorial tablets and marbles belonging to a stair. The real situation is so serious the scientific community must denounce it in order to start a suitable safeguard and preservation of such an astonishing architectural complex.

Keywords: Royal Estate, Royal Palace, Royal Sites

Fig. 1: Carditello, the estate before the construction of the Royal Palace (historical map, detail)

Fig. 2: Carditello, the estate after the construction of the Royal Palace (historical map, detail)

1. The story of the Royal Site

The Royal Estate of Carditello, former fiefdom of the Earl of Acerra, located in the rural territory between San Tammaro and Capua, in an area which is bounded by Regi Lagni canal to the south and Volturno river to the north, was acquired by Charles of Bourbon in 1744 to settle a stud farm in the buildings once used as stables by the prince of Caramanico. In the 80's Ferdinand IV decided to build a royal palace and to add around it a modern farm, entrusting the planning to Francesco Collecini, his special architect. Elaborating a just existing model, once experimented in San Leucio, he conceived a complex where royal residence and output buildings were in close contact. The construction of new buildings began in March 1782 and the royal possession has been often enlarged till 1816 getting nearby forests and parks.

A number of administrative documents of the Bourbon period, held by the State Archives of Naples and the Archive of the Royal Palace of Caserta, allow to retrace the steps of the building construction. Historical maps of the Royal Site describe the condition of the premises during the construction of the royal residence and completed works. Artists and craftsmen of great value attended the construction of the palace, overseen by Collecini. His closest collaborators were the architects Domenico Brunelli and Gaetano Bernasconi; in the definition of decorations collaborated with the famous painter Philipp Hackert and the theatrical architect Domenico Chelli, King Ferdinand IV's favorite artists; the gardener John Andrew Graefer, who was author of the English Garden of the Palace of Caserta, collaborated for the arrangement of green areas around the building. Before starting work, an accurate three-dimensional model was made by the cabinetmaker Antonio Ross, first presented to the king to evaluate the project and then brought on site June 9, 1787, to serve as references during the construction.

The work, conducted with unusual rapidity, ended in 1792 with the construction of the riding track, adorned with marble fountains and a small doric temple in the centre. The magnificent palace built in the centre of the large landed estate is the melting pot of roads conceptually similar to Luigi Vanvitelli's, the same he used for the Royal Palace of Caserta, and which is linked to the different rural buildings of the estate. Concurrently with the construction of the royal residence, were built new buildings for agricultural production in various areas of the estate and created works of consolidation of the channels and ditches for the outflow during periods of high flood waters of the Volturno. In 1790 the construction of the mills near Sant'Antonio's bridge required new measures of hydraulic engineering to allow the use at full capacity of the new milling plant. In 1792 it was approved the creation of a system to lift water from the River of Capua, in order to make it available for the mills, but changes to the hydrology of the area to improve efficiency were found harmful to the cultivation of hemp and flax in the surrounding land and to supply water to the city of Naples. It was thought to solve the problem entering the headwaters of the Mofito, near the town of Cancellò, in the course of the Regi Lagni, and then channel them into the aqueduct of Carmignano, the main source of water supply in the urban area of Naples. This proposal was rejected because it was deemed harmful to traditional agriculture.

During the insurrection of the Republicans in 1799, the Bourbon army clashed with the French troops commanded by General Championet in the territory of Capua and the Royal Estate of Carditello was occupied by the revolutionaries and the French military. The Bourbon palace, considered the emblem of the monarchy, suffered serious damage. In particular, frescoes depicting members of the royal family were mutilated as a sign of contempt for the monarchy, while the lead pipes that fed the ornamental fountains were removed to be melted down and turned into ammunition. Once restored the Bourbon government, restoration work was undertaken by Collecini, who was attended by numerous artists, many of whom have already been engaged in the construction of the building.

During the French Decade, from 1806 to 1815, agricultural production went on in the structures of the Royal Site but recreational activities were stopped. After the Bourbon restoration new projects were designed to improve the profitability of the agricultural areas. For this reason, in 1819 the construction of a new canal, called in contemporary documents "Canale di Terra di Lavoro", began and were designed by Bartolomeo Grasso and Luigi Giura, engineers of the Corps of Bridges and Roads. This building would allow an efficient irrigation of agricultural lands of the Royal Site of Carditello and a good supply of water for milling plants. In addition, the new channel would enable river transport of agricultural products and the construction of four new mills in surrounding areas. The completion of the work was opposed by landowners and by the administrator of the province of Terra di Lavoro, Sant'Agapito Marquis, who felt irrigation practice detrimental to the traditional crops of the area. They obtained the suspension of work in 1825 and the construction of the canal was finally abandoned, despite numerous proposals by technicians of the Corps of Bridges and Roads in attempt to make working at least the portion already built, from Acerra to Marciariane.

Later in the Fascist era, the colonization of agricultural land in the province of Caserta included even the Royal Sites of Carditello and Calvi, assigned at the "Opera Nazionale per i Combattenti" in 1919. In this

period infrastructural works were carried out, such as the arrangement of the drains, the installation of a pipe of cast iron in replacement of old pipes, the realization of a new electric power line, interventions of deforestation of wooden areas, which could be grown. The management of the Royal Sites of Carditello and Calvi was distinguished by other territories administered by the “Opera Nazionale per i Combattenti” for the experimental nature of the agricultural process, while the neighboring lands were consecrated to local production. As in other regions administered by the “Opera Nazionale per i Combattenti”, such sites were run out by a coordination centre, which would have been housed in the Royal Palace of Carditello and adjacent buildings. Two task projects were introduced involving the use of the Royal Palace of Carditello as the administrative seat of agricultural activities in the area. The first, drawn up by engineer Leopoldo Barini in 1929, forecast the restructuring of the towers arranged between the low service buildings. The second, drawn up by engineer Luigi Giura (namesake of the previously cited for the "Canale di Terra di Lavoro") in 1939, involved the transformation of the palace of Carditello in a service centre for the surrounding farm located in the territories, with functions similar to those in rural villages founded by the “Opera Nazionale per i Combattenti” in the territories of the “Basso Volturno” in the same years.

At the moment the royal palace which is one of the most interesting architectural 18th century building - according to the critics – is managed by a local government which has recently decided for an auction sale. In the recent past such building has been damaged and forgotten, moreover it has recently been stolen especially in its memorial tablets and marbles belonging to a stair. The real situation is so serious the scientific community must denounce it in order to start a suitable safeguard and preservation of such an astonishing architectural complex.

RECOVERY COLLECTIVE MEMORY OF PLACES. THE CIRIO INDUSTRY IN PAESTUM (SA)

Mariarosaria VILLANI

Dipartimento di Storia dell'Architettura e Restauro , Facoltà di Architettura, Università Federico II, Napoli, Italy
maryvil@hotmail.it

Abstract

The fabric "ex-Cirio" abandoned by 1987, placed in the archaeological area of Paestum in front of the ancient Justice Gate, represents a great potential for the area.

Inserted within the feasibility study for the creation of the "Archaeological Site of Paestum" (realized from CIPE with funds from the Ministry of Heritage and Culture), in which prefigures a restoration and new functions of the factory with the excavation of the Sanctuary St. Venera placed beneath one of the sheds.

The proposed contribution to knowledge, through the historical and bibliographical researches directly related with the direct study of the architectural structure, aims primarily at providing a contribution of a cognitive type of architectural structure.

This is part of a series of early industrial architecture of the 900 lots in Campania at the behest of Cirio, but is unique not only for the value of collective historical memory, which represents the area, even for of the relationship with the archaeological pre-existence of the Sanctuary of Santa Venera.

Secondly, it aims to show how the recovery of material values (architectural and archaeological) and intangible (a collective memory of historical production site), represented an inseparable and preparatory poles for the recovery activity aim to the conservation and the development of the architecture.
facendo attenzione a non modificare gli stili ed i formati.

Key words: Cirio, Paestum, Recovery, Memory, Sanctuary of Santa Venera

1. Recovery collective memory of places

The monuments are carriers of flexible values over time, but at the same time the value of the same monument, as well as its definition, is subject to change.

Already in the preamble of the Charter of Krakow 2000 we find that "Each community, by means of its collective memory and consciousness of its past, is responsible for the identification as well as the management of its heritage."

The enlargement of the protection from a single monument to the "Cultural heritage as a means of providing material evidence of civilization" allowed to consider since the 80s of the 900, the heritage of industrial archeology as a material to be preserved and passed down to future generations as a bearer of material values related to the peculiarities architectural own industrial manufacturing, and intangible assets, related to the culture of work and production.

The industrial archeology therefore introduces a new concept of industrial monument as an inalienable heritage of the community.

1.1 The development of Cirio industries in Campania

Besides the automotive and manufacturing, the food industry was certainly one of the sectors that have greater contributed to the development of Italian economy.

In 1895 Francesco Cirio founded «Cirio General Society of canned food», basing on the fortunately industry "method Cirio" of conservation, which in turn drew on the method preserves the products introduced in France by Nicolas Appert.

Since the end of 1800, when the Piedmont factories exported huge quantities of canned abroad, it became clear to the entrepreneurial spirit of Francesco Cirio such as distance from places of production of raw materials would make unattractive the industry and its development.

He saw in Campania, thanks to the wealth of raw materials for processing in situ, especially in the Neapolitan area, through the land of agro-Nocerino-Sarnese goes up to the fertile Sele's plain, the possibility of a wide range, and in 1882 opened in Salerno the first factory of canned food of South Italy.

In 1889 the production moved in Castellammare where was built a new factory, followed by the establishment of Pontecagnano in 1900, and that one of Vigliena in 1925 designed by Angelo Trevisan [1], where was fixed the national headquarters of the company.

The spread of the company Cirio in Campania becomes strong engine of economic development so as to be shown in 1935 as the most important industries of the Province with a record of national level in the canned food [2].

Economic development is associated with the social one, so much that in 1909 in the *Queen Magazine for Ladies and Misses*, we can read "Quite rightly our magazine was in charge of the House Cirio, since this provides jobs and income to hundreds of young girls, and it ensures an exemplary life, giving them equal time with the money used to support the existence of even the education that comes primarily from a life of work well understood and regulated" [3].

1.2 The plant of Paestum

Located in front of the walls of the ancient city of Paestum at the Justice Gate, the factory Cirio represents, along with near to the industry of Caffasso, an important architectural evidence of the production characteristics of the area developed in the early decades of the 1900.

At the beginning of 1900 still showed Paestum is described as the travelers of the Grand Tour as a swampy and unhealthy [4].

The establishment of Paestum was built in 1910 but began production only in 1935.

During the Second World War, was occupied by American troops who landed on the shores of Paestum in 1944 and use it as a military base, using the opposite area as a park for vehicles.

Production resumed in 1946 and continued uninterrupted until 1987 when, following the sale of the brand to the SME in 1970 we are witnessing a profound economic crisis that will lead to permanent closure of the factory, almost simultaneously with the closing of the plants situated in Castellammare, Pontecagnano and Pagani.

Hanging in part under the modern shed of the Paestum's plant, are the remains of the Sanctuary of Santa Venera, dating from the fifth century A.C. represents one of the most interesting examples of suburban sanctuaries.

The discovery of traces of a bridge, suggests that the temple was connected to the city through the Justice Gate beyond the river as yet that was one of the founding elements of the matrix of the cult.

The sanctuary was composed of several buildings including the so-called rectangular oikos within which was inscribed a circular structure detectable by the remains. Not far from here was the oikos, the rectangular building, probably used in purification rituals and sacrifices. Through some discoveries and inscriptions, it was assumed that the temple was dedicated to Aphrodite [5].

Excavations in the Sanctuary starting from the 50s by the Superintendent of Cultural Heritage Pellegrino Sestieri and will be pursued by Mario Napoli. Will then be taken in 1981 as a collaborative effort of the University of Michigan and University of Perugia under the sponsorship of Soprintendenza Antichità e Belle arti of Salerno and Avellino. The discoveries made during excavations were published in the two texts that describe the results of a dig [6].

After the closedown in 1987 and the sale of the production machinery, the factory was bought by private and since that moment it was abandoned to a state of decay.

Only in 2009 was bought by the Archaeological Superintendence of Salerno, but already since the year earlier included in the Feasibility Study for the archaeological site of Paestum [7].

The study led to the archaeological park aims to overall recovery of the ancient urban fabric through the elimination of the road that cut off the special continuity of the city. In addition to not allow correct perception of the ancient fabric, the modern road cut off and cover up in half many of the most important monuments such as the ancient Amphitheater, the head of the Forum, the Ekklesiasterion.

Among the main topics, besides the recovery of the continuum of the city and the path along the walls, we find the involvement of museum display of the Sanctuary of St. Venera - rehabilitation of the ex-factory Cirio. The proposed intervention assumes to keep the veil on the road, pull down the two sheds added in 1960 under which it develops the Sanctuary and through the use of inner square, placed higher than the excavations, would allow a view from above archaeological remains. Inside the buildings along the road, it provides for the establishment of a thematic section on suburban sanctuaries.

The factory as a architectural organism is born with its architectural form, released a cademic styles, with concerns of a purely functional.

In the plant in Paestum it is clear how the functional distribution derived from the typical production cycle of canned food.

The entrance located on the main road introduce to the inner square used for unloading of goods.

By the services for employees begins the sequence of spaces closely related to the sequence of moments of production.

The first step of the production sequence occurred in the room where they select tomatoes unloaded in the yard. Through a conveyor belt that ran through the square, the raw material was carried out in the shed in front of which occurred in the processing of concentrate. From here the passage to the shed in adherence occurred in which the canning and the load on the means of transport which had an output of its own way.

The original structure of the factory, represented by the block on the street, consists of masonry bearing in local limestone, typical of the Paestum, regular-sized, slightly rough-hewn, which at present shows no disruption of static types. The main degradation due to abandonment and consequently to exposure and growth of vegetation. Also for the two sheds added in the 60s made up of two curved metal roof trusses, the main cause of deterioration is represented by exposure to the atmospheric agents.

1.3 Preserve is more

The purpose to keep in mind for each type of intervention on behalf of the monuments, should be aimed primarily at keeping intact the document without making selections and breaks, refer to the basic principles of modern restoration, which take account of material compatibility with the existing use, reversibility, the concept of "minimal intervention", and the distinctness of the modern additions.

Moreover, in the specific case, the simultaneous presence of two structures so different from each other, the archaeological and industrial one, require a coordinated multi-disciplinary approach capable of maximizing the potential of use through the conservation of both the different monuments.

The purpose of preserving the architectural artefacts through new uses, could assume that the site as a catalyst of innovation, helping to create a new cultural environment in the region. Preserving the factory, embodies a symbol of a society that has based its economy on canning production for nearly a century, through the conversion of the local economy could obtain the redevelopment and the creation of new type of economic growth for the local population.

The conversion to new uses of the property would bring a new trend of socio-economic development which is linked to the dissemination of knowledge of history and texture of the material and immaterial well through the use of the monument.

As stated in the 'International Cultural Tourism Charter of ICOMOS (1999), we must ensure that programs promoting tourism are able to protect and enhance the features of the cultural and natural heritage sites.

In other terms it is necessary, as expressed by Giorgos Seferis "a faith in these old signs within the landscape: the faith that they have a soul", and through conservation ensure that this soul is felt like a testimony of the intrinsic value of cultural heritage keeping alive the memory of the production site, as an inseparable part of the soul of the place.

Abstract

This essay aims to propose a work on the villas of Plain of Hills in Palermo and Bagheria, "rereading" the famous book by Margherita De Simone "Palermo Villas, a historical profile and surveys" published in 1974, with the aim of representing – through digital design by comparing it with the traditional survey back then - the architectural phenomenon of the holiday residences in the eighteenth century in Palermo and its surroundings. These buildings had a very strong presence, characterizing its agricultural territory for more than one hundred years. A phenomenon, that of the villa in Plains of Hills and in Bagheria, which deeply studied in the book by Margherita De Simone, still holds a special interest. This is because often the renovations on these houses show the will to eradicate their nature by attributing them functions and destinations not strictly appropriate to the architectural "sense" that have characterized their "figure" for many years. The aim is to spread the dimensional, typological and morphological changes through the elaboration of "models" that can be explored and seen today as "updated" surveys of the cultural heritage and of the special phenomenon of the villa in the Sicilian eighteenth century, with particular reference to the territory of Bagheria.

keywords: paradigm_model_survey_villa_de-construction

1. Between memory and mediterranean paradigms [*]

This work puts forward a survey about villas in the area of Plain of Hills in Palermo and Bagheria, "rereading" the famous book by Margherita De Simone "Palermo's villas, a historical profile and surveys" published in 1974, with the aim of representing - through digital design by comparing it with the traditional survey back then - the architectonic phenomenon of the holiday residences in the eighteenth century in Palermo and its surroundings. These houses had a very strong presence there, characterizing its agricultural territory for more than one hundred years. A phenomenon, that of the villa in Plains of Hills and in Bagheria, which deeply studied in the book by Margherita De Simone[5], still holds a special interest. This is because often the renovations on these houses show the will to eradicate their nature by attributing them functions and destinations not strictly appropriate to the architectural "sense" that have characterized their "figure" for many years. And it is the "figure" of these works that is developed in this essay.

The aim is to spread the dimensional, typological and morphological changes through the elaboration of "models" that can be explored and seen today as "updated" surveys of the cultural heritage and of the special phenomenon of the villa in the Sicilian eighteenth century, with particular reference to the territory of Bagheria.

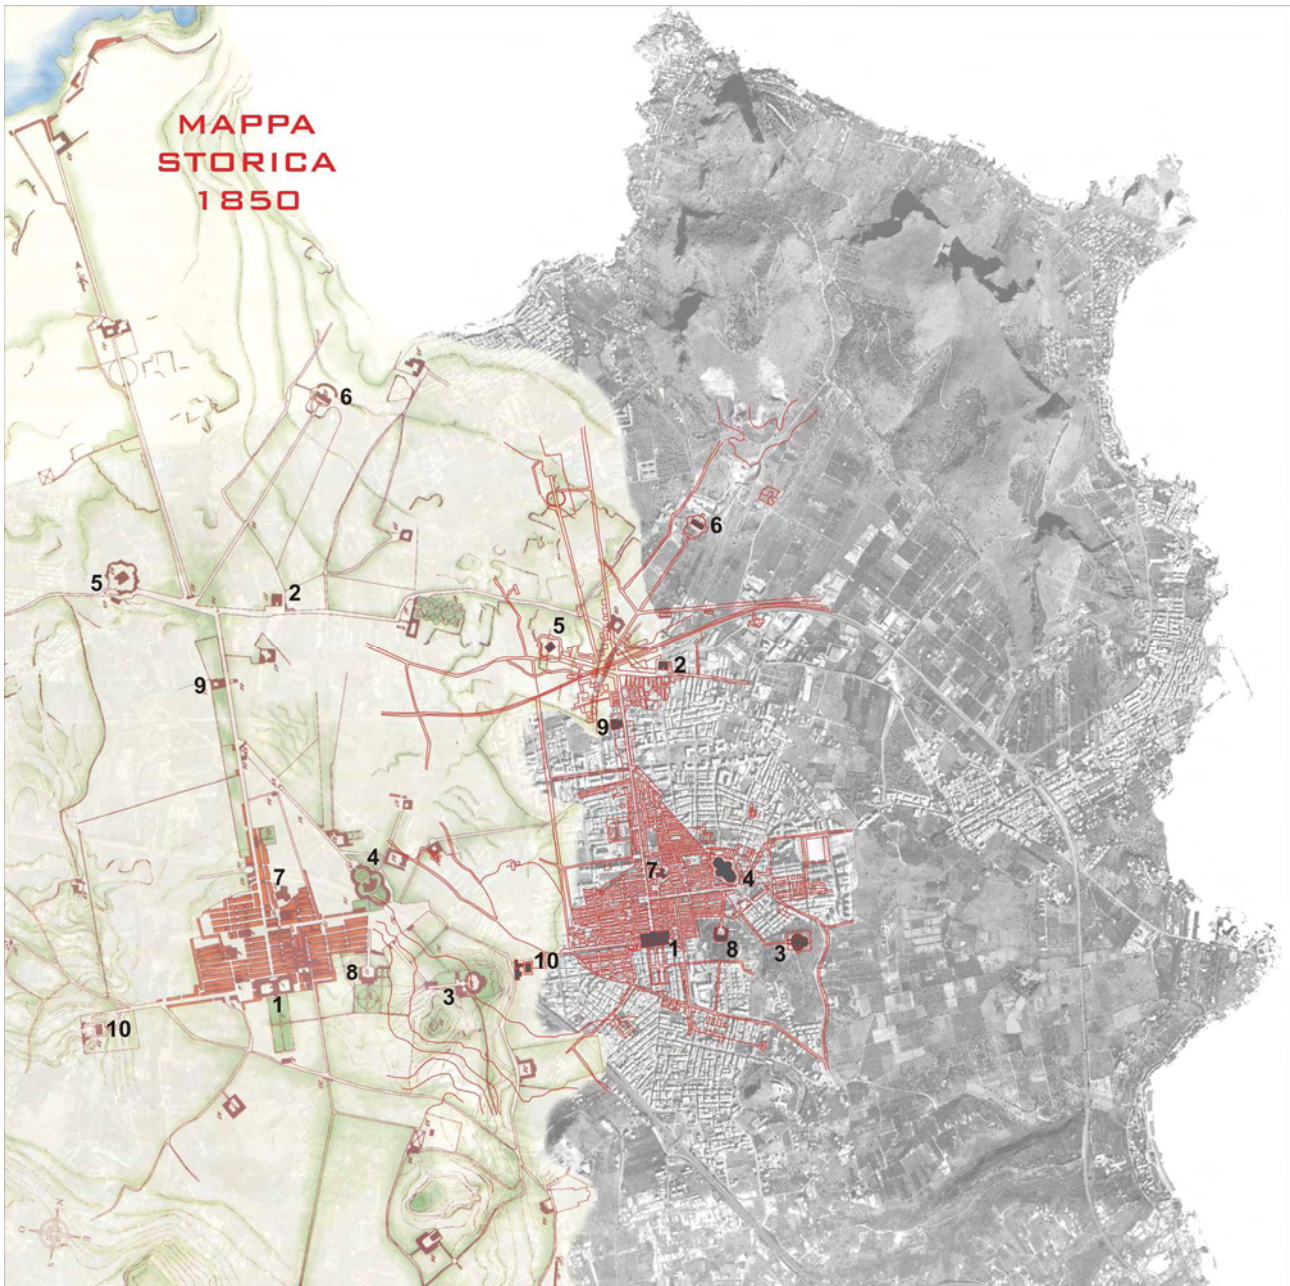

Fig. 1: Territorial framework (Bagheria, district of Palermo).

This is a topic which is at the base of a complex set of ideas that affect the didactics, the design, the representation of the architecture in my research. The subject matter tends, in fact, to highlight the interest in the topic of the design-*image* and the design as *techno-digital culture*, complex topic to decode with traditional keys of interpretation. The purpose is to look into genres of intellectual processes translatable into images of spaces following what we have experienced over the past few years - in the study and in the didactics of the field of the representation of Architecture.

The attention given to some of these works (and in particular to some buildings that have been duly studied with other methods and intentions) aims to represent a desire to investigate the original essence which they were made with, together with the will to promote the knowledge of them. They are in fact architectural values, unknown to many, but fundamental in the history of late-Baroque architecture of Sicily and that, having undergone various alterations over the years, especially in terms of intended use, have lost their

vocation of suburban residences.

The study and so the representation of these structures has revealed the presence of common compositional elements, made in a different and original way in each of them, but which over time, through questionable works of renovation and recovery, changed their essence, not only as a single element but also as overall structure.

The essay must be understood as an opportunity to delve into methods and techniques of representation, and, above all, as a step of a training process that allows you to experiment with forms of expression for a critical understanding of the potentiality of the "image" in the field of the architecture; then showing how the potentiality offered by the graphical language, is crucial nowadays "to understand the direction" of the creative, communicative, popular and cognitive process of the architectural thinking.

The purpose of this paper is to provide a general framework on the main theoretical and practical aspects,

useful to understand critically at a communicative, expressive and historical level, the techniques, methods and languages of the architectural *representation*, starting from existing surveys which for many years represented a unique reference on the subject matter.

We've taken into account the villas of Bagheria already masterfully explored through a long campaign of survey (*) in order to highlight some "*interpretative keys*" by using the three-dimensional *image*.

The result has been to re-interpret these models with a series of graphic exercises which have as object the study of the model, its representation and, more generally, the visual language of the model itself in his perceptive, communicative and expressive aspects.

Thus, one of the main goals to achieve emerges: to represent, understand and communicate *Architecture* through a mature and conscious use of the graphic language with stimulating modeling systems useful to understand the contemporary architectural expression as a laboratory for experimentation and testing, a time

of study designed precisely as a research *laboratory*.

From the above considerations, the central theme on which our observations rotate is therefore the image, but especially the study of a new kind of *images*, spatial forms generated by all the relations between architecture and elements through the use of new technologies.

This *new kind* of images - while maintaining (and amplifying) the semantic value peculiar to the representation, occur in various ways, creating perceptions, works and new critical elaborations. But also deeply and conceptually different from the basic images produced in the survey campaign launched in the seventies on the topic of suburban villas.

Images with multiple expressive values that analyze the architectural space in various directions. Images that seem to prefer expressive statutes strongly hybridized, where "*communicating an idea*" requires actions and elaborations different from what has gone before.

Images that invite the user to following steps of knowledge in favour of a progressive growth of the initial fact. Images that reveal their structure with further processes of knowledge from which derive the planning idea at the base of a model both simple or complex.

Therefore the role of the digital image is, in fact, for many reasons that of a visual *medium*.

Indeed, in our case, the meaning of image is "*a category both ambivalent and misleading, which lies midway between the concrete and the abstract, the real and the conceived, the sensible and the intelligible*" (J.-J. Wunenburger, *Philosophy of the images*.)

Images that simulate, simultaneously, a double essence: on one hand the realistic trend of information that takes place in the faithful re-production of the "truth" of the reality forms; on the other hand the tendency to formal decomposition and interpretation of the constituent process.

A kind of "*synthetic and paradigmatic construction of the images*".

Imagines that - following what Virilio calls the *stereophony of reality* - allow us to develop a model through which watching-ourselves from an external point of view; images able to duplicate reality, offering simultaneous experiences different and more complex than reality.

A new kind of images that are reopening known issues, in particular on the topic of the shape in architecture and introducing interesting innovative contributions.

Innovations that expand the study, but still generate distrusts and difficulties in critical and operational elaboration.

Thus it is necessary to understand and better distinguish the role played by digital images in various reports above mentioned and, specifically, in the process of contemporary research on the representation of architecture and the importance of modern in architecture.

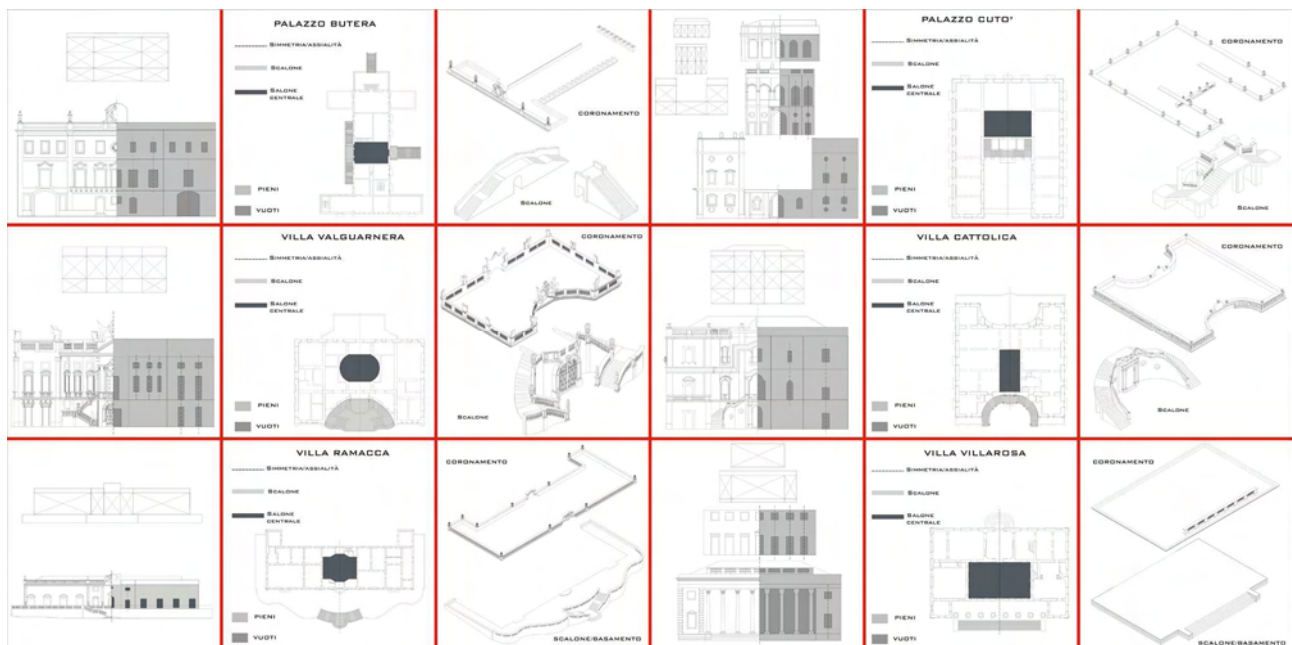

Fig. 4: Study of the facade (Morfemi).

Fig. 5, 6: Villa Cutò; Villa Cattolica.

Fig. 7,8: Villa Ramacca; Villa Valguarnera.

Looking at the new forms of digital processing of these works and considering , in particular, the planning, cultural and social results of the phenomenon, emerges, in fact, a scene not different from its original in which the *image* - as "*laboratory*" of *representation* and *conformation* of the architecture - is the favourite *medium* for displaying and elaborating thought, in a scenery where the notion of reality and space, filtered through the technological eye, takes a different value.

A multifaceted reality of this new kind of images (*surveys* in our case), based on the lightness and clearness. We want to remind that as new technologies have helped to expand and renew our notions and the messages in the era of digital dematerialization look for more and more metaphorical languages, they still remain tied to "figurative representations". This study involves "the need for an upgraded critical review of the whole stormy field of the relations between language and thinking and, inside it, of the relations between logical thinking (and language) and figurative thinking (and language) ." (Bettetini).

The central topic of this paper seems to be then:

- What results may have this new way of thinking and enjoy the *image*, the survey (in our case) and its representations, at a stage where the three-dimensional digital model assumes the role of *medium*?
- *Re*-productions that can interact, communicate, evolve, change and re-change invading multiple genres simultaneously.

Thus putting yourself critically before the work of architecture means, then, coming out of the flow of time to bring into focus the processes during which such testimonies were produced and have become what they are.

It is the notion of space, then, that takes on extraordinary importance to us.

Operating in space, in fact, represents, at the same time, a way to sort in one configuration the parts of a building and a form of ontological knowledge to which the human sensory experience is connected. The analysis and the representations consistent with the formal, expressive and cultural nature of the object under investigation, are then studied as systems of representations, that, starting with "*classic*" elaborations (plans, elevations, sections, axonometrics and perspectives), are oriented toward complex representations related to the notions of design and animation.

Thus there are two key words put as a link between thought and reality since each operation which generates meaning, involves an artistic production compressing in itself both the medium used and the use of interpretative models of creative processes and logics of carrying out.

The simulation can therefore be defined as an activity through which we create models, whether real or virtual.

The transition from analogical to digital does not determine changes of great importance, if not in the nature of the system of representation. A new era, which is configured as a valuable instrument by means of which you can represent reality investigated through modellistic formalizations increasingly complex.

The boundaries of the representation seem thus to tend toward a gradual expansion, far from consolidated graphical languages, the design of architecture become the search for expressive values that refer to something else. The digital images presented here and that ideally want to continue the study of several decades ago by Margherita De Simone, represent the idea of the villa as a "*movement*" simulating a particular perception and mainly giving birth to the foregoing considerations.

Creating a "global directory", an information network of the goods of cultural interest to create circuits that interact through models of interpretation, thus defining an interactive code of preservation which, through a multimedia platform implements the data testifying the specificity and the typical values of the places and the architecture works of the Mediterranean landscape.

Abstract

The cultural heritage meant as a territorial system definable as “museum field” needs ad hoc valorisation models. The **Progetto di conoscenza** becomes essential to allow the detection of cultural resources, the definition of the socio economic context and the compatibility of the use in order to calibrate the **Progetto di Valorizzazione** for a “qualitative” requalification of the areas.

From this consciousness, the International Telematic University Uninettuno UTIU fixes an additional “**Educational Offer**” able to supply on different scales and for different users, suitable tools that allow to operate in the field.

This offer is characterized through **percorsi didattici**:

- *training*;
- *scientific educational training*;
- *the definition of non normative fields*.

Keywords: Cultural heritage, telematics, museum, conservation, defense.

The contribution of the telematic university in the field of cultural heritage: the museum system between preservation and valorisation ^{1 2}

Today, more than in the past, we are conscious about the value of the cultural heritage not only as a subject of art and history but also as the integral part of policy, social and territorial dynamics that contribute to define their identity.

The “territorial systems of cultural heritage” meant as “museum fields” with precise connotations need ad hoc models of valorisation that find in the analysis of the condition of things, the foundation for the definition of a new operative procedure.

The *leit motiv* of the event *Less – More* fits positively to the will of the present contribution to emphasize for the cultural heritages meant as museum fields, criticalities and values, limits and potentialities.

Less – as a decay and decadence condition – is the term used to define: the general crisis that involves all our heritage, the situation that characterizes the way to understand the museum valorisation that is at a stop to the eighties acquisitions.

More – meant as most – is the term used to define: the existent cultural heritage on the national heritage; the growth of the fruition demand from stranger countries from Mediterranean Basin to different continents: missed opportunities to intend, in a suitable way, the valorisation of our heritage.

The cultural heritage, meant as an independent entity from the reality in which it falls on, has brought to different shapes of unsuitable and non homogeneous valorisations compared with the context on which they fall; considering – on the contrary – the cultural heritage as part of a system brings to the detection of new models of valorisation detected through the definition of cognitive information systems or through the philological prosecution of the territorial history to discover again its identity.

In both cases, the “**Progetto di conoscenza**” is workable through the definition of monitoring cards that allow the detection of cultural resources, the definition of the socio economic context and the compatibility of the use. (Fig. 1)

On the base of the furnished data of the cognitive analysis it is possible to identify the indicators for the definition of the **Progetto di conservazione/valorizzazione** aimed at a “qualitative” requalification of the places through the integration of the cultural, material and immaterial resources.

This new way to understand the cultural heritage needs some professional figures able to manage, both during the analysis and projection phase, complex realities that include different shapes of knowledge. This is not changeable, according to the strict rules of our system; it is necessary to provide somebody who works in the field of cultural heritage of updated and suitable tools in order to satisfy the new needs.

From this consciousness, the International Telematic University Uninettuno UTIU fixes an additional “**Educational Offer**” able to supply on different scales and for different users, suitable tools that allow to operate in the field.

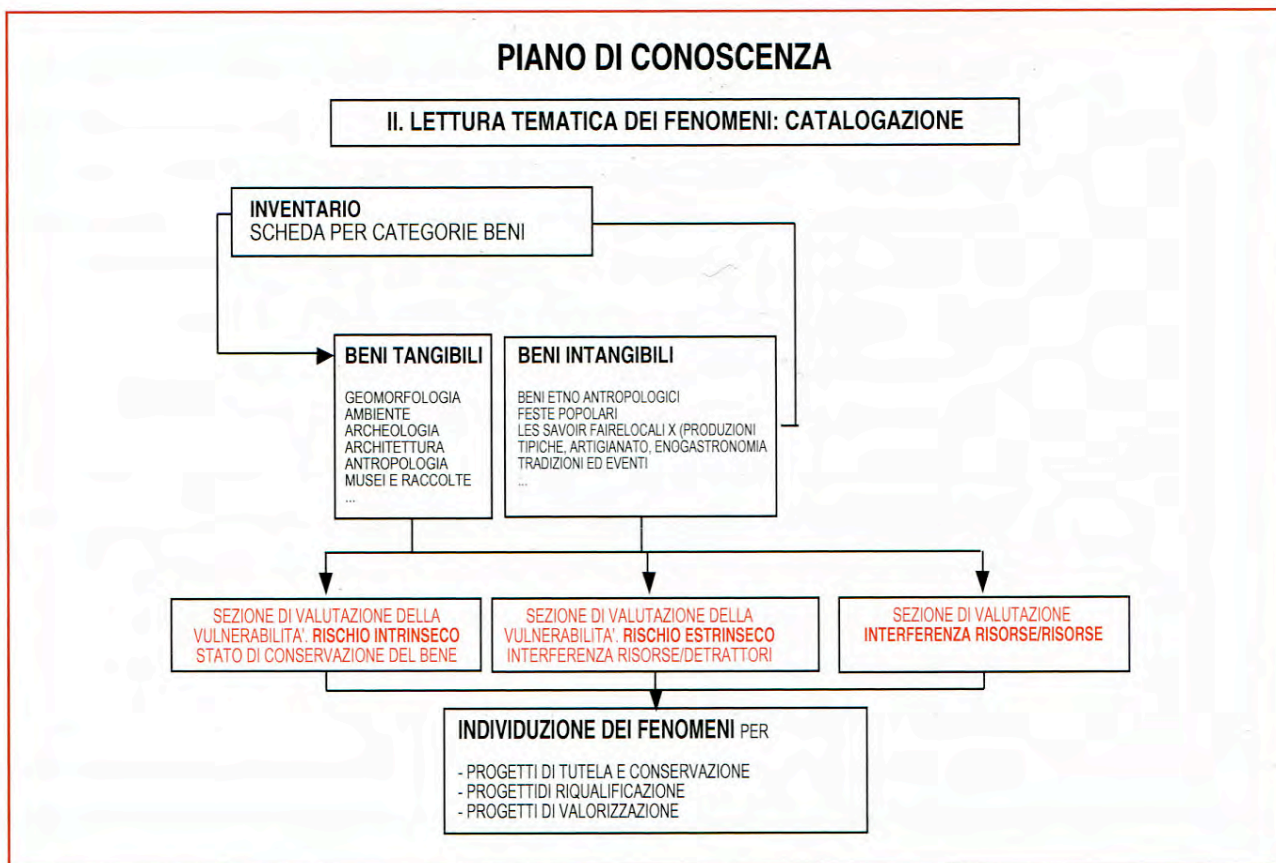

Fig. 1 – *Modello del Piano di Conoscenza dei siti UNESCO* – Lo schema conoscitivo, attraverso la definizione di schede, prende in considerazione i “beni tangibili/materiali” e i “beni intangibili/immateriali” di un ambito territoriale utili alla definizione dei progetti di tutela/conservazione/riqualificazione/valorizzazione. (T. K. Kirova, *I siti italiani iscritti nella Lista del Patrimonio Mondiale dell'UNESCO*, 2004).

Described as **Progetto di Istruzione Permanente**, the educational offer through the telematic system is articulated in three phases:

In the first phase called **CONOSCENZA**, led through video lessons, it will supply the necessary tools for the cognitive analysis of the cultural heritage to different scales, from the architectural one to the urban one and finally to the normative one in order to define a valorisation model.

In the second phase, every single student will try, through the support of the tutor, to define a **PROJECT**, shaping the ideal model achieved during the cognitive phase to the reality of a specific context.

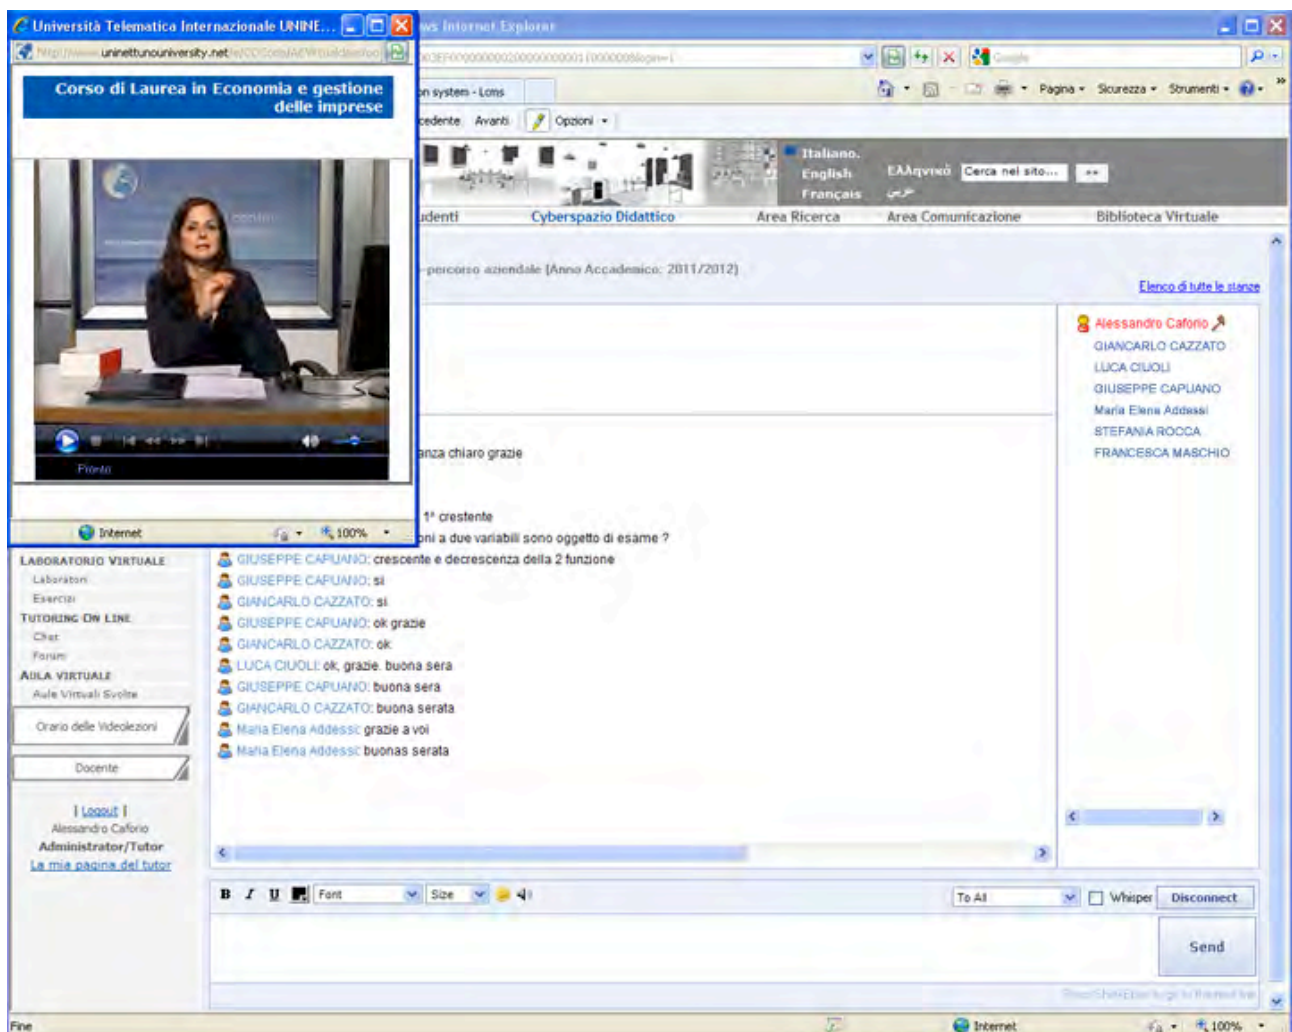

Fig. 2 – UTIU - Esempio di aula virtuale in cui il tutor interagisce in tempo reale con gli studenti.

In the third and last phase, through a *virtual laboratory*, tutors and professors will proceed with a punctual check of several offers. (Fig. 2)

As a privileged observatory of the market needs and taking as a model the UTIU project with TELECOM students, some specific *percorsi didattici* will be created and addressed to whom is working in the field of cultural heritage. (Fig. 3)

Fig. 3 UTIU, *Facoltà di Lettere – Operatore Beni Culturali* – Formazione degli studenti Telecom iscritti. Modello su cui sono stati calibrati per altre aziende i pacchetti dell'Education Permanente.

Starting from the supervising of the models already made or obtained from the seasons of the financing funding sources (European Council, European Community, Cultural roads, Cities, Castles and villages) they will follow the following steps:

- training for students coming from primary and secondary school;
- educational scientific updating for whom is working in the field (Superintendent), reference models supply for the operative procedure;
- the definition of non normative fields.

The figure of the cultural heritage operator needs an education like an Interdisciplinary system that involves not only humanistic subjects but also anthropology, chemistry, architecture and engineering.

An Interdisciplinary system that has to involve even who is now working on the *landscape*, a specific field that lacks of a precise connotation and that needs an univocal involvement from natural sciences (environment/ecology) and from esthetical/ecological sciences (territory/man/nature).

Adjustments and Guidelines for innovating the museum system ³

The contemporary definition of the concept of landscape then contains a multitude of issues covering both conventional methodological approaches aimed at the enhancement of the historic - artistic, is the consideration of the natural landscape and sometimes built as part of cultural interest, is still evaluating intangible assets such as traditions, languages, dialects, enogastronomie etc.

An essence therefore extremely heterogeneous, whose approach can not be divorced from the wider multidisciplinary training banner.

Operator training is dedicated to the cultural heritage of interdisciplinarity, a necessary condition for the best action to safeguard the good historian, archaeological, heritage museum.

In the sixties the promotion of historical and artistic heritage was through the use of the museum, his was an elite audience of art lovers and scholars, a place in a quiet conservation activities, contemplation and research.

In recent years, the museum concept and methods of use have been greatly developed, so that today there is a need for a reformulation of the basic ideas, without denying the validity of some previous solutions.

Develop our knowledge about the functions of the museum and how they are evolving from the 70 came up to our present time, is very important. Discover activities, provide new opportunities with the use of technology for the improvement of museum system and in line with the latest addresses of multidisciplinary should be a goal shared by all. You need to learn new research and solutions appropriate to our times and our problems, so that the new reports between the museum and the environment are integrated with more and more settlements in the reform of the museums.

Rarely, the debate between conservation and innovation, the assessment of unresolved dichotomy between the value of the past and need to use a contemporary, as is interest in such a meaningful part of the dissertation on the museum, intended as a single item, container or state of art expression of art, or as a plurality of elements, physical and / or afisici, which may help define the "knowledge network" so valuable for the preservation of a historic monument.

Thus we can understand the challenges of balancing two requirements, still not fully resolved: one is to ensure the protection and readability of the monument, so to preserve the cultural value of the "container", the other to set up a proper museum exhibition that can and must balance the most appropriate to emphasize the work "container" and the most effective level of enjoyment and use by the public.

In recent decades of the museum has changed its appearance according to the discussion that led to a profound revision of the concept of cultural and artistic heritage, taking into account the increasingly consolidated model of social and educational use resulting from implementation of the methods transmission of knowledge from a distance or in e-learning, developed and borrowed developed very well in academia.

The Mav (Virtual Archaeological Museum) at Herculaneum represents a good example of innovative multi-sensory, effective transmission of knowledge from anywhere using teaching methods acquired in the university, the use of three-dimensional images, computer-made and accompanied by music influences the ad hoc represent a new method of cultural enjoyment to learn and discover in detail the historical realities of Herculaneum and Pompeii before the eruption Vesuvius in 79 AD. (Fig.4)

Fig. 4 – *Museum Mav of Ercolano.*

The visitor is transported into a virtual context faithfully reconstructed by the use of modern technologies. The journey begins after passing a sort of ancestral door dematerialized bodies in streams and connective intelligence leading to the discovery of names and faces of the ancient Herculaneum, with which it is aware of the history of the community and their way of life.

A potential transmission of knowledge is not diminished but actually strengthened by this essence fisica, can contribute to the creation of an excellent network of knowledge and potentially infinite strutture, therefore, a real "network museum" free from the constraints imposed by conflict between conservation and utilization.

The increase of contact channels, and then the implementation of the flow of visitors, physical or fisica has, for a museum, also effects of strictly commercial nature: the increase of potential users and, therefore, the potential demand, can make the museum a commercially more attractive in terms of investment or sponsorship, a further opportunity for lenders to advertise your brand or your company.

Cultural tourism is proving, for several years, one of the fastest growing economic sectors in Europe, one in which "people are increasingly willing to spend money not on Their consumer goods but services on That allow Them to have Personally enriching and memorable experiences". Which is why invest in cultural tourism should be a resource on which to bet. Even museums, should be able to offer a product that can guarantee you a memorable experience, so it is worth to spend.

The versatility of the museums that run on multi-media contexts has direct consequences on the global supply museums, its cultural transmission and economic impact in terms of revenue and induced local: it is a monetizable value is not always easy to quantify, but that could prompt investors and lenders, public and private media to decide to invest in the appearance of cultural communication.

In the seventies Rosenberg stated: "In Italy, there are laws, regulations heavy, a bureaucratic system complicated enough, but behind it there is a knowledge and a defense of the artistic, popular among the people of each city, which is by far higher than that of other countries. Beyond the law, government, bureaucracies, there is actually very close to the Italian heritage, who has his eyes open on its importance and his salvation".

Today, unfortunately, our areas of protection have expanded over the past, the area of conservation is very extensive as the need to protect the artifacts and monuments that can no longer be exposed outdoors and which in most cases should be replaced with copies or musealizzati. Insufficient commitment and resources for this to happen.

The modern museum structure must therefore be able to provide a service of cultural information organized, at the same time carrying out a pilot function educational.

From here the necessity for each school ask its scientific services, education, preservation, even to the outside, as supports for the performance of other functions.

The question comes from the public it is no longer a passive audience: you must live in museums, or, even better, experience.

There is another important aspect overlooked because, today, in Italy as in France: that a museum is a place for the public. The American museums such as London are more open than ours: places where people go to enjoy the art books, etc.

They are places of culture and civilization. There is no incompatibility between the museum organized and attentive audience, but, in general, there may be an instance of conflict between conservation and the use of. The real conflict comes on if the museum becomes the object of a fetish market with unskilled and the media.

If sold, as is often the case, along with the package, the museum no longer serves no function, it simply becomes an asset to exploit. The same thing occurs occasionally and for reasons entirely different with the schools, particularly elementary and middle school education, often introduced as a walk in the museum. It is, in both cases, the examples of misuse of museum complexes, which arrives to empty results for users and produces negative consequences, even destructive, for assets subject to a mass-use indiscriminately.

From this born the need to establish a connection between tour operators and inspection services, designed to be a more effective distribution of admissions criteria, and museums in the area, taking into account the cultural level of the user. The organization of tourist routes, for example, should gather educators from the museum's suggestion of different routes, which in any case provide a historical overview, so as to leave even a single day in the visitor, structured picture of the known .

Even for the museum-school relationship, you need a job preparatory visits, which can be done under the museums themselves but assisted by personnel capable of using appropriate technology, such as projections and video. Too often students are accompanied on a visit in the cultural scene by personnel not trained and not suitable to illustrate the path.

A useful contribution to the refinement of the training function can also result from the opening of the museum to visit restoration laboratories, where knowledge of artistic techniques will complement the information on historical works.

Preserving, protecting the fragile work of art, irreplaceable, one in perfect condition and transmit to future generations must be our common objective.

So how to defend the historical collections held in the original sites and still privately owned and endangered by the growing economic difficulties and abandoned all'incuria and degradation. We must pursue the possibility of preserving monuments and art of great importance. The situation in which there is the Palace of St. Carditello Tammaro currently represents a good example of cultural property is not protected and abandoned. (Fig. 5, 6, 7).

Fig. 5 – Royal Palace of Carditello.

The “holding of Carditello”, fifteen acres of land and a royal palace built by the architect *Francesco Collecini* for *Ferdinando IV di Borbone* to *San Tammaro*, in the area of the province of Caserta, which the Romans called “*Campania felix*”.

Inside were the frescoes of the painter Philip Jacob Hacker, who hosted Goethe in his “*Travels in Italy*”. The verb in the past is a must: most of the decorations have been lost, destroyed by years of neglect and water infiltration.

But the Palace is owned by the Consortium for reclamation of the lower basin of Volturno, a Regional Authority founded to govern the discharge of wastewater and stormwater. The Consortium, unfortunately, is disastrously in debt, which is why the Palace has been foreclosed and auctioned to the highest bidder.

In places the object of cultural heritage, the number of visitors and of itself constitutes a problem: you know the damage caused by changes in temperature and moisture of the breath, and even the physical consumption of the monument caused by the continuous flow of people. Contact with a large audience, sometimes uncontrollable, also poses a problem of physical safety of the works and monumental building that houses them.

Fig. 6 - 7 – Inner Royal Palace of Carditello.

So there is a safety threshold between conservation of the building and operation of the museum included in the monumental place, which is sometimes exceeded. However, it remains true that, especially for historical collections, the relationship between monument or monumental buildings and works of art can work, within the limits of a previous target compatible with the new function. And since the monumental buildings, once restored, if used, are for a new rapid deterioration, the museum re-use is advantageous. But to say that the museum would necessarily be included in a monumental force is also an indication of our predecessors.

It also means even close the door on the possibility of being able to build a new structure designed and engineered specifically. A museum built in the language of modern architecture, is visited by an audience not only attracted by the works of art, but also the manner in which they are exposed.

A monumental building is an organism that lives or dies. You just give him a chance at life, even accepting small changes. This is a problem of measurement, the calibration difficult, which must be taken into account. There are very good examples of the rest: some renovation of monumental buildings have yielded good results. He added that there is a sort of rebound of communication between the character of the building, and things exposed, in the sense that the building can transform itself into a vehicle of communication of the culture transmitted by the works contained.

If the answer to these problems with a new update also theoretical functions of museums, not to be forgotten, however, that some endemic deficiencies can be solved with elementary precautions. Haskell said even "trivial": "that all objects are well marked by plaques and that the museum is better integrated with the local community. Everyone should be able to come and go as they wish, without cards, without a ticket. The museum director has to have respect for the audience, letting go, explaining that what is responsible, explaining what are the most beautiful things, most important, non-academic way, but giving everyone a chance to understand.

The organizational structure of museums appears easier to implement the model of science museums, art or history, but has more difficulty managing the museums of archeology and art. Probably because most of the museums and galleries Italian derives from private collections flowed back into public schools. Archaeological museums are fueled by the discovery of specific areas of excavation, and therefore have a more organic, and tendency to a gradual enrichment linked to its territory. As for galleries and museums are used, the story changes, their development is generally determined by occasional events, such as the presence in the market for works that would otherwise be dispersed, their presentation to export or what is more, in payment of taxes. The museums are they therefore have to act as a shelter for the works whose conservation is threatened.

The randomness of such acquisitions produce disastrous consequences, which affect the exhibition halls, where often an excessive presence of artifacts, including non-significant or repetitive. The Italian warehouses, on the other hand are already a fundamentally flawed, full of works that can not be displayed because of low interest, small paintings of modest quality, copies, furnishing the state with private purchases received or bulk donations.

We must consider the importance that the museum will in our lives, and in Italy than elsewhere.

Over the countryside and cities deteriorate, the more things that were part of our daily life, such as the "Ara Pacis" in Rome, which we used to see outside, we see now caged in a museum. We must accept the emergence of a culture of museums. It is increasingly important that you allestiscano and museums that are well organized, respecting and protecting the object.

e-mail: pina.novello@polito.it, massimiliano.loturco@polito.it

Abstract

The paper explores the potential of methods and languages designed to facilitate the communication of appropriate information content for the different levels of detail required in the creation of an architectural design, levels with different purposes, but nevertheless co-ordinated.

Within this thesis, the many different facets of drawing and the language of graphics are confirmed as agents of intellectual mediation, as a support for expression and also as dynamic cultural and evolving factors. In order to reply to the new demands of performance, due to the increasing fragmentation of responsibility for design, some adjustments in the workflow are needed, essential to support renewed practices; in fact, supporting this dynamic, the representation seems to have recovered a role of increased visibility and importance, regaining an effective recognition through a reconfirmation that remarks the delicate function of communication, interpretation and criticism.

The added value of the BIM methodologies (Building Information Modeling), is not limited by the ability to handle graphical representations at different scales with a single 3D model, but it answers to some requests connected by the data complexity inherent with the design and construction, actively supporting the engineering process: this means to relate actors or the building process to each other in a new way, reforming the assets and the processing modes, requiring explicit coordination for activities and procedures.

At this regard, we analyze new operational workflow through a brief description of some designs carried out through the collaboration between DISEG (Department of Structural, Geotechnical and Building Engineering) and the Building Service of the Politecnico di Torino [1], speaking about drawings and representations.

Keywords: Building Information Modeling, database, drawing, representation

1. Foreword

It is always very hard speaking of architectural design ; on the other side, talking about some kind of work that may occur during the process that takes place between the moment of conception till its complete realization it could be paradoxically easier. Indeed, this statement is useful to limit the area of interest of the following arguments, having the contribution that is declared in the title: being able to identify some critical aspects of the working-out processes, focusing the attention on those methodologies that are best suited to manage the complexity information of the design representation. [2]

The theme is not certainly new, but the purpose is to update some mentioned thoughts with the comments suggested by the latest operating procedures, in order to present some experiences conducted directly on the field. We are inspired by the intention “to exert ourselves”, in order to critically analyze and to abstract some principles of methodological value; this seems to be still the task of our way of doing research, looking at the drawing and the representation techniques as media collaborating for a deeper knowledge. It is required a renewed focus on other forms of knowledge and of action, as well as a position of listening to the needs that are expressed by other actors involved in the design process. During this process the Representation field is involved as a dynamic agent, stimulating action and collecting instances, working to

produce ideas that, responsibly, must be evaluated and verified through a series of tests. In order to better operate, those checks ask for an ever higher quality and quantity of data.

Are there some advanced tips to improve the efficiency and effectiveness of this complex process? We will try to answer by addressing to topic issues such as the role of the use of digital technologies, evolved from more established practices and based on a systemic and relational approach. We examine the limits and the virtues, exploring new communication languages and investigating the diffusion levels [3]; while we are still working on it, we anticipate some evaluations that could be discussed, deriving new demands from the debate, surely an essential topic for future studies. [4]

Digital graphics processing has become standard practice in recent years: it is a compulsory stage in design today. On the other hand the tool is not considered equally efficient in reducing the risk of omissions and errors. The reasons are to be sought in the limitations of the software, such as for example the types of Computer Aided Design (CAD) applications used, largely employed for the production of two dimensional drawings. The inefficiency perceived by users is the direct consequence of a certain difficulty in using the tools compared to the simpler interfaces found for office automation. The division of a drawing into classes of layers has always been a topical argument for the standardisation of information and methods of use and always an important subject for study by international standards authorities. One of the most significant international models is that drawn up by the American Institute of Architects (AIA), the BS1192 standard for Great Britain, the French System Unitary de Communication (SUC) of the 1990s and the Swedish CAD Guidelines Bygghandiingar 90 - SIS 1999.

Although BIM software applications in current practice ensure results of a much higher standard than those of traditional two dimensional CAD software applications, structured use of them can further improve the conception and design processes as well as the construction and maintenance processes. Often the BIM concept is associated with a quicker method of virtual modelling, which definitely guarantees faster results and higher quality, but it is not yet able to fully unleash the potential which a database for data of a different nature inside it possesses.

Here too standards must be adopted: at this regards, we mention the National BIM Standards Committee (NBIMS), based on standards for the interoperability of data and on the relative taxonomies and they put the various information sets into hierarchies following an approach that is appreciably different from those of the past, including classification systems, guidelines and best practices. Today's construction scenario contains a plurality of positions behind which lie just as many cultures which represent different conceptual approaches to design.

This paper explores the capabilities of the latest languages (both the analytical and/or the synthetical ones) of the new methodologies, connected to the preparation of the architectural design.[5] These techniques, exploiting the opportunities offered by parametric calculations, improve the communication of content using correct information for the various levels of detail. The increasing complexity of the project actions, often shared by a plurality of subjects, must be highly coordinated.

So, there is therefore the Useful Drawing, [6] which is pragmatic and functional, whose results exceed the drawn architecture characterized by information systems organized in a database constantly interrogated and quickly changed. Here the updating processes foresee automatic controls, overcoming the traditional analogical representation forms, adapting themselves in more dynamic ways. In other words, it is therefore a less sequential Drawing, and a more relational one. Within this complex background, the many different facets of drawing and the language of graphics, a broader concept and perhaps a more preferable term here, are investigated. They are confirmed as agents of intellectual mediation, as a support for expression and also as dynamic cultural and evolving factors, which have frequently been adapted, to contribute to a renewed quality of the design process, thereby recovering a role of greater visibility and effective relevance.

According to this view, the representation role seems to have recovered a role of greater visibility and importance, regaining an effective general recognition that has substantiated the delicate function of communication, interpretation and criticism. The surplus value of BIM methodologies is in fact not only connected by the ability to handle graphical representations at different scales using a single three-dimensional model; moreover, it seems to answer to some urgent requests moved by the complexity of design and construction. In fact, this approach actively supports the engineering process relating professionals to each others in a new system, reforming the processing mode, requiring more explicit coordination of activities and procedures, particularly through the management of *parameters*.

2. The importance of being Parameter

At a time when professional practice is demanding increasingly specific competencies and extremely tight timescales, a tendency is emerging for software technologies to be used in a more deliberately structured

way, in a continual quest – one which is at times laborious, at others more fruitful – for procedural strategies that enable the use of shared platforms. At the same time, the market is responding by offering a large number of applications devised to resolve the various specific requirements. The term *parameter*, from which some of the considerations in this book are derived, assumes different connotations depending on the context in which it is applied. Whereas in mathematics it represents an arbitrary constant used in systems, formulae and equations, in a design environment it can take on other, different shades of meaning. This is a good opportunity, then, to unravel this terminological tangle: unlike parametric software, BIM object-oriented software has more in common with architectural design, where the internal libraries available are actually classified by building element type. So there are software applications in which the parameter is central to a system of associated dimensional relations and is given flexibility by procedures that facilitate not only the formal conception but also the changes occurring in the subsequent construction stages, which is fertile ground for experimenting with programming code. In other contexts, the same term refers to the control of a certain number of variables (geometrical, relational and other ones) that enable a particular process (design, construction, management, etc.) to be managed. [7]

For computer science, a parameter is a value that a function expects to receive in order to do its job. In other words, the function, the program itself and the operating system expect (values) and want to know (what to do), because the programmer has expressly envisaged that information be supplied for those purposes, i.e. by requiring that parameters be defined. In the familiar context of design software packages, the process of constructing relationships and generating objects via modelling procedures is often carried out using a programming environment provided within the individual applications that is known as scripting. This refers to a programming language available within a software application that enables it to be tailored from the inside, by customising the tools and creating new ones.

These tools have made functions available to designers that were previously inaccessible (or required special, complex operations), thus enhancing not only the modeling procedures but as a result also making it easier to use shared formats to exchange information. The purpose of this is to enable interoperability within the individual products. Both parametric and object-based software are moving toward this common objective, on parallel paths: For the former (in terms of the most authoritative names on the international scene), we are seeing new operating processes being developed in which the professional works closely with the programmers, creating tailored applications as and when required. As for object oriented software applied to the architectural design sector, the most effective use of software tools enables some procedures to be customized, as discussed earlier, through an ongoing search for shared methodologies for organizing the data that are managed by the system.

3. BIM: Building INFORMATION Modeling

Current technology has useful virtual alternatives to offer, then, such as the adoption of three-dimensional models for display, simulation, analysis and calculation purposes. If, on the one hand, there is a risk of making the control of some highly sensitive procedures more complex, on the other, the BIM approach, whose potential is yet to be fully realised, has the power to confine traditional CAD tools to the role of producing series of drawings. Although two-dimensional drawings are certainly able to convey the designer's intention, they are often blighted by errors, omissions or inconsistencies, which can easily be identified using automatable checks. It 's definitely a less poetic Drawing if compared to some representations of the past, but its contents are highly informative.

Although a host of design studies are taking an interest in these issues, few are using this methodology to best effect. These tools enable significant changes to be introduced throughout the traditional architectural design process; in particular, the benefits can be estimated using a multi-functional diagram that compares the effort made by professionals to produce the design documentation in the various phases of the process with the time required to do so. The diagram provides a comparison of the distribution of the technicians' efforts through the various phases in a traditional CAD environment (graph 3) with how it looks when basing the design process around the use of a BIM (graph 4). The impact of later alterations to the design can also be assessed: it can be seen that the effort needed to make these changes is equal to, if not greater than, the effort required in the initial decision-making stages (graph 1). What's more, the impact of the costs of the subsequent alterations increases exponentially throughout the process. To that end, it is useful to refer to the procedure proposed by Lachmi Khemlani [8] in which, as the author suggests, "[...] *minor variations from this sequence can occur from time to time, but the essence of it remains as shown*".

Fig. 1: Macleamy curve comparing the course of the current design process with the results of using a BIM approach in terms of effort, timescales and costs

In architecture, the process of progressive automation has taken and continues to take a path that is well-trodden in the history of the evolution of software, as most of the applications were primarily intended to support a process known as *Drafting*, including the initial forays into computer-aided drawing. The use of the third dimension in the representation of architectural designs and a systematic recourse to three-dimensional modelling have established a subsequent stage, known as *Modelling*.

The design process typical of the drafting stage is not affected by the use of three-dimensional modelling software, as the two-dimensional design phase is followed by a three-dimensional modelling phase, independently of the Monge representation. For this very reason, the three-dimensional model is very often developed outside the design team and only after the design development stage has been completed, as a natural “dead end” of the design process, one which is used only for the purposes of disseminating the design.

The process of progressive automation moved on with the introduction onto the market of the first “object-based” architectural software packages. Indeed, the introduction of the BEMs or Building Element Models, in place of abstract geometrical entities, represents the main step forward with the BIM philosophy: whereas the Drafting applications made possible the two- and three-dimensional geometrical representation of any architectural construction, the Modelling software applications make it possible to build it, albeit in the form of a virtual building. Hence the term *Designing*, for a tool dedicated to design in a completely innovative environment.

The automation of some of these processes will lead to the point when all the design information will be created and handled digitally, thus maximising the benefits of this new “virtual format”. In other words, we will have a digital model of a building, one that is not just geometrically accurate but can support completely different kinds of information. For this reason, the final stage is called *Collecting*, which corresponds to the design of the architectural construction in a purely BIM context. The introduction of BIM has brought a radical change in the management of the design process, and it is crucial to understand the impact that this has had, and will continue to have, in the construction industry. The very concept of the BIM is based on the possibility of incorporating meta-design information of a non-graphical nature, such as numerical and tabular data, into the 3D model.

Here the Drawing and the Representation roles are completely renovated, being able to coordinate and control the entire design process, through the management of complex procedures.

4. BEM: Building ELEMENT Model or Building ENGINEERED Modeling?

As previously stated, the BEM acronym stands for Building Element Models, a digital representation of the architectural elements that are introduced and used within the BIM environment for the creation of 3D models. At the same time we propose a new sense of BEM, in which the meaning of Element could be approached by the term *Engineered*, underlining the need for engineering process for new technologies, making them more efficient.

Information flows in the building industry to today are compared with the continuous return or feedback of that same information, given the need to relate different types of data to each other and take account of their reciprocal influence. The concept of “quality” in the building sector defines particular aspects of the building process for which a direct relationship between requirements and performance is necessary. At this regard, Drawing has always constituted a privileged means of communication, but the subject of “design as a measure of quality” does not end with the communication of the ideas or with the specification and verification of the ideas with regard to those who implement them.

The monolithic character of traditional building is flanked today by the requirement for an analytical dimension that can be broken down, the design of which results from the overlap and reciprocal coordination of the various sub-systems and the use of BIM tools seems to be the best answer to these requirements. We can talk of out-and-out codes for design drawings, constituted by a set of rules that allow to “regulate” the graphic data communication. Below there is a summary of the main procedures that maximize the concept of engineered model.

4.1 Process engineering and standardization of procedures: the case of the design of new student residences

The engineering procedure is well defined referring to the process performed to design of new university residences (Ministerial Announcement for the construction of new residences for students - Law n.338/2000, published in Official Journal, the 28th of April, 2011 n. 97). This case study is particularly interesting for the organization of work carried out by adopting standard codes, easy to understand and easy to use in order to effectively implement the dialogue among designers of different expertise.

In practice, it was drawn up prior document for the designing phase, greatly simplified compared to the international protocols, in order to capture two aims: firstly, to harmonize the procedural expertise to the same basic level, ensuring that professionals could adopt it in a shared environment; then, to update standards and procedures to those experienced in the BIM environment. Doing that, it is possible to enter and extract data from CAD applications, allowing less critical information workflows.

| CAD Color | Printed color | Weight | % Filled | Contents |
|----------------------------|---------------|---------|----------|---|
| 1 – Red | Black | 0,1 mm | 100% | Quote systems, layout |
| 2 – Yellow | Black | 0,1 mm | 100% | Elevation lines, not sectioned lines |
| 3 – Green | Black | 0,15 mm | 100% | Frames |
| 4 - Cyan | Black | 0,09 mm | 100% | Sectioned Walls, Structures |
| 5- Blue | Black | 0,4 mm | 100% | Ground line |
| 6 – Magenta | Black | 0,05 mm | 90% | Furnitures |
| 7 – Black | Black | 0,1 mm | 100% | Layout lines |
| 8 – Dark grey | Black | 0,05 mm | 70% | Hatches |
| 9 – Light grey | Black | 0,05 mm | 80% | Edile per impiantisti/linee molto sottili |
| 10 – Red for Construction | Black | 0,25 mm | 100% | New elements |
| 50 – Yellow for Demolition | Yellow | 0,25 mm | 100% | Demolished elements |
| Other colors | By color | 0,4mm | 100% | HVAC, electrical, plumbing systems |

Fig. 2: Proposal for standardization protocols: the scheme summarizes the connection between CAD and BIM standard used for new architectural design of the Politecnico di Torino.

Shortly, the protocol includes a set of prescriptive guidelines that contain elements of unification for the management of the projects, specifically dedicated to its representation such as layout templates, layers, text size and pen thickness. We tried to use standardized naming and symbols, also available for CAD drawings and for the treatment of processed data in a BIM environment. Moreover, this work had as intermediate

Even in these cases, which present specific and non interoperable information, procedures can be organized by adopting particular protocols, so as to guarantee the efficiency and effectiveness of technical communication.

Also within the BIM platform, the second topic was the adoption of various templates according to the different types of intervention (referring to different levels of design: master plan, preliminary, final or executive designs, new or existing buildings...). The time constraint seemed the perfect opportunity to put into practice certain procedures till now known only in theory.

The two design project, although characterized by different plan distributions, show remarkable similarities in relation to manufacturing technologies, components and building materials chosen for walls and floors, reducing the time used for drafting of construction details, quantity take-off and its evaluation of economic costs and exposure. From the operational efficiency viewpoint it is important to decide in advance the view models, such as the standards for the visualization of the project at different scales (1:200-1:100-1:50, in order to speed the transcription of drawings at different scales, equipped with some topics expressly required by the announcement. It was organized an information system based on relations between some parts and the entire design project, thanks to a graphic representation organized through a unique model. This methodology is destined to bear the complexity that occurs whenever it is needed to start from the conceptual phase up to the construction one, working as the product of data processing and, at the same time, being challenging and fascinating if collectively shared.

4.2 Teamwork: the case of the reutilization of a heating station into new classrooms

Each new project provides interesting ideas to carry some innovations in the working methodology, maintaining the desire of doing research and trying to compare results issued from previous experiences. In the mentioned case study, some areas will be converted into new classrooms; it was decided to adopt a working system that would allow multiple users to work concurrently, using the same file. The goals of the trial were to assess how and whether it was possible to:

- maximize efficiency production through adopting a coordinated and consistent BIM working approach;
- define the standards, settings and best practices that ensure high quality results and uniform drawing output across an entire project;
- ensure that digital BIM files are correctly structured, in order to enable efficient data sharing working in a collaborative environment.

There are several methods to enable collaborative working in a BIM environment, including working practices and team management. This topic deals with the principles of subdividing a model for the purposes of:

- multi-user access;
- operational efficiency on large projects;
- inter-disciplinary collaboration.

We must honestly remark that each project carries out a period of knowledge and testing able to improve the traditional workflow. Doing that, each new project means an improvement of the traditional workflow. Till now, the information sharing technology was done using external references (linking) in order to split the architectural part (Revit Architecture) from the structural one (Revit Structure).

The design of new classrooms was the ideal chance to progress in the trial: also in this case it was carried out on the basis of international experience, first of all the example of AEC (UK) BIM Standard for Revit, a workable implementation of the AEC (UK) BIM Standard for the Architectural, Engineering and Construction industry in the UK. This Standard is aligned with BS1192:2007 Collaborative Working, which defines the process for project collaboration and efficient data sharing. Focusing the attention on collaborative environments, we have defined specific processes aimed at effective data sharing in real time.

Regarding to this, the technology called Worksets allows multiple users to simultaneously make entry on a single template file, called central file, which is frequently updated by implementing multiple local copies.

The use of worksets is useful when the design phase is already far from the initial stages, in a phase in which it is requested the production of a significant amount of executive drawings that can hardly be quickly delivered by one person.

The work is then divided into different skills (structural, construction, engineering ones) so that the individual professional is responsible for a particular scope.

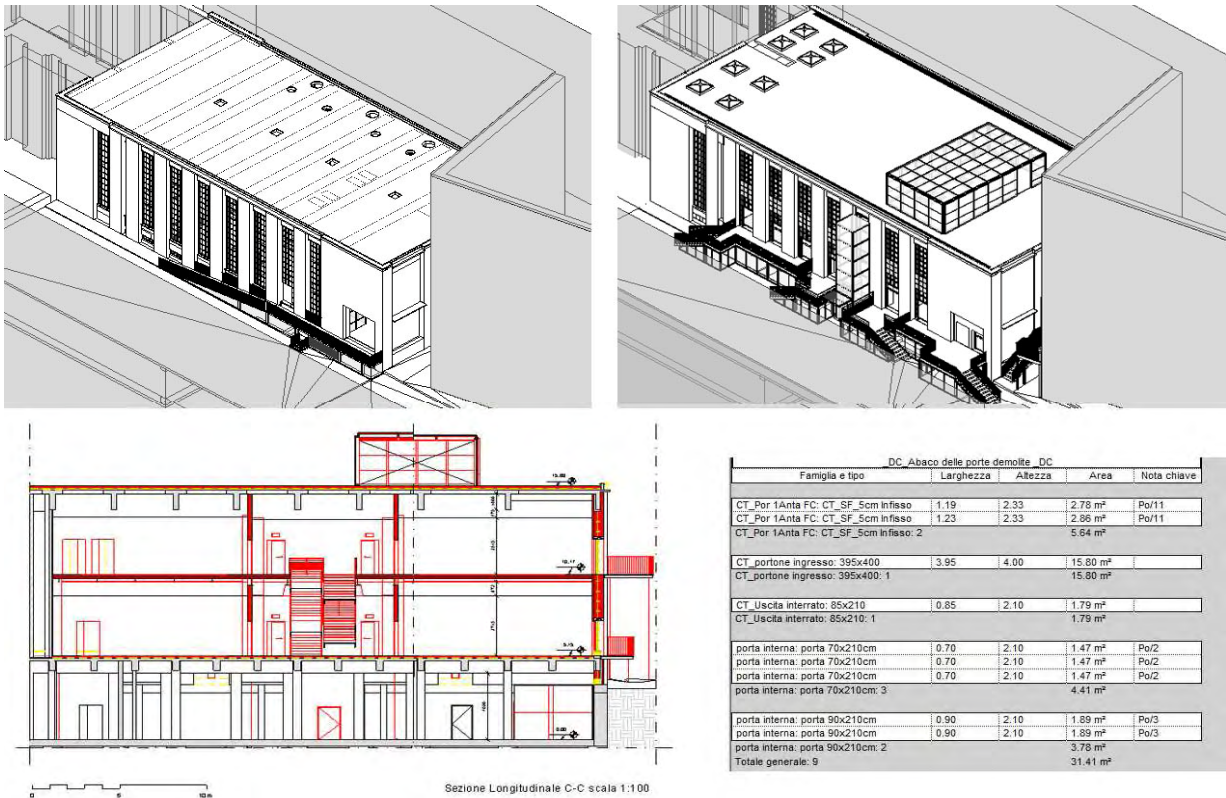

Fig.4. The variable time can be effectively managed within the BIM, as demonstrated by the following documents that compare the status of fact, the future project, demolition and construction section view and extract theme of schedule. (Authors of the virtual model of new classroom design: eng. G. Cangialosi and eng. M. Lo Turco).

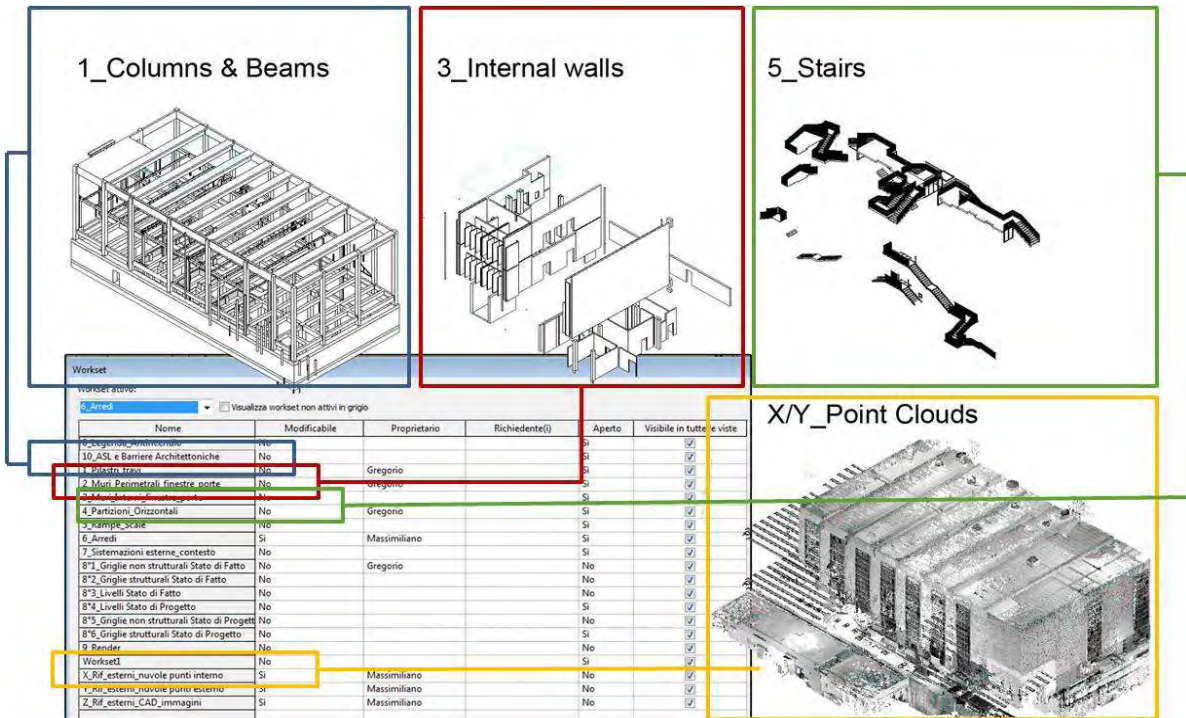

Fig.5. Through the workset management based on a set of simple rules that govern the interactions between the owner of a particular area (structures, walls, horizontal elements, point clouds,...) and some applicants, it is possible the current work using the same virtual model.

It is also possible to keep track of different changes applied to the model so that we can have a record of undertaken actions. This work is an excellent example of integration between the various professionals, both for the survey made by 35 laser scans directly imported into the parametric software, and for the planning, dividing the digital model into several worksets, as shown in fig.5.

5. Conclusion and future proposals

The adopted methodology has seemed very productive, as it has greatly reduced the design time and the number of errors, especially those related to interference between architectural and structural elements, (identified in both graphical and tabular views) contained within the shared platform. The most obvious benefit is the permanence of information of different nature: this is a topic element not only for the success of the design process but also for an equally controlled and organic process of management /maintenance.

As for purely design aspects, future versions of the standard are intended to enlarge the skills involved, including other actors, such as plant engineers, builders, contractors.

From the operational point of view, Politecnico di Torino created a dedicated department to deal with the integration of processes and information systems (known as IPSI), which, under the guidance of the Board of Directors, launched the Politecnico's Facility Management (FM) plan in autumn 2009.

The plan aims to optimise the management of the University's internal processes, by providing an information system containing the data on the various activities, thus creating a single database as a reference point for sourcing information and carrying out subsequent analyses.

It is a "time Drawing ", able to handle a before, a during and an after, not only in the design process than with the capability of the database to be associated with design changes over the time. A drawing, therefore, apparently less iconic, but with strong information contents.

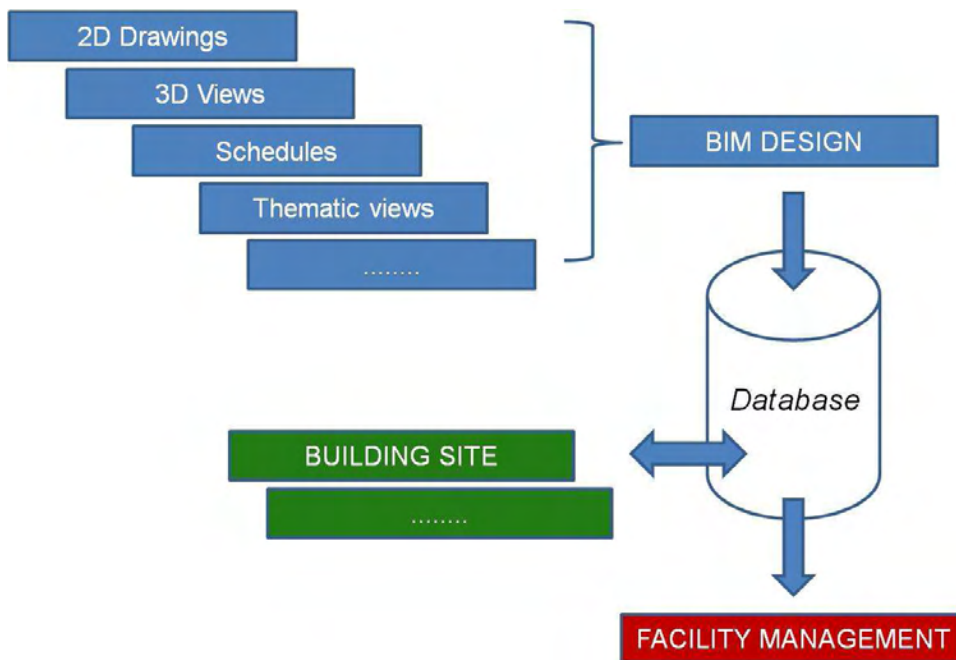

Fig.6. The diagram shows the main themes that constitute the design phase, ordered and managed by the database that is used again in the construction phase and for subsequent management applications.

The availability of an information system of this kind makes it possible not only to manage the data but also to devise and administer effective working and procedural processes. The technology can also be used in combination with BIM software and can facilitate an interoperable exchange of information between the two. For the FM project only, the basic virtual model will gradually replace the traditional CAD plans. This change will be no mean feat, as it will bring a real quantum leap in quality, one that will require the whole logistic area to adopt the BIM methodology. This change will encourage greater interaction between the parametric software systems and the FM applications, such that all the analyses can be carried out against linkable data, thus ensuring greater control over the processes and eventually enabling full data interoperability to be achieved. [9]

Finally, the methodology represents a new way of thinking about Drawing, in a fresh and renewed role, which organizes, arranges and manages a multitude of possible representations, constantly comparable: so, data sharing of different expertises enrich the relational database proper of the new systems.

Investigating on boundary. Integration approach to architectural rapid characterization

Pasquale ARGENZIANO, Alessandra AVELLA

Dipartimento di Cultura del Progetto, Facoltà di Architettura "L. Vanvitelli", Seconda Università di Napoli, Aversa, Italia.

pasquale.argenziano@unina2.it, alessandra.avella@unina2.it

Abstract

In this manuscript, we investigate the diagnostic acquisitions that is possible to run on the surface of the built in order to develop a protocol for remote sensing diagnostic activities - which are fast and low cost - for the characterization of all visible objects. Particularly, we investigate the relationship and the integration between 3D laser scanner data, photographic and colorimetric data and thermographic ones.

This experiment was tested on a segment of the medieval town wall of Pisa.

Keywords: multidisciplinary analysis, masonry wall, digital survey, 3D architectural modelling, thermography

Introduction (P. Argenziano, A. Avella)

Every natural or anthropogenic 'element of reality' manifests itself to our senses through its surface conformation. The surface is the limit that contains the object; it is visible expression of exogenous actions that modify the object in time and space. From territory to city, from architecture to design product, digital diagnostic technologies allow not only to characterize each visible (morphology, material, color) and invisible (temperature, deterioration) manifestation of object surface, but also to establish the 'deep' consistency of the object with non-invasive or semi invasive analysis. The data set contributes to the definition of a multi-dimension model, as already experienced by authors inside research activities of the CRdC Benecon.

This study, however, integrates the topic with a much wider multidisciplinary approach and takes into account the archaeological and the architectural heritage researches undertaken by the Second University of Naples, Faculty of Architecture with coordination of Carmine Gambardella. The Multidisciplinary approach allows to investigate the Reality from the territorial scale to the scale of architectural structure, the scale of the minutes object, through the discretization and measurement of tangible and intangible values that characterize it. This survey method associates the n dimensions of the survey with relevant scientific expertise, expanding the widespread concept of Representation to an integral of multiple disciplines that contribute with their own specificity, integrating data and techniques, to study complex object of investigation. The tool that enables a synchronic and diachronic interpretation of the investigated object is represented by the layer of knowledge. The layer is the 'plain' on which the homologues data are organized after being acquired through multidisciplinary investigation. According to the thematic of the Forum, the authors focused on diagnostic acquisitions that is possible to run on the surface of the built in order to develop a protocol for remote sensing diagnostic activities - which are fast and low cost - for the characterization of all visible objects. This experiment was tested on a segment of the medieval town wall of Pisa. The fortified system of Pisa dates back to the mid twelfth century and is still in place for more than two-thirds of its original length. The square towers are connected by crenellated walls about 10 m high and 2.2 m wide with an articulated stratification. The wall hangings are limestone square blocks while the brick battlements are approximately 1.5 m high. Established the current situation of the places with focused inspections, a integrated digital

survey has been planned and implemented by means of 3D laser scanning, topographic station, GPS station, thermal camera and high-definition camera aimed at the development of a geo-reference discrete model 'point cloud' of a wall segment as an example and to the relative thematic modelling. This multidimensional model allows to label the "status quo" at survey time (t) and to build up a digital model that is the synthesis of critical acquisitions. It becomes the starting point for a cyclic monitoring (Δt), performed with the same sensors, as well as the reference for the choice and for the planning of further non-invasive or semi-invasive investigations ("touch sensing"), that can be carried out in contact with the built and that will require more time and cost.

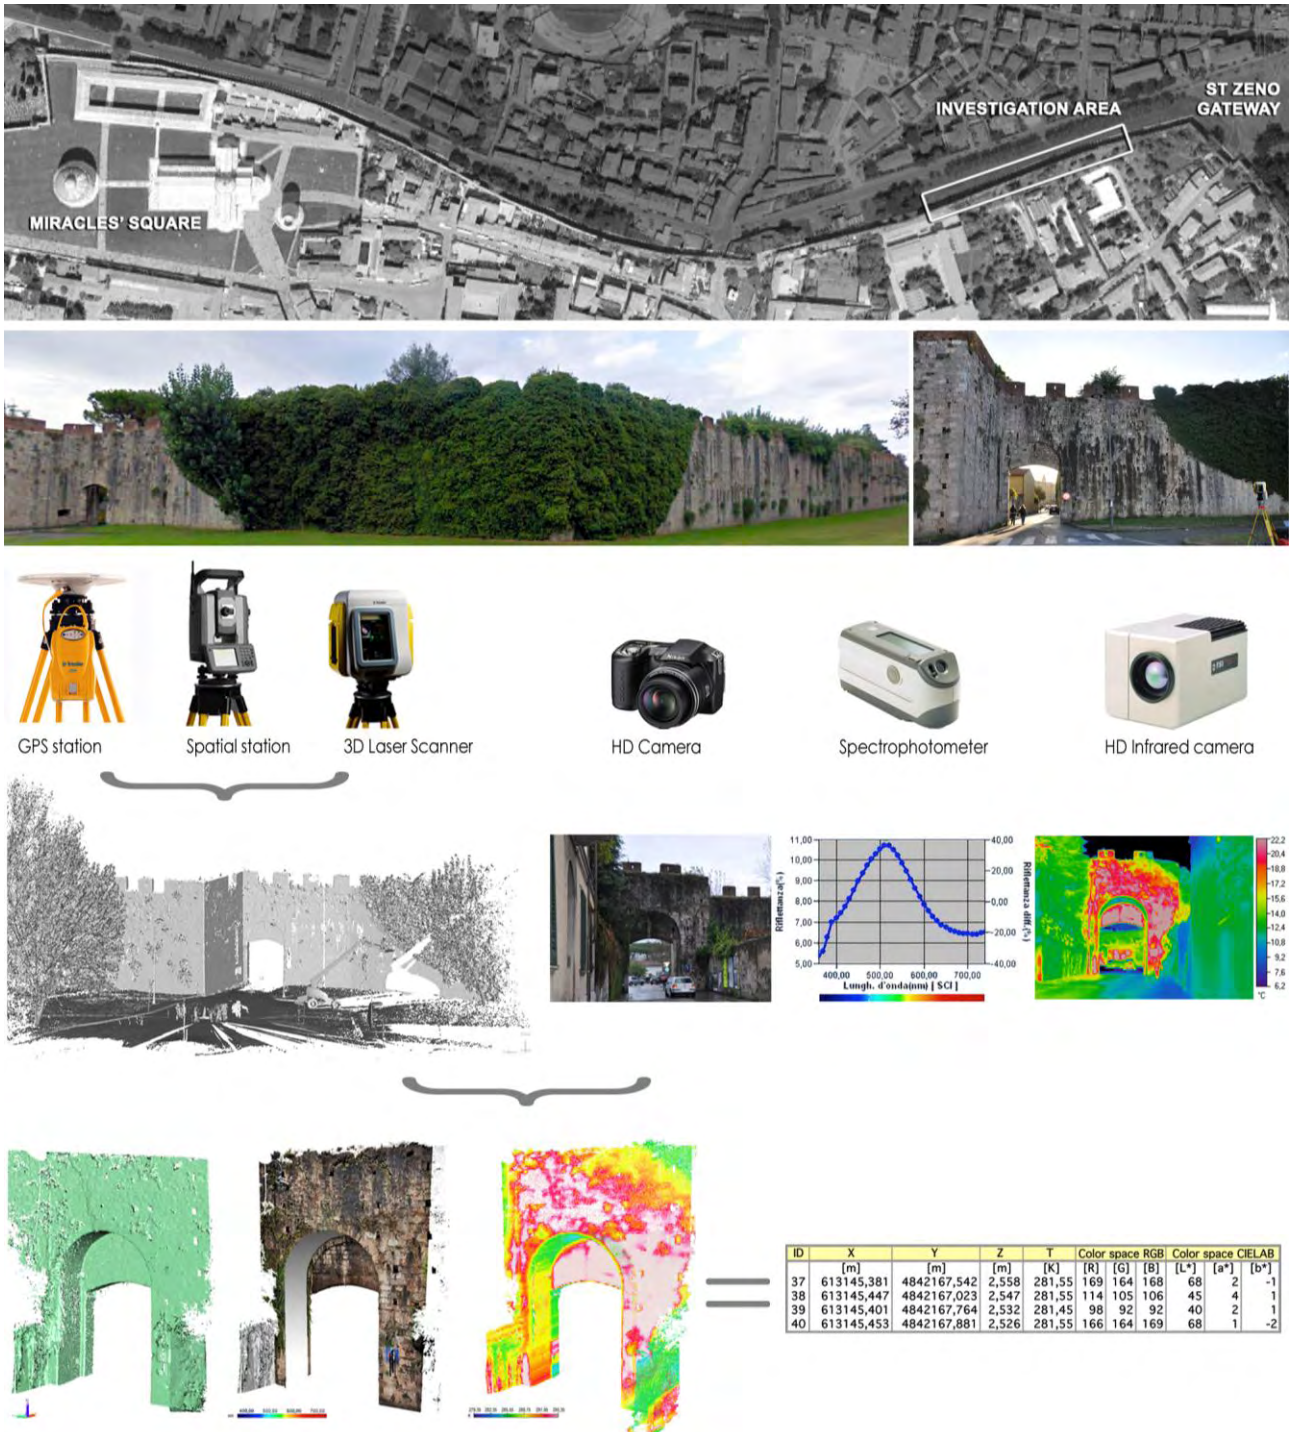

Fig. 1: Integrated digital survey: 3D laser scanning, topographic station, GPS station, thermal camera and high-definition camera (P. Argenziano, A. Avella, 2012).

3D Geometrical characterization of surrounding walls as basis of the integrated digital model (Alessandra Avella)

The integrated digital survey of a portion of Pisa's city walls, which unwind around the town for about five and half km, is the result of a method of approach based on the integrated interpretation of acquired data.

The following research provides:

- measuring the metric and morphological features of architectural elements, through advanced monitoring survey techniques;
- devising a discrete (punctual), 3D digital model of a portion of the surrounding walls, which may embody the whole surveying/rendering process described in the survey protocol given in this study.
- implementing geometrical surveys with feedback from high-definition thermal and colourimetric methods.

The so described 3D digital model acts as a fundamental geometrical layer, collecting metric data (which reproduce the spatial and structural features of an architectural element) together with thermographic and colourimetric information used for surface characterization.

The first step of a survey field work, following a preliminary activity-planning (as mentioned in the last part of the study), consisted of measuring a topographic network to identify the study area: that is accomplished by using an open polygon line constrained at its extremes to the IGMGPS95/ETRF2000 network in two geo-referential vertexes (coordinates were calculated based on the ETRF2000 European conventional system, which is currently one of the most updated systems adopted by Istituto Geografico Militare, Firenze).

The detection of two benchmarks at the polygon's far ends was carried out statically, by placing two GNSS antennas respectively on the IGM trigonometric vertex, of known coordinates, and on other benchmarks within the area of interest (the IGM trigonometric vertex selected as a geo-reference was n. 104613, in "Le Rene", Pisa).

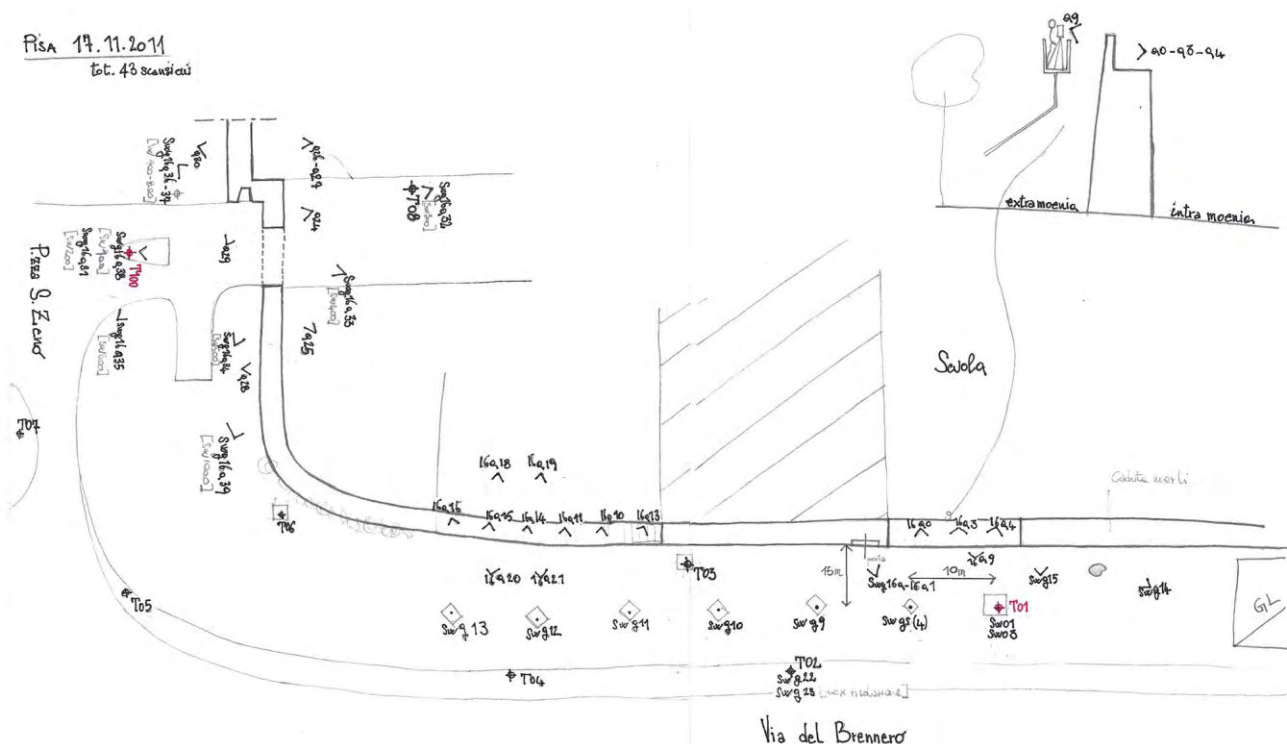

Fig. 2: Points of view or scan worlds of 3D laser scanner, GPS, and spatial station in a survey sketch (A. Avella, 2011).

The geo-referenced benchmarks, placed along the perimeter walls in the green area that stretches from Porta San Zeno to Bastione Parlascio, are used for further topographic reading and survey analysis with laser scanning.

Fig. 3: Portion of the city walls between Porta San Zeno and Bastione Parlascio: georeferenced topographic polygon (P. Argenziano and A. Avella, 2011)

In such regards, the topographic survey was designed and accomplished by means of a robotic total station through an open, nine vertex polygon line that was measured with standard procedures based on combined reading of vertexes, set out ahead and behind the reference station point.

Processing of topographic data was then obtained during the work in progress and according to geoid ETRF2000, in the UTM map projection, Time zone 32, acknowledged by IGM.

The XYZ coordinates were entered in the 3D laser scanner- control software to generate point clouds that had been previously geo-referenced with absolute coordinates, then dynamically aligned during data capture. This operation allowed for the optimization of the data post-processing phase in lab, and offered this research a quicker and more convenient approach.

Therefore, the first task of fitting the architectural element in its context into a geo-centric coordinate system was later followed by the geometric characterization of a segment of Pisa's city walls, rendered by the 3D Discrete Digital Model.

The metric and morphological description of a portion of the walls was carried out during a 3D laser-scanning work, and obtained in two steps:

- resolution calibration, depending on the average distance between the object's station points, the surface texture, and the quality of feedback.
- repeated monitoring from well-defined station points, that were selected depending on the rate of overlapping scanning and on coverage of all shadow cones (which happen to be hard to avoid when using a 3D laser scanning in open environments affected by human action).

To be more specific, the 3d laser-scanning was accomplished with an LS3D Trimble GX sensor, after installing forty-three monitoring stations (Scan Word) for an amount of 54742957 million points, detected through a constant 1x1 mesh network on all surfaces and at an average 15m scanning distance from the object. To this end, the innovative Trimble GX technology was used during the laser scanning phase to control the depth of scanning itself, in order to keep the user's defined space unvaried between 3D points, thus yielding a uniform 'point density', whatever the scanning distance is.

The result is a well-ordered set of points (called point-cloud) arranged in Cartesian space on a real scale to render the surveyed object as a material body, which one can virtually explore by moving across the billions of dimensional coordinates that reproduce it; such possibility enables the "visitor" to remove some parts, in

order to highlight others, and to filter data (which vary in density and stratification), and also places the observer in free spots, according to the altitudinal acquisition logics. The city walls' punctual model was created by lining up fifty two 'point clouds' on a geo-referential basis: these clouds had been variably creamed off during data processing, based on the morphology of the object to reproduce in a range of 0.5 - 1cm, thus reaching the lowest density possible in every square cm. It may be remarkable that the survey project studied for this case didn't consider using artificial targets for the relative alignment of all scanning, in order to preserve the historically relevant architectural work from deterioration (a consequence of these targets clinging to the walls). All visual perspectives were recorded using at least three 'natural' singular points, that were easy to recognize in the survey area. During laser scanning with Trimble GX sensor, we proceeded to thicken the topographic network acquired through the robotized station, by using the already aligned polygon-vertexes as stations and monitoring positions. Furthermore, due to the complex planimetric and altimetric geometry of the above-mentioned wall sections, and the peculiar environmental conditions, it was necessary to perform 3d terrestrial (twenty-five SW) and aerial (twenty SW) laser scanning at different hours and times of the day, that better suited our work. Scanning at different heights off the ground (fulfilled by lifting the laser scanner on an up to 30 meters-extendable crane) allowed for coverage of all areas, removing the shadow-cones resulting, from flower-beds vegetation, walkways and battlements, when filming on land. The Trimble GX laser scanner, equipped with an integrated digital camera, enabled a live rendering of the scanned object as point clouds, textured with its actual colours; that is a crucial aspect when it comes to recognize, at first glance, the material texture of a digitalized architectural element's surface, or when it comes to take close ups of the same object to enrich its details. In addition a high definition photography field-work was launched to allow a photorealistic colourimetric texturization of 'point clouds', thus completing the takes from the Trimble GX sensor-integrated camera. The survey field-work was followed by data processing at Benecon SCaRL's ARS (Environment, Representation, Structure) laboratories. The advantage of using sensors of the same brand, during the survey, consists in the possibility to process all data, from raw feedback to the mapped point-cloud model, in a Real Work environment, where they can be easily confronted and aligned. This survey integrates data, provided by the 3d-scanning of the architectural element's geometry, with high definition-digital photography, and finally implements them with surface characterization; that is the path that best describes our notion of 3D-Discrete Digital Model.

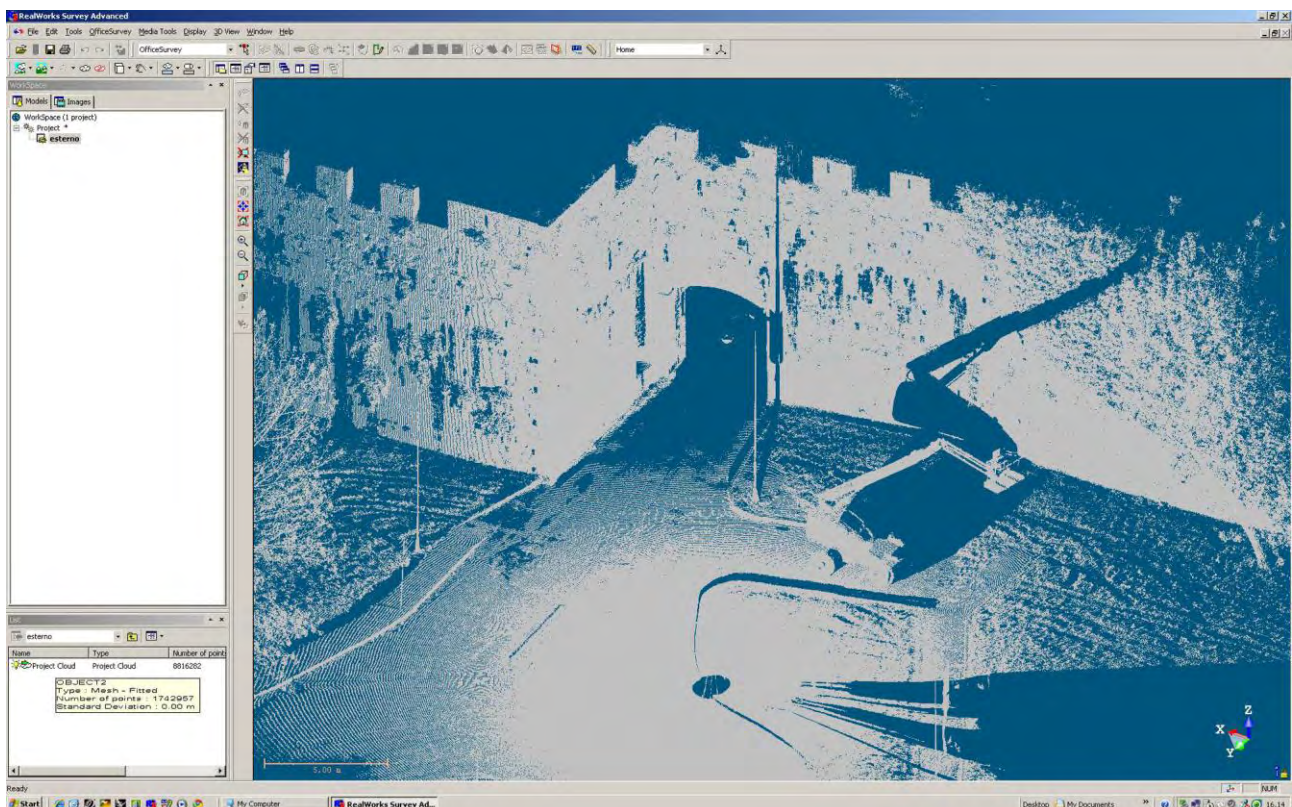

Fig. 4: Pisa, Porta San Zeno. Point cloud scan station (P. Argenziano and A. Avella, 2011).

The photorealistic, colourimetric and thermographic characterization of the surrounding walls meets the Integrated Digital Model (Pasquale Argenziano)

The palpable surface of an architecture is the visible display of its material features, as well as the result of internal and external stress and transformation, caused by a number of factors. Appealing to the prompt, convenient approach we mentioned earlier, it is possible to make a comparison between medical science and architectural studies: doctors can infer the possible cause of an illness by drawing on the careful and direct observation of the patient, and by performing routine examinations (such as, measuring body-temperature, heart-beat, blood pressure, muscular reflexes etc.), in order to make a preliminary diagnosis that will have to be confirmed by further, more accurate investigation. A well-sorted teamwork of experts and technicians can use their skills and knowledge to get the full picture of a building's structural situation through preliminary observation and the digital technology used in characterization, thus collecting information on the surface's chromatic texture and on the heat absorbed/released by its walls in different time slots. The use of technological instruments obviously follows and converges on the 3D-geometrical characterization of the architectural structure. As an application to architecture and to the specific case Pisa's surrounding walls, such characterizations concern the field of image diagnostics, that is supported and controlled through 'punctual sampling' with a method of approach and goals that largely differ from 'texture mapping' (which allows for a three-dimensional visualization of the architecture). Still, the integration of pixels with punctual data is handled during post-processing, and before mesh modelling: the digital images are projected on the overall 'point cloud' representing the architectural structure, preserving the discrete approach of the geometrical model. This turns to be not only a chart filled with Cartesian coordinates, but also the first step for the creation of broader multidimensional database.

According to specific parameters, the digital technology used on field consists of: a high definition camera (Nikon D700), a spectrophotometer (Minolta CM2600d) and a thermographic camera (Flir SC3000). The digital camera recorded the architectural structure's real image, depending on environmental conditions that normally influence visibility and the chromatic quality of RGB pixel-converted surfaces. The digital spectrophotometer – that was applied to a number of chromatically distinct points of the architectural structure's surface – allowed for chromatic correction of the pixelated images, going from a qualitative estimate in the RGB photographic space to a quantitative estimate in the Cielab space. Through the integration of such digital instruments we managed to characterize the architectural structure's surface in the visible spectrum, that is, in the electromagnetic range of 360-740nm. Finally, the thermographic camera recorded surface temperatures in the format of pixelated images, adding quantitative information (depending on the used parameter) that are invisible to the naked eye, since they result from lower electromagnetic frequencies (740nm- 1mm infrared). In the survey's interest, all instrumental operations were sequentially coordinated according to their acquisition method. The thermographic screening was performed in two day-slots around dawn and sunset, that provide the highest peaks of absorbed and released light. The photography field work was carried out in excellent light conditions, that is, when light hit the wall's opposite (and chronologically different) sides. In both cases, the image capturing was obtained by applying practical photography techniques borrowed from traditional architectural photogrammetry, that would reduce perspective distortion to the lowest extent possible.

Last, the use of the spectrophotometer was enhanced by placing it on a crane equipped with an adjustable man-lift, so that the operator could record the architecture's surface at different heights and distances.

Fig. 5 - 6: Porta San Zeno and section of wall at Bastion Parlascio. Two infrared images (P. Argenziano and A. Avella, 2011).

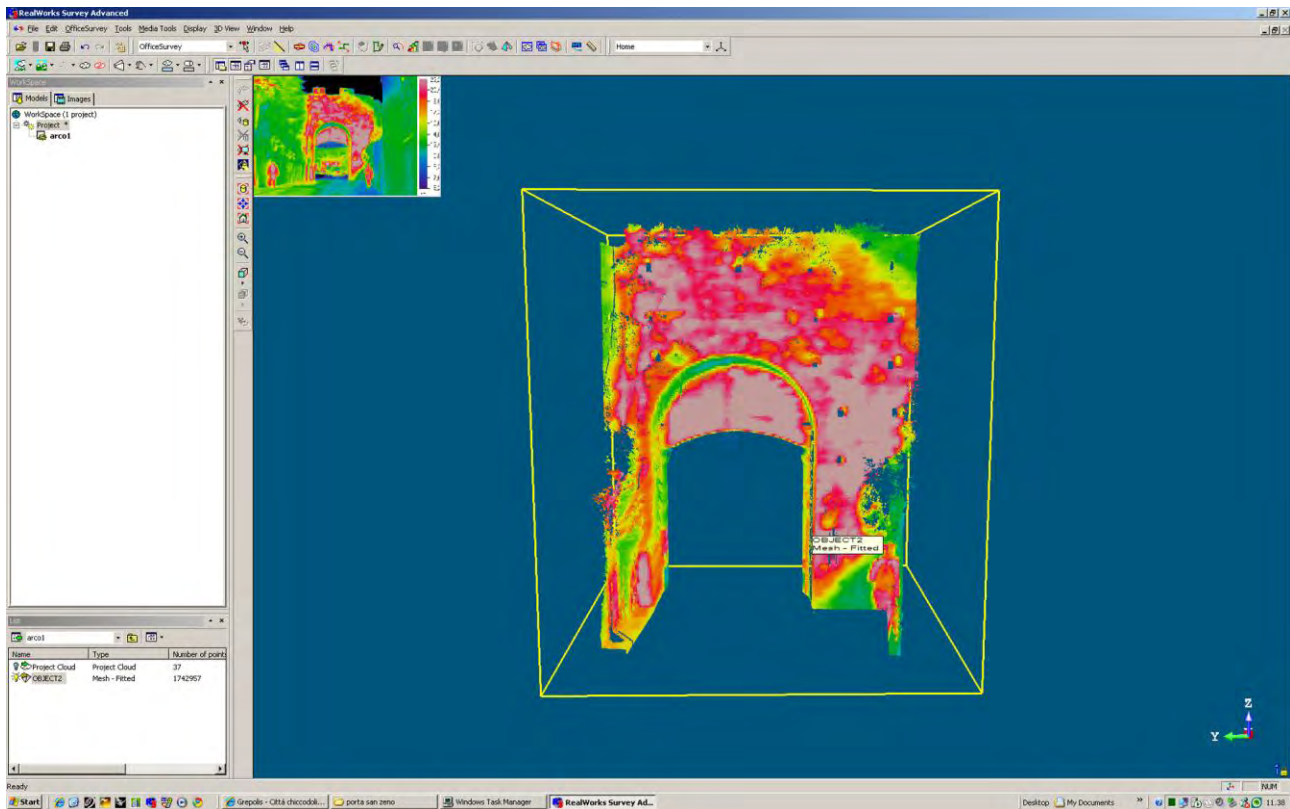

Fig. 7: Porta San Zeno. Projection of a thermal image on the particular point cloud model (P. Argenziano and A. Avella, 2011).

Considering the walls' shape and architecture, as well as its surroundings, such technique turned out to be fundamental for all digital data capture. The collected information was later processed by dedicated software and selectively adjusted to the point cloud model (a fixed and geo-referenced geometric entity).

Since no artificial targets had been positioned in the scanning field (in order to preserve the architectural structure's artistic value and its surface) the projection of digital images on the point cloud was operated by matching homologous points with the two given reference spaces.

Thanks to the photographs taken with a low resolution—digital camera (pixel 768x576), integrated with the 3D laser scanner sensor, this procedure has been reduced to the simple task of pre-emptively detecting singular and unambiguous points on the surrounding walls. This operation is fulfilled, on field, with actual hand-made drafts and sketches before proceeding to remote sensing.

The 'point cloud'-photorealistic mapping technique, performed by a sensor, has certainly simplified the projection of high resolution images, improving the accuracy of colourimetric coordinates associated with the cloud's corresponding points; on the other hand, the introduction of 'natural' singular points has aided the projection of all thermographic images that lend themselves to a difficult interpretation, compared to the cloud's discontinuous geometry and the photographic representation of reality.

To give an example, we could think of a thermographic camera recording invisible phenomena, that are rendered on computer displays in a variety of false colour scales (set before acquisition), some of which may lead to a difficult interpretation in space. Beyond the case of Pisa's city walls, it is important to underline that the projection of photorealistic and thermographic images (pixels) on the point cloud recalls the basics of 'reverse perspective' and 'interior orientation of a photogram', pertaining the field of architectural photogrammetry. By fixing, at least, three homologous points shared by the 'point cloud' and the actual image (a few software can detect up to 21 points), an operator can set the camera in retrospect when taking the photograph and, thus, solve the unknowns related to the outer system's projection centre and to the angular alignment of the photographic/thermographic camera. So, pixelated images are re-projected over the 'point cloud', reproducing the moment at which the digital snapshot was taken in a 3D geo-referenced space, and still respecting proportions and shape, though in a virtual environment.

That generates a correspondence between the digital image's pixels and the cloud's points, which is proportional to the camera's resolution and rounded up/down by dedicated software (provided that no photographic hardware on par with the 3D laser scanner resolution is available on the market). Considering the point cloud's average 10 x 10mm density, the resolution of photographic and thermographic cameras

(respectively pixels 4256 x 2832 and 640 x 480), their 'fields of view' and the average uniform distance between cameras and the surrounding walls (respectively m 15 and m 10), we can estimate that each and every photographic pixel has been projected on a 4 points/cm² spot of the cloud (that is to say, a 4 point area adopted RGB and Cielab colourimetric coordinates as its own), whereas every thermographic pixel has been projected on a 256 points/ cm² spot of the cloud (in other words, a 256 point area adopted Kelvin degrees by its thermal coordinates). Considering the average size of masonry blocks, equal to 540 cm², the relationship between thermal data and point-cloud model is well-defined. The underlying relationship between points and colourimetric/thermal pixels add further 'dimensions' to the 'point cloud model', and to its corresponding tabular layout.

Fig. 8: Spectrographic graph of a point measured on a stone wall (P. Argenziano, 2011).

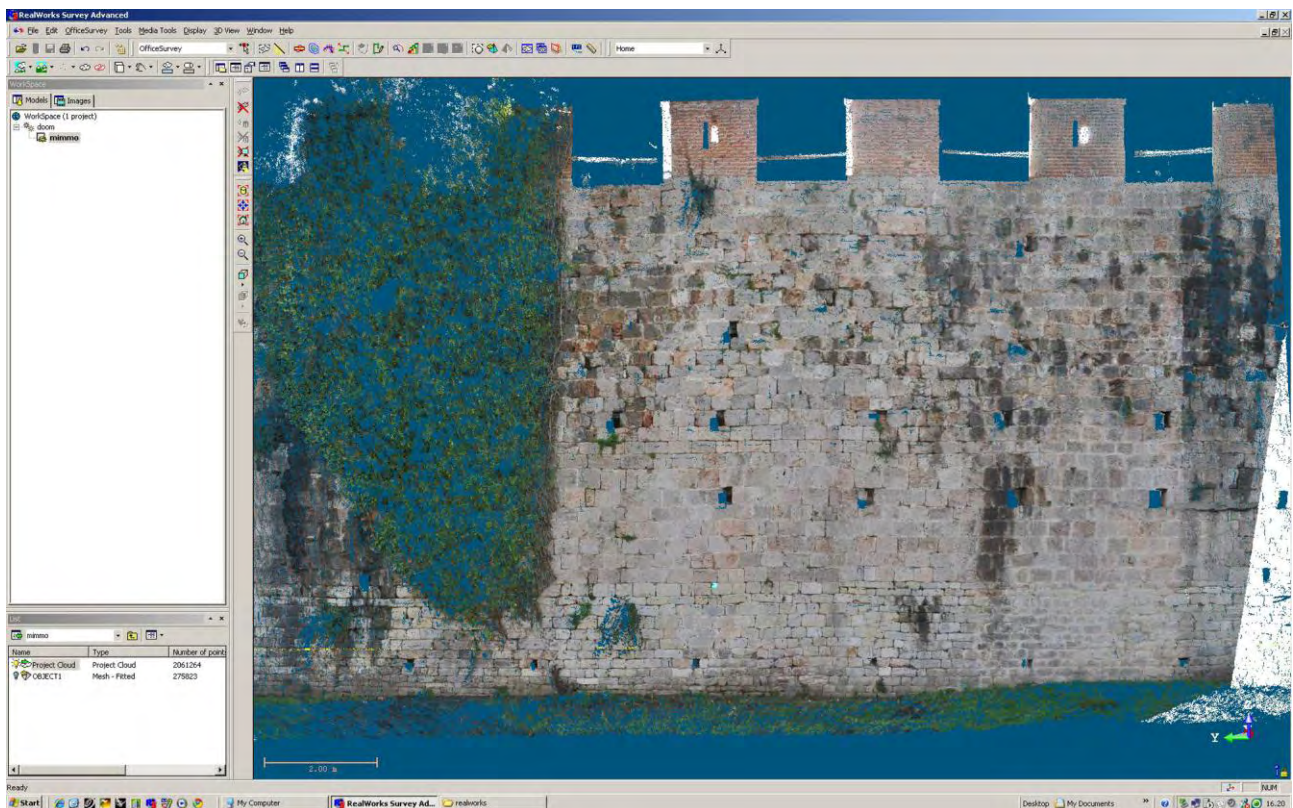

Fig. 9: Section of wall at Bastion Parlascio. High-definition photographic image corrected with spectrophotometry and projected onto the point cloud model (P. Argenziano and A. Avella, 2011).

Conclusions (P. Argenziano, A. Avella)

The underlying relationship between points and colourimetric/thermal pixels add further 'dimensions' to the 'point cloud model', and to its corresponding tabular layout. The conditions of promptness and "reduced costs" (on which this protocol is based) little have to do with the use of low cost-sensors, that provide a rapid capture technology: their aim is, indeed, the overall optimization of the survey process. Managing working-time duration and costs of a field survey, or a post-processing activity, means optimizing human and technological resources.

This goal can be easily pursued by introducing a teamwork of three people with same technical skills and methods on direct-instrumental surveying, and with a good knowledge of the sensors' functioning and potential. Instrumental resources can be optimized by obtaining the most accurate metric (S.I. unit: m), thermographic (S.I. unit: K) and colourimetric (S.I. unit: RGB, CieLab) acquisition of data, and through a thorough planning of all survey operations, in the best environmental and logistical conditions (as briefly explained in the chart to follow).

The captured data can be scientifically integrated, as they refer to the GNSS technology (the only world-wide reference system).

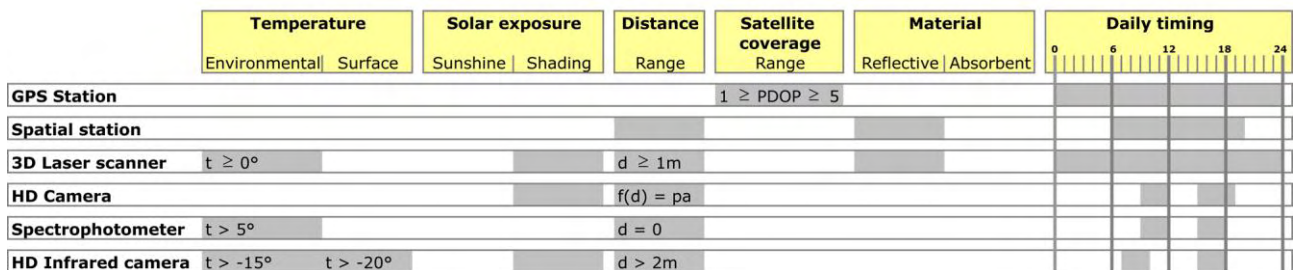

Fig. 11: integrated digital surveying plan on November 2011.

The collected data define a 'discrete model' that may give us insights on the architectural structure's state of preservation, and acts as:

- 1) a 'digital database;
- 2) the first step of diachronic monitoring (Δt), which can detect possible changes in the object's surface both in the visible and invisible spectrum. In fact, what happens on the architectural object's surface is the effect of external causes (weather, pollution, human activity, vegetation growing over, seismic movements), that are presented in this discussion, as well as internal factors (humidity, deterioration etc.), that will be subject to further study. The digital database's architecture is laid out as a chart where each row represents a point from the 'discrete model', while columns feature the S.I. units of measurement.

| ID | Color space RGB | | | Color space CIELAB | | | | | | |
|----|-----------------|-------------|-------|--------------------|-----|-----|-----|------|------|------|
| | X | Y | Z | T | [R] | [G] | [B] | [L*] | [a*] | [b*] |
| | [m] | [m] | [m] | [K] | [R] | [G] | [B] | [L*] | [a*] | [b*] |
| 37 | 613145,381 | 4842167,542 | 2,558 | 281,55 | 169 | 164 | 168 | 68 | 2 | -1 |
| 38 | 613145,447 | 4842167,023 | 2,547 | 281,55 | 114 | 105 | 106 | 45 | 4 | 1 |
| 39 | 613145,401 | 4842167,764 | 2,532 | 281,45 | 98 | 92 | 92 | 40 | 2 | 1 |
| 40 | 613145,453 | 4842167,881 | 2,526 | 281,55 | 166 | 164 | 169 | 68 | 1 | -2 |

Going into detail, the first column (ID) identifies any of the cloud's point, and is generated by the SW; any other column features respectively geometric data (X,Y,Z), temperature (K), and colourimetric values (R,G,B, and CieLab).

Before closing the protocol, a few more considerations are required:

- if it is, indeed, possible to create a database like the one showed in fig. XX, then we must make it clear that all currently available SW are able to visualize only 'coupled information', for example, XYZ and RGB coordinates, XYZ and K, or still XYZ and reflectance, however they don't allow to make queries into the 3D Integrated Digital Model database (by coupling, for instance, a number of geometric data with an equal number of carefully selected colourimetric information);
- despite the introduction of the CAD three-dimensional modelling software thirty years ago, the integrated reading of data is still carried out through thematic maps and bi-dimensional, analog or digital visual-patterns, reducing our possibility to handle 3D-data to a plain bi-dimensional projection of the data itself.
- given such remarks, in the field of cyclic monitoring it is possible to confront only mono-thematic variations, i.e. the modification of a 3D or 2D geometry in time, a temperature variation in time or still a colour change in bi-dimensional space, whereas it still isn't possible to make queries concerning different themes in three-dimensional space with varying time (t).

On these grounds, we may assume research will continue to value the importance of visualization and representation of 3D and 4D data.

Fig. 13: Porta San Zeno. Comparison between the point cloud model, the photo-realistic model and the thermographic model, extracted from the multidimensional database (P. Argenziano and A. Avella, 2011).

Abstract

The *new UNESCO Recommendation* on the Historic Urban Landscape (HUL) states “Urban conservation is an important part of modern heritage policies”. That is mostly exploited in Southern Italy, even associated with cultural tourism. Towns are the result of historical stratifications, represent a harmonious complex of architectural styles, and are a cultural heritage independently of the presence of monumental buildings. In 20th century first two decades in Naples, new middle class quarters developed, especially on Vomero and Posillipo hills. The new architecture was influenced by the so called “Floreal” or “Liberty” movement developed simultaneously with “French Art Nouveau”, with the German and Austrian Jugendstil, as well as with the Spanish Modernism. The main building typology responding to the bourgeois expectation was the Liberty villa or the 3-4 storey house, characterized by decorative elements inspired by medieval period as turrets and bow windows. Restoration policies cannot neglect structural safety, requiring an accurate knowledge of seismic risk of existing buildings. The aim is the quick evaluation of the safety level (LV1) of buildings in the most seismic areas. This assessment can be performed by simplified methods that are different from the specific ones used in the intervention design. In this paper, a methodological example concerning territorial seismic safety evaluation (LV1) and appropriate survey is presented, with reference to a specific building typology representing the liberty movement in Naples.

Key words: Seismic safety, Naples, Liberty, Masonry buildings, Territorial scale.

1. The Liberty architecture in Naples

Around the end of the nineteenth and the beginning of the twentieth century in Naples as much as in other European cities a movement that would mark figurative arts and architecture in the first two decades of the 20th century started to take place (to spread around). This movement in Italy was labeled “Floreal or Liberty” (from a well-known London firm manufacturing floral styled furniture objects) and developed in parallel to Art Nouveau in France, to Jugendstil in Germany and Austria, to Modernism in Spain. In the city of Naples architecture is primarily affected by this new artistic current and its diffusion in the two decades 1900-1920 is most evident in the newly urbanized middle-class neighborhoods located on the Vomero and Posillipo hills. The building type that best responded to the residential character of the bourgeois hilly quarters was primarily the liberty style villa or petit-palace. Their typical features follow the movement lines that prefer the basic asymmetry expressed in architecture by a wavy linearity inspired by flowers and vines and realized through stucco reliefs and painted bands both inside and outside the buildings. The site plan also is released from the rigid forms to win a plan freedom that abolishes the unique perspective and enhances the façade surface movement and the light and shade effects by the use of glass and polychrome materials as well as by the woven game of wrought iron railings and canopies. In addition to examples classifiable as fully

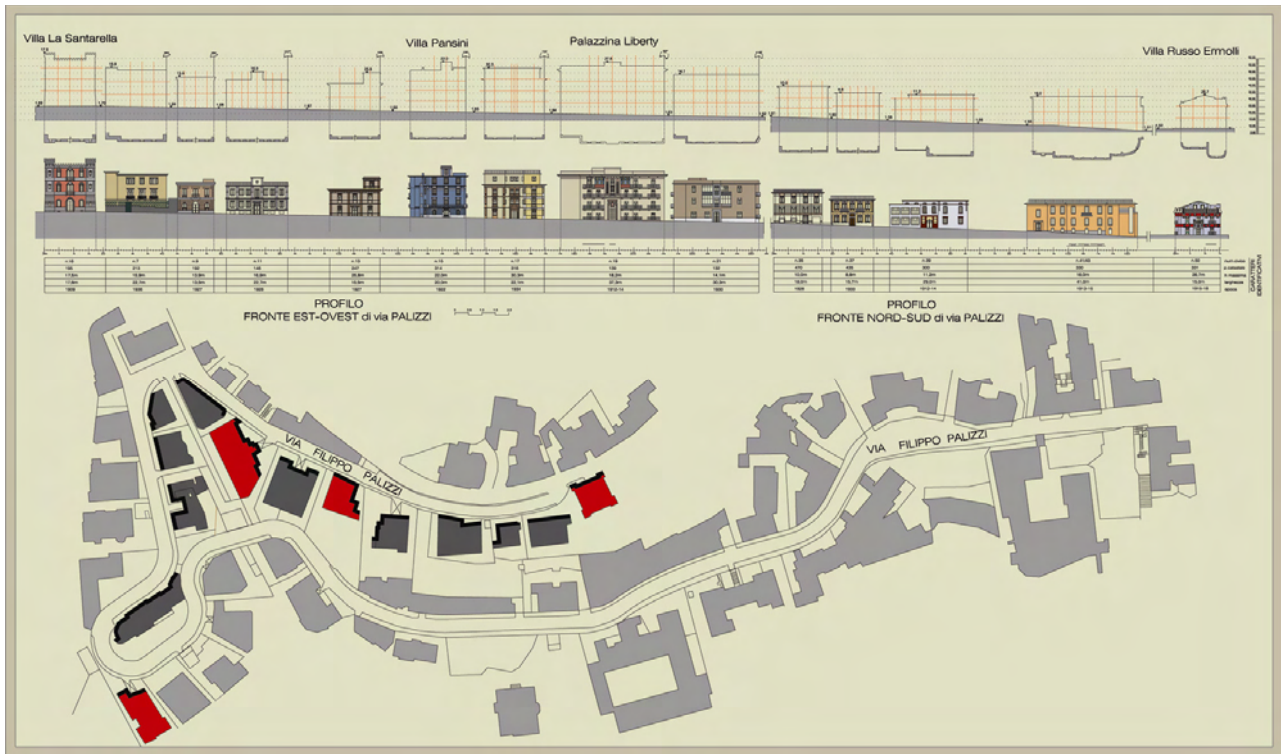

Figure 1. The Liberty architecture in via Palizzi

respondent to the liberty peculiarities, several contemporary petit-palaces on the Vomero hill are to be attributed to a hybrid mixture generated by the use of eclectic accents. This is for example the case of Villa Peruzi, in via Aniello Falcone and Villa Spera in via Tasso, both considered more pertaining to a neo-romanic taste, or the case of Villa La Santarella in via Luigia Sanfelice, that waves toward a neo-renaissance style. In the bigger palaces also economic needs result in abandoning the free plan scheme, and then the liberty language is only limited to the façade decorations.

1.1 The floral roads of the Vomero hill

The most significant urbanization of the Vomero hilly area starts around the last decades of the nineteenth century with a well defined program, consequence of the approval of a wider planning and road expansion project that included the whole city; and that is in line with the taste and the contemporary trends of the European town-planning. Up to the second half of the nineteenth century, as a matter of fact, the hilly area was considered as a suburb with a number of suburban villages around the magnificent villas Belvedere and Floridian, the Certosa di San Martino and San Francesco di Paola monasteries. Around 1885 within the program of "Risanamento", the construction of the new hilly district began following a radial scheme around large squares and new roads. The roads were arranged in an orthogonal layout and were entitled to those Neapolitan artists who frequently lived nearby. Where instead the steep terrain did not allow a regular lotting out, the new middle class roads were connected to the existing roads in the city lower part, thus outlining a system of winding roads at exclusive residential character such as via Palizzi (Figure 1), via Aniello Falcone, via Tasso and Parco Margherita. These are by the way the roads where the most representative liberty villas and palaces were found. Buildings that are work of the major architects of the period like Leonardo Paterna Baldizzi, Michele Capo, Stanislao Sorrentino and Adolfo and Gino Avena. The buildings here examined are all characterized by a marked eclecticism that determines sometimes neo-romanic, sometimes neo-renaissance peculiarities and in any case composite forms. Their characterizing elements besides the stucco and frequently painted decorations are the balcony corbels in shaped iron quarrels, the curvilinear and frequently spiral staircases, the existence of cylindrical turrets or polygonal bow windows.

1.2 Examined buildings

1. Villa La Santarella, via Luigia Sanfelice n.16, (1909).

Built on behalf of the playwright Edoardo Scarpetta, it has a square-shaped plan marked in the top by four embattled and protruding turrets that confer to the building the shape of a small neo-renaissance three storey castle. The wealth of decorative elements is expressed by the gray ashlar stone covering, by the round arches, that surround the balcony openings and the windows, and by the continuous battlement all along the upper perimeter.

2. Villa Lorely, via Gioacchino Toma n. 14, design by Adolfo Avena (1912).

The residential palace of villa Lorely is located in a hairpin loop of via Toma. It presents a corner solution with a semi-circular tower with a ground floor entrance and a window marked by six small columns. Façades are asymmetric, one defined by a register of three window openings decorated with stuccoes representing intersections of geometric shapes and patterns, the other marked by a corner balcony that opens with a sequence of low arches supported by column-pillars which reduce the construction compactness. On the back there is a garden at a level lower than the roadway.

3. Palace in via Palizzi n. 19, (1912-14).

This four level late-liberty building with one level lower than the roadway is marked by compactness animated by the broken movement of the street front. This is emphasized by a protruding central body with the greater part of the stuccoes of the entire façade which is instead monochromatic and horizontally articulated only by the lines of continuous balconies supported by corbels and bordered by iron railings.

4. Palace Russo Ermolli, via Palizzi n.50, design by Stanislao Sorrentino (1915-18).

This palace built on a steep terrain is marked by a street front with a main entrance corresponding to the fifth level above ground and connected to the road by a suspended walkway. The entire façade is enriched with a bundle of stuccoes reproducing creepers and with a cornice that becomes the slab of the last level crowning balcony. The façade balconies facing down-hill are supported by corbels and furthermore embellished with a high frieze, with medallions and balusters of complex design.

5. Villa Catello-Piccoli, via Cimarosa n. 79, design by Adolfo Avena (1918).

This villa presents the same decorative elements derived from the medieval repertory of villa Giordano. The villa is built on a pre-existent building complex and a nice rational arrangement of the interior is successfully obtained. The external configuration resembles a small fortress with a basement characterized by a rustic ashlar while the lateral façade is marked by apparently random fluctuations of the ashlar. The first floor in its central part opens a simple window while in the upper floor the openings are embellished with stucco decorations. On the main façade along the roadway a large opening in catalan style, today a shop, is present as well as a tapered corbel.

6. Palace in via Parco Grifeo n.28, design by Adolfo Avena (1920).

This building evolves on an almost rectangular establishment marked in the front right corner by a full-height circular tower and in the left one by a bow window starting at the fourth level and ending with a double pitch cover right under the building crowning cornice. The peculiar position of the main staircase space in the right rear corner with a mist linear trend, the use of mullioned windows sometimes at lowered and sometimes at round arches, the use of masonry interwoven balustrades colored to contrast the façade red all this makes the whole work especially rich and well in line with the liberty current.

7. Villa Spera, via Tasso n. 615, design by Adolfo Avena (1922).

This villa built on an existing rural house exhibits medieval decorative elements such as loggias, turrets, terraces and bow windows as expression of a neo-romanesque style. The rectangular plan evolves on three levels gradually stepped back from the entry prospect. The irregular openings are framed by arched windows with columns and prominent keystones on both sides. They were once embellished with polychrome glass but were asymmetrically distributed on the facades made of light red bricks and animated by casually protruding bricks that induce a soft ashlar effect. In some strategic points on the façade esoteric symbols are engraved. The interior is characterized in the down-hill corner by a remarkable spiral staircase that wraps at full-height the inner space. The roof in renaissance style is pitched.

8. Villa Pansini, via Palizzi n.15, (1922).

As in several other examples villa Pansini too is marked by prospects at different levels as a result of the via Palizzi slope. The villa plan is comparable to a square. The higher valley façade as well as that lower uphill show facades marked by a different distribution of the openings that appear only decoratively uniform and connected by the eaves continuity.

Table 2. Examined buildings built between 1920 and 1928

9. Palace in via Lordi n.6, design by Adolfo Avena (1928).

This building realized together with the adjacent Avena Palace during the rearrangement of the square in front of the main funicular in piazza Fuga, exhibits a system consisting of two distinct bodies linked by a central volume that acts as a hinge. The whole building ends with a continuous crowning but with a front articulated and offset with respect to the road course. The front is marked by a continuous ashlar basement common to the first two levels and with simple openings. The next two levels are marked by arched openings supported by small columns while the last level is highlighted by lodges and turrets. Peculiar is the central body solution with a polygonal plan and topped with a half-dome on the second level that recalls the north European architectonic avant-garde.

1.3 The geometric survey to evaluate seismic safety

The knowledge of the masonry historical construction is the prerequisite for assessing the present seismic safety and choosing effective improving actions. Techniques of analysis and reading of historical buildings are

linked to the different cognitive steps of different reliability and effect on the building. Indeed the knowledge can be obtained with different levels of detail, depending on the survey accuracy, on the historical and experimental investigations. The making features are used to define an interpretative model that in the various stages of its calibration permits a qualitative interpretation of the structural functioning as well as a quantitative structural analysis. The model reliability, that is closely related to the detail level and to the available data, enters a growing deepening process to which confidence factors to be used in the current or project states are linked. At any rate the geometric survey is constructed at a detail level consistent with the requirements of the geometric model adopted in the analytical evaluations. At first, the construction identification, its location with reference to specific risk areas and its relationship with the urban environment, thus producing a first schematic survey of the building, were carried out. The next geometric survey of the building in its current state has been correlated not only with the system whole geometry but also with that of its constructive elements. The stereo-metric description of the building has led to identify the plain-altimetric features of its constitutive elements. Thus at each level the geometry of all masonry elements as well as the inter-storey and roof height and the location of possible niches and skylight passages has been detected. The survey results are reported in the drawings of plans, elevations and sections in a scale not exceeding 1:100. The processed survey graphs yield the overall geometric configuration and permit to identify the structural scheme which is thought to be resistant in the two orthogonal directions. Such scheme then becomes the computing model in order to determine the shear strength of each floor whose sum yields the overall resistance of the entire building and then the first level seismic safety.

2. Territorial seismic safety evaluation
