According to A. Renier [1] "*Architectural space can not be reduced to its physical size, it must be seen and understood considering all its dimensions*". Thus, we consider the space in both its physical size and in its relation to man, as a being with particular socio-cultural dimensions that lead to user behaviour result. The architectural space is then formed by a material object and a social context. The purpose of the architectural design is therefore a complex and interactive system that integrates both the hardware and the social/cultural aspect, the building is a part that can not be defined autonomously. Thus, there can be no question of considering only the "built", but also the "use" of the built and the furnished, which turn into living spaces as they are lived by man.

Our problem raises questions about the relationship between designs as a response to a functional program on the one hand and as a response to a need and a lifestyle reflecting a specific culture to users. In other words we try to see if there is a gap between the developed and the experienced

space? And to what extent our devices incorporate architectural production or can they integrate perceptions / multiple representations of future actors in a given area? In this study, we propose to focus on the complexity of the relationship between man and space; we will try to see how the space is invested with dimensions other than those which are represented in the conceptual design. We will notice that dimension and functionality are essentials in conception of space but are not sufficient. Space users need more to feel better in using. We need to know how architects can understand such a feeling and help users to live on space.

This study is part of a research on the complexity of human behaviour in a space. The study is based on two assumptions primarily on the development of the singularity of being in the behaviour of a part. Thus man is a being that is and is it reacts and expresses himself facing a space apparently satisfies his needs but it is often forced to live there. On the other hand the importance of the integration of future users of space in the design to reduce the gap between the developed and the experienced and highlight the relational complexity of these two actions, taking as investigation medium a banking space.

According to A. Renier [2] "An architectural space gives the appearance of stability. These forms allow them in the co-presence of other forms of nature". These configurations exist and are integrated in the architectural field, leaving no traces. Man is thus faced with an architectural thought to serve and in which he lived experimenting with a different one that is designed and represented mentally. The study allows us to put the first point on the concepts implemented by the designers of the space when thinking about the project, the second time, the study of configurations allows us to identify areas of "significant substance "of the architectural space experience.

Our body operates from choosing a space integrating various stakeholders between designers and users. As previously mentioned banking space was choosing as an experimental support. This example of space seems a representative case study to the extent that it is scalable it incorporates the latest in design and use but it is open to all, regardless of cultural and social background, attendance is not limited to a particular type or class. This will enable us to verify that the multi-dimensionality of space depends on the size that involves in representation. Our choice of bank space is structured with respect to types incorporating both novelty in spatial design and positioning of banks in differentiated tissues of the city of Tunis. For this purpose we opted for four bank branch part of the same brand "BIAT" newly redesigned. Among the four banks two are located in the suburbs, the other two in the city centre. We note that the four banks selected are diverse enough to be of great interest for the qualitative study business. The supports of analytical part are identified as follows:

- N 1: BIAT Menzah VI is a bank "intermediate", it has undergone some changes compared to the old design BIAT.
- N 2: BIAT Lake is a bank "new concept."
- N 3: BIAT El Manar, it is a bank "new concept", it is spread over two levels.
- N 4: BIAT Street of Egypt, it is a bank "old concept" and is being edited.

The analytical method used during this work is divided into two main phases: the first is questionnaire based for both designers and for a sample of users (clients). Analysis codes transcribed by the banking system "BIAT" helped us to identify the concepts as reflected by the designers during the design phase - production of architectural and compare these with the concepts experienced by users in their use of the banking space bank if they are lived in the same way. The confrontation of different concepts such as investment by developers during the design of a hand, and experienced by customers in the use of space allows us to distinguish similarities and differences in the perception of the concept itself or even how it is lived.

The second phase is based on the superposition circuit schematic customer as reflected by the designers and transcribed during the observation of the behaviour of customers in the bank. The observation of customer behaviour in space allowed us to model space-time patterns identified in the study of the behaviour of actors in space and compares them with the channels used by users of the bank in their movement and raised in our on-site observation of the bank. The banking space is usually designed based on existing technological solution and the branding that designers want to display. Design from a quantitative approach subject to financial and technical constraints. However, space is subjected to several stresses that the designer must identify in order to incorporate in the design. The process consist of analysing the architectural space from the developer side to the customers, the aim being to capture the design process as seen by the designers of the space, and on the other side starting from the customer perception towards an attempt to decrypt the premium for them when communicating with their banks. This approach taking the concepts from designers and

verifying its impact on the customers allows us to identify the importance of certain concepts over others for both designers and users.

1. Designers and users concepts on space banking

The design of the space is a response to a pre-determined program and an idea developed by the architect as a viewing of the best way to organize a space. The designer (architects) study the program and tried to offer a transcription by drawing material that is commonly called "sketch", which is supposed to consider the program, the project budget and integration with the environment.

But he needs to consider also that the space evokes not only a geometric concept defined by measures and surfaces, space is also defined by the user, his behaviour in this area, his feelings and that he returns this space. Indeed, the space also includes the concepts of sociological, historical and symbolic that we will develop. Designers use their knowledge and pre-requisites for the design space in terms of size and shape of the space, as well as the quantitative approach and the allocated budget for this project. Same space can be designed in a multitude of ways depending on the parameters implemented for this design, where the ambiguity and danger to both. If the requirements are clearly identified, the spatial responses are therefore less complicated, as explained in R. Prost. Formulation needs functional, physical, aesthetic, and symbolic and social facilitates architectural design. Designs convene several "measures of relevance" temporal, segmental, cultural, social ... The impact of these measures or parameters on user behaviour are extremely complex.

As a first phase we process with meeting the designers of the bank space to grasp the concepts implemented by them during the design. We were able to conclude that the banks operate to attract clients by serving those best, being efficient and quick. Design helps to organize space, to make it comfortable, attractive, pleasing and clear, so it can attract a maximum number of customers.

The goal is then to ensure speed and efficiency in terms of performance of the service by hiring qualified staff. We were able to capture four basic concepts used by the designers of the bank:

- 1- Symbolic dimension: Reflecting an image that stands out and has a research interest in colours, noble materials transparency through the use of glass facades.
- 2- Functional dimension: The distribution of space within the agency is reflected in a circuit driven by the designer
- 3- Security dimension: Differentiate between customer needs and the degree of privacy needed for each service and allocate space according to privacy and confidentiality.
- 4- Technological dimension: Through the use of new technological providing a quick and easy communication with customers and easy access to information.

The study allowed us to conclude that the designers based their work on functionality, symbolic, security, social and technical dimensions. To be operational, we will now try to understand from the users side the concept experienced in the use of the space, in order to verify whether concepts are lived according to the interpretation of the designers or not.

A phase shift between the perceived and experienced provides us with an intelligible frame that will be used for the study. To this end, we conducted a survey for 25 people in each branch (total of 100 people). The survey consisted of a set of open questions recorded using a Dictaphone upon the customers' approval in this way.

The customer has complete freedom in the answers, he expresses this way concepts that attract attention (positively or negatively) and which influence his behaviour. This method allows us to get objective opinions. The results allowed us to conclude that customers choose their banks based on the location that is usually closest to their home or work. The second criterion is knowledge of one or more staff officers in the bank that reassures and provides a faster and easier access to information and ultimately the cost of service, for banking operations and loans.

Then we try to ask clients by testing the impact of design concept on their behaviours. This way helped us to identify the importance of designer's concepts and the way that users interpret and appreciate them or not. Thereafter we draw a conclusion that is the conducted sampling is categorised in 5 concepts.

- Financial concept: customer attaches great importance to this concept. Indeed, the charges taken by the bank appear to some expensive.
- Social concept: The presence of a friend or relative in the bank largely comforts customers and encourages them to choose the bank.
- Security concept: the customer does not feel safe in the bank when transparent and open space exposed to the outside.

- Aesthetic concept: this concept is important for some and not for others, the customer sees
- Functional concept: this concept is perceived by the client, although not expressed but he appreciates the speed of services.

The analytical approach taking by the designers in one hand and the feed back collected by the users in the other hand reveal a gap of scales that involve both for the same space. This analysis allowed us to qualify the difference in interpretation, and understanding the impact of concepts seen on the designer side or the client side.

Indeed, analysis of the same concept (ex. safety) shows that this concept is understood differently between designer and user. The designer sees in it an opening to the outside and an indirect invitation to the customer via transparency in service, while the user sees this customer transparency, as a lack of security and a violation of his privacy withdrawal or payment of money. The customer does not agree to be controlled or be subject to external eyes when handling money. He has a fear to be targeted by thieves outside the bank.

As a first phase, speech analysis of both designers and users allowed us to delineate the different levels of "gap" between the concept seen from the designer point of view and way of thinking and the space user's one. The study by the way of semiotics, and particularly laying down the syntagmatic chains by doing a transcription of the behaviour of the space users shows us the diversity of valences in an architectural space. This diversity is seen through the presence of multiple space time configurations and translating into potential places.

Confronting the acquired results allowed the partial validation of the assumption, as the concepts take different meanings and values according to the different users. We can then say that in the same spatial conformation intertwine several levels of topical places themselves dependent spatiotemporal configurations set by the user, it is clear values or concepts to qualify these differences between static configuration and dynamic configuration. Differences have to highlight the different levels of topical places since the concepts are "interpreted" and "expressed" in a different way according to their understanding, perception and representation by the various actors. Furthermore, this first level validation has the merit of showing that in architecture the conception act requires mechanisms of "doing" others than geometrical and metrical ones.

The multiple interpretations that could be giving by different "Actors" to a same defined space or according to a same concept justify the necessity of the integration of singular forms and meanings diversity in a conception process. Therefore the participation of space users during the architectural phases becomes important in order to compensate up to a certain degree the imperfection in the architectural doing mechanisms. In the second part of our analytical study, we proceed to study the temporal space patterns by observing and analyzing the various configurations of the players in the banking space. Cognitive modelling allows us to translate the conceptor programs observed as spatial configurations. Modelled in each configuration we distinguish relevant fragments approached by individuals and by interacting with the space. The variety of programs shown by the users allows us to define the multiplicity of space use by customers and agents either separately or in a common space.

It is therefore an inventory of programs users / clients observed during the visit of banks. These programs are similar in part because the players come to the agency for the same purpose (cash withdrawals, transfers, balance inquiries, account opening, credit application, agents visit friends ...) Gold the behaviour of actors varies depending on the player itself and the architectural space. Programs generate interaction between the path of the player and its movement in space so the social and spatial. This interaction can define the path space time users. The displacement varies in terms of tracking and goal orientation. Indeed, customers choose paths more or less variable depending on the client.

2. The gap between the developed and the experienced space.

The actors (Man) is a being who interacts with the place it occupies; it has different needs that vary from one person to another, sometimes mechanisms or reflections in the components of the space can intersect some of them but not all, which is for us a semiotic reading, so-called areas of relevant segments. These areas are seen as constants in a reading space.

For that will use for the second phase of our study a semiotic method study and especially the statement syntagmatic chains via the transcription of user behaviour. This way can allow us to read the variety of using of the same architectural space. This diversity is manifested by the presence of multiple temporal and spatial configurations resulting in a potential "topical places". The syntagmatic chains resulting from a variable number of segments according to the actors and spatial configuration. These segments are sometimes stable especially when they follow the path pre-established designers. Players draw the same line when travelling but this line incorporates it plural scales (social,

psychological, etc ...). This brings us to see the project as a whole architectural image conveying concepts, the understanding of which is dependent on the player and its singularity.

Upon spotting, this gap between the developed (corresponding to a form of "conduct of the project") and the experienced (during the occupation by the actors), we highlights the importance to involve the future occupant (potential) in the design of the space. By integrating the users in the conception phase, we achieve a better understanding of the concepts that were introduced previously by both designers and actors.

Starting from the observation of customer behaviour in a workspace (in this study: the banking space) we could transcribe and make the distinction between the different interactions or "path creation" brought into play as well by the designers in the design of an architectural project as actors in the use of space. The comparison of the results obtained allowed us to validate the hypothesis in part insofar as the concepts are worth understanding and different depending on whether it is placed on the side of the designer or client "actor". These diagrams summarize our analytical approach starting from the initial plans of banks, in the first illustration we can read the paths used by the designers when thinking about space. The second illustration is a superposition of paths as reflected by the designers and those fingerprints by customers, allows us to see the gap between the developed and the experienced of the banking space.

Fig. 1: Spatial and temporal patterns as reflected by designers.

Spatial and temporal patterns as reflected by the designers allowed us to read a linear organization, illustrated by the main direction of movement (to counter, to cash machine or reception in red), the nodes, schematized in ellipses, mark the change in direction of the users. It is a stopping point to choose the direction needed. We can also say that according to the designer, using space is the same; it is completely independent from the plan of the bank. It seems like using any space and putting in functionality according to measures need. In any of the four examples we see that the principal orientation is directed to the counters, where users need banking operations, two small directions exist also and are oriented to the cash machine or to the information. These configurations

are limited, direct and reflect a systematic using of a bank. For the conceptions, it is like a model that can be used any were in bank space, it make relation between functionality and banking style without thinking about users differences. Through our second part investigation we will observe in the same banking space the way that users move in the banking space.

Through space time superposition of configurations both designers and users, we have seen that the configurations as reflected by the designers are linear and direct, they start from a departure point: moving towards the reception counter or to the internal distributor.

While transcription when observing the movement of customers, reveal a multitude of configurations paths that incorporate more flexible and not limited only to service counter or reception. Customers faced with such a space, have moments of pause between observation, reflection, hesitation, back and throat a poster reading or searching for personal information.

Fig 2 : superposition of the designer's configuration (red) and the user's use of the space (blue).

The study of course customers in the banking space has allowed us to highlight that for the same space are spatial and temporal patterns in multiple dimensions or concepts (relative to the framework that we have established) interrelated, and changing distanced in the same time. And segmentation paths are realized due to various parameters in addition to that related to the physical form of a place called topical these parameters can be functional, aesthetic, sensory, symbolic,...

Course distribution syntactic Customer consists of several sequences. The syntagmatic sequences corresponding to various programs of users consist of a different number of segments according to the social actor space and spatial configuration. Superposition of syntagmatic chains run clients from different banks allows us to see that there are stable path segments, these segments are the result of the path predetermined by the designers and followed by clients. For example, the space of the hall is a very important place for the customer. In fact, customers are not accustomed to the bank, marking a pause of several minutes, the time to scan the area and establish benchmarks guidance. The regular customers go directly to the service they want, the hall has a space for them to pass.

According to A. Renier¹ "In the same space, we appropriate the different places between individuals and objects that inhabit them." Thanks to the graphical representation of various configurations changing places it is possible to distinguish between the conformational spaces constructed and

equipped one hand, configurations and locations for those who use the other. This illustrates the relativity of these configurations are likely changing as social actor through space to study.

We concluded that the architectural space contains temporal space configurations that emphasize the use and behaviour of men in space. These configurations are numerous and vary according to the concepts (understood, perceived and represented by the designers) transcribed by users on the move. The implication of this variety in the use of space allows a better understanding of the needs and practices within it.

This study has allowed us to highlight how taking into account certain parameters such as the man and his perceptive and interpretative singularity, its specificity and context is of importance in the "trial" architecture. Starting from the observation of customer behaviour in a workspace (in this study: the banking space) we could transcribe and make the distinction between the different interactions or "path creation" brought into play as well by the designers in the design of an architectural project as actors in the use of space.

Moreover, confrontation or the superposition of different modes of transcription of these pathways has identified "valences" or different way of using, moving and feeling on the space. Man is a being who lives in interaction with its space, it acts and interacts depending on how it is organized and organizes its report, its perception and representation of space elements. Its behaviour is defined from its history, its sensitivity and its relationship with others. Also, the questioning of this research is to qualify the idea that architectural space is not restricted to geometric measurements or typological concepts, or even topographic economic only. The space is defined and understood "by" and "through" the interaction with human behaviour. Architectural space contains temporal space configurations that emphasize the use and behaviour of men in space. These configurations are numerous and vary according to the concepts (understood, perceived and represented by the designers) transcribed by users on the move. The implication of this variety in the use of space allows a better understanding of the needs and practices within it.

Designers use their knowledge and prerequisites for the design space in terms of size and shape of the space, as well as the program, site and budget for this project. How often this "mimetic" design spaces rest somewhere insufficient because customers are often dissatisfied. This is to meet the challenges and reasons for this "dissatisfaction." Also, it is noted that airspace users are involved at any stage of the design and implementation of the project; the designers only design the space for the benefit of future occupants.

Thus, a gap (with various levels of interpretations) could be detected between the developed and the experience. There are probably other forms to detect differences in varying media and sampling actors. The study of user behaviour through the spatio-temporal configurations is used here as a tool to identify the differences between spatial conformation designed by designers and values in the spaces.

The gap between the developed (corresponding to a form of "conduct of the project" players in the design) and the experienced (during the occupation by the actors) highlights the interest to involve the future occupant (potential) in the design space. Thus, the architectural design is not limited to a combination of geometric shapes, it implements concepts vary according to the position they occupy and that is the design: designers and actors. The analytical investigation based on semiotics by the study of spatial and temporal configurations make intelligible some scales on the socio-cultural. Spatial and temporal patterns are multiple dimensions (concepts), the movements of players depend not only on the physical form of a place, but also parameters functional, aesthetic, sensory, symbolic. The syntagmatic chains resulting from a variable number of segments according to the actors and spatial configuration are not as simple as the designers imagine. These segments are sometimes stable especially when they follow the path pre-established designers but some times variable. We can say that each user has his own way of doing things and acts in the same banking, and more for the same users the way of proceeding in the same space is not the always the same. But this point can be the object of others study. For us we are focused on the gap between the designers and users space. The discourse analysis designers on the one hand and users on the other emphasize the gap in "scales" that involve each other and for the same space. "Concepts" (whatever scale they imply) even if they are common are not interpreted and understood in the same way.

Players draw the same line when travelling but this line incorporates it plural scales (social, psychological, etc ...). This brings us to see the project as whole architectural images conveying concepts, the understanding of which is dependent on the player and its singularity.

The main feature of our study is to highlight the life process in space-time by confrontation, as a first step, of designers and users, of their conception and interpretation of space and then by using of graphical representations of their movement in space. This study does not purport to be exhaustive. Rather it allows us to highlight how taking into account certain parameters such as the man and his perceptive and interpretative singularity, its specificity and context of importance in the "process" of the architecture. In this work we tried to represent the structures of experience starting from the observation of facts that reveal the practices of people in their living environment (bank space). From these abstract representations of concrete phenomena, we could interpret the facts themselves.

The spatial conformation identifies multiple configurations of life. It appears more experience than the spatial conformation does specifically. The architectural space is not only a framework, but an active agent by interacting with the people who live and by active programs, delegated by them to the device environment. The environment is not reduced to the volume of architectural space. It has all the elements (people, decor, furniture, lighting, etc.) That differentiates the life of every configuration path corresponding to program. These elements are brought together by the intellect into a three-dimensional geometry. More precisely, any architectural space is the conformation of support globing multiple spaces living spaces generated by programs and potential users. Architectural space is not only in relation with space dimension and functions' needs it is in relation also with the practices of potential users.

The space requires a certain mode of behaviour that the user is forced to either mechanically without a priori to its natural way, without wondering if the space suits designed to serve. This is the man who built to meet their needs, and that the relation man / space are reversed so that the space needed to man the proper behaviour. The relation between human and space is complex. Indeed, the space is not limited to specific dimensions from predefined requirements; it is defined from a plurality of dimensions in relation with the human being.

These initial findings emerged from this study will have at least the merit of enhancing the value of interpreting parameters other than those related to architectural forms, geometrical or functional in any "project management" whether professional or educational situation . They will implement awareness on the part of architects on the importance of integrating users in the design space.

Abstract

"Public interest and affection for the industrial heritage and appreciation of its values are the surest ways to conserve it." The paper is a reflection on the re-use of the Arsenic production complex in the Lavrion Technological and Cultural Park (LTCP) in Greece and aims to make the complex known to the wider scientific community. The paper presents the various findings and aspects of a research project concerning this listed, polluted building and its outputs: the history and evolution of the buildings from their conception in 1913 up to their abandonment in 1957, the poisonous product, the pollution and the production line. A design proposal for the re-use of the complex as a Digital Media Centre is also presented. The Centre, through an edutainment business cluster would contribute to the work of the LTCP as a scientific and research community and would ensure the survival and promotion of the buildings which are still in decay, waiting for salvation.

Keywords: decontamination, arsenic, Lavrion, Greece, industrial, heritage, contamination, re-use

1. Introduction

"Public interest and affection for the industrial heritage and appreciation of its values are the surest ways to conserve it." [1]

Greece is not widely known for its industrial past and heritage which lies in the shadow of the rich cultural one. Chemical plants, shipyards, railway restoration facilities, mining facilities and power generation plants are some examples of industries that thrived in the Greek peninsula in the past century, taking advantage of the rich underground, producing various products and machinery and, mainly, contributing to the development of the recently formed country. [2]

The following paper is a reflection on the re-use of the Arsenic production complex in the Lavrion Technological and Cultural Park (LTCP). The aim of the paper is to raise awareness to the wider scientific community and share various findings concerning a rare, listed set of industrial buildings of the early 20th century. The paper will highlight the unique and intriguing aspects of the buildings: heavy, decayed machinery, oversized masonry buildings, various spatial qualities and the high level of engineering coexist in a weird set with the weary past of a poisonous product, pollution and death. A design proposal is also presented, concerning the re-use of the buildings as a Digital Media Centre, a centre for production and research on edutainment.

The paper is mainly informed by the findings and outputs of our Diploma Project that was presented in July 2011 at the School of Architecture of the National Technical University of Athens (N.T.U.A.) and was academically supported by the Ass. Professors E. Efesiou and Y. Kizis. [3] The research on the complex is on-going in collaboration with the administration of the LTCP in order to clarify the undocumented history of the monument.

2. Lavrion

2.1 City-Past

The city of Lavrion is located in Greece, 42 km south east of Athens and about 30 minutes by car from Athens International Airport "Eleftherios Venizelos". Lavrion is a brownfield-city as it used to be a pure industrial region since antiquity.

Lavrion was well-known before 3,000 B.C. for its silver production. The ancient Athenian economy and the golden age of Pericles were based on the Lavrion silver mines. The ancient coin of the

“tetradrachm” was made of silver mined in Lavrion. The mining activity ceased in the 2nd century B.C. until 1864, when new metallurgical methods were invented. In 1864 Andreas Cordellas and Giovanni-Battista Serpieri established the company “Roux-Serpieri-Fressynet c.e.” for the production of lead. In 1867 the company employed over 1,200 employees. The “Lavrion issue”, as was then named the conflict between the Greek government and the company about the rights on the ancient mine residues, from 1869 to 1873, led to the formation of two companies, the “Greek Company of the mines of Lavrion” and the company “Kamariza mines”. The latter, gave place to the “French Company of the Mines of Lavrion”. As a result, the city of Lavrion in the turn of the 19th century became a company-town of 10,000 inhabitants. Major technological innovations like the railway, electricity and phone lines were first applied in Lavrion.

The heavy industries of that period produced a great amount of pollution in air, water and grounds. Workers worked in high risk, poor conditions and died young. As macabre as it sounds, industry in Lavrion back then was linked with injury and death. Our contemporary perception of health and safety, ecology, nature preservation etc. was not an issue.

Today, the mining activity has stopped and the city is expected to become one of the main ports of Attica with the development of port facilities and the suburban railway. The reconversion of this brownfield-city seems to be an exemplary one and citizens go along with this project.

Fig. 3: Location of the Lavrion Technological and Cultural Park in relation to the city of Lavrion.

Fig. 4: The Lavrion Technological and Cultural Park (left) and location of the arsenic production complex on the LTCP topographic chart (right).

2.2 The Lavrion Technological and Cultural Park

In this context, the Lavrion Technological and Cultural Park (L.T.C.P.) (Fig. 2), is a body of scientific research, education, business and culture, located in the northern part of the city, occupying the site of the former “French Company of the Mines of Lavrion” (in French “Compagnie Française des Mines de Laurium” - C.F.M.L.) as a result of the initiative undertaken from the National Technical University of Athens.

The C.F.M.L. was permanently shut down in 1989 and in 1992 the facilities were given to the N.T.U.A. to create a technological park and a technological museum. The entire plant, along with its machinery, has been listed [4] and has been divided in three phases of intervention. Today, 19 buildings of the first and second phase out of 43 have been restored and are rented occasionally to companies of technology and research.

The activities of the C.F.M.L. left back a great quantity of polluted material, scattered in the premises of the factory, contaminating the soil and the beaches of the city of Lavrion. Since 1992 the L.T.C.P., in order to face the pollution, has performed the following projects:

- decontamination of 155,000 t of soil in the metallurgical waste dam
- construction of a landfill for contaminated soils, with a capacity of 113,000 m³ of soil
- construction of an underground storage for hazardous waste, with a capacity of 5,000 t of waste

Given that the restored 19 buildings were not heavily polluted, the LTCP has not yet completed any big scale building decontamination. Pollution is still present on most of the buildings of the third intervention phase. These consist of the arsenic production complex -where the product itself was poisonous- and the main smoke filters. The main contaminants in the LTCP consist of Lead, Arsenic and Cadmium and their elimination is one of the main goals of the LTCP.

The pollution, however, contributed to the survival of many of the buildings of the LTCP, as ironic as it may sound. In this harsh environment, no living organism survived. As a result of the absence of bugs and pests, the majority of the wooden parts (roofs, floors etc.) were preserved in an excellent state, needing minimal interventions.

3. As [5]

3.1 The buildings

The arsenic production complex is a monument of the modern industrial history of Greece with European significance, and part of a larger industrial complex. The complex is part of the third intervention phase of the LTCP. It was constructed as an independent production unit and includes four buildings (Fig. 5):

- administration and baths (no 33),
- main furnaces (no 34A), silos (no 34B), condensation (no 34C) and ventilators (no 34D)
- barrel workshop (no 35)
- packaging (no 36A,B) and lead oxide production (no 36 C,D)

The design of the buildings began before WW I, but construction of the first phase was not completed until 1917. Main products of the complex were white arsenic and, later, lead oxide. Part of the buildings housed at some point the cupellation of silver.

Fig. 5: Aerial view of the buildings.

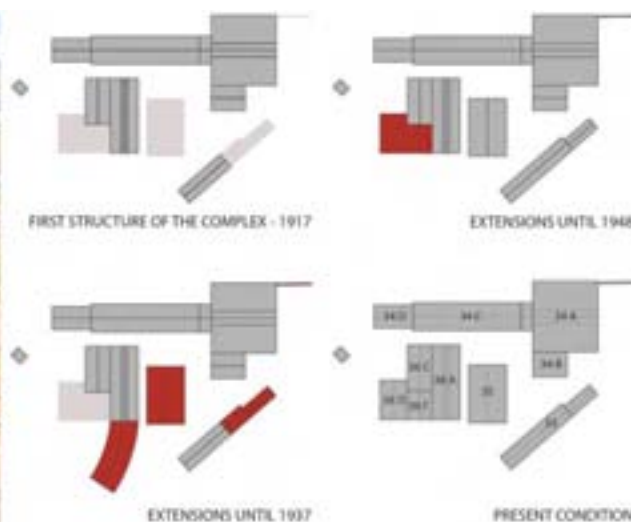

Fig. 6: Evolution of the complex.

The over-sized buildings of the complex are a typical example of machine-buildings, where equipment and structure function together to produce the final product. The buildings are not just a shed for machinery, they are the machine itself. Each part is designed as part of a huge mechanism that serves the sole purpose of production. The production process is the one that generally defines the architecture of the complex. The specific arrangement of the buildings, the variety of spatial qualities that can be observed, and the different types of openings are directly associated with the production process, covering operating needs. For this reason no main entrance can be identified on the complex.

In times, various interventions were made, by means of new constructions or modifications that served new needs that arose (i.e. electrification), without modifying the previous functional structure of the complex, as seen on the evolution chart. (Fig. 6)

Stone, brick, steel and wood are the main materials used for the structural elements of the buildings. The termination of arsenic production in 1957 and the abandonment of the buildings led eventually to deterioration of the steel roofs. However, the relatively good current state of the masonry walls indicates the high quality of building design and construction.

Fig. 7: South-east (top) and south-west (bottom) elevation of the complex (original scale 1:100).

Fig. 8: Polluted material on the furnace wheel (left) and the condensation building (right).

3.2 The production line

White arsenic (otherwise arsenic trioxide or As_2O_3) is a substance generated by processing arsenic ores, by the hydrolysis of arsenic trichloride (AsCl_3) or by smelting arsenic (As). White arsenic is used in pharmaceutical products, wood preservation, electronic components and production of white glass. At the same time it is poisonous and deadly. Approximately 50,000t of white arsenic are produced yearly around the world.

In the C.F.M.L. white arsenic was the product of the smelting of arsenic residues of the smelting process of lead. Production started in 1917 and was ceased in 1957. Arsenic can be still found on parts of the complex, polluting the buildings and their soil. (Fig. 7)

One key aspect of this research was the decoding of the long lost production line, as there are no records of the buildings in use. The production of white arsenic being ceased since 1957, no workers are still alive in order to tell the stories of the buildings. The process of this decoding is still in progress, in collaboration with the LTCP and the School of Mining and Metallurgical Engineering. At this point a graphically simplified drawing of the production line is the one in fig. 9. Part of the machinery was digitally represented, according to the existing remains and the original drawings (1913) of the complex (Fig. 10). A detailed list of the existing industrial equipment was produced, evaluating it in terms of the present condition, knowledge of the initial state and reconstruction possibilities.

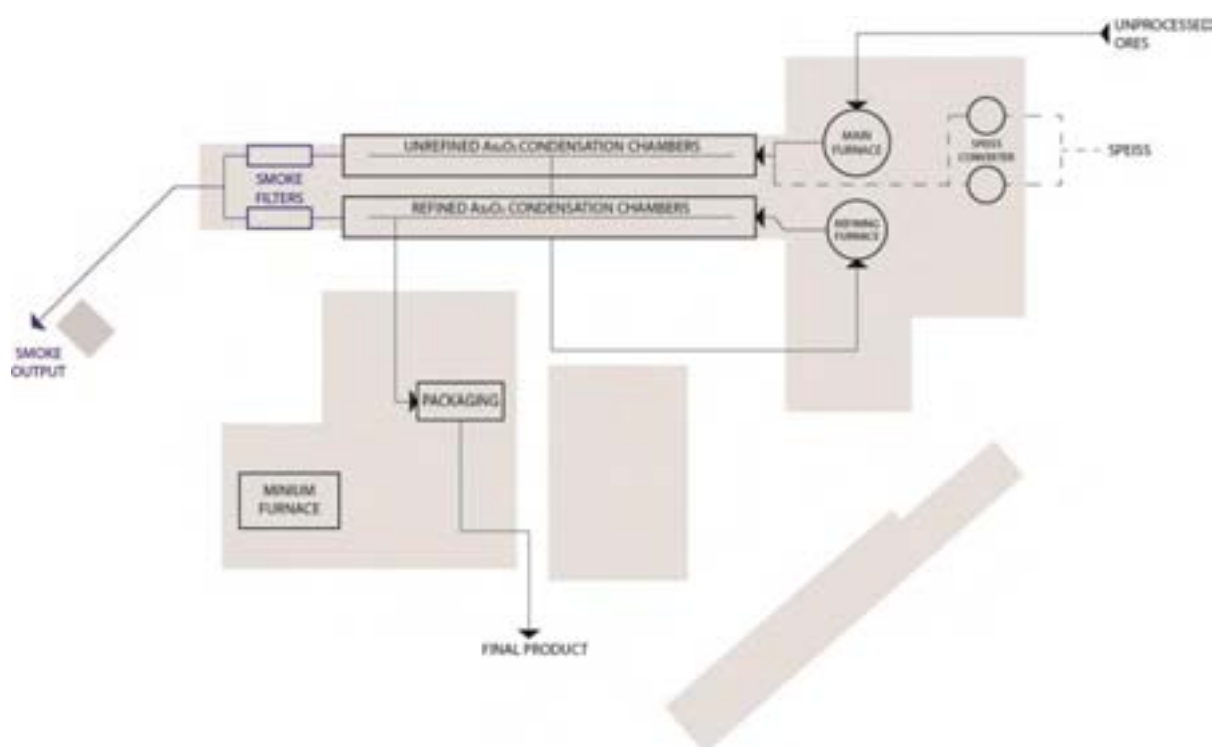

Fig. 9: The production line of the complex.

Fig. 10: The digitally reconstructed main furnace (left) and speiss converter (right).

3.3 Re-use

Through the strategic plan of the LTCP, two were the main uses that the building could accommodate: either a guesthouse for the official guests of the LTCP or a Digital Media centre. At first we were charmed by the idea of incorporating living spaces in such an interesting industrial environment. Soon we realised that the weary past of the buildings could have a negative psychological effect to visitors. Additionally, the financial feasibility of a guesthouse would rely solely to the LTCP, whereas a Digital Media Centre could be funded by a business cluster on education and technology. Business clusters, as strategic management could incorporate the decontamination cost.

The Digital Media Centre could contribute to the work of the L.T.C.P. by means of:

- disposing facilities for the production of digital movies,
- conducting research on new media display and projection, introducing innovative technologies
- producing 3d entertaining and educative programs for use on computers (edutainment),
- organising projections for the public with new digital media (3d, 3d mapping, pepper's ghost, holograms, virtual reality etc.)

The proposed structure of the Digital Media Centre is shown on fig. 11.

Fig. 11: Structure of the proposed Digital Media Centre.

Fig. 12: Paths and access around the complex.

Basic goals of the rehabilitation set as constraints to our design ambitions were:

- the preservation of the industrial identity of the complex
- the preservation or reconstruction of the of the industrial equipment as an integral part of the buildings, depending on the decontamination process
- the preservation and enhancement of the qualities of the complex's spaces in conjunction with the industrial equipment
- the re-integration of the complex in the life and operation of the L.T.C.P. and
- the sustainability of the complex, according to the needs of the new usage.

In order to accommodate the new use we proposed a series of interventions that would ensure the rehabilitation of the buildings architecturally, structurally and health-wise. These interventions can be summarized to:

- The decontamination of the complex through a carefully planned and risk assessed scheme,
- The design of free walkways around the buildings and their connection with the existing network of walkways of the L.T.C.P. aiming to highlight the industrial complex (fig. 12).
- The organisation of accessibility in buildings by redefining the function of open spaces and the level of accessibility, combined with the free walkways. Thus, two outdoor areas with different functions are organised: i. The south outdoor space, which is a transitional area between the technological park and the internal life of the Centre. This space operates as a rest area on the free walkway and it is directly related to the use of the café. ii. The central outdoor space, which receives the new entrances of the buildings and works as a link between them.
- The location of the operations of the new usage based on the qualities of the existing spaces
- Conducting modifications on the buildings with basic principles:
 - i. the morphological-geometric relationship of the old and the new constructions,
 - ii. the function of the new usage and
 - iii. the promotion of the architectural and cultural values of the original structure.

Fig. 13: Proposed south-east (top) and south-west (bottom) elevation of the complex (original scale 1:100).

Fig. 14: The proposed structure of the new building.

In order to support the new use of the building and enhance the complex, we proposed along with the modifications on the existing buildings, a series of new structures, both small and large. The new structures where:

- Two steel lightweight shelters each with a specific role in the organisation of the buildings. The first one is designed to separate the two open spaces defined by the buildings and to indicate the reception of the complex. The second one, at the west end of the central open space, in order to organise and indicate the entrances to the different buildings.
- A new building volume that respects the shape of the collapsed upper floor of the condensation building in order to cover the needs in new spaces and to house the innovative production processes of the complex. The new structure is formed as a continuous folded metal surface, detached from the existing building in order to create to the viewer a smooth transition between the existing and the new building. The structure of this building has a dual, interactive role, both supporting the new usable space and reinforcing the existing structure. This volume is proposed to be covered with zinc, a material with a colour relevant to the surrounding built and natural environment colours.

Although the new structures seem to be architecturally simple, they are a product of a careful evolution of initially bold design attempts. Bearing in mind the established charters on conservation and through continuous re-design informed by the theoretical background and our understanding of the buildings, we proposed an architecture that would be simple, but not simplistic.

Fig. 15: Model of the proposed new structures (scale 1:100).

4. Future

Industrial buildings are not appreciated by the public as “real” monuments as they are linked with a harsh past and a polluted, unsafe part of the history. However, they are a part of our history that cannot be overlooked. The amount of embodied energy in these buildings is huge. As mentioned in the Nizhny Tagil Charter for the Industrial Heritage: “Continuing to adapt and use industrial buildings avoids wasting energy and contributes to sustainable development. Industrial heritage can have an important role in the economic regeneration of decayed or declining areas. The continuity that re-use implies may provide psychological stability for communities facing the sudden end a long-standing sources of employment.” [6] The role of the architect in these cases is not to project his ego and design ambitions, but to design a supportive background that is architecturally smart, protects and promotes the buildings. It is this kind of relation between new and old that will help the building survive for the next generation. The survival of important industrial buildings, as the one mentioned above, relies, unfortunately, on economic factors. Technical solutions are always available, but their unique application to each building creates major financial setbacks that delay indefinitely the process of rehabilitation of a listed, polluted monument. The Arsenic production complex is still, up to this day, standing in decay, its past being still not fully documented and its future being uncertain, relying mainly on financial factors as many other buildings around the world...

URBAN STRATEGIES TO REGENERATE THE MOROCCAN PUBLIC SPACE IN THE URBAN HISTORICAL TISSUES

Study case: Boulevard Mohamed 5, Casablanca

Fatimzahra BENHAMZA

Casablanca's architecture school (EAC), Casablanca, Morocco

Fati.ben6@gmail.com

Abstract:

The proposal aims to define a potential strategy to investigate and intervene into the core of the historical tissues of Casablanca's inner center. We chose the Boulevard Mohamed V as a representative site of the actual situation of most historical areas in the city.

Those areas, had been neglected and undergo the pressure of external forces, consequently they are into perpetual transformation and change in the opposite direction of the natural environment. Changes that are suppressing their own identity. Renewal programs are actually ignoring the specific typology, architectural heritage and collective memory of the areas.

Public spaces are important structuring elements of Casablanca's urban space and they represent the essence of her identity. This project proposes a new way of thinking the Moroccan public space, with innovative strategies, to revitalize the Boulevard Mohamed V through the realm of public space, an itemized analysis of the Boulevard had lead as to specific physical and social components, that will support our reflection, The boulevard Mohamed V is constituted with interconnected public spaces, (inner galleries, inner courtyards, piazzas etc), that work as whole, it's important to rethink the public space in this historical area according to this elements through a small scale interventions that involve an interaction between the public buildings, housing, and public spaces within the area, in order to regenerate the existing spaces, and to create a compact and sustainable spaces that are closely linked to the community daily life and urban morphology of the area.

The project calls for a contextual approach that takes into consideration the complexity and the different components of the Boulevard Mohamed V in order maintain equilibrium into the historical areas and to preserve our tangible and intangible patrimony.

Keywords: regeneration, historical city center, public space, small-scale interventions, Casablanca

1. Introduction:

Cities all over the world are in a state of continuous transition, getting better, bigger, or maybe smaller or just worst, cities experience periods of growth and decline, being shaken by economic, industrial, political and social changes, with an intrinsic transformation of urban space from one economic and social use to another. Public space is the realm where of all this collisions, fissures, transformations, happen and take form.

Since 1914, Casablanca has been in perpetual changes that had influenced the development of the city's urban space. With its transformation, decay of inner urban space is an inevitable result. Those areas, had been neglected and undergo the pressure of external forces, consequently they are into perpetual change in the opposite direction of their natural environment. Nowadays, it becomes clear that the making of the Moroccan public space must be revisited in the historical tissues of Casablanca city center; otherwise its identity will be lost.

The purpose of this paper is to highlight the importance of public space in the historical tissues of Casablanca city center as a tool to regenerate its lost dynamic and vitality, through a contextual approach with urban small scale interventions which take into consideration the local identity, communal way of living and the very specific architectural features.

Fig. 1: Context, Boulevard Mohamed V's situation by order from left to right, in Africa, Morocco, Casablanca, and the Casablanca's historical inner city center.

The Boulevard Mohamed 5 is widely renowned as both the commercial and symbolic centre of Casablanca, although it's a residential area; the boulevard is dominated by commercial use.

Casablanca's Mohammed V Boulevard is lined with buildings from the 1920s and 1940s, it is regarded by historians, scholars and architects, as an important heritage of the colonial architecture; it's an important leg of art deco architecture. For the Casablanca's collective memory, it represents along with the medina one of the oldest parts of the city. It's a meaningful element of the Casablanca's historical core center; it hosts important historical building, with a specific architectural typology, and way of living. [1]

It was one of the most prestigious boulevards with prestigious shops, but due to visible deterioration and destruction since the late 1970s, it fell apart. In fact Casablanca's historical city centre have faced stiffer competition, generated both externally by other cities, and internally by the emergence of new centralities (like Maarif or Anfa districts).

The Boulevard that becomes abandoned was a symbol of social and physical decline of Casablanca's inner town center. A renewal program has been implemented, with the installation of the tramway one year ago, the boulevard Mohamed V went from a carrossable way to a pedestrian zone that hosts the passage of the tramway, with a tramway station in front of the "Marché central and "hotel Lincoln", which are emblematic buildings in this Boulevard., However In most Moroccan's redevelopment projects public space is often seen as performing a secondary or supporting role within urban regeneration projects; one that merely adds the finishing touches to a broader project rather than being a driving force.

The project tries to incorporate those missing urban interventions, in the actual renewal program, by grasping all the particularities of the Boulevard Mohamed V.

Fig. 1: Boulevard Mohamed V historical buildings, 1: "Grand Socco" building, 2: central market (Marché central) entrance, 3: inner gallery Tazi, 4: a view from the Marché central interior

2. Urban small-scale interventions in the Boulevard Mohamed V:

Fig 1.

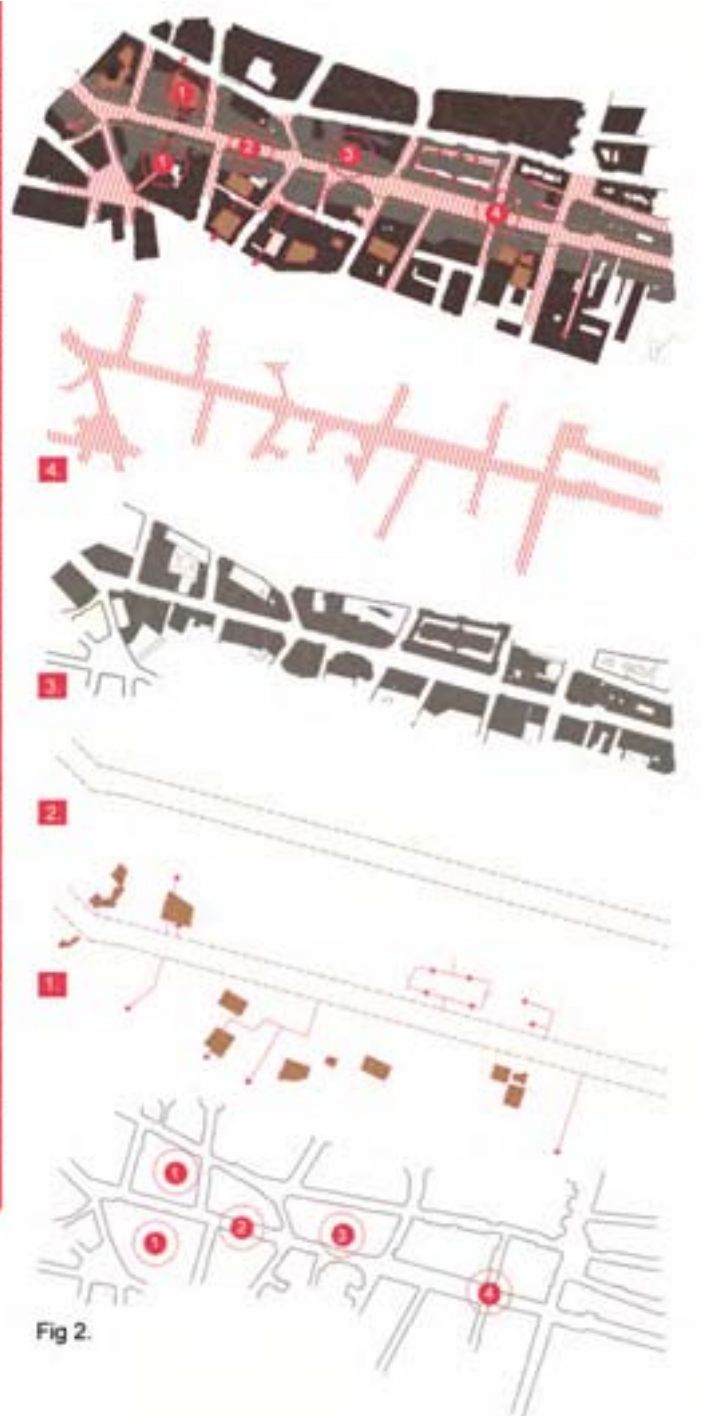

Fig 2.

Fig. 1: Urban interventions Master Plan

Fig. 2: Concept schemes, 1: inner courtyards and inner galleries, 2: the passages under the portico, 3: the rooftops, 4: The Boulevard, the perpendicular streets and the piazzas.

The proposal aims to cling into the specificity of the site, which means to use its historic and architectural features and social organization in order to regenerate its own public space. The project explores potential strategies for urban interventions in the city historic core area, in opposition of the renewal programs that ignore the existing cultural and architectural heritage. Urban settlements that enhance the local way of living respect and harness the architectural identity of the site. Analysis of the tissue reveals a need of small scale interventions to regenerate the existing urban space. Community life is strictly attached to the urban morphology and, for this reason; the proposal tries to restore the identity of public space as a place for daily life, to reinforce the ongoing processes. The

analysis of the characteristics of this historical urban tissue, had lead to representative sites that will work as a catalyst for regenerating the existing space.

2.1 Inner courtyards and inner galleries:

The intervention tries to restore the inner passages and inner courtyards entity, as an important component of the boulevard Mohamed V architectural heritage, they are considered as shortcuts that bring you in the inner core of the historical buildings, they also form one of the most important points for communal sociability and commerce, along with the boulevard. The first one was built for El Glaoui, Marrakech's pasha, by Marius Boyer. Those passages remind also, the Moroccan "souk and kissaria"s constitution (wish means the traditional market in the Moroccan language). Unfortunately, they are today, subject to abandon, a source of insecurity for inhabitants, and lack of ventilation and lighting. The passages of 5 m height are constructed in a way to receive natural light, the light penetrates by a glass-made roof, due to hygiene and maintenance lack, the passage looks miserable, it became a deserted place without commercial activity. We propose an adapted system, which grasps all the particularities of those passages in order to re-activate the social activity. In fact, commerce are not only in the ground floor, but also in the first floor, sometimes in mezzanines, in fact the original street pattern has been overwritten by a covered invisible pedestrian network of interconnected shops at the first floor[2]. The scheme below shows that the best way to regain, light and redynamization of the passages, is to open the first floor to the ground floor, and to replace the deteriorated and no longer useful glass made roof, by new one that respect the original design and will allow a better natural lighting and with integrated ventilation system. The fact that the passage will be used in its ground and first floor, will enlarge its scale (8m height), and invite the population to reinvest it again.

Fig. 1: The before/after inner galleries state, 1: Inner gallery Tazi (19/2013), 2: the inner gallery El Glaoui (19/2013), 3: The inner gallery Sumica (19/2013) [3]

Fig. 3

Fig. 1: Location of the urban intervention in the master plan

Fig. 2: the invisible network of commerce at the first floor

Fig. 3: example of the intervention: inner gallery Sumica, the schemes are showing how we integrate the first floor to the ground floor.

2.2 The passages:

Those passages, are constructed under a portico, and extend the Boulevard by 5m; they are a continuity of the boulevard's urban space. At that time when the boulevard was a roadway, it was the pedestrian passage of the boulevard. Restaurants, fast foods, cafes, shops, banks, societies, are filling the passages. The proliferation of that commerce has negatively changed the view of the boulevard, posters, billboards, notes are destructing the esthetics of this historical area. We propose a graphic charter, to be respected by the new implemented shops commerce, in order to work as a model for the old and new commerce, shops, cafés etc. The graphic charter incorporates a simple work in the ground floor's façade, first of all to eliminate all the insignificant billboards, the only one to keep is the brand shop or commerce or café, brand, with a homogeneous dark colour for all, posters are allowed in the columns as signing tools.

Fig. 1: a commercial ground floor façade treatment on how it could look if the graphic charter is respected.

2.3 The boulevard, the perpendicular streets, and the piazzas:

The actual renewal program, disregarded the spaces that are forcefully linked to the boulevard, and its approach was rather linear and 2 dimensional. Which restricts the interventions only to the boulevard Mohamed V; this emblematic boulevard is an open network of interconnected public spaces, it works as a whole. It is also the main body that supports all the historical built area. Our approach is to include a perpendicular network to the boulevard's streets _mainly crossable streets_ to the pedestrian public space. Which is going to regenerate the old piazzas and makes them "areas for rest stops". Those areas are; The "place de France", "place du 16 Novembre" and the "place du Marché". The market square (place de Marché) is related to "Marché central"(central market), wish is one of the oldest markets in the city, it is very known for its products and food quality, in fact, small restaurants take place in the market's interior space. By making them more active outside the market as well will create interesting human activities in this area. We can use the presence of those piazzas as a structuring element to attract tourists and residents along the boulevard course (1200m). A very important social issue is yet to mention, in Morocco, the informal economy is a reality, and take part of our daily life, what we call "Les petits métiers"; that regroup artisans, street vendors, day laborers, etc.. Those informal jobs propose a fast, direct and punctual service at a low cost, wish constitute a huge economical benefit to the city. Today, the challenge for Casablanca city is to recognize this economic system, and to integrate it in her development strategies. The boulevard Mohamed V is not an exception, it hosts very specific informal jobs, what we call "El ferracha", a term commonly used in the Moroccan dialect to point out the vendors that put in the ground the products that they sell, it includes books, magazines, clothes, food, there are also day laborers (plumbers, carpenters etc..) and street vendors especially for the food. What is important to relieve here, is the juxtaposition of the informal and formal worlds wish create a novel condition that respond to a punctual need. For example, the professionals that are working in the Boulevard Mohamed V , may not have time, everyday for a power lunch, and there will be days when grabbing a grilled meat from the street vendors is the most efficient use of time [4]. In order to maintain those very interesting interactions and juxtapositions, it's compulsory to maintain the activity of those informal jobs in the Boulevard, it's an identity element for the historical areas, otherwise it will be lost, hence we will try to restore the place of the informal jobs, by giving them a more dignified role in the public space's Boulevard Mohamed V realm. The idea is then to create a system of trees and branches, where the boulevard med 5 is the main branch, where we inject, a number of artifacts that will organize the existing urban scene by restoring the identity of public space as a place for daily activities and social interactions. these artefacts, embrace the needs of the population that use the boulevard every day, the first device is a multifunctional kiosk, it's a station, with a shelter and modular benches, that provides the daily labourers a place where to stay, while waiting for an opportunity job, this is also a place where the "El Ferracha" can put their products and sell them, or maybe it can just be used as rest stop for the tired street vendor. It's not only a device, it's a structure that acknowledges a marginal social class, and keeps a social cohesion

between them. The Boulevard Mohamed V lacks from urban furniture, so we thought for an another device, that can respond to the needs of workers, students, passants, or tourists for an adapted equipment for resting, eating or just wandering.

Fig. 1: Daily activities in the Boulevard Mohamed V, 1: street vendors and professional workers, 2: day laborers waiting for a job opportunity, 3: "El Ferracha", a vendor is exposing books and magazines to be sold, 4: visitors, residents..., 5: workers at small businesses

Fig. 1: a urban equipment to rest, eat and play.

Fig. 1: Photomontage of the redynamization of the “central market piazza” with cafés and small restaurants in the outside of the market

2.4 The rooftops:

The boulevard Mohamed V presents a very diversified built template, with various heights, that vary from only a commercial floor to a eight floors + commercial ground floor. The experience in the Boulevard is strictly horizontal, we can only wander in its streets, passages, inner galleries or piazzas, what about the roofing? Terraces are an important component of the Moroccan culture; it's a predilection zone for sociability, leisure and relaxing. We propose then to reinvest some interesting rooftops that present important points in sociability by putting cafés for example or just transforming it into a place where residents or tourists, can come to appreciate the magnificent view of all the historical area.

Fig. 1: The different built templates in the Boulevard Mohamed V

2.5 The infrastructure:

The use of water in the Boulevard is a waste, the municipality use drinking water, for cleaning. Creating rain water collection areas will support the existing water supply network, and will help to clean the boulevard and the market “Marché Central” in the end of the day.

Acknowledgments: this work has been directed by professor and architect M.Mohamed El Malti

Spomenik in Flux

Erika LINDSAY

Architecture, Taubman College of Architecture and Urban Planning, University of Michigan, Ann Arbor, USA; erikalinds@gmail.com

Abstract

This research into former Yugoslavia's spomenik (monuments) explores the critical relationship between a series of material memorials, their mediatized representations and their most recent appropriation in order to underscore the transformative nature of historic signification as both a built and symbolic continuum. Erected over the span of twenty years before Josip Tito's death and just prior to Yugoslavia's disintegration, the spomenik currently epitomize a gradient of decay, some fixed while others are in rapid flux at a critical point for conservation efforts. In each instance, however, their contemporary condition in stark juxtaposition to an original intended meaning points to the persistent power and allegorical potential of counter-monumentality. Tracing the modes in which these contradictory and semantically charged sites operate in response to or in spite of contemporary preservation efforts, allows for reflection upon both authoritative and informal cooption of singular cultural connotation and speculation about the power of memorial elasticity.

Keywords: spomenik, post-yugoslav context, counter-monument, conservation, monument

1.Context

1.1 Anti-fascism, Partisans and the Yugoslav Republic

Spomenik were built by a regime set on moving forward and forgetting wartime atrocities committed on all sides by commemorating partisan victories over the axis powers. During World War II, many battles were fought on Yugoslavian soil by the anti-fascist partisan resistance against the fascist axis powers. At the same time, the region was enmeshed in a civil war, which resulted in the formation of the Republic of Yugoslavia, comprised of six republics. In the post-war years nearest to the war, this gave the Yugoslav people something to unite around. Anti-religious propaganda of the postwar era unified Yugoslavia and attempts at ritualizing the act of remembrance around World War II anti-fascist struggles were done in an effort to seek this unity and focus on what the peoples of the newly formed republic had in common.

Josip Tito, leader of the partisan resistance during the war years, had constructed a collective memory upon which to build the new Yugoslavia from the end of the war in 1945, when he came to power until his death in 1980, at which time, Yugoslavia remained peaceful. Spomenik comprised a large part of this new Yugoslavian nationalism under Tito's leadership. When communist states began to fall in the late 1980s in neighboring eastern Europe, the republic began to separate, focusing instead on its differences rather than what it had in common, the battles of the Second World War, mere stories of their grandparent's generation. The new generation was interested in an attempt at re-discovering the cultural heritage that generations before had been expected to leave behind. Ethnic and religious tensions were heightened as each group sought to find its lost identity that was relinquished or forgotten in order to live as a united Yugoslavia under Tito. Within a decade after his death, the Yugoslav Wars ensued, and with it the disintegration of the republic, as those who inhabited geographies of opposing ideologies, ethnicities and doctrine attempted to make territorial claims and proclaim independence. It is also important to note that not everyone within the Yugoslav territory had been a part of the partisan resistance. Tito's nationalism alienated groups who had sympathized with the fascist occupation, as the victorious partisans wrote the history.

1.2 Abstraction and Universality

The abstract form of the spomenik was an attempt to provoke collective forgetting in an effort to create a far-reaching, productive amnesia capable of galvanizing groups once pitted against one another. Productive gaps produced by abstract monuments allow the viewer to situate their own narrative

Fig. 1: Grmeč, (2007) [5]

Fig. 2: Podgarić. Croatia (2006) [5]

Fig. 3: Petrova Gora. (2006) [5]

within the form which holds the possibility of universal signification, thus becoming all things to all people. This stands in opposition to the man on the horse as a traditional and figural form of monument which has been used to commemorate significant human achievements for hundreds of years. In the abstract partisan spomenik, signification is varied and fluid, rather than specific and rigid. Operating through pure signification, many partisan monuments did not use existing symbology such as that of the red star, or hammer and sickle indicative of many communist memorials, nor did they use religious symbology, opting instead to create their own symbology for each site, as part of the branding of the new Yugoslavian republic. This variability allows for multivalent reads, which is what has ultimately lead to their continued relevance today. [10]

Partisan spomenik standing today can do little more than represent a failed regime. Through acts of vandalism, natural forces and neglect, monumental decay writes a counter-narrative for the spomenik, which have come to stand in opposition to what they originally signified. [9] It is in this moment that the spomenik are rendered in their present state to be *dialogic*, that is, in dialogue with the ghosts of their former glory.

2. Spomenik Case Studies

2.1 Ilinden Memorial (Makedonium)

Fig. 4: Makedonium / Ilinden Memorial. Near Krusevo, Macedonia. (Zlatko Avramovski 2008)

Ilinden Monument, space age in form, commemorates the anti-fascist liberation of Macedonia after World War II as well as the Ilinden uprising against the Turkish occupation of 1903. Both events have been pivotal to the creation of present day Macedonia.

Along the conservation gradient, the Ilinden Monument has been well-conserved, due to its alignment with the nationalist narrative of Macedonia. This monument has endured through the parasitic linking of partisan endeavor to the long-standing local commemorative practice of Ilinden. Its added significance comes from the entombment of a local hero. The site recently saw the equivalent of 350,000 US dollars of investment for renovations in 2003, just in time to mark the 100th anniversary of the uprising. Each year on the day of the Republic, also known as Ilinden Day, memorial reenactment celebrations take place. It is due to this commemorative use that the monument continues to have cultural significance. Known to some as the Makedonium and others as Ilinden—the monument, which is not formally tied to one or the other can exist to commemorate both. [4]

There have been multiple attempts by the Macedonian government to keep the site relevant to the nationalist narrative. In 1990, 85 years after his death, Nikola Karaev, the schoolteacher who led the uprising in 1903, was entombed in the memorial. This worked as a means to further strengthen the local narrative while at the same time, solidifying its role in the greater national narrative. In 1993, renovations were made for celebration of the 90th anniversary of the uprising and ten years later, further investment was made in the site, marking the 100th Anniversary of the uprising, which also marked a televised event. [2]

2.2 Conservation Through Parasitic Cooption

This imposed significance on the part of the state began at the inception of the memorial in 1974, with the negation of the rich local heritage associated with the site. Instead, favoring the nationalist Macedonian narrative of Ilinden as the beginning of a Macedonian state as well as the formation of the current Macedonian state by way of the influence of those within the Anti-Fascist Assembly for the National Liberation of Macedonia (ASNOM). ASNOM was the group which determined the parameters of the People's Republic of Macedonia, as part of the Yugoslavian republic. In keeping with their Yugoslavian nationalist agenda, the anti-fascists, now in power, with partisan war hero, Josip Broz Tito at the helm, were interested in making monuments to partisan war achievements, as a way of reifying their power. They did so by building numerous spomenik across the landscape, as both a means of celebrating the partisan victories of World War II and honoring those who were casualties of war. With each successive move, history was being rewritten by the victors, and with it an erasure of the idiosyncrasies of the many cultures represented in the region. A ritualization through indoctrination, as an attempt at making the sites meaningful to new generations, came to surround the spomenik, as schoolchildren were bussed to the sites for state-mandated visits. In this case, the authoritative power of the state has been used to co-opt the memorial, imbuing it with a multitude of significance and turning it into a site of heritage consumption. It made the transition from Yugoslav to Post-Yugoslav memory with relative ease, due to its alignment with the Macedonian nationalist narrative, only further amplified by the Macedonian state after the disintegration of the Yugoslav republic through the entombment of Karaev, acting in ways that a standard conservation practice could not.

2.3 Petrova Gora

Fig. 6: Petrova Gora Condition of Facade. Near Gvozd, Croatia. (Damir Krajac 2008).

In a bold gesture, the monument sits perched atop the highest point of the Petrova Gora mountain range, built as an anti-fascist monument to commemorate the underground partisan field hospital operating on site during World War II. Monumental in size, Petrova Gora stands at 37M, an 8 story tall inhabitable structure with a form reminiscent of curvilinear late modernism. The monument was designed in 1970, and due to financial difficulties, it was finally built over the course of 8 years, beginning in 1981. Following its completion in 1989, it stood as an empty signifier, representative of a lost ideology, marking the demise of the Yugoslav Republic. In an ironic turn of events, the structure itself is said to have been used as a field hospital during the Croatian War for Independence in the 1990s, shortly after it opened. Today, its visitors include those interested in its formal qualities as well as its place in the current context of Croatian identity politics. Forgotten by its people and neglected by the state, Petrova Gora succumbs to a slow disintegration, as a site of active material extraction, opportunistic use (note the telecom antennas which have sprouted) and natural decay. [3]

2.4 Conservation as Product of Impossible Circumstance

Petrova Gora is enmeshed in the kind of circumstances that produce a ruin. At its core, a hulking mass of cast concrete makes the structure impervious to demolition. A lack of existing documents for the building and its site, has rendered any opportunity for security and protection of the monument impossible. There is little interest in the ideologies of the past, partisan spomenik and fewer people feel that they signify anything about the Second World War worth remembering. Sections of stainless steel cladding remain, though the vast majority has gone missing, appropriated by locals with whom the ideologies that made such an icon possible no longer resonate. [6]

Fig. 7: Petrova Gora Stripped of Metal Facade. Near Gvozd, Croatia. (Armin Linke 2011).

2.5 Makljen Monument

Built on the highest point on top of Mt. Makljen in Bosnia and Herzegovina, this Spomenik was a gesture toward political unity. Makljen Monument is one of many anti-fascist memorials commissioned by the state to commemorate the triumph of the partisans over the Axis powers. Opened to the public in 1978, on the anniversary of the Battle for the Wounded, which had happened in 1943 on this site, Makljen Monument was one of many anti-fascist War of Liberation memorials commissioned by the state and designed by renowned sculptor, Boško Kućanski. Its bears an uncanny resemblance to a fist, and Makljen has not been able to shake the associated narrative of being “Tito’s Fist.”

Fig. 8: Makljen Monument Prior to Explosion. Near Prozor, Bosnia. (198?).

2.6 Conservation Through Destruction

On November 13 2000, the same date as the battle which the monument commemorates and only five years after the end of the Yugoslav wars, there was an attempted erasure of the monument via explosives. It was not entirely successful in its aim, having made the monument more visible. The blast had exposed the skeletal remains of the flower’s heavy concrete beams, while its concrete skin lay crumbling at its feet. Though the form may have been lost, the monument gained new significance from this iconoclastic act. One could argue that it holds greater commemorative value, and therefore functions as a stronger monument, in its ruined state than it did when pristine. In the attempt to render invisible, the act of iconoclastic ruination made what had already been rendered invisible with apathy and time quite visible. It was not until after the monument was re-rendered visible through destruction that it became protected through a petition to the Commission to Preserve National Monuments in 2010. It now stands, protected as a National Monument as a skeletal form, the ruin of a monument, perhaps having gained new significance. [2]

Fig. 9: Makljen Monument. Near Prozor, Bosnia. (flickruser: rb.fzz 2008).

3.Counter Spomenik

3.1 Signification and the Remnant

It is perhaps through their corroded patina, showing signs of wear, that the aura of time is rendered visible. Some spomenik are still in use; visited annually to commemorate a national holiday, such as Ilinden, in the case of the Makedonium, which has received facelifts for the past two decades, just prior to both its 90th and 100th anniversary celebrations. Petrova Gora and Makljen are being reappropriated as sites of intrigue in their ruined state, a product of resource extraction, and iconoclastic actions made against each of them, respectively. It is with their newly minted patina that these spomenik find cultural relevance today.

Built of materials meant to stand the test of time, these material remnants often outlast the regimes that commission them, leaving their fate to the next generation, heir to a forgotten past. Once sites of commemoration, cultural memory and significance, at worst they become sites of neglect, disuse and abandonment; at best, they lose significance and become invisible, blending into the landscape or being removed all together. Often, we are met with these immense pieces of the past, signifying a specific ideology, no longer in favor. Designated at a specific time and place, they have trouble standing the test of time as relevant cultural signifiers. As meanings change and interest fades, the spomenik are relegated to the backdrop, little more than a place to picnic. Many have problematized the notion that once a memorial is made prosthetic, memory fades. No longer necessary to remember, the material form does the memory-work for us. [7]

Can a monument transform its signification if the cultural signification, commemorative use and perceptions encircling it change? In post-war Yugoslavia, spomenik were built in an attempt to unify a region divided. What do spomenik signify as they stand within the landscape of a fractured past and present?

3.2 Spomenik at Risk

From the fully restored, to the unlocked, overgrown and reappropriated, these spomenik operate through a gradient of conservation efforts, both sanctioned and illicit. While the majority of preservation groups remain focused on much older histories of civilization found in this region, it is the recent past that is most at risk. Spomenik sit in varied states of disrepair, neglected by newly formed democratic governments who do not wish to align themselves with the past and all but forgotten about by those who have inherited them. [5]

Sites in southeast Europe which tend to garner conservation attention do not belong to a shared national heritage or recent past. Instead, ICCROM and other preservation-minded entities, are focused on preservation of much older, heritage sites “at risk” within the region, rendered as the fallout of wartime atrocities. These sites are often sacred spaces, aligned with the Post-Yugoslav narrative which places importance on independent nationhood based on ethnic and religious difference. With a focus on the differences of the peoples of the former republic, priority has been given to preserve the contrasts, rather than the unifying principles of the former socialist regime. Today, this practice finds resonance within people of the smaller ethnic populations of Croatia, Bosnia-Herzegovina, Macedonia, Serbia, Slovenia and Montenegro.

To this end, World War II partisan monuments are not considered “at risk” as part of the Bosnia and Herzegovina Commission to Preserve National Monuments and are therefore not protected from illicit building, inept construction or lack of maintenance. The Commission acts as a watchdog group that monitors activities relating to national monuments. Few spomenik are protected as national monuments. [1] These monuments, transformed by time, sit in relation to their original context, becoming monuments counter to, yet in dialogue with the memory of their past life as partisan monuments. Is it this dialogue which allows them to remain relevant long beyond the disintegration of Yugoslavia.

Abstract

The present study addresses the identification of the factors and elements that contribute to the improvement of thermal comfort within traditional buildings and their built environment. This investigation is part of an ongoing research programme that is funded by the Republic of Cyprus and the European Regional Development Fund (through the Research Promotion Foundation) regarding the vernacular architecture of Cyprus that includes *in situ* measurements of temperature and humidity using data loggers and weather stations. Two areas of the historic centre of Nicosia, which have preserved their original character, were selected for the study. After an overall historic and architectural investigation of these areas through historic documentation and survey maps, a study of a large number of buildings from a typological, bioclimatic and construction material point of view has been carried out. The bioclimatic strategies of heating, cooling and microclimatic conditions were studied in detail. This preliminary research showed the various environmental features of vernacular architecture (central yards, semi-open spaces, construction and materiality etc.). The research aims at establishing a bioclimatically-based approach in the conservation of traditional buildings and thus contributing to the regeneration and sustainable development of the urban environment of such a solid traditional historic core as that of the Walled City of Nicosia.

Keywords: vernacular, bioclimatic, traditional construction, courtyards, semi-open spaces

1. Introduction

Vernacular architecture, which incorporates rural settlements as well as urban historic centres, has always constituted an important part of the cultural heritage of every country. Traditional dwellings are considered by definition sustainable, incorporating many features friendly to the environment (use of local materials, adaptation to the landscape, central yards, arrangement of open and semi-open spaces etc.). The identification, protection and preservation of these features in the rapidly changing context of contemporary cities is imperative in order to maintain the values linked to sustainability.

A "BioVernacular" research project (ΑΝΘΡΩΠΙΣΤΙΚΕΣ/ΑΝΘΡΩ/0609/BIE) is currently underway in the aforementioned domain. It is funded by the Republic of Cyprus and the European Regional Development Fund (through Cyprus Research Promotion Foundation's Framework Programme for Research, Technological Development and Innovation *Δέσμη* 2009-2010) and was initiated in July 2012 in the historic centre of Nicosia in Cyprus with the selection and detailed analysis of two neighbourhoods in the historic core, using typological, architectural and structural criteria. The project incorporates the following goals: identification of the bioclimatic elements encountered; monitoring of temperature and relative humidity levels in a selected number of dwellings; definition of the bioclimatic and microclimatic conditions that affect thermal comfort; simulation of the energy efficiency of a selected sample of buildings; calculation on an hourly basis of thermal and cooling loads; drafting of technical guidance and proposals for traditional buildings and measures so as to improve bioclimatic features and comfort conditions within the building envelope.

This paper presents some qualitative findings of the project regarding the identified environmental design elements in the built heritage of Nicosia. The observations refer to the urban tissue as well as the vernacular dwellings. The paper aims at identifying and documenting the bioclimatic

characteristics of traditional dwellings in the Walled City of Nicosia and their immediate built environment which is essential for enhancing an environmentally-friendly approach in the rehabilitation process.

2. The methodology

The methodology used in the initial part of the research project refers to the preliminary qualitative analysis, diagnosis and assessment of the bioclimatic elements of the urban tissue and vernacular dwellings of Nicosia. The main objective is to confirm all the individual factors that constitute the so-called “environmental approach in vernacular architecture” through scientific and systematic investigation.

Initially an in-depth research through historic documentation which provided insight into various historic, ethnic and social factors that contributed to a series of events such as the setting of the city in a specific location and the relation to the evolution of the built environment was conducted. The reinterpretation of the urban evolution and examination of the interrelated structural and morphological components provides significant information with regard to the origin of elements such as the urban tissue and form, the types of buildings and their architectural characteristics that may embrace an environmental essence.

Another important tool of great significance is the study of survey maps of various periods. The relative information, derived from the study of the maps, refers to: “the area and city level”, “the urban tissue level” and the “building types level”. With regard to the “area and the city level” the information refers to macroclimatic conditions, geomorphological and landscape qualities, city shape and form. With reference to the “urban tissue level”, the orientation of the streets, shading and sunlight provisions, ventilation and cooling factors as well as urban vegetation and quality of open and semi-open spaces are investigated. Under the “building types level”, the typology in terms of arrangement of spaces (courtyards etc), the building materials and techniques and the cooling and heating strategies and use of local resources such as water are examined.

At this stage of investigation, a field study is of great significance. It provides updated information on the fusion of civil components and the historic stratification. Furthermore, the personal communication with the residents, the actual users of the vernacular dwellings and the city form, enhances evaluation of the comfort offered by the specific urban tissue and the individual buildings. The wide variation between objective and subjective sense of comfort, the residences’ observations, opinions and experiences are a valuable tool in both the comprehension of the bioclimatic function of the houses as well as the evaluation of its contribution to the achievement of comfort.

Concluding this part of the research, the findings are presented according to the scale they apply: beginning with the territory and city level (location, geomorphology, limitations of topography), moving on to the urban tissue level and the scale of the neighborhood (urban development), and focusing on the building level and the applied bioclimatic strategies (cooling, heating and microclimatic environment strategies).

3. Territory and city level. Evaluation of environmental elements

Initially, the main parameters for the location of the city of Nicosia were examined with the aim of commenting on the suitability of such a location from the environmental point of view. The location of Nicosia in the central area of the island, in a fertile plain, between two mountain ranges and the spring torrent that crossed it played an important role in the creation of its climatic conditions.

A main characteristic of the Mesaoria plain as well as of the whole island is the large fluctuation between the highest temperature during day and the lowest temperature during night (being between 8-10°C during the winter, and 16°C during the summer in the plains). The sunshine during the summer has a duration of about 11.5 hours and during the winter 5.5 hours. The prevailing winds during the winter are southwest and east, during the summer west and north and during the spring and the fall west and northeast [1]. The relative humidity level, due to underground water sources, is another factor to be considered. The city elevation and the distance from the seaside play an important role in the amount of relative humidity in the air. During the days in winter and the nights throughout the year the relative humidity varies between 65-95%. At noon during the summer the relative humidity becomes very low to a level of 30% [1].

It is quite evident that the location of Nicosia has been crucial for the city’s evolution. The Pedieos river has played a vital role in Nicosia’s setting and development [2]. Even though it is practically a spring torrent, the Pedieos has nevertheless sustained human settlements in its vicinity for thousands of years. Nicosia has been inhabited without an interruption since at least the Chalcolithic period (4000 BC), but it was not until the 11th century, in the Lusignan Times, that Nicosia became the capital of the island [3]. Under the pressure imposed by the Arab raids on the island, which eventually resulted in the abandonment of the coastal towns [4, 5], the administrative centre was moved to the interior of the island. The location of the ancient “Ledra” (Nicosia), being at the central crossing point of the commercial routes, offered comparative advantages for the new settlement [5].

From a geomorphological point of view, Nicosia lies in the middle of the island's two largest plains (the Mesaoria in the East and Morphou plain on the West), at the foothills of the two mountain ranges. Troodos Mountain lies in the South, at a distance that prevents it from being considered as a physical obstacle causing obscuration and shading. However, the range of Pentadaktylos Mountain extending on the north side prevents the wind descending from that direction in the summer period. As a result, a summer day is noticeably hot and dry, while at night north-westerly wind accesses and cools the area. The winter is moderate and rather rainy [1].

As far as the city form is concerned, there were a few limitations posed by the topography; the river bed and the rather moderately low hills in the vicinity. The importance of the Pedieos river in the formation of the built environment of Nicosia was great; it crossed the whole walled city, transporting water and other materials (clay and marls from Troodos Mountain) and divided the city into two areas (north and south) connected with bridges. When the Venetians began to build new surrounding walls of the city in fear of Ottoman attack, the route of the river was diverted so as not to pass through the city; a route which is followed even now. With the primal criterion of the defence of the city the fortification wall formed with the 11 bastions defined the size of the city incorporating the aesthetic idea of the renaissance "citta ideale" [3].

Concluding on the evaluation of the environmental parameters incorporated in the design of the city, as far as the location of the settlement is concerned, despite defensive and financial issues, the location offered comparative advantages. The presence of crucial and vital sources, such as the river and the fertile land of the plain providing arable land and necessary building materials were decisive. The limitation of the location is the insufficient ventilation in the summer due to the mountain in the north. Consequently, vernacular architecture in such a location is called upon to respond to the favorable winter and rather unfavorable summer conditions, especially during the daytime (taking advantage of the winds and being protected from the direct sun radiation).

4. Urban and building level. Bioclimatic design parameters

4.1 Urban Evolution. Typology

Nicosia began its development by following the type of rural development of the settlements in the plains with houses occupying a large area and adapted harmonically with the surrounding geomorphology and the climatic conditions. Gradually the urban development of Nicosia was directed towards a more compact character with houses occupying a smaller area and adapted mainly to the street network [4,6].

According to the study of Demi Danilo [4], the first building type adopted in Nicosia was the so-called "domus" or "rural courtyard house", built in the most elementary form of a single-storey building inside a fenced area used as a farmyard or orchard. The entrance was achieved through the courtyard from where access to the living areas of the house took place. The area occupied by the building in the plot varied in relation to the road access and the plot orientation, while the courtyard was always south orientated [1, 4]. In order to protect the doors and windows of the main living areas from the rather uncomfortable summer sun, a kind of semi-open space (covered area) was developed along the south side of the building, locally referred to as "iliakos" based on the Greek word "ilios" (sun) [6, 7]. This element was clearly incorporated into the building shell with the purpose of providing shelter from the climatic conditions, thus its bioclimatic function cannot be argued. Due to its size (3m in depth) it provided shading in the summertime when the sun was almost perpendicular, and allowed the sun to enter the living areas in the wintertime when the sun was lower.

With the development of the city, the increase of its population and prestige, the house gradually acquires more urban characteristics while the road allocation adjusts to a more urban dimension. The Byzantine "domus" presents a significant increase in the number of the original cells, capable of filling the entire plot area and facing the road, yet allowing an empty space for entrance, which was always achieved through the courtyard and never directly into the main living areas. In the cases of north south allotment the entrance was soon covered by a roof joined with the roof of the "iliakos", irrespective of the position of the plot; it was always extended so as to protect the entire southern facade of the building [4]. It is worth mentioning that in cases of east-west oriented roads the expansion was notable, increasing in this way the south-facing elevation and the corresponding area of "iliakos" (figure 1: B7). In the cases of north-south oriented roads, the buildings were located on the northern side of their plots, enlarged by filling the whole of that side [4]. The courtyard in this way remained south orientated, excluding obstructions and shading from neighbouring buildings. Consequently, in all plot cases the criterion for choosing the direction of the extension was purely climatic; the preference for a south orientation and direct solar gains is evident.

Another element of great importance that became remarkably widespread and eventually constituted one of the most important components of Nicosia's development in the 19th and the early 20th century is the appearance of special function buildings such as shops, inserted into the house courtyard fence as an independent space with direct contact with the road and access from it. In some variations, depending on the size of the plot, this individual function occupied the space between the covered

entrance area and the fence (figure 1: B2, A3). The resulting shape was the articulation of the main living areas alongside the road and the creation of a central covered entrance hall called a “portico” with lateral rooms opening into the yard and covered by a roof [4, 6] (figure 1: B3, A4, figure 2).

During the Lusignan Times intense urbanisation and increasing population within a limited available area initiated a process of land fragmentation using “cul de sac” type roads which are actually branches from the road, providing access to the inner core of the plots. The plots themselves were subdivided by an irregular tissue, embedded smaller and simpler variations of the courtyard house, while at the same time, some streets became wider. Serial allotments along the main axis appeared along with the urban mansions, prevailing in architecture design and height [4, 6]. The first extension of the original courtyard made by filling the side facing the road, was followed by a supplementary extension: i.e. the addition of a floor and a relevant loggia to protect the south façade or the addition of an extra room to one or both short sides of the plot which resulted in the typology of “L” (figure 1: B8, A5, A7) or “C” (figure 1: B5, B9). The access to the first floor was achieved mostly by an open-air linear staircase. The side facing the street beside the main entrance had small square windows at a considerable height above street level for security reasons [6] while the first floor windows were sometimes arched but considerably larger [4].

Actually, it was not until the Ottoman Rule that the urban tissue and the building types changed considerably; serial allotments along the main routes were largely increased by further land fragmentation using the “cul de sac” roads. The direct contact with the road became the prime criterion for the location of the building in the plot and more than any other variation; the “L” shaped arrangement became the most popular form for urban life [6]. Within a few decades after the arrival of the British in the late 19th century, the tissue was definitely completed by filling up all the empty areas. The traditional courtyard house was replaced by a “serial type” building which contained all the house functions within a smaller area; in this case, the central entrance door provided direct access to the central room and the yard acquired a decreasing size and importance (figure 3). The windows on the street front appeared at a lower level and acquired a larger size due to the change of social life (feeling of security).

Looking at the 1920s and 1930s, many variations of the “serial type” house appeared [4] and a new development was created: the “new courtyard house” (figure 4) as a combination of shapes and concepts of the two previous types (the position of the building facing the street-front and the courtyard type house looking into the yard in the back side). Consequently, the environmental criterion of the best orientation was left behind under the new development of the urban tissue and the necessity of direct contact with the street. In contrary to the above, the importance and the use of the semi-open spaces prevailed, being attached to the custom of living in the open air, which is actually a cultural expression related to the mild Mediterranean climate. It is notable that all the semi-open spaces are situated at the back of the house, leaving a plain frontage, as the social life of the family took place in the inner courtyard due to the introverted character of the society.

Fig. 1: Evolution of the original courtyard house - interpretation from reference [4]

Fig. 2: Example of a typical courtyard house

Fig. 3: Example of a "serial type" house

Fig. 4: Example of the "new courtyard house"

The following map (figure 5) graphically presents all kinds of semi-open spaces encountered in the south part of the Walled City of Nicosia; it includes the semi-open areas described in the typology report as a main entrance to the courtyard or as a shelter in the form of loggia or "iliakos". Partially covered alleys on the first floor are also marked. The map does not necessarily represent an accurate present situation because "porticos" were originally considered as semi-open spaces. However, at the present time many "porticos" are more likely to be closed, becoming part of the main internal living areas. Concluding on the number of semi-open spaces, it is evident that they are widespread; even denser in residential cores such as Ayios Antonios neighbourhood in the southwest and Chrysaliniotisa and Ayios Kasianos in the west. As far as the main direction of the spaces illustrated on the map, it is pointed out that, in accordance with the typology report, the "portico" as a main entrance space is perpendicular to the street, marking the entrance to the house. When the semi-open spaces are arranged in other directions or locations they can be considered as shelters serving as a protected transition from the internal to the external environment. The north-west quarter of the city, Chrysaliniotisa neighbourhood, offers a representative example of the evolution of the urban tissue where the presence of the "cul de sac" roads is recognizable and the dwellings preserve much of their original features. The map in figure 6 shows all the courtyards which appear in the Walled City of Nicosia, with various sizes thus underlining the introverted character of the social life. Figure 7 focuses on the neighbourhood of Chrysaliniotisa showing all courtyards and semi-open areas of the traditional buildings. All traditional dwellings incorporate a central yard and most of them have at least one semi-open space (more often a "portico" serving as an entrance to the houses). A number of dwellings incorporate a second semi-open space, an "iliakos" as an intermediate area between the separate rooms and the yard.

Through the study of the historic architectural evolution of the typology of Nicosia it is clear that some elements that remained and have been used during all periods are: the central yard at the back of the plot, the arrangement of spaces around the yard and the prevalence of semi-open spaces (used as entrances and shelters). These elements underline the aim of the residences to adapt their dwellings to the climatic conditions of the area (hot summer, mild winter, limited winds). The dwellings were frequently arranged in compact patterns, closely built with common walls, one attached to the other,

following the continuous urban system leaving small empty spaces in the form of public narrow streets and private courtyards. Thus, the vertical surfaces (walls) exposed to exterior environmental conditions are reduced and the thermal protection of the building envelope is increased. The shade between neighbouring buildings reduces the warming up of their walls by radiation. Thus, topography, geomorphology and climate are important parameters that play a significant role in the design.

4.2 Building techniques and constructive materials

Besides the typology and the organisation of the traditional dwellings, building materials and techniques played a very important role in the design of vernacular architecture (morphology etc.). Descriptions of travellers visiting Nicosia in the late 19th century provide interesting information and perspectives of the city with regard to the urban morphology, the building materials used and the local architecture. In one such description Deschamps [8] stated: "Nicosia comprises a complex of mudbrick built houses with some stone constructions. Nicosia resembles a large village with narrow and winding streets. The newly built and quite presentable buildings do not constitute a separate neighbourhood but are to be found everywhere".

As mentioned in the above extract and still evident at present, the materials used in the vernacular architecture are earth and stone which are to be found in abundance in the vicinity. The traditional dwellings constructed with earth and mudbricks, have stone foundations of local limestone, of Athalassa-Nicosia Formation called "Stone of Gerolakos", [9] so as to protect the mudbrick walls from the rising damp. The building practice and techniques used are also described by several travellers. Louis Salvator [10] stated: "Building is carried out with great rapidity; some mortar composed of earth and straw, is poured from a mason's tray with two handles over the mudbrick, another mudbrick is put on top, some more mortar is put on top of it, another brick and so on and the house is finished in almost no time. It also has the advantage of drying very soon after the process is finished".

The financial aspect described, that is related with the cost of the construction and preservation, is also worth mentioning, as an indication of the value of each material according to its accessibility, cost of transportation and mechanical properties. According to Louis Salvator [10] "These houses (earth houses) are exceedingly cheap; a fine building costs hardly more than about half the price of the finest stone house in Nicosia. Houses made of mudbricks will last a hundred years, but they must be frequently repaired, as the plaster with straw with which the mud bricks are covered up will get rotten and leave holes in the wall."

4.3 Bioclimatic strategies in traditional dwellings

The selection of appropriate building materials, apart from being partially imposed by availability, is also climatically driven. The suitable use of materials in the building's envelope provides direct protection from the climatic conditions, while the materials of the buildings' surroundings contribute to the development of desirable microclimatic conditions [11]. Thermal inertia secured by the thick mud brick and stone walls and the mass of the roof materials provide a small fluctuation in the internal temperatures [12]. The materiality of the floor surfaces, covered often with gypsum slabs, also affects the temperature of the immediate environment. Materials with high thermal inertia, such as stone,

were used in the open and semi-open spaces; their capacity to store heat and emit it with a delay, when the air temperature is lower, was appreciated and used [13].

Fig. 8: Bioclimatic design strategies in traditional dwellings in the historic centre of Nicosia, Cyprus.

With regard to the Mediterranean climate, vernacular architecture contributes during the entire year towards the bioclimatic strategies as follows: During the winter period improvement has been achieved by direct solar gains through the building envelope and the buildings openings (figure 8) and also by the protection against strong and cold winds. During the summer months the climatic conditions are improved by the reduction of the exposure to the solar radiation and the ensuring cross ventilation (figure 8) of the building envelope [12]. Cooling, heating and microclimatic environment strategies are described below in detail.

i) Cooling strategies

As mentioned before, vernacular architecture had to provide a climatically-responsive building model that could handle ventilation during the summer daytime, due to geomorphological limitations. Therefore, the building form had to offer as many ventilation possibilities as possible by combining night ventilation and cooling and at the same time being protected from the direct sunrays during hot summer days [13].

Suitable openings, frequently of small size, in the walls (figure 8) function as valves ensuring control of the air flow. Thus when they are closed during the winter they offer protection from the cold winter wind while when they are opened during the summertime they allow the circulation of cool air. The movement of the air through the building envelope depends greatly on the size, the shape and the position of the openings [13]. The small size openings on the façade on the streets (called “arseres”), located at a considerable height, were designed for the privacy of the domestic life [4]. Nevertheless their bioclimatic function cannot be disregarded. Due to the difference in temperature and density of the air, the hot air was forcibly extracted from the building envelope (stack effect) during the summer period (figure 9: C3, C4) [13]. The semi-open spaces (“iliakos” or “portico”) also enhance the air flow (figure 9: C5) especially due to the cross arrangement of the “portico”.

Another important cooling strategy is sunshading which protects the interior spaces from overheating during the summer period [13]. Shading covers, “iliakoi” and light pergolas with plants (in front of the south side of the buildings), solid plank or adjustable (movable) shutters (figure 9:C1, figure 8), roof overhangs, small or large balconies offer shading (figure.8, figure 9:C2) thus minimizing the direct sun radiation. In addition they favourably influence the natural lighting by reducing the reflection and offer protection from the rain.

Fig. 9: Bioclimatic design strategies of the traditional courtyard house during cooling period

ii) Heating strategies

Direct solar gains constitute the main strategy of bioclimatic design during the winter period (figure 10: H1). Such gains are derived from the south orientation of the building and its openings [13]. In cases where the south orientation is not an available option, indirect solar gains are derived from the building envelope, as solar radiation is captured through the walls and the roof (figure 10: H2). The elimination of heat losses also functions as protection from the strong cold winds (figure 7: H3).

Fig. 10: Bioclimatic design strategies of the traditional courtyard house during heating period

iii) Strategies on the microclimatic environment

The existence of water elements in courtyards and in the surrounding areas of the buildings provides evaporation cooling which results in the decrease of the high temperatures during the summer (figure 11: E1). The watering of plants and the courtyard is a widely used technique -that has prevailed as a traditional activity since the beginning of the last century- for enhancing evaporation cooling. The relationship of the built and natural environment in addition to the improvement of the microclimatic and consequently the comfort conditions also provides a visual pleasure [11, 14].

Small scale central courtyards (figure 8, figure 11: E2) enhance the increase in temperature in relation to the larger open air spaces. This is desirable during winter as the floor materials (stones and/or earth) and the surrounding walls of the courtyard increase the urban heat effect. During the summer months the necessity of cooling such an area is imperative. In several cases the largest part of the courtyard is shaded from the surrounding building volumes and thus the temperature is kept at lower levels. External shading, especially with plants on pergolas (figure 11: E4), prevents the sunrays entering this area. Evaporation from green leaves causes cooling of the air which becomes heavier and falls down under the tree shadow, while the hot uprising air outside the house drives it through the archways and cross openings of the rooms, causing cool breezes in the interior spaces. During the summer nights the downlink nightly cooling air enters and is channeled through the rooms (through open windows and arches) because of the rising hot air outside the house and thus removes the heat stored in the rooms during the day. The combination of shading and the night cooling reduces the temperature keeping it at a level more close to thermal comfort in relation to the outside environment.

The vegetation forms a naturally protected environment, which reduces the high temperatures during the summer period, shading the building envelope and reducing the sudden changes in humidity (figure 11: E3). Besides shading, vegetation can also prevent, filter or divert the air flow, thus affecting the internal ventilation of buildings (figure 11: E2). Evergreen as well as deciduous trees offer protection from a substantial amount of sun radiation, thus reducing the ground temperature. Shading provided by vegetation varies according to the kind of trees planted. Trees can also be used to prevent, filter and divert the air flow, thus influencing the ventilation of a building. It is worth noting that deciduous trees are usually planted in the south side of the buildings so that they allow the sun radiation onto the building during winter time. The planting of evergreen trees on the sides of the buildings affected by strong winds functions as a barrier to air flow and thus offers prevention against undesirable hot dry summer or cold winter winds [13].

Fig. 11: Microclimatic environmental strategies of the traditional courtyard house

5. Conclusions

Vernacular architecture was mainly developed on the principle of providing the necessary requirements through the local resources and nature's energy. Throughout time, while architecture and urban morphology were subject to different socio-economic, cultural and political factors, different solutions have been provided, always based on the fixed environmental factor which is the climate. This study refers to the main climatic design considerations in the early stages of Nicosia's settlement. From the analysis made above it is evident that the choice of the location of Nicosia, in the middle of Mesaoria plain, between two mountain ranges and the existence of the Pedieos river played a crucial role in the creation of the climatic conditions of the city. According to the typology study, as described, if a plot did not have any limitations, the building volumes and the courtyards were located in such a position that its longest side had the optimum orientation. In parallel, with the proper isolation the building envelope dealt successfully with matters of sun shading, cross ventilation and other bioclimatic principles. The practice of choosing the optimum orientation remained valid for as long as the degree of urbanization and the availability of space did not impose any restrictions. It was not until

the Ottoman Rule, that these factors became apparent and the direct contact and access to the street became the prime criterion for orienting the building. Nevertheless, the strategies applied in the building form and its immediate built environment, show high adaptability to the climatic conditions. The prevalence of the central yard, the arrangement of close and semi-open spaces around the yard, the use of materials with high thermal inertia showed the environmental consideration during the erection of traditional dwellings.

Further investigation is being conducted and selected buildings are being monitored in order to proceed with the goals of the overall research programme and introduce a quantitative documented bioclimatically based approach in the rehabilitation of the built heritage.

Abstract

The object of study is a roman aqueduct which construction was ordered by Emperor Augustus the first century b.C. in Tarraco, a city in the north of Spain, today known as Tarragona. The city was declared Heritage of Humanity by UNESCO in 2000, some restoration works were planed since then and those concerned the aqueduct as well. The restoration work consisted of a landscape performance and a physical and mechanical review of the aqueduct state in order to reinforce it if it was required. The landscape performance had the responsibility to rehabilitate a green area. Its direct relation with the River Francolí makes it a performance of great interest for the city, since it is its most important green corridor.

The study analyzes the entire structure of the bridge considering several load cases. The purpose is to obtain data about the structure physical and mechanical behavior. With this information we will reach several conclusions concerning deformation and stress parameters.

Hypothesis of load cases will take into account weathering effects since these would have changed stone properties through the years. Furthermore the aqueduct will also be analyzed when affected by horizontal loads. By superimposing the entire cases we will highlight the weak points of the aqueduct. This could help taking relevant decisions in order to reinforce the zones detected as well as streamline the restoring process.

Keywords: Structural Assessment, F.E.M., Aqueduct, Weathering, Heritage.

1. Introduction

Aqueducts are a sample of the Roman Empire engineering resources.

Water engineering had been widely developed in times of the Roman Empire. They had conquered most of the land surrounding the Mediterranean Sea, and at their step they funded the most important cities which began as a military campus and have remained until today. These were located thoroughly in strategic and favorable places. Several parameters were considered for their set up. Topography, vision range and resources like freshwater were taken into account, parameters such as these formed the basis for a new urbanism which would help developing a new civilization over the rest. Tarragona is one of these cities which origin goes back to these times. Even though there is awareness of the presence of previous cultures in this site (Phoenician, Iberian,...), Romans were the ones who decided the nowadays city location. Moreover, they are responsible of its urban planning structure which considered as well the incoming canalizations of the aqueducts in order to provide the city with freshwater.

The water supply was effectuated by 2 aqueducts; they brought water from the River Francolí and from the River Gaià respectively. From these two hydrological structures just remain a few traces and stones. However, as these water webs were studied from a topographical point of view, sometimes,

romans were forced to build big structures to cross valleys they couldn't save in any other way. These great constructions had survived through the years because of their size and consistency. It is a structure of this nature in which we have focused on our analysis.

2. Aqueduct physical and mechanical description

2.1 Physical description

The aqueduct was built in order to save a distance of 217m and a depth of 27m of a valley named "Vall de les Ferreres"(Fig.1). It is said that the name of the Valley rises from the idea of the shape of the bows recalling yellow bright horseshoes. The equilibrium of the structure is based on download arches. The bridge was built up with ashlar, superposing stones without any adding material. On the other hand, the bases of some of its pillars are widened to the contact with the ground. And there, in the basis they may be provided with a matrix of concrete which function is to fill the structure and promote its monolithic behavior. We can say that the structure of the bridge has survived until today due to stress compression. The more weight the aqueduct had, the more stable it would be.

Ashlars had variable sizes. The bigger ones were placed at the bases whereas the smallest were placed at the top. Furthermore as can be imagined, there were other singular pieces specially sliced, and modeled. These are the belonging to the arches and the capitals.

As can be seen in Fig. 1 the bridge is composed of 11 arches in the base and 25 in the first level.

2.2 Material Parameters

Most of the stone used in the construction of public buildings and spaces of the city was taken from the Mèdol Quarry, located 6 km far from the aqueduct. However, recent studies have reached new evidence that the aqueduct was built with a stone coming from a quarry that used to be immediately under it. This seems to be logic since the pillars of the bridge rises on visible rocky foundations (Fig.2). IGC (Institut Geològic de Catalunya) studies have detected that the area where the bridge stands corresponds to a kind of sandstone "Calcarenita escullosa"(Fig.3).

Fig. 1: 2D Plans for the aqueduct model.

Fig. 2: Image of the base of a pillar in contact with the ground.

Fig. 3: Image taken from de IGC data base. NMe - Local Stone.

This is a sedimentary rock. It may contain fossils and be quite soft but on the other hand may be well cemented and resistant. Its color changes as the weathering processes advance. In its origin, the color may have been pink and white but it can turn to grey or yellow depending on its composition.

The porosity degree is high; this is a reason why it might be a rock which can be easily sliced.

In consequence rock density is neither high. It is 24 kN/m^3 approximately. This affects directly to the results of the tests required to get the value of the resistance compression of the rock.

So as to prove this resistance to compression we proceed to make a stress analysis. Its purpose is to compare the resistance of the stone of the bridge and the resistance of the rocks found in its surroundings. This way we could see how much the weathering processes have affected the stone of the structure.

Data was obtained in the same place. The device used to help the analysis being developed was a Schmidt Hammer (Fig. 4). It had to be found a reliable stone in the surroundings which could be used

as a basis. The same had to be done with the bridge, looking for a surface not too damaged to carry out the test.

Fig 4.

B*	12,9	↙	16 kN/m ³	16 MPa

A: Local Stone. Found in the surrounding of the bridge.

B: Weathered stone of the bridge.

B*: Weathered stones of the bridge. It fades with the touch of the hand.

Fig 7.

Once a reliable surface is detected, we proceed to do several tests in order to get an average result. The results of the tests gathered with the ones obtained by the Schmidt Hammer, are shown in Table 1. These values correspond to the value for the rebound of the hammer when applied perpendicularly to a surface. The lower 50% of the results are not taken into account, and the average is obtained with

the other 50% of the higher values. The Table 2 is used in order to determine the uniaxial resistance to compression of the stone. This Table relates the value gotten from the Schmidt Hammer with the density (kN/m^3) of the rock so as to get the uniaxial resistance to compression (MPa). Results for tests uniaxial resistance to compression are shown in Table 3.

It is shown that local stone presents higher results in comparison with the weathered one. These results could be associated to the starting properties of the stones of the bridge just being cut. The values in the second and third cases are not higher, as they belong to weathered stone tests. We can see that stone resistance tends to 0 as the weathering effects are more adverse. This kind of stone, calcarenita escullosa, turns to dust as it weathers as shown in Fig. 7. It is easy to imagine that a stone in this state of conservation will not offer any resistance to compression (Values of 0 in the Schmidt Hammer test).

3. The model

The object of study was drawn and modeled in order to perform the structural assessment by the Finite Element Method. The calculation was carried out by the free software Salome Meca 6.3. An accurate drawing of aqueduct is made using a CAD application (Figure 1). These were the basis for the 3D model, done with the same software. The Model is drawn as a single solid and it could not contain any other elements such as lines, polylines or surfaces. These were basic impositions to enable the assessment.

The modeling process is shown in Figure 8.

Figure 8: Modeling Process. From 3D CAD model to Mesh .med file in preparation for FE study.

These impositions do not allow modeling an exact replica of the aqueduct, so it is necessary to make a simplification of the geometry, which means the analysis will offer us a general view of the bridge behavior. When the model is prepared, stress assessment in Salome Meca 6.3 can start.

We considered one single and homogeneous material which characteristic properties are introduced. The software will not consider the complexity of the components of the bridge, since the aim of the study is to approach us to a general acknowledge of the behavior of the entire body.

Once the model 3D in .stp file is imported to Salome Meca 6.3, we turn it into a 3D Mesh (Hypothesis Netgen Simple Parameters). The mesh will be given nodes values. And the body is finally given the data gathered in the previous studies.

The calculation procedure will be an isotropic linear elastic study on the 3D Mesh. The first material properties required are the Young's modulus and the Poisson's ratio; these are shown in Table 4. Since the value of the density of the stone is known in each state we can deduce the Elasticity modulus by the checking Figure 9:

In addition we will have to decide the boundaries conditions, such as adding imposed degree of freedom on groups of the Mesh or adding pressure on them, depending on the case we will be working on.

3. Calculation Cases:

The aim of the assessment is to get qualitative data about the structure behavior in order to detect the weak points of the structure, those which are more likely to fade. Highlighting these areas can help preventing future damage among the structure.

First cases will look forward to get information about the structure natural compression working behavior. Horizontal loads will be studied as well in the last cases so as to figure out what are the lines and zones affected by this kind of load. The calculation cases look for the comparison between an ideal state of the rock and a weathered state of it, after 2000 years. This will show how much weathering affects the behavior of the structure in addition to the information related to the potential damaged areas provided by vertical and horizontal loads.

This way the calculation cases are the following:

Figure 9:

Table 4:

	Elasticity Modulus	Poisson's ratio
A	30 000 N/mm ²	0.23
B*	7 000 N/mm ²	0.23

Fig 9: Rock classification based on the relative modulus (E/σ)

Table 4: Elasticity Modulus and Poisson's ratio for Local sane rock and for weathered stones of the bridge.

Vertical Load Cases:

- a) Ideal Behavior of the bridge. Local Stone Data.
- a1) Under weathering processes. Bridge Weathered Stone Data.

Horizontal Load Cases:

- b) Wind effect over Local Stone Data.
- b1) Wind effect over Bridge Weathered Stone Data.

Case A

This first case looks forward to find the qualitative behavior of the initial state of the bridge. The model is provided with the values belonging to the local sane stone in order to approach the initial situation in which weathering agents had not affected the structure yet.

So as to carry out the assessment an external load is needed, in this case as we want to know the behavior of the bridge against its own weight we divided the bridge in two so that we calculated the load of the top first 2 meters, and used it as a load. A scheme of this division is shown in Figure 10.

The value for this 'external load' is 16 600 900 N.

Figure 10:

Figure 10: Scheme of added pressure on the bridge mesh.

After calculating the case, the information of the stress is offered as a Scalar Map (Figure 11). The degradation of the colors shows the magnitude of the tensions. Reddish points are the ones which stand more compression stress while cooler colors show which parts of the aqueduct do not suffer as much. This kind of representation makes it direct and simple to detect such critical areas.

As can be seen weight goes directly to the ground through the vertical structure while the arches just help bracing the structure and download their own weight to the supporting pillars. It can be observed that capitals and other bulky items do not make any structural function as their coloring is the coolest.

The deformation shape (Figure 12) shows which points are the ones to suffer more deformation.

Case A1

The second case is a replica of the first. Otherwise, we will use the data belonging to the weathered state of the stone (B*). We see that the degradation and distribution of the compression stress Scalar Map colors is the same since the scale in which stress is distributed does not change (Figure 13 and Figure 14). However stress and deformation values have increased. In this case the porosity increases and so the density drops, the resistance of the material is reduced and as a result deformations increase.

So, logically the structure becomes much more vulnerable to the attack of weathering agents. In addition to the effect of the wind, water or salinization, there are others such as insolation which can

make the stone surface suffer superficial movements of expansion and contraction which may weaken it. The collection of weathering agents can turn the stone into dust until it disappears.

Case A

Fig 11: Compression Stress Scalar Map. Case A.

Fig 12: Deformed shape. Case A.

Case A1

Fig 13: Compression Stress Scalar Map. Case A 1.

Fig 14: Deformed Shape. Case A 1.

It can be said that this case is a case of a state in the procedure of a stone in weathering, which means in the procedure of disappearing, unless any external agent acts in order to avoid it.

Case B

The following two cases will make an assessment of the effect of the horizontal loads on the structure. To carry out the study we will take into account the year average load of the wind (0.52 kN/m^2) in the location in addition to its own weight load.

In this first case the properties of the stone will be the ones belonging to the sane rock. The load of the wind will be applied on the face facing the wind direction. Although the surface hit by the wind is lightened by arches still it offers resistance to the horizontal load. The Scalar Map and the Deformed Shape for the wind horizontal load first case show how much and in which zones the stress and the deformation are higher.

Pillars are subjected to cut stress showing a kind of a circle stress area which center is in the middle of the top of the structure. This can be clearly seen in the deformation Scalar Map. So we can guess that in an extreme case, only the base of the pillars connected to the ground would remain, while the area described by the stress circle would collapse.

Moreover, wind as a weathering agent, transports salinity from the sea, as well as grains of sand which hit the named surface. At the place we could check how a face of the aqueduct is more affected than the other because of the wind weathering effect.

With this case we can add a stress line to the results gathered in the first two cases. Not just some isolated points and corners suffer stress, but the whole structure in case of horizontal loads. It can be seen in the Scalar Maps that the arches help the structure working as a web in its entirety.

Case B1

In this last case we will assess the structure of the bridge in a weathered state (B^*) for horizontal wind load. Again, the Scalar Maps are similar to the previous. The values of deformation and stress increase since the stone is not as resistant as in Case B. It is proved that the structure suffering is higher if nothing stops the weathering effects.

Figure 18 shows the effect of the wind on the edge of one of the first floor arches. The face hit by the wind tends to lose its original shape while the other remains. Lost volume of the edge of the arch is colored in red.

Case B1

Fig 17: Deformation 3D Scalar Map. Case B1.

Fig 18: Picture showing the bad state of the face of the arches facing the wind.

4. Results

Structural assessments enable us to detect the points we have to take more care of in this type of structures. Cases A and A1, which carry on an assessment of vertical loads, show that in this case corners and the parts in which the volume is reduced such as singular points and edges are the ones that suffer more stress. In this case, some parts of the bridge held the function of bracing the structure and do not really support important loads. This would be the situation of the arches and in an ornamental way, of the capitals.

After seeing the third case, we can see that there are other critical areas to take into account. We could add a new critic line to the scheme of points we have to beware of. It consists of an approximate semicircle drawn from the top center of the structure. This line marks the place that suffers most when the bridge supports horizontal wind load.

As the Scalar Maps show the distribution of the stress and the scale of the deformation are the same in N and N1 cases, otherwise values change because of the loss of resistance. These values will always get worse due to the weathering effects, up until the extreme situation of making the stones disappear.

Recently some restoration works have been done so as to protect the monument, among them to reinforce of weak points of the structure of the bridge. Some parts of it had been replaced in their entirety because of their bad state. In order to contrast the data gathered in this study with the current state of the aqueduct some pictures were collected to portray some damaged zones or parts of the bridge (Fig.19). Weak points detected in the analysis are highlighted with a red point in the Scalar Map elevation. These images corroborate the fact that the small parts of the structure such as corners and edges are the ones to suffer more and are harder to maintain trough time due to their fragile state. It can be seen that some of the parts have been already restored by the recent works due to the opening of the new green area surrounding the bridge (Fig 20).

5. Conclusion

Structural assessment by Finite Element Method using software Salome Meca 6.3 enables easy and fast analysis of structures behavior. Although it is qualitative data what we get in the assessment, these procedures make the task of preventing deterioration of monuments more precise and comfortable. This kind of analysis helps deducing which parts of the object are likely to suffer problems. This is due to the collection of several weathering processes in addition to the own stress efforts. As seen the areas affected correspond in most of cases to bulky surfaces and parts in which

the area of the stone is reduced. These are the cases in which weathering processes are more violent with the stone breaking it into small pieces or even turning it into dust so that the monument slowly reduces its shape and volume.

Fig.19

Fig 19: Pictures taken on 28th December, 2012.

Figure 20

Figure 20: Panoramic view of the bridge and its area.

Knowing the exact points that require more attention in the prevention of deterioration, it becomes necessary to imagine solutions so as to slow down the rhythm of the harming weathering processes. Sometimes there is no chance to act forcefully replacing damaged stones by new ones which weathering state is not as advanced. Other times, we may find ways to protect monuments in an indirect way. It should be necessary to develop a project focused on protecting the surface of the monument stones. These could consist on an aerodynamic project, for example proposing obstacles to the wind such as trees in order that it would not hit the surface of the aqueduct as hard. Water should also be considered proposing drains surrounding the aqueduct to reduce the capillarity of the stones. This kind of performances might be helpful to protect monuments while taking care of landscape.

Nowadays, protecting Heritage of Humanity has become a worrying topic because of the dramatic fading of the entire built Heritage. It is a problem that deserves a special attention since it advances quietly. However, there are simple ways, such as this, to start preventing and taking into account those parts of the monument which require immediate attention.

Plurisensory Approach as a New Technological Way for Building Design

Abstract

Normally, the perception of the built environment occurs through visual exploration, but if the user is visually impaired or guidance cues don't get a single view, (i. e. with contemporary architecture), users can feel a sense of anxiety and frustration, leading to the rejection of the space. To think about an imageless communication is nowadays almost impossible, however another way of communicating exists. To get into this different way of knowing, it is enough to pay more attention to information coming from the "view-helper" senses. This new design approach is the so-called "multisensory approach", which promotes connections between the different sensory information, avoiding them reaching the user in a disconnected and meaningless way. The innovation that this design method can make, is to put men in contact with the main features of the architecture, thanks to the relationship between him, the space and its elements: light, voids, sounds, smells etc. This way, a remake of the classic eye-leading based architectural concept is achieved and structural elements can help more and more people to explore the built environment. Multisensory design then is a new interpretation of the whole design concept.

The aim of this paper is to examine the main elements of the built environment - signs - to be used in the design of buildings usable by people with visual impairment (blind or partially sighted).

Keywords: Plurisensory, Approach, Building, Technology, Design.

1. Introduction

The knowledge of a place or a built space, occurs through the acquisition and subsequent development of sensory information, which must be processed in order to hand back to the user the perception of the environment in which he moves. The interest to these aspects of project has produced a new design approach called multi-sensorial approach; the designer, to realize it, must be able to promote connections between the various perceptual information.

Until now, the predominant attitude was to allow the orientation using the welter of data coming from visual exploration. When, as it is often the case in contemporary architecture, the alone guidance clues are no longer sufficient to report of the various components and architectural functions or they are not organized according to a unified vision, it is generating in the individual a sense of anxiety and even of fear, that adversely it affects the balance and state of well-being.

This condition is accentuated when, to make use of a built space are people with mobility problems. In the current society, where visual communication is predominant and where seem that without it the world cannot progress, it thinks of a communication without images is almost impossible. Nevertheless there is another way of communicating which, although not usually used, provides infinite resources and possibilities of application. To enter in this different way of knowing, it is needed to pay more attention with to information coming from the senses that replace the view. They allow to understand how the object can provide information various and articulated. It is, after all, a concrete and effective system because the understanding of a message or information occurs through direct stimulation of all the senses.

The innovation of this design methodology is to put in contact man with the main dimensions of architecture thanks to the direct physical relationship that he can have with space and elements that compose it: light and vacuum, sounds and smells of materials. So it changes classic architectural concept based on the primacy of the eye and it puts under discussion the capability to help to explore the built world of the various and different building elements, for a handicapped as well as for a normal persons.

Therefore, the multi-sensorial design is a new way to live the architecture and to feel the architectural design and so it isn't only the way to approach and overcome the problems associated with removal of architectural barriers.

It is clear that the view is the predominant sense and the most of information are received through the eyes. Eye first one serves to maintain the position taken as well as it permit to characterize and to define spaces to live and to walk

Hearing have an equal role in the orientation and mobility. In fact, it contributes significantly to the formation of cognitive map of the living space. Therefore, it plays an important role for the understanding of the environments in which it moves (it thinks, for example, a seachone has capability to perceive in dark the position of a noise source) although it is a sensory input less understood, less stable and less rich of eye.

The sense of smell, while allowing to detect environment's nature and characteristics by picking up odours, does not allow to determine the position of the source.

Touch, whether direct or indirect, allows to obtain more information about the space in which you are located. In fact, radiant objects in a room can be detected thanks to the energy emitted or absorbed. More information can be obtained from the environment humidity levels (i.e. the feeling entering a cellar). Further these clues there are the ones from haptic perception, which provides information about the position of surrounding objects when in direct contact with you. A wide range of information can be also picked up by through the contact with the floor because *"attraverso il senso tattile plantare si ottengono informazioni sulla texture della superficie del suolo, sulla sua rugosità, levigatezza, regolarità e sulla pendenza. La percezione aptica fornisce informazioni sulla posizione attraverso la direzione dei piedi e la pressione dei vestiti sul corpo"*¹.

Further information about the position of man in the world around him are provided by kinesthesia: it supplies important data related to the perception of distance and three-dimensional dynamics.

To enjoy the architecture as a sensory whole *"basta considerare per esempio, i numerosi fattori che concorrono alla percezione completa dello spazio interno di una grande cattedrale. Qui giocano un ruolo fondamentale la temperatura e l'irraggiamento delle pareti, l'immobilità dell'aria, l'odore d'antico, di polvere e degli aromi usati nelle funzioni religiose, il tempo di riverberazione dei suoni registrabile come eco, rimbombo e coda sonora, l'elevato grado d'isolamento acustico dall'esterno e la consapevolezza delle reali dimensioni delle navate, il tutto inquadrato nella condizione di notevole emotività in cui si trova l'osservatore"*².

For the blind, the spatial image corresponds to a "data set" acquired through direct experience with all the components and parts of a given space. For a normally-sighted person is sufficient to dwell on the threshold of a room to understand it because he's able to acquire through sight the most of the information required to mental space construction.

The blind man, on the contrary, needs to "verify" the space crossing it, listening to it, touching it and paying attention to all the non-visual stimuli characterizing the spaces.

Below the main characterization elements of the built environment will be examined. The distinguishing features, to be used in design of buildings usable by visually impaired people (blind or partially sighted), will be defined "signs" because, as those used in one-sensory design and perceived by sight, are the guiding elements in the project and use of architectural space.

To respect the maximum length required, in this paper only acoustic and olfactory signs will be examined, referring to other publications for tactile signs, already widespread in practice.

2. Acoustic signs

Acoustic signs employed in interior design can be divided into two groups: active signs and passive signs, used in combination in the design of architectural space. In fact, to guide blind people inside buildings, it is possible to modulate the acoustic response of technological elements both with the use of suitable construction materials and with an adequate configuration of the internal spaces and even with a suitable arrangement of the emitting sources. Obviously it is impossible to use independently the three opportunities, but it is more efficient to organize them into an organic system of guided tours. Emitting sources are useful but can often cause discomfort to able-bodied so they should be reduced to a minimum by restricting them only to the doors-opening (main door, elevator, etc.). It would be

¹ T. Empler, *Progettare il comfort urbano e d'interni*, Rimini 1997, pag.18

² R de Rubertis, *Progetto e percezione*, Roma 1971, pag.69

more useful to be able to activate them only in the presence of blind people. In fact, it is not a difficult task. It is sufficient to report architectural barriers by placing sound sources, switchable by blind people, in correspondence of them. This solution would provide a safe guide to movements without causing nuisance to other users. Another solution could be to place some rattles, sounding only when struck by doors opening.

This acoustic emissions system however, is only one element, often secondary, in the organization of sound-guided paths. Usually the blind person can emit sounds himself; for example, thanks to his sense for obstacles, he can snap his fingers to exploit passive signs thus obtained as a guide. At this step the attention for design plays a key role because, appropriately changing the dimensional relationships between components, it's possible to change the passive response, providing useful information to blind person. This effect can be improved by making appropriate technological choices about materials and construction techniques.

The first information you should know is that inner depth should not exceed 3 m^3 . Above this height (Fig. 1) the effect of reflection is practically zero. So, it should be appropriate that rooms' internal height does not exceed 2.70m, reducing this value till 2.40 m in corridors. Below this value, perception becomes virtually zero if rooms are less than a meter wide. Another key data is about the walls provision. In fact, a person walking on a floor emits sounds spreading in all directions and, even if in the presence of the slab they permit locating a covered space, these sounds are substantially useless as a guide. Walls are therefore essential to create an acoustic path. A final suggestion concerns changes of direction. Thanks to acoustic signs, blind people can perceive correctly only changes of direction at 90° . Any other angle has to be signalled in other ways, avoiding curved direction changing³.

Basically, only materials able to modify acoustic characteristics of the room have to be used. Such materials can be acoustically insulating or soundproofing, but for the prefixed purposes only soundproofing materials are used. They can be divided into two categories:

1. Materials able to absorb thanks to special characteristics of their surface.
2. Materials that absorb noise because of their construction technology, i. e. vibrating panels and acoustic resonators.

For the first ones, it is possible to refer to the material's intrinsic characteristics definable through experimental tests (many data are available in the literature).

For the second ones, being understood to refer to market products, it seems appropriate to clarify how they work. As is known, a part of sound energy investing the absorbent material is converted into heat, another part is reflected and another one can pass through it. Porous materials have an internal cavity filled with air which starts moving when sound waves penetrate and propagate in the interstices, creating friction between air and the walls and transforming acoustic energy in heat. Vibrating panels (Fig. 2) are characterized by a thin panel nailed or elastically glued on two up rights connected to the wall the way of creating an air chamber behind the panel.

Fig. 1: Height limit for sound reflection in a room

³ T. Empler *op. cit.* page 52 and following.

Fig. 2: Vibrating panel

Panel's sound absorption creates a selection between waves having different frequencies, as it becomes absorbent only for its resonance frequencies. The larger is the panel's distance from the wall, the lower are the absorbed frequencies.

Panel's absorption at various frequencies can be increased by interposing behind it an open-pores or fibrous material, with the aim to increase the damping produced by the air behind.

Cavity absorption (exploited by acoustic resonators) is more complex. An example is the Helmholtz resonator, consisting of a known volume bottle: when a sound wave enters the bottle, it compresses the air contained in, producing a push-pull wave due to its own elasticity. If the incident sound frequency is equal to the resonator frequency, there is a perfect resonance with cancellation of the incident waves' energy.

Cavity sound-absorbing panels (Fig. 3) are formed by panels a little bit distanced from the wall and have holes of different diameters in order to form different frequency resonators.

In the graphic schemes, reference was made to a ceiling panel but the same principle is also applicable to wall coverings or floating floors.

3. Olfactory signs

The first thing that comes into our minds when we think about a Greek temple is the purity of the lines and the sublime harmony between the parts, but no one of us thinks about *cosa succedeva, tanto per dire, sull'altare? C'erano mucche, tori, si sacrificava macellando gli animali. Quindi c'era sangue e puzza... Non si pensa mai a queste cose, all'odore di un edificio... Invece questa è una parte importante della conoscenza che si può avere di un edificio*". Plurisensory design aims to recover this aspect of buildings' use, particularly with regard to issues related to the elimination of architectural barriers for blind people and visually impaired. For these people in fact, the smell, joined to other senses, must contribute to the definition of places' maps. The smells, although being unstable references, can provide impressions and information about the surrounding world which, if supplemented by other sensory references, help people fully understand the characteristics of the environment.

Fig. 3: Cavity sound-absorbing panels

To olfactorily characterize environments, the designer should use three ways:

1. Exploit odours related to the use classification;
2. Exploit materials' natural odours;
3. Exalt with olfactory sources certain spaces or paths.

These three design approaches, are not divergent or conflicting between themselves, so they must be integrated to achieve the maximum effectiveness of olfactory signs in the construction of plurisensory buildings.

Whatever the design process is, it seems appropriate to point out that odours produced or used in design should not create discomfort or allergic reactions. Therefore they must be within acceptable levels, also considering the greater senses' receptivity in people with visual impairments.

Since the odours level cannot be measured with ordinary chemical analysis, a few years ago two measurement units have been introduced (although with other purposes): the *olf* and the *decipol*⁴, which can be adopted to evaluate the maximum emission levels of odours in buildings. To ensure an indoor air quality acceptable for the majority of users, in agreement with the indications of ASHRAE Standard 62/1989, it is assumed that the indoor air is characterized by a value of pollution perceived (C_i) of 1,4 *decipol*/m² (20% unsatisfied).

Known that⁵:

$$C_i = C_e + G/Q$$

where:

C_e = perceived value of outdoor air pollution [*decipol*]

G = ability to emit bioeffluents from all sources in the room [*olf*]

Q = outdoor air flow rate [l/s]

it is evident that, being constant the values of C_i , C_e and Q , the designer who wants to include the olfactory signs, exploiting natural odours or putting in new ones, must necessarily act on G . However, according to studies carried out⁶, the value of G for a building occupied by one person every 10 m², should be between 0.2 *olf*/m² (for non-smokers) and 0.4 *olf*/m² (for 40% of smokers). These values in fact, can guarantee a value of $C_i = 1.4$ *decipol*/m² keeping, at the same time, the external air flow within reasonable values (1.4 l/s per m²). Considering that one person each 10m² is equivalent to 0.1 *olf*/m², the designer's choice is very limited because he can only act on the remaining 0.1 *olf*/m² (the value of 0.2 *olf*/m² has been adopted, because of the net reduction in areas where smoking is allowed). It's also evident that this odour load cannot be generic or annoying but should be a clear sign design providing the user with useful information on the ambience. The reduction of disturbing odours (which could be defined as "odours fund", by analogy with the acoustics) should be the designer's priority. As in all fields, the reduction of complexity is a factor of ambient noise reduction. In other words, the possibility of obtaining air changes through the windows without using air conditioning or ventilation constitutes a considerable reduction of the environmental *olf* load. Obviously this is not always possible, and then the technician should search for technological solutions and material able to reduce the facility's *olf* emission. It is recalled that currently ventilation systems contribute for about 0.2 *olf*/m² to a building *olf* load. It's also important to pay attention to the average age of the air and to the efficiency of ventilation: the *olf* load in fact, is directly proportional to the average age of air and inversely proportional to the ventilation efficiency.

Another important interference component are emissions from the use classification and the construction materials of the building and decor. Actually this *olf* load is part of what the designer can exploit as sign design. For odours related to the use classification the designer's attention should be directed towards a careful study of ventilation with the aim of obtaining for each ambience different intensity and characteristics of odours such as to constitute a characterization of the ambiances similar to the colour for the non-blind.

For *olf* load due to construction materials, the designer's attention should be paid to the study of technological solutions not only in terms of architectural requirements but also taking into account the creation of spaces olfactory usable. These two choices must be integrated with the adoption of ornamental plants such as olfactory sources. The green interior, if properly designed according to the *olf* load, is a useful guide for the blind and at the same time a comfortable piece of furniture for the able-bodied.

A last consideration is of a social nature: the development of new ways of life and the development of Western civilization are pushing towards the total elimination of odours from cities and housing. This

⁴ The *olf* is defined as the rate of bioeffluents issued by a standard person; the *decipol* is the perceived air quality (PAQ) in a space with a sensory load of 1 *olf* ventilated by 10 l/s. So 1 *decipol* = 0.1 *olf* l/s [Manuale di progettazione edilizia, Milano, 1994, vol. 2 pag. 195].

⁵ Manuale di progettazione edilizia, Milano, 1994, vol. 2 pag. 197

⁶ Manuale di progettazione edilizia, Milano, 1994, vol. 2 pag. 199

act certainly constitutes an impoverishment of sensory perceptions but also represents a cultural impoverishment as cities and architectures are losing, also through this process, another typological evolution link in the history's continuity and in harmony with the physical and socio-anthropogenic environment.

Monitoring and storage: integrate survey of the old towns “crater”

Caterina PALESTINI

Dipartimento Arch., Università “G. d’Annunzio”, Pescara, Italia

caterinapalestini@libero.it

Abstract

This contribution aims to present the experience gained by the emergency created by the earthquake that struck L'Aquila in 2009 and several neighbouring towns. This event represented the reason why we began our research at the Faculty of Architecture in Pescara.

Specifically, our research refers to surveys, targeted monitoring and conservation of some municipalities of the “crater”, including those belonging to the homogeneous in area n.5. This area contains of seven historical centers. We have surveyed the effective damage, with its representation topics, bidimensional and tridimensional studies. Priorities dictated by the knowledge and documentation of the damage caused by the earthquake have structured the different phases of our research, articulating them within an operating system specifically designed with integrated methodologies. The draft survey and the related interventions have been planned in accordance with the prefixed objectives and purposes. Furthermore, they have been organized in stages and in different levels of detail, established according to the urgency of the first actions of intervention regarding the “emergency phase” and the subsequent stages decreed by the reconstruction policies. This strategy aimed to provide the technical assistance in view of the reconstruction plans, pilot projects and strategic plans to re-evaluate the territories affected by the earthquake in a new cultural perspective of sustainable development.

Keywords: Integrate survey, representation, monitoring, earthquake, heritage.

1. Integrate survey and representation

The strong earthquake that on 6 April 2009 devastated the city of L'Aquila radiating in an area of about three thousand square kilometres and affecting, to various degrees, more than 57 municipalities in Abruzzo, provides an immediate idea on the extent of the damage, the analytical and planning difficulties related to various organizational stages of the reconstruction.

The coordination of activities related to the different moments of emergency, the definition of a unified methodological framework for the management of operations, required multidisciplinary experts who were called to operate on the territory. This is where the dutiful commitment of the University of Abruzzo derives from, the research conducted in these years by the working group of Pescara at the places hit by the earthquake.

The different experiences assembled on the field primarily concerned the investigation of the current situation and competence of our subject area, the organization of a cognitive system, which provides analytical data that can graphically help the various issues of intervention.

Firstly, it must be specified that the so-called “seismic crater” has been divided into nine equal areas, decreed by a committee that was established to handle the emergency in a systematic way, through a Technical Structure of Mission (STM). The homogeneous areas, voluntarily grouped together, have strengthened the ability to collaborate between the small towns that belong to it. In particular, our research unit occupies of the N°5 homogeneous area, extending between the valley of the river Pescara and the foothills of the eastern side, adjacent to the two National Parks of the Gran Sasso and Monti della Laga, and Velino Sirente, where there are nine municipalities. The SCUT research centre of the G. D’Annunzio University specifically designed seven of them.

Fig. 1: Localization of the seven towns under study, included in the Homogeneous Area n°5.

The integrated survey activities, included in an exact Technical Specification, covered the municipalities of Brittoli, Bussi sul Tirino, Civitella Casanova, Cugnoli, Montebello di Bertona, Popoli and Ofena, for which an operational work-program was set up that describes the methodologies used in the different stages point by point.

The contribution shows the operational plan and the achieved results, reporting methodologies that were used for the acquisition of data and results, which derive from their processing, documented through the attached graphic material.

Beginning with the support network and topographic survey, the definition of the absolute reference system was realized, which was obtained through the identification of 4 reference points, defined with topographic nails and appropriately positioned in respect to the perimeter of the study areas individuated in the single historic centres.

The calculation made with GPS helped us to obtain the vertices of densification, attributed to the IGM95 network of Abruzzo region.

These were the preparatory procedures for the geo-referencing of the settlement and for a subsequent scanning carried out with Laser instruments.

In each municipality, every topographic survey was therefore anticipated by the research of the extremities, closest to the boundaries to be defined.

This first operation, performed in order to reconnect the measurement systems, was carried out first on the official documentation issued by the Region, and later on the site to verify the accessibility, the status of the vertexes themselves, and their correct position.

Fig. 2: Topographic surveys, identification and materialization of points with GPS.

On the basis of the principal topographic polygonal lines the secondary ones were defined, inside the settlements, and arranged in a way to be crossed longitudinally and transversely. These latter ones allowed the topographic map coverage to be guaranteed and the restitution of the orographic situation of the historic centres under study. The internal reference grids were realized according to the scheme of the closed polygon rings, so we tried to create a single, large ring that surrounds the confined zone to be pointed out, crisscrossed by linking the opposite extremes. At the same time the targets, the points of connection were fixed and at this early stage they were detected with topographic instruments and then got relinked with a 3D laser scanner in order to geo-reference the point clouds. These targets were placed evenly in the area covered by the survey, with particular attention to the crossroads, squares, open spaces and, in general, to public places. The detection of the areas included within the delimitations, at this stage, required the acquisition of photographic documentation, accompanied by graphic notes that show rapid judgments about the damage done to the architectural and urban structure, indicating the location of subservice networks that will be useful for future inspections of internal pipelines. The photographic survey was organized in two phases, the first is referable to the indicated image shooting, carried out with the aim to document the damage immediately after the earthquake and to monitor the initial state and the following interventions. The second and more detailed one, with the aim to control the metric data and to provide a preliminary feedback between the photographic and measured information.

Fig. 3: Overview of some of the phases of the survey, referred to one of the historic centres under study.

Another test regarded the existing maps, comparing them with the urban reality of the individual municipalities; these interventions allowed a first comparison to be done on the actual correlation between the existing map data and present post-earthquake instrumental surveys.

We then proceeded, in each municipality, with the plano-altimetric survey of the urban environment, the architectures and built spaces, aiming to resituate contour plan of the area with its altimetric profiles.

The surveying, carried out with total station, covered the detailed survey of the facades and individual building elements for the definition and placement of the joint to the ground and, off the ground, of the previously affixed topographic targets. The sketches and the reference monographs correspond to the detection of the single points, which are numbered and are shown in charts.

For motives of optimization of the measurement system, it was decided to proceed in blocks, giving priority to main roads and areas identified by the "Pilot Projects".

To reach the desired effect, in other words the definition of a map equipped with the maximum information, the following main elements were identified, measured and summarized: blocks, appliances, buildings, elementary volumes, public spaces, visible points of the coverings and networks of subservices. As regards to roads and public spaces, all the necessary elements for the preparation of a detailed plan, scale 1:500, were acquired.

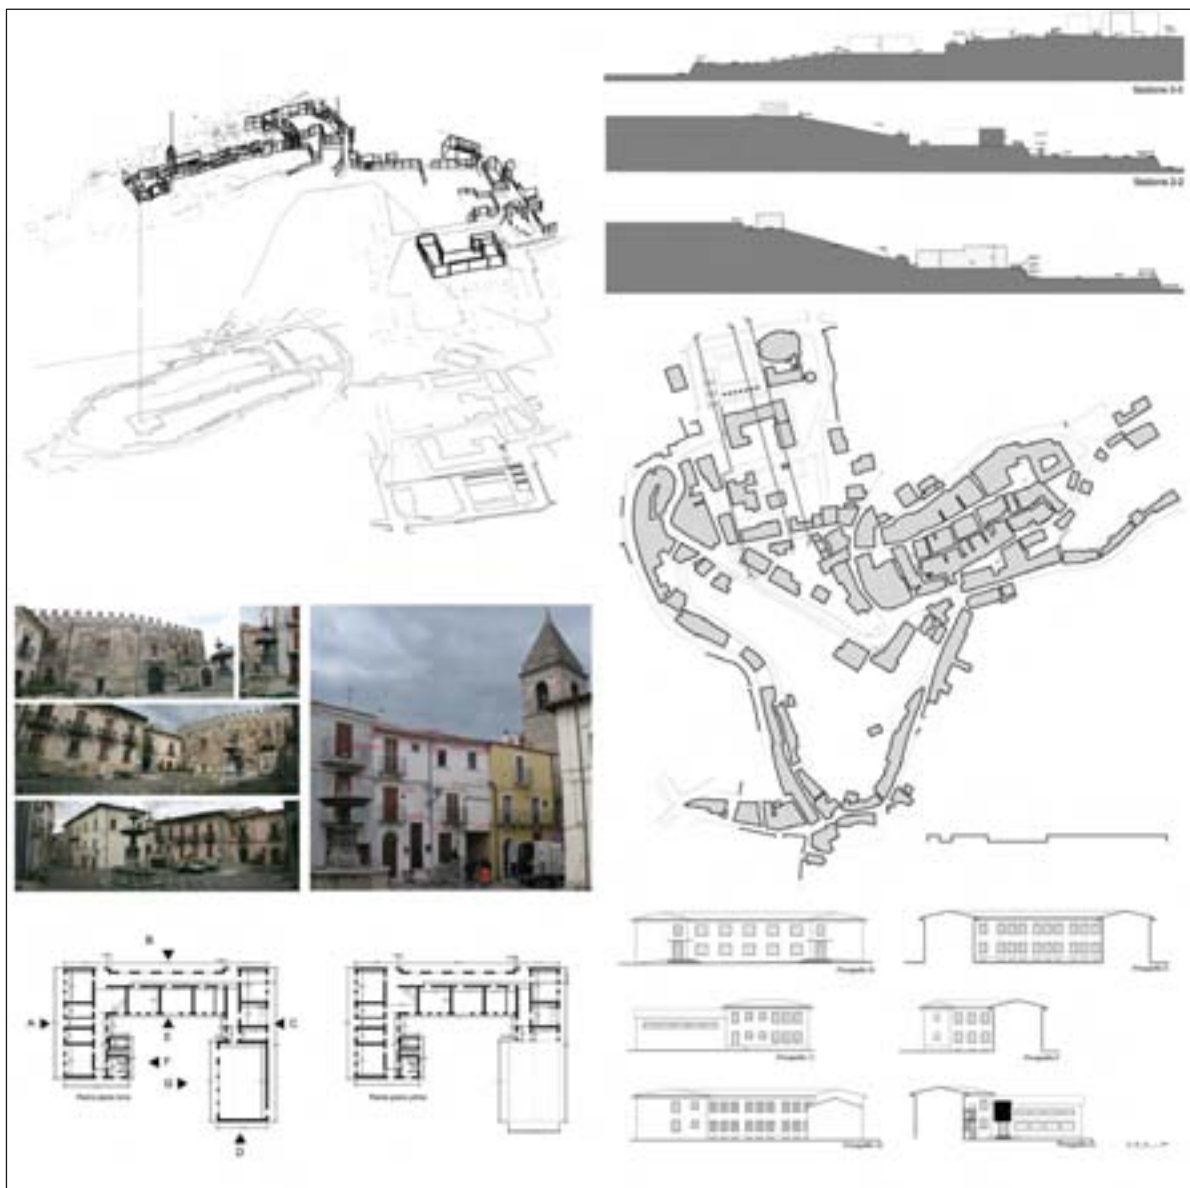

Fig. 4: Overview of some graphic representations and elaborations relating to one of the surveyed historic centres.

The surveying underwent some limitations due to the presence of scaffolding, shoring, and demarcation of off-limits areas to the public for obvious dangers; in such situations the information regarding the undetectable surfaces was still supplied.

The second phase, concerning the processing of the acquired data, determines the moment of the representation, the preparation of the graphic work in two- and three-dimensional format.

In particular, the materials collected during the enterprise of photographic documentation, were partly used to make image rectifications of facades. It has to be said that in many cases for the small road sections, typical of the historical centres, it was not always possible to realize the appropriate photo rectifications, balanced, in these situations with the aid of orthophotos, obtained by the restitution of point clouds, acquired with the laser scanning. Where it was possible, the photo rectifications introduced within the graphic design for the development of fronts were shown. In addition to the survey operations with total station, laser scans were carried out, as required by the technical specifications. These operations, after the apposition of the target of reference, allowed the geo-referencing of the point clouds. Each scan was then catalogued and reported in the plan for a proper file organization and to facilitate future merge operations.

The laser scanner survey of municipalities produced a substantial amount of information relating to the structural, morphological, material and chromatic characteristics of the urban centres. The individual data sets were ordered to the main streets that make up the historical centres. Following this scheme, registration of individual scans was carried out with the aim to make the complete point cloud model.

The scans were then aligned in advance through the identification of homologous points, which are recognized directly on the 3D (natural homologous points), after which it was decided to register "fine" performed by software through ICP (interactive closet point) algorithms implemented in applications devoted to the processing of 3D point cloud models. Recording operations allowed, moreover, to assemble the data within a single three-dimensional workspace; the explained tolerances, for each recording, from the values of Standard Deviation (RSM) and Average Deviation (AD) were maintained below 1.5 cm. The 3d models, corresponding to every street of the city centre, were then roto-translated in relation to the topographic network indicated by the targets, acquired bi-univocally both through the topographic station, both the laser scanner. This way, complete models of the surveyed area were obtained, which are oriented to the national cartographic system.

As to the production of two-dimensional works, after having optimized the model, horizontal and vertical sections have been realized in order to obtain maps and longitudinal and transversal sections of the urban areas. On the contrary, a series of virtual floors have been constructed on the street fronts, parallel to the layout of the individual facades, to which the view has been aligned. Using the 3D model of colored point cloud, orthophotos were produced of every facade by *screen shot* mosaicking. To finish the orthophotos, scaled and reassembled in CAD, they were aligned with sections that derive from the model and they provided the basis for the preparation of line charts and photomaps.

To conclude, such study models were obtained from this experience that can be explored and monitored in laboratory and that, in the first place, made it possible to provide the necessary technical assistance for the preparation of the Plans of Reconstruction in the emergency phase, allowing then to assist the Pilot Projects and Strategic Plans, designed to revitalize the areas damaged by the earthquake in a new cultural perspective of sustainable development.

Relocating the Past in Amman: Iraqi Architecture and Identity after Displacement

Sonia AL-NAJJAR¹

⁽¹⁾ Department of Architecture, Faculty of Engineering, Philadelphia University, Amman, Jordan
Email najjarsonia@hotmail.com

Abstract

It has become common to observe that the spatial and social displacement of people has been accelerating around the world at a fast pace. Displacement provokes disruptions and shifts of meanings and conventions. Architecture can function as a receptacle, as an instrument, or as staging of displacement. Sometimes, architecture manages to generate possibilities to turn contradiction into ambivalence.

Cultural representations of memory, migration and migrant experiences provide fruitful points of departure for the development of new theoretical concepts of place and belonging that have direct effect on built architecture and urban form.

Jordan has received two primary waves of Iraqi refugees; the first arrived after the 1991 Gulf War. Many of these Iraqis were middle class, including doctors, intellectuals, and teachers. Since the start in 2003 of the war in Iraq, increasing numbers of Iraqi nationals have left their homes for different parts of Iraq or have taken residence in neighbouring countries, particularly Jordan and Syria. Iraqi refugees and migrants in Jordan represent a large sector of society; this research looks into the current architecture or urbanisms of displacement which took place in the city of Amman as a result of Iraqi migration into the city.

This research proposes a theoretical framework to examine the effects of Iraqi migration on urban form and urbanism in the city of Amman. The author looks at four agencies of impact (movement of capital, people, information, and culture) and their effects. These consequences, the author suggests, are expressed in the configuration of urban space, urban form, and urbanism in Amman. The goal of the research is to offer a critical framework for studying impact of migration and refugees on third world cities urban form.

Keywords: Displacement Architecture, Iraqi Refugees, Amman, Identity.

1. Introduction

It has been noted that refugees, through the process of forced migration, lose aspects of their identities that were embedded in their former communities, jobs, skills, language, and culture. Upon arrival in a new society, they seek to reconstruct their identity.

The increasingly complex relationship between the local and the global, 'the near' and 'the far away', has emerged as one of the defining characteristics of contemporary societies. With globalization's increased mobility of people and speed of information exchange, and the cultural encounters resulting from it, traditional essentializing and stabilizing definitions of terms such as 'home', 'belonging', 'place', 'identity' and 'memory' have long become problematic and more adequate understandings of these conceptions are much sought after.

The issues of migrant resettlement, adaptation and acculturation have received increasing attention from social scientists. A dominant paradigm is Acculturation Theory, proposed by Berry in the 1980s, explains how individuals from a cultural background react when in contact with another culture (mostly in the context of immigration). The theory posits that, depending on how these individuals react to the "host" culture and how much of their "home" culture they retain, individuals will either; integrate, assimilate, reject or become marginalized.

Thus Iraqis in Amman are not recognized as refugees as the international meaning of the word suggests, but they are active residents of Jordan, participating in transforming the community's economic, social and urban status of the city. [11]

2. Research Hypothesis

This research aims to identify how the built environment is rendered and shaped by community identities. The object of the research is to pinpoint the effect of immigration on place transformation. It also aims to examine both new and historical urban fabric, and discover the different ways that they are occupied and transformed in reference to identity formation.

By examining both urban and suburban conditions, and discovering the different ways that they are occupied and transformed in reference to identity formation. Also by examining the experience of identity formation in a representative cross section of the city; the research seeks to identify both the significance and nature of architecture and urban form as part of the identity of individuals and communities. It will question whether 'place attachment' is still a valid concept, and should look in detail at the changing notions of cultural identity, as well as concepts of place identification and community belonging, through examination of displaced Iraqis influence upon architecture and urban form in the city of Amman. The aim is to look at new buildings and new urban influences, and also to examine the existing and historical urban spaces that are being occupied and transformed by Iraqis for different purposes.

The case with the Iraqi Diaspora in Jordan, and in Amman specifically, is that they have mastered the art of impact without real-time integration with the Ammani society. They're main catalysers of social and urban development. Empowered by strong capital and investment talents, they seem to transform and influence many changes inside the urban realm of the city.

Melvin Webber's celebrated "Non place Urban Realm" is what best describes the new metropolitan multicultural new city of Amman; where the built environment is subject to constant change due to different waves of immigrants coming into the city. Each group bringing part of their culture to the new city that does not represent a singular one identity place but a multi layered one urban realm.

The current forms of urban morphology that are occurring in the city of Amman, and the responsive developments initiated by new waves of displaced Iraqis and their counter effects build on what Melvin Webber describes as: "Dynamic, locational patterns of human communication that occur through space but transcend any given place." The Iraqis in the city are creating points of arrival for their trans-placed identity and culture inside the urban fabric of the city. In these points of arrival Iraqis can meet and socialize with fellow Iraqis and create a sense of home within their new city. One important point of arrival, is the restaurant or café, where 75% of guests are Iraqis, it is the new found Iraqi "medieval church" within each neighbourhood of western Amman, where an adequate number of Iraqi families are clustered. [15]

3. Refugees in Jordan

Jordan has the highest ratio of refugees to total population of any country in the world, and is host to the largest number of Palestinian refugees under the mandate of the United Nations Relief and Works Agency (UNRWA). Jordan acted generously towards these refugees, granting them fully-fledged citizenship while UNRWA provides health and education services.

Although Jordan is not a signatory to the 1951 Refugee Convention, both the authorities and civil society are sensitive to refugee and human rights issues. The Government considers the Iraqis in the country to be guests, rather than refugees, which ensures that they are secure and respected, but fails to provide them with a clear legal status.

While most Jordanians show tolerance and hospitality to the people of concern to UNHCR in their midst, the country's national systems and infrastructure have come under strain. The pressure has become more acute over the past two years due to the financial and economic crises, and was exacerbated in early 2011 as a consequence of the "Arab Spring". As refugees from many Arab countries have taken refuge in the country including those from Libyan and Syrian nationalities. One of the largest groups of Syrian refugees resides in Al-Zaatari camp, figure (1) which is home to more than half a million Syrian refugees [1].

Fig. 1: Refugees fleeing the violence in Syria gather at an emergency camp for Syrians in Zaatari village, east of Mafraq Governorate, Jordan. Le Monde, 2012.

3.1 IRAQI Refugees in Jordan

Throughout the 1990s hundreds of thousands of Iraqis fled their country, mainly Iraqi Shia and Kurds. Iran took the bulk of those refugees but by 1995, Iraqis also began to head to Jordan either to settle there or to use Jordan as a transit base to other countries. Although there are no accurate statistics on Iraqi refugees in Jordan before the 2003 war, it was estimated that by 1996 there were 100,000 Iraqis. By 2003, their numbers were put at 250,000 to 350,000 and only 30,000 were legally permanent residents in Jordan [2].

Fig. 2: Iraqi women in Downtown Amman area selling smuggled cigarettes, 2003.

In the immediate aftermath of the 2003 invasion, the first waves of Iraqis to flee were similar to the initial groups of refugees in the 1990s.

One of the issues facing international humanitarian organizations and research institutions is the fact that the Iraqi refugees, unlike refugees in many other war-torn areas, are not living in camps or tents; the vast majority of them are urbanites heading to urban centres [3].

The majority of the Iraqi community in Jordan resides in Amman, and had originally come from Baghdad. The population of Iraqis in Jordan is almost exclusively urban and hence most of them benefit from the infrastructure in the capital city of Amman and other large cities. Almost all households are connected to the public electricity network, the water network and the sewage network.

Fig. 3: Downtown Amman in 2003 home to less privileged Iraqis of pre 2003 migration waves.

Many Iraqis have been forced by their financial circumstances to move to poorer parts of Amman. Fafo's survey [4], indicates that 25 per cent of Iraqi households in Jordan own their dwellings. Household wealth plays a factor in home ownership; 60 per cent of the households in the highest wealth group own their houses, whereas only 1 per cent of the poor households do.

Lowest Wealth	21.5
Low Wealth	19.8
Middle Wealth	13.3
High Wealth	11.0
Highest Wealth	34.5

Table 1: Iraqis in Jordan, household wealth and employment of household heads (in %) - after Fafo [4].

In fact, with the passage of time, a real gap in wealth and status has evolved among Iraqis in Jordan. While there are stories of successful entrepreneurs whose business is booming, 100 thousands of other Iraqis are relying on humanitarian aid for food and blankets.

Fig. 4: Three Commercial Buildings in Mecca Street owned by one Iraqi investor. [16]

Fig. 5: Neighbourhoods in western Amman marked with (A) where wealthy Iraqis and investors own houses and businesses, and have invested in real-estate market. (B) Is the old Down Town of Amman where less privileged Iraqis prior to 2003 settled.

Some of the better-off groups have investments in and outside Jordan, and some even kept their investments in Iraq. Again, the survey shows a strong correlation between the household's economic status and the size of their investments. Within the households in the highest wealth group, 40 per cent have investments in Jordan, Table 2. [4].

Apart from purchasing their own houses to live in, some Iraqis invested in the property market which is considered one of the backbones of Jordan's economy. From 2002– 05, the value of Iraqi transactions in the Jordanian housing market has doubled each year, rising from about five million Jordanian dinars (JD) to JD 100 million (one Jordanian dinar is equal to \$1.4). The value of Iraqi transactions as a percentage of all foreign transactions also increased dramatically from 21 per cent in 2002 to 68 per cent in 2005. Obviously, these purchases boosted property prices in Jordan and added to the inflationary pressures in the housing market [2].

During 2004– 06, the Jordanian economy witnessed strong gross domestic product (GDP) growth rates of 8.4 per cent, 7.2 per cent and 6.3 per cent respectively. The reasons for this growth have more to do with external and regional factors than government reforms.

Fig. 6: Photo rendering of JD 80 million mega mall project in Sweifieh District in Western Amman by Amwaj Properties owned by Iraqi investors.

Among those reasons were the ramifications of the Iraq war, increased wealth and savings in the oil producing Gulf countries which led to a rise in foreign flows into Jordan. One of the engines behind the impressive growth of GDP is the construction sector, which has grown by an average of 10.7 per cent each year from 2003– 07 to meet the demand for housing by the new wave of refugees. The Jordan Times estimated that the arrival of Iraqi families in 2004 and early 2005 pumped \$2 billion into the Jordanian economy, and that 'clearly contributed to accelerating the cycle of the economy' [5].

3.2 Displaced Iraqis Identity

Identity is the foundation to a sense of belonging. It is the means by which people locate themselves as members of communities and groups and how they define their place in society. Identities are not singular, nor are they stable. New patterns in population movement, developments in transport and advances in electronic communication have loosened traditional ties between residence and identity. There has been a move from the community sociality of physically localised connections, to an increasing "network sociality" of informational, ephemeral and often temporary associations [6].

Fig. 7, 8: Esagila is an Iraqi restaurant in Western Amman owned by an Iraqi investor named after Esagila the famous ancient temple in Babylon.

Fig. 8

The globalizing era of rapid economic and cultural transformation has unsettled cultural locations and their settled ways. Those practices, beliefs, and ideas that were once considered folk culture and defined as organic expressions of locally lived experiences are, with ever increasing speed, being unsettled. The mobility and mobilization of both populations and territories raises questions about the nature of the ties social groups have to their places, about the durability of these ties and the kind of settlement practices enacted for those on the move [7].

The idea of belonging to a “community,” for example, is never simply the recognition of cultural similarity or social contiguity. It is instead a categorical identity that is characterized by various forms of exclusion and constructions of otherness [8]. Berry’s acculturation theory when applied to Iraqi diaspora represents varieties of adaptation that differ according to the group economic situation. But Berry’s model recognizes the importance of multicultural societies, minority individuals and groups, and the fact that individuals have a choice in the matter of how far they are willing to go in the acculturation process [11]. Immigrants involved in cultural transitions because of migration must cope with their new cultural-societal pressures and standards. They must make sense of their new social environment and decide how and/or whether they are going to integrate themselves into the host culture. How is it that they develop situated behaviour patterns that are adaptive within the larger context [12].

Many Iraqi restaurants in western Amman are social Iraqi hubs where Iraqis could meet, and wedding ceremonies could take place. The interiors of these restaurants are vivid and have nostalgic elements that echo Baghdad or Mosul or any other city in Iraq. The naming of the restaurant is also nostalgic; it may refer to street names in Baghdad or Mesopotamian references or traditional dishes, etc.

The Iraqi restaurants of western Amman are not only places where Iraqis can eat, but they also represent political arenas. Scattered between the streets of Sweifieh, Abdoun, Umm Uthaina and Rabiah districts; they mark the territorial zones and act like middle ages churches or Islamic mosques, or as points of arrival for Iraqi displaced culture and identity.

Fig. 9: Interior of (Zad El Khair) Restaurant in Umm Uthaina District - framed pictures on the walls are vintage photos from Baghdad and Mosul.

Fig. 10: (Zad El Khair) Restaurant in Umm Uthaina District – Exterior. Detached restaurant buildings became prevalent Iraqi investors' favorites. Restaurant and café culture has been a significant trend of post Iraqi Amman.

4. Displaced Iraqis and the Changing Face of Amman

Jordan experienced a high rate of urbanization during the last five decades leading to concentration of population in the main cities. This has created high demand for the opening up of huge areas to meet housing, commercial, industrial and other service planning requirements.

The Urbanization in Jordan is the result of a rapid population growth caused by high natural growth and a flow of refugees. Historically, urban immigration in Amman has increased at rates that have exceeded those of infrastructure development in the destination cities, resulting in concentration of population and increasing of population density. Continuous migration flows have largely contributed to an increase of the population density and built-up areas, one of the main effects of such a situation is the transformation of settlement structures and urban services, figure 10.

Fig. 11: Increased population means more demand on housing and a construction boom, but more strain on public services.

The population growth of Amman since the second half of the 20th century has been phenomenal, in terms of its population, density, and socio-economic characteristics. This has transformed Amman from small town in the early 1920s of little more than 3000 people to a major city with a population of 2.4 million people. [9].

Currently, the spatial characteristics of the urban areas of Amman had become increasingly complex. The peak in the population number indicated an increase in the fragmentation of the urban areas, and decreases the existence of open spaces inside the urbanized areas, figure 11.

Fig. 12: The peak in the population means more congestion and less open spaces inside the urbanized areas. Due to the marked difference in socio-economic conditions, the form of urbanization in west Amman is considerably different from that observed in east Amman. The urban growth under the Amman Land Use Master Plan has been influenced by economic development of the country and the city. In the east it is over populated while the west is more fragmented, thus the wealthy Iraqis found holes to fill in the vacant pricy lands of west Amman.

Fig. 13: Name of one of the streets in Umm Uthaina District in Western Amman: Al-Furat after the famous Euphrates River of Baghdad.

The urbanization of Amman has also produced several patterns. The new urban areas were quickly assimilated into the old urban centre by the rapid and unexpected economic growth that followed the privatization reforms, while the areas of east Amman remained relatively less developed [9]. Amman, a city of refugees and migrants, Amman's inhabitants arrived in waves that resonate with the convulsions of the landscape upon which they settled. The steep hills of the city's eastern parts and natural setting reinforced distinctions between groups. It provided shelter for the reconstitution of poor communities of Iraqi refugees, those were the ones that claimed the status quo of politically displaced and under privileged [10]. Jordan's population is just over six million people and its informal economy is small and there is no doubt that the influx of so many Iraqis in a period of several years has put tremendous pressure on the quality of the infrastructure and the level of government services, particularly in Amman.

5. Summary

Iraqi diaspora in Jordan are not like any other ordinary refugees and displaced people as a result of war. They are residents of a city that they are participating in transforming socially and economically, in a way that is changing its urban typology and development.

The majority of Iraqis in Amman come from good economic backgrounds and a very good percentage are active investors in the real estate and construction sectors.

Effects of Iraqi migration on urban form and urbanism in the city of Amman are tangible. Four agencies of impact including movement of capital, people's identity, information, and culture have affected the lifestyle and urban morphology of the city.

The configuration of urban space is affected by Iraqis in a way that is felt in the city's urban form. The effects of migration on third world cities urban form and social life are tremendous, because cities like Amman have not formed their own strong identity yet. Amman is less than a century old city, which means that a large number of people moving into a small populated city and country can have their impacts on social life and also on the urban form, as well as architecture and architectural behaviour of the residents from all backgrounds.

Abstract

During the XIX century, Giuseppe Jappelli (1783-1852) worked in Padua both as architect and city planner. His projects changed the urban aspect, even if the appearance of the city would be modified more deeply with the construction of his unrealized designs. There are, nevertheless, two engravings which represent a virtual garden thought for the interior of *Palazzo della Ragione* in Padua to wave the arrival of the Majesties Franz I and Maria Ludovika in December 20th 1815. Jappelli, who had a great experience in theatre sets, was influenced by the Projective Geometry rules, that during those years had been entirely codified. Our paper reconstructs those virtual spaces and links the engravings by Maina, that show the Jappelli's design, to the geometric rules and their exceptions. Starting from a study on the Jappelli's way to draw architecture and engineering machines, considered inside the international context of the Descriptive Geometry, we proceeded to create from an inverse perspective a virtual garden to reach knowledge on perspective theories and practices in scenographic screens for theatre.

Keywords: Descriptive Geometry, 3D modeling, Architectural Drawing, Giuseppe Jappelli

1. Jappelli and the Architectural Drawing in the XIX century (A. Giordano)

Among the studies on Vision and Perspective, in the first decade of the nineteenth century a new prevailing model of observer comes in Europe, radically different from the type that characterized the earlier centuries and this for a series of phisio-philosophical researches on the act of vision [1] but, according to some researchers, thanks to a broader range of social practices and domains of knowledge, based on the use of optical instruments, ancient (such as the *camera obscura*), or new invention (such as the stereoscope). Studies of Herman von Helmholtz, John Ruskin, Arthur Parsey, William Herdman, just to mention some few scholars [2], become emblematic of a century that takes another important step towards the complete mathematical generalization of Perspective, with the coding, as we know, of Projective Geometry by the French-Swiss mathematician Jean-Victor Poncelet.

However we see, throughout Europe, a renewed scientific production in the context of Descriptive Geometry, particularly in Germany, with specialized publications that accompany, at the dawn of nineteenth century, the education of the architect and, beside the study of Physics and of Mathematics, Drawing plays a foundational role in the theoretical corpus of studies of architecture [3]. Drawing has been finalized till nowadays to the representation and communication of the architecture, particularly in nineteenth century when this discipline reached its technical and expressive peak. Drawing thus emerges as privileged means for the construction of the project and the subsequent construction of the buildings, but also as an autonomous art that allows image processing, whose interest is independent from the represented object [4]. During the XIX century, like pictorial and sculptural works, architectural drawings are also shown on several occasions and prestigious venues such as the Annual Exhibition in Paris and the Royal Academy in London, clearly intended for the pure enjoyment of the general public, thus inaugurating a trend - not only operational - which will last until

the early twentieth century, to the point that sometimes the architectural drawing compete with the architecture itself [5]. There is thus a wide graphic production, supported by the methods of representation now known and understood not so much as a figurative expression of the design process or as a tool of interpretation of the designer intentions, but rather as exercise imitating the reality, which identifies in the relationship with the antique a preferential model to copy. Italian art and classical antiquity, active elements in the formation of the architect after the Renaissance, in the nineteenth century play an even more important role. And the journeys to Italy or, as in Anglo-Saxon most famous diction, the Grand Tours, until then reserved to a small *milieu* of privileged people - as guests of the *Academie de France* in Rome, or artists or architects as part of the *entourage* of a prince or a collector/connoisseur - become more affordable; to them it is due the copious graphical works of personalities such as Henri Labrousse, Pierre Martin Gauthier, Paul Marie Letarouilly, to name just a few of the protagonists. Their works, essential for the emergence of the modern Drawing disciplines, will greatly contribute to lay the foundations even of the idea of Survey, if we consider that the basics “... di una così notevole produzione sono da ricercare nello studio delle esperienze dei secoli precedenti, nel perfezionamento della strumentazione messa a punto nel ‘700 e nella codificazione della geometria descrittiva, mentre la produzione stessa è caratterizzata da un vivo interesse per la conoscenza e il restauro dell’architettura monumentale, dallo studio dei periodi storici esulanti da quello classico e da quello rinascimentale, nonché da un nuovo modo di concepire il rilievo, proprio di alcune grandi figure di rilevatori...” [6].

But certainly, among others, we want to emphasize the presence of three personalities that characterize this century for the use they make of the Drawing. Let's start with Jean-Nicolas-Louis Durand (1760-1834), author of two famous collections of buildings surveys published in Paris, the most famous of which is *Recueil et Parallèle des Edifices de Tout Genre, Anciens et Modernes* [7], where it is possible to find pictures of ancient and modern buildings represented in the same scale of reduction. But the importance of Durand lies in its contribution to the architectural design process, that he considers inseparable from the graphic-figurative substrate of the methods of representation, now encrypted. Professor at the *Ecole Polytechnique* from 1799 to 1821, in this prestigious academic institution he holds his *Leçons d'Architecture*, collected in two volumes. Durand articulates and develops its course both from the theoretical point of view - supporting the thesis of the disciplinar autonomy of the architecture - and from the practical point of view - with a research directed to the development of a code for the rational construction of the architectural design. He also prepares a methodical catalog of types because he thought that, to reach a good design, it will be useful the knowledge of *exempla* as well as the mastery of a method based on Geometry and Drawing [8]. The first volume of *Leçons* ends with a table (Fig. 1) that pragmatically illustrates the “Marche à suivre dans la composition d’un projet quelconque”: starting from a pair of orthogonal axes, Durand get to the creation of a modular grid that plays the role of structural spatial warp, where the architectural elements are hierarchically ordered.

Fig. 1: J.-N.-L. Durand, *Marche à suivre dans la composition d’un projet quelconque*, from *Précis des leçons d’architecture*, Parigi 1813.

Fig. 2: J.-N.-L. Durand, *Exemple des funestes effets*, from *Précis des leçons d’architecture*, Parigi 1813.

Fig. 3: E. E. Viollet le Duc, Saint-Denis Survey, from *Dictionnaire raisonné dell’Architecture française du XI au XVI siècle*, Parigi 1854-1869, voce ‘Trait’.

The mongian projections, which – through their tyrannical orthogonality – make measurable and executable the draft, in this cultural horizon play a decisive role, sublimated by the simultaneous presence on a single sheet. Compared to Boullée, although he considers this visionary architect his master, Durand prefer not to represent atmospheric effects or shadows in order to ‘redeem’ the inevitable bi-dimensionality linked to the Method of Monge, laconically rejecting the use of watercolor, preferred by those who believes that purpose of the architecture is to support the eye (Fig. 2).

Similar importance, but with different purposes and different cultural approaches, is ascribed to Drawing by Emmanuell Eugene Viollet-le-Duc (1814-1879), which will contribute greatly to convey different intellectual energies towards the birth of modern Handbooks [9].

It is through these words that Viollet-le-Duc, probably the most influential theorist of architecture of the nineteenth century, decrees the end of the eighteenth century and of Classicism. In the thought of Viollet-le-Duc, the Technique becomes the rational basis of each architecture. In the Gothic structure he sees a constructive principle that must be methodological paradigm of the future architecture, not determined by a taxonomy of external historicized forms, but internal and fundamental (Fig. 3).

In this regard, le-Duc writes in his *Entretiens sur l'Architecture* that the real art matter are symmetry and shape and each architecture is based on a principle first condition of structure [10]. Discussing the relationship between the parts and the whole into a building, he highlights a deep relationship between nature and architectural structure. And recognizing this romantic and organic feature of Viollet-Le-Duc, intrinsic in his interpretation of the Gothic, it is possible to explain his influence on the twentieth century Avant-Garde, on the Art Nouveau artists and architects, as well as on those of the Chicago School [11]. Keeping in mind these considerations, what is the contribution to Representation given by Viollet-le-Duc, whose graphic production plays a key role? In fact, his views will have the greatest impact on issues of Representation, as we have seen for the Design. And the Drawing will be placed as dialectic term between theory and practice in the definition of architecture. "L'idea di sottoporre l'arte e le pratiche dell'architettura a regole scientifiche della geometria e della matematica è un'aspirazione, con origini molto antiche, che prende sostanza nei nuovi insegnamenti che si vanno strutturando nelle scuole politecniche alla metà del Settecento" [12]. Le-Duc's ideas will encourage this dialectic, which already found in the treatises the theoretical explanation, and will find in the handbooks the practice explication.

Precisely in the context of nineteenth-century handbooks authors, a leading figure is Jean Baptiste Rondelet (1743-1829). His *Traité théorique et pratique de l'art de bâtir* [13] is, despite the programmatic statement of intent, a handbook since not only implements an architectural theory through case studies, but also because it refers explicitly to Monge *Géométrie Descriptive*. This handbook, structured as a precise and scientifically informed 'breviary' of building technology, addresses both eminently practical questions - such as the organization of building site, the estimation of artifacts, the durability of the materials, etc. - , discussed on the basis of tectonic exempla drawn from the past and from current events, but turns its attention also to the architectural Representation, so that construction problems will find their solution not only in the building site but on the designer drawing board, by virtue of graphic-geometric procedures (orthogonal projections) that can guarantee a faithful and rigorous two-dimensional representation of three-dimensional objects [14]. In particular, the third book of his *Traité* deals with Descriptive Geometry applications, organized as a classical text of this subject: after an initial part set to the teaching of plane curves tracing, Rondelet follows up a chapter - entitled *Tracé des épures* -, where the projections and the development of solids, contextually to problems of determination of true shape of figures and amplitude of angles, find solution in easy and understandable way, with the aid of clear construction drawings (Figs. 4-5). Rondelet accepts the concept of projection, proposing an effective analogy between the orthogonal projections and the shadow that solids (to be represented) projecting, if exposed to sunlight, on a plane perpendicular to the rays.

Fig. 4: J. B. Rondelet, Projections of solids, tab. 24, from *Traité théorique et pratique de l'art de bâtir*, Paris 1802.

Fig. 5: J. B. Rondelet, *Vis de Saint-Gilles*, tab. 62, from *Traité théorique et pratique de l'art de bâtir*, Paris 1802.

However, if on the one hand the strict codification of Monge Method shows how the question about Representation is following principles strictly functional and educational, on the other hand Perspective - even if Poncelet will codifies and systematizes its projective origin - occurs in nineteenth-century thought with considerations on the physiological and psychological act of seeing, considerations that introduce significant elements of discussion in the cultural debate of the time, with non-negligible impact on attempts to make the drawn image more consonant with the structure of the eye.

In this cultural period Giuseppe Jappelli (1783-1852) operates: the Venetian architect greatly contributed to 'redraw' the configuration of Padua [15]. His large graphic production consists of 375 specimens (cartographic drawings, gardens designs, palaces, public buildings, monuments, landscape interventions, building details and even furniture), all stored within the same *dossier* in the *Gabinetto Disegno e Stampe del Museo d'Arte* of Padua [16]. This extensive collection unequivocally demonstrates the long career of the Venetian architect and, although most of the projects never found effective realization [17], embodies an ambitious idea, as general as homogeneous, which could deeply has changed the aspect of the city. To fully understand the nature of these drawings is necessary to turn our gaze to his training period, linked to Napoleonic French culture. Although subjected to an approximate analysis, it is not surprising that almost all of Jappelli's drawings have been performed using the Mongean Method, as we can guess from faint traces of construction lines that link two 'images' of the same architectural, civil or mechanical, subject (Fig. 6); and even when, for practical reasons, some representations of a subject are on separate tables, construction lines retain their connection (Fig. 7): Jappelli then joined with enthusiasm to the new method, proving to be well ahead of the Italian academic circles; in fact, although the orthogonal projection immediately find fertile ground in the Germanic professional culture, Italy will adhere much later - probably for political reasons, as in case of England. This is demonstrated by the fact that the first real contribution on this subject comes only in 1868 with the publication of Giusto Bellavitis (1803-1880) - Professor Emeritus of the University of Padua - titled *Lezioni di Geometria Descrittiva* [18]. In spite of in Italy Descriptive Geometry has not found a ready acknowledgment in scientific circles, Jappelli, who unlike his colleagues comes to the profession of architect after receiving a less academic and more practical training, recognizes the revolutionary impact method of representation introduced by French officers, with whom he has certainly the opportunity to confront during his stay in Lombardia. Jappelli's design drawings reveal a close correspondence between plans, elevations and sections, highlighting how he caught perfectly the convenience of representing through figures that lie on a single plane, on which among other things can solve some problems of space - such as finding the intersection of the surfaces in the genesis of the geometric vaults - using rigorous constructions such as to allow the passage from reality, or from the idea, to its precise two-dimensional representation and vice versa. Yet, it is ironic to think that for an installation project on to the Palazzo della Ragione, did not remain any graphical trace, if not an interpretation made by Maina which, as we shall see, adopts without hesitation the graphic tradition of Perspective.

1.2 Jappelli and the informal garden: an illusionistic set in Padova (C. Monteleone)

It was 1815 when, for the visit of Emperor Franz I, the "builder of romantic gardens" [19] Giuseppe Jappelli introduced, first in the cultural landscape of his region, the so-called informal garden, setting, inside the huge hall of *Palazzo della Ragione* in Padua, a mixture of optical illusion and reality, combining painting with physical elements such as: hedges and shrubs, rocks and fountains, colonnades and temples [20]. This particular episode helps to correctly position in the European scene

the multi-faceted personality of our Venitian engineer-architect, which took advance – we can assume – of the diplomatic opportunity to relate his illusionistic garden to the dispute over the paternity about the origin of the landscape garden, started in Padua, in the late eighteenth century, by some prominent members of the Italian culture. In these discussions, for example, Pindemonte defended the italian birthright of the “English” garden [21], because in the *Gerusalemme liberata*, describing the one belonged to Armida, Torquato Tasso had described it using these words: “E quel, che'l bello e'l caro accresce a l'opre, L'arte che tutto fa, nulla si scopre” [22].

Figs. 8-9: Illusionistic informal garden: view of the spiral column and view of the circular temple. Design by. G. Jappelli, engravings by G. Maina.

Two engravings (Figs. 8-9), performed by Maina for the important historical event, show that Jappelli proposed a romantic garden, on the one hand, leaving the rigid geometric “French” organization, which was widely used in the previous two centuries, and on the other, maintaining the close relationship between artifice and nature, vision and deception, typical of the same tradition, as evidenced by the chronicles of the time: “[...] Con notturno spettacolo, tramutando in giardino la nostra gran Sala della Ragione. Ascendere scale, entrare una stanza, e vedervi una notte d’inverno bosco, viali, prati, acque correnti, ponti, grotte, colline, diverse fabbriche di ornamento; e gli effetti gradevoli della luce usata con pittoresco artificio, incoronata dalle fronde, riflettuta dai zampilli della fontana, [...] parve un racconto arabo diventato realtà; e durò appunto, come uno di que’ fantastici racconti, una notte” [23]. The design of this informal garden cannot be solely attributed to the desire of adhering to the changing taste of his time; especially if we keep in mind the cultural training of Jappelli, it is necessary to consider not only some political implications, but also the creation of a skillful interplay between nature and engineering artifice, designed to visually impress and deceive the observer. The Venetian engineer-architect began his career in 1803 as an expert surveyor, falling back on this profession after attending only for one year the Clementine Academy in Bologna, to become an architect, according to the usual path [24].

At first he worked with cartographers and experienced technicians [25] until, forced by the changed political circumstances, he joined the *Armée d'Italie* [26], in particular, it was this last experience to generate his substantial professional advancement [27], following the French armed forces, who at that time conveyed the latest scientific knowledge, developed at the *École Polytechnique* in Paris. This cultural debt is confirmed by his unconditional adoption of the Mongean Method as best tool suited to the representation of architecture and engineering machines, as well as by his use of the Durand’s Module as foundation design for the plans of buildings [28]. It could be argued, therefore, that the establishment of a illusionistic informal garden have played for Jappelli a political role, embodying “social freedom” in a “free-garden” and coming into conflict with the formalistic design, symbol of the nobility of France [29]. By the way it is interesting to note this kind of free compositions could be found also considering the European engineering tradition, in particular the one developed during the early seventeenth century by the figure of Salomon De Caus.

It is above all the ‘cave’, one of the most characteristic elements of the informal garden, that clarifies the link between Jappelli and European engineering tradition, linked to the perceptual deception, carried out using mechanical artifices, masked by natural elements. For example, the *Grote of Orfee* (Fig. 10), depicted in the De Caus’ treatise, entitled *Les Raisons des forces mouvantes* (Paris 1624), welcomes the mythological figure of Orpheus, moved by hydden machines and placed inside an apparently natural cave, but in reality created by placing the appropriate artificial material; in the same way during 1817, only two years after the “stage” set for *Palazzo della Ragione* in Padua, Jappelli designed and built *ab ovo* – still emulating nature – for Andrea Cittadella Vigodarzere’s garden in Saonara (Fig. 11), a cave within which a stream of water made its way among artificial stalactites and

stalagmites, surrounding the giant statue of the hermaphrodite idol Baffolometto [30].

In conclusion, the garden built in Padua for the visit of the Emperor Franz I, falls, though conveyed in the romantic context of the beginning of the nineteenth-century, in the sphere of the "illusionistic scenes", optically constructed to deceive an observer, as it will be shown in the subsequent analyzes.

Fig. 11: G. Jappelli *Cave of the Cittadella Vigodarzere's garden* in Saonara, 1817.

1.3 Two engravings (I. Friso)

According to what has been emphasized till now this kind of practice of combining painted scenes with solid objects, that mislead the observer, was developed during the XVII century. One of the most important example of this practice is the Refectory of Trinità dei Monti by Andrea Pozzo in Rome (Fig. 12), where the autor artificially juxtaposed some architectural elements, that appear as drawings, with painted scenes that allude to real spaces, deceiving the view of the observer.

Fig. 12: A. Pozzo. Refectory of Trinità dei Monti. Fresco, Rome 1694.

Giuseppe Jappelli turns to this tradition when prepares a scenography for the great party inside the hall of Palazzo della Ragione, so that this big hall will look like a night garden, as the same Jappelli would have liked.

The installation of the architect – who was one of the most important figure in the artistic and architectonic *milieu* of Padua, at that time –, proposes to transform the main room of the palace into an English Garden [31], using some scenographic expedients already tested in theatrical scenery.

The project provides a theatrical *mise en scène* in which the role reversal becomes the focus of the night: reaching the fixed place, the Emperor and his entourage leave the role of passive spectators,

assuming the one of unaware protagonists of the spectacle [32].

There are so many books where we can find some descriptions of this important event, and in their pages we can also find a lot of documents who talk about Jappelli's installation [33] attesting its realization, but unfortunately it isn't possible to find any original drawings by him which show the project's development: G. Maina realizes the only two copperplate engravings in the 1816 that represent two perspective cross sections of the huge room inside Palazzo della Ragione, using a perspective with a vertical pictorial plane. The Municipality of Padua gave to Jappelli these engravings as a sign of esteem and gratitude for the important work that he made.

Through the study of these engravings we are able to begin the activity of graphic representation of Jappelli's project. The first one (Fig. 8) shows a column decorated with bas reliefs ascending upward along an helix, relating Cesar's triumph: this kind of columns refers to the most famous Trajan's Column which is often used in representation in a similar way, assuming the meaning of glory and fame.

The great tree-lined avenue with the urban furniture and the public lighting seems to break off, leaving a wide space to an hemicycle building with its Corinthian columns and a decorated trabeation; furthermore a fountain and a Faun are in the scene. All the elements are developed along the perimeter of the hall and stand over a basement as tall as a man [34].

Instead the second engraving (Fig. 9) represents the counter-shot of the first one and alludes to a perspective breakthrough of the scene, bringing out the natural elements from the background which refer to the landscape of the Euganei's hills. We can admire a little ionic temple – the place intended to the emperor –, the Brenta's sources and a far wood bridge that marks the western boundary of the deep promenade.

We were able to apply the reverse perspective process [35] only for the first of the two engravings in which it is possible to locate the correct inner orientation, identifying exactly the projection of the observer into the pictorial plane, his distance from it, the horizon and the ground line (fig. 13).

Figs. 13-14: Illusionistic informal garden: view of the spiral column and view of the circular temple. Design by. G. Jappelli, engravings by G. Maina.

Not by chance, applying the same process to the counter-shot (Fig. 14), we can observe that the perspective doesn't lose its coherence, despite it was built basing on an wrong perspective procedure: as we know, in a vertical pictorial plane the main point (V_0 in our case) is the vanishing point of all the straight, orthogonal lines to the plane; considering this second Maina's perspective, only the straight lines that locate the architecture of basement of the hall of the building, satisfy this condition, because all the others don't converge in that point. Therefore, not being able to identify exactly the position of V_0 into the pictorial plane and having no other elements to identify other more vanishing point, it was impossible to obtain the inner perspective reference of the image and so that we were not able to obtain the formal and dimensional information about the architectures inside this scene. In particular it was impossible to specify the exact location of the temple that was intended to the Emperor.

Back to the restitution of the first image, maybe the engraver would have represented a landscape much deeper than the one that the hall of Palazzo della Ragione could contain, although relying on cartographic material and historical documents. In fact the cross section of the building –opportunistically reproduced in the scale of representation – corresponds exactly to the one that is on the architectural survey, both in form and in size. First of all we have to recognize correctly the inner perspective reference system and then we can apply the reverse homology giving back the exact planimetric conformation of the space. If we place it on the hall's plan of the current survey we could reveal a deepness of about half more in reference to the one that is measured (Fig. 15), these kind of formal inconsistencies could be better visualized by a comparison between virtual models instead of a planimetric view.

Figs. 15: Prospective restitution. Drawings by T. Fietta and L. Viel.

1.4 The Model (M. Pedron)

The construction of a 3D model can follow different processes that depend on the object that have to be virtually represented. In architecture these objects are usually buildings, but frequently we have to work with different subjects or unusual situations. Furthermore the architectural subjects are entity located in time that require a diversification of the three-dimensional modeling to visualize transformations.

Working with an existing building, if the aim is to create its 3D model in the actual shape, there are several technologically advanced instruments: metric survey and point cloud data that add to an architectural model more rigor and less complications. On the other hand, the reconstruction of a specific historical landmark or the rebuilt of a precise outfitting, like our scenic sets, is essential to have visual information and analytical data (historical documents, primary and secondary sources, digital cartography). These sources are important to define the features of the architectural objects analyzed in a specific historical moment.

Figs. 16: The two overlapped 3d models. Drawings by T. Fietta and L. Viel.

In our study case, we tried to virtually rebuilt the set designed by Jappelli in 1815. The available information are a couple of images by Maina engraved the year after the installation and gifted to Jappelli to thank him for the success of his design. The reverse projective rules, applied to these perspective images, permitted to establish the successive three-dimensional model. Through this technique of reverse perspective it is possible to link what is represented on the engravings with our final product: the virtual model. The first and most important output we obtained from this process is the map of the main hall of Palazzo della Ragione (Fig 15). All the elements are proportioned to each other but they were not scaled with the real space. In other words, we need a reference system to define the orientation and scale of the map. To convert these geometrical data in spatial ones we used the width of the main hall. The historical documents show that this size of the hall have not changed during centuries: its only transformation was the removal of all the inside partition walls and the restore of a unique space. This statement is useful because we could use the width of this huge rectangular room as a continuity element through the centuries [36].

The part of the building we could use for this purpose is the height of the main room, that has not changed during time: the last restoration dates back to 1756. During years the entire roof was rebuilt due to a violent tornado. After the operation of scaling, it is possible to underline that the result of the reverse perspective shows an incongruity. The hall has a bigger length than its real size. We can suppose that this overstatement was a choice of the author to emphasize the depth of the space in the engravings.

Using this map as a starting point, we worked dividing the modeling procedure between architectural objects and artistic ones. This division was necessary because the three-dimensional modeling required different rules for each case. Indeed the architectural objects, for instance the big Corinthian column or the semi cycle, can be easily redrawn using also the classic ratio of architectural rules. Conversely, the artistic elements like trees, bushes and lampposts had to be modelled using only the information of the two engravings, because they were specific and typical of the scenic set. We streamlined the free-forms and removed all the details that were not essential. This way we reduced the modeling procedure: trees and bushes don't require a perfect modeling, it is sufficient to create shapes that represent generically the space they occupied. Specifically, these elements were drawn as rotation surfaces [37], later repeated in sequence (Fig. 16).

Comparing the two 3D models it emerges a big difference between them. The size of the model obtained by the engravings is longer than the one created considering the real dimensions of this huge space. Therefore the three-dimensional model helps the visualization of these differences, highlighting how useful could be the use of Projective Geometry rules to compare real space and designed one. Furthermore, these technologically advanced tools confirmed their utility for visualization of historical transformation of architecture and cultural heritage.

Semantic 3D models: surveying and drawing the virtual city

Maurizio UNALI

Department of Architecture, Faculty of Architecture, University "G. d'Annunzio" of Chieti-Pescara, Pescara, Italy

E-mail: m.unali@mclink.net

Abstract

The themes examined in this essay are situated at the barycentre between the surveying and drawing of the contemporary virtual city. The text presents a selection of experiments with a particular form of representation – the so-called “semantic 3D model” – that, above all for didactic purposes, would seem to represent an important medium for the expansion of knowledge, the discretization of heuristic processes, for triggering hybrids of dialectic couples and exercising the imagination; actions propaedeutic to the representation of cyberspace in all of its various declinations.

As a conceptual form of drawing it consents the elaboration of ideas through visual expression structured similar to a map-manifesto-index, with a strong identity and open to successive developments aimed at the creation of inhabitable online sensible environments.

The model of representation described in the text was developed as part of a educational project examining the aesthetic-spatial characteristics that shape the architecture of Virtual Worlds, elaborated through visual-conceptual syntheses derived from interdisciplinary processes of hybridisation. The principal objective of this type of drawing is not to expose an a priori form, but instead to test, in a unique sphere of operation, the “substances” identified for each project: selected references; preceding ideas; possible forms; consequent results based on a logic of forecasting. Not a predefined form-project, but instead “fluid objects” to be selected by our intellect from consequential series of coherent transformations triggered by the process of representation.

Keywords: Virtual City – Semantic models – Drawing – Hybridisation – Cyberspace

1. Semantic 3D models for the architecture of the virtual city

This text summarises the latest results of the study of a particular form of representation, defined here as the “semantic 3D model”. This model was tested and investigated within the broader study of the *Architecture of the Virtual City* (cf. www.lineamenta.it).

The research (still underway) experiments with visual elaborations produced using mixed media, for the most part digital, situated at the barycentre between the surveying and drawing of the contemporary virtual city: conceptual drawings that consent the explanation and communication of ideas through visual expression, structured as a map-manifesto-index, strongly imprinted by identity, and open to successive developments focused on the creation of inhabitable online sensible environments; drawing as an interactive model and result of a specific plan for the thematic organisation of information, that conserves forms and proposes an archive of sub-models to be examined; representations that practice “semantic crossmediality”, experimenting with the technocultural convergence of various fields – educational, educational, information and entertainment – available online in diverse formats and techniques.

It is becoming clearer that these semantic models serve as representations of the particular moment that anticipates and prefigures design; conceptual models as an instrument for understanding and verifying existing architecture, rather than prefigurations for new designs; representations useful to the visualisation of parts of the infinite quantities of information we bear and transmit; laboratories in which to recompose fragments of space, create relations between parts, study geometric characteristics and quantify groups of thematic elements; to visualise, personally and for others, the ideas we conserve in

our memory; images in which to elaborate that magmatic and sublime aesthetic chaos from which to discretize forms; graphic exercises that can be structured as methods for understanding, transmitting and elaborating cultural processes, ideas and forms; organisms similar to a “matryoshka” to be discovered.

Representations that, above all at a didactic level, appear to be a significant medium for broadening knowledge, reading the richness of historical stratifications, metabolising the conceptual and visual references of design, discretizing forms and exercising the imagination, unconditioned by the “myth of originality”; fundamental elements for prefiguring inhabitable architectural spaces in the digital realm, in all of its multiple declensions.

In particular, as anticipated, the model of representation referred to here has been developed above all through didactic experiences (at different levels of university education), pursuing the general objective of studying the aesthetic-spatial characteristics that shape the architecture of Virtual Worlds (cf. www.lineamenta.it/avc).

This study was developed primarily through visual-conceptual syntheses derived from interdisciplinary processes of hybridisation.

The principal objective of this type of drawing is not the depiction of an aprioristic form, but instead that of identifying and experimenting, in a single sphere of elaboration, with the creative “substances” useful to shaping the virtual city itself: selected references; preceding ideas; its possible forms; the consequent results according a logic of prediction.

This representative strategy is founded on the continuous comparison between the idea and its representation.

Not a closed and predefined design-form, but “fluid spatial objects” that our intellect selects from a consequential series of coherent transformations triggered by the process itself.

Semantic models as instruments of critical research that trigger relational processes; free (re)stagings of “things observed” that generate references to other works in turn transformed by this process of hybridisation; scenographies of ideas in which meanings must be interpreted; ideal and utopian drawings depicting atmospheres characterised by various aesthetics; spaces for experimenting with techniques and methods of visualisation, deformations, chromatic tonings.

This elaborative process originates in the hypothesis that all phenomena can be represented, and thus elaborated and communicated using shared disciplinary methods and techniques. What is more it is founded on the theoretical premise – a cornerstone of our studies of the *Architecture of the Virtual City* – that “inhabiting digital space signifies representing”, emphasising the central role of drawing (in the sense of “New Lineamenta”) in giving form to cyberspace (the design of the interface, the spatialisation of information, the conceptual map, etc.), in its multiple declensions.

Within this process of configuring spatial conditions, representation is the most natural and universal dimension of elaboration.

In primis as a multidisciplinary, synthetic and direct language, an expression that is simultaneously historical, theoretical and practical.

In other terms, the meta-linguistic coincidence between visual forms (drawing) and architectural forms (ideal, utopian, metaphorical or real as the case may be), practiced and transmitted through the graphic sign (iconic, symbolic, allegorical, etc.), makes representation the natural tool for the elaboration of digital space: for its unfolding in forms, intentions, actions and times; for aesthetic experiments and multidisciplinary processes of hybridisation.

Let us further examine this last aspect.

If we consider that the most interesting manifestations of contemporary creativity appear to be the result of a convergence between rapidly changing disciplines – in some cases shedding the traditional confines of specialisation – then it can be stated that an interdisciplinary approach will play a fundamental role in the creation of the virtual city, in research and didactics alike.

One of the most interesting conformations of contemporary architectural space appears in fact to be the product of a conscious and simultaneously instinctive intellectual action of multidisciplinary hybridisation involving “dialectic combinations”.

We can consider, for example, the following dialectic couples: original and copy, known and unknown, possible and impossible, real and virtual, centre and periphery, analog and digital, archaic and contemporary. Dialectic couples that, in our liquid contemporary culture may be integrated and comprehend one another, giving rise to new representations.

This fundamental structuring of the research is of a cultural order; it helps trigger open elaborative processes in which to represent spaces in the midst of apparently antithetical meanings.

In particular, in the best elaborations of inhabitable online environments – shaped, architecturally, by the idea of “cities of bits”, “information highways”, virtual worlds and social networks – the creativity of the spaces proposed appears to be nurtured by an awareness of the stratified and articulated history of architectural space and, at the same time, by the value ascribed to forms and messages we perceive in the rapid and fluctuating action of contemporary technoculture, by its very nature shifting, chameleon-like, super-fast, interactive and crossmedial; in a commonly accepted term, “liquid”.

Fig. 1: Examples of 3D semantic models developed by students as part of the course in *Scienza della Rappresentazione 3*, Pescara Faculty of Architecture, 2011-2012, prof M. Unali (specialist G. Caffio).
Cf. <http://www.lineamenta.it/avc/category/semantic3dmodelsurvey>

Within this theoretical context representation does not always constitute a “flight from reality”, but in some cases an improvement: from this point of view for architecture the notion of the virtual means above all “broadening vision”.

This produces an “ulterior substance” of design that may serve as an input to the action of modification and its concrete outcome. The latter is not always possible to distinguish from the former.

As observed, contemporary architecture appears to renew its cyclic need for interdisciplinary; it seems to elaborate theory and practice directly through a process of hybridisation with “the other”, producing representations often generated by intrusions and procedural deviations along critical-technical lines of reasoning, and as part of operative practices and the observation of reality.

Finally, the semantic 3D models being analysed may express concepts that develop and reinvent theories and practices treated by the historical traditions of architectural drawing (testifying to a contemporary declension), actualising them with respect to the interactive visualisations introduced by current technoculture.

Examples that come to mind within the furrow of the historic tradition of representation include: the notion of “interior design and exterior design”; the drawings of ideal, utopian and radical projects; the phenomenon of paper architecture; the “morphemes” designed by Franco Purini.

As anticipated in the premise, this study of “semantic 3D models for the architecture of the virtual city” is an experiment (still underway) that mixes research with teaching, and wishes to broaden and further investigate methods and techniques of visual elaboration, prevalently digital, positioned at the barycentre between surveying and designing contemporary online inhabitable spaces: spatial conformations for inhabiting digital space as a free container of experimentation and information.

Abstract:

The traditional medieval house of Kosovo, almost always in its functional and architectural structuring of the guest room and other rooms, even in the more modest homes of the time, implied a functional node. The functional node inside the room, with its complex architectural features, appears as a peculiar and distinctive feature of traditional Balkan architecture. The functional node, with its architectural features framed by a functional scheme - uniquely stereotyped, reflects a high traditional residential culture. In terms of architectural and functional disposition of the functional node, the earthen furnace with elements of faience appears as a central element. The stove, as the central element of the functional node is connected with other areas of the house into a functional whole, realized by a stereotyped scheme. Increasingly, the central element - furnace is placed at the entrance of the room, and functionally interconnected with the room - the main part of it, then with the bath and small alcove or fireplace. Igniting the fire inside the earthen furnace is always done from the outside of the room, i.e. from a separate alcove, of smaller dimensions, or the fireplace. In the traditional home of Kosovo the functional concept is not just a functional scheme, but is also a concept of compositional architectural structuring of these spaces and their functional elements. This means namely that the functional concept of architectural configuration merges with the functional concept into an organic whole. So, all of this has to do with a high degree of creativity of the Albanian popular craftsman who created top and unrepeatable values of various genres. In this context, traditional home of Kosovo after a multi century development has reached an organic harmony between function, structure and form. Given the fact that the functional node is found in certain typology homes, inevitable in this study, according to the analytical method, we will elaborate typology and architectural values of Kosovo traditional house, built over the centuries.

Keywords: traditional house, functional node, earthen furnace, functional concept, shaping concept.

Introduction

The earthen furnace in traditional residential culture was wide spread. From the literature we know, that the earthen furnaces in Europe appear from the 13th century. The oldest data of its appearance were presented in a coat of arms of Zurich, from the middle of the 14th century. In these appearances, according to R.M. Franz, *Der KACHELOFEN*, Graz 1969, a square based bottom is clearly distinguished with an upper cylindrical dome part, on the top of which is placed an element in a baked form with respective configuration. In this view of the stove faience elements are depicted, the order of which reminds us of the earth stoves built in traditional homes in Kosovo, as in Fig.23. Earthen furnaces in traditional homes in Kosovo stand for another harmony between proportions and outline. Earthen furnaces in traditional homes in Kosovo, in the final stage of the development process, in a broader forming and functional context gained designed characteristic features. Earthen furnaces as an important element of the interior, as we can see from the floor plans presented in this study strongly influenced the concept of home interior architectural structuring. The earthen furnace in all the traditional homes of Kosovo is heated by another alcove. There is evidence that, igniting the stove

from the outside, i.e., from a special alcove has occurred in the seventeenth century, the same century when a number of room baths (hamamjiks) were built. As we see from Fig.19, the old town house of Prizren, built in the 18th century, had four hamamjiks on the first floor, with two others on the ground floor. Construction of baths (hamamjiks) in the house, and later in each room, raised the residential culture to a new high level. In general, by the half of the 17th century, the number of hamamjiks built in the house was enormous. "In the 17th century, Prizren as one of the most important Balkan cities had over 10.000 homes. River Lumbardh with rich waters and Prizren's convenient configuration enabled the neighborhoods to build a network of channels with running water, which passed through the yards of every house" [1].

Architectural concept of functional node

We said that in the context of architectural and functional disposition of the functional node, the earthen oven with elements of faience appears as a central element. The stove, as the central element of the functional node is connected with other areas of the house in a functional entirety, performed according to a stereotyped scheme, as presented in Fig.1. So, in Fig.1, is shown a general diagram of earthen furnace's overall functional connections with other units that made up the functional node. This scheme, in concept and in its composition hardly changes. It, however, appears in different variations, depending on the position of earthen furnace in the context of the functional availability of the room within the floor layout. The functional node in all floor plans presented in this study is marked with a circle, in the center of which is the central element – earthen furnace. As we see from Fig.1, and other plans related and presented in this study, the entirety of the functional node consists of alcoves from (1) to (7). These alcoves, which will be discussed later, are structured, i.e. functionally related between them under the general stereotyped diagram shown in Fig.1. The entirety of the functional node consists of the following elements: 1. Earthen oven with elements of faience; 2. Introductory part of the room; 3. Main part of the room; 4. hamamjik; 5. Copper water cauldron; 6. Small alcove; 7. Corridor, or garret (d); 8. Earthen furnace ignition space; 9. Cupboard; 10. Fireplace; 11. Fireplace and chimney constructed in rich homes, guest rooms, or in the hallway (Fig. 8, Fig.16, and Fig.17)

A. Floor plans of homes listed in: Fig.2, Fig.3, Fig.10, Fig.15, Fig.19, Fig.22, Fig.26, Fig.33, and Fig.34, show that in the earth stove (1), turning on the fire is made from a small alcove space (6). This alcove, as we see from the figures, is connected directly to a relevant floor corridor. Starting the fire in the earthen furnace is made through a notch (8), open in the corresponding wall, to which the bottom cubic wall of the earthen furnace is scrambled. Usually from the same small alcove two earthen furnaces are lit.

B. from Fig.6, Fig.7, Fig.8, Fig.9, Fig.13, Fig.14, and Fig.16, we see that in the earthen furnace (1), fire ignition is done from the fireplace (10) or hallway respectively (7). Fireplace (10) has access through the hallway or garret [2].

So, from the above results that depending on the fact that the earthen furnace is lit from the small alcove (6) or from a fireplace (10), the general diagram of functional nodes (Fig.1.) is presented in two variations. The first variation has to do with the case when the earthen furnace is lit from the small alcove, as above, under A. The second variation has to do with the case when the stove is ignited from the fireplace (10), as above, under B. In both these variations, the central element is always the earthen furnace (1), placed in the introductory part of the chamber (2), and is functionally connected with the chamber - its main part (3), with hamamjik (4) and small alcove (6), or fireplace (10). In the room or in the main part of the room (3) the access is through the introductory section (2), in which the earthen furnace and hamamjik are placed. Lighting the fire in the interior of the earthen furnace is always done from the outside of the room, i.e. from the small alcove (6), or from fireplace (10). Stove's rational position in the diagram of the functional node enabled simultaneous heating of the room (3), hamamjik (4), and copper warm water boiler (5), which is installed at the lower bottom cubic part of the stove inside hamamjik. Therefore, from hamamjik, the use of hot water for cleaning was directly enabled, and Igniting the fire in the stove from the outer alcove allowing the room to be kept clean, without smoke, and likely to be turned on at any time without disturbing the guests or family members who stayed in the room was possible. In the above context, the concept of architectural structuring of compositional space, functional concept, are in a direct creative attachment.

Functional Concept and Architectonic Concept

In the traditional home of Kosovo the functional concept is not just a functional scheme, but is also a concept of compositional architectural structuring of these spaces and their functional elements. This means a functional concept with the concept of architectural configuration merging into an organic whole. In line with the general idea of structuring architectural spaces, the entrance of the room (2) is smaller and lower than its main part (3). The introductory part of the room, as well as its main part, are equipped in a standard way, and made entirely of wood elements beautifully framed, in conformity with the architectural concept and distinctive characteristic features, as in (Fig.4, Fig. 5.) and (Fig.23). In

most cases, as we see from the floor plans presented in Fig.6, Fig.15, Fig.16, Fig.18, Fig.19, Fig.22, Fig.26, etc..., [3], access to the room environment is done through a door with an angular position. The angular position of the door conditions a diagonal access into the room environment.

Diagonal approach

This particular angular positioning of the door allows for an inclusion of the entire space surrounding the room with a glance. As a result experiencing of interior architectural values becomes more powerful. The perception or experiencing of architectural values within the movement through the space of the room is driven by the functional architectural concept truly planned by popular Albanian master, with creative ingenuity. Experiencing of architectural sequences of a room interior is connected with a continued thread of movement in the space, in conformity with the idea or architectural concept of organization of space and movement through this space. With the opening of the door are in the introductory part of the room with lower rooftops (2), compared with the ceiling of the main room. At the same time, these two parts of the total space of the room stand for an organic interface in the context of interior elements architectural configuration.

Space Spacing

The introductory part of the room has access through a door of human proportions. Above this door, as seen from Fig.4, Fig.5 and Fig.23, appears the ceiling with height somewhat greater than that of a human body. Therefore, in the next sequence of movement in the room space appears the main part of the room with ceiling size, comparatively larger than that of the entry of the room. This gradation space causes the feeling of an immediate change perception of space dimensions. All this creates optical effects, impressing the observer. At the same time, this concept of spatial modulation within a single space results in the effect of an optical illusion. This effect creates the illusion in the observer of the main room space being much larger than what it really is.

Ideal of ancient harmony

In general, the interior of all the old town houses of Kosovo, including the most modest ones, is rich, and with a preponderance of organic harmony, elegance and full functionality. It should be noted that, in: Fig.4, Fig.5, Fig.23, Fig.24, Fig.29, Fig.30, Fig.31, Fig.32, only a small segment an altogether more upscale interior traditional home built in Kosovo has been shown. In this context, I would add that the interior of the guest room of a house built in Prizren, in the 18th century, as presented in Fig.24, has achieved the ideal of ancient harmony. So, from the whole composition of this interior one cannot add or remove anything. Genuine perception of these values of the interior is provided by quality lighting. This lighting quality is made possible by the formation of systematic windows located in the front of the room, especially in side walls of the room. As we were dealing with floor plans related presented in: Fig. 6, Fig. 8, Fig. 13, Fig.18, Fig.19, Fig.22, Fig.26, etc., this window system, with a contemporary concept, enables illumination of interior spaces, as well as a balance of internal and external lighting. Consequently, this feature allows for a combination of architectural interior space with the exterior, thus making the external environment of the green part of the traditional home interior Kosovo. In plans related with traditional houses presented in this study we see that the functional node is contained both in houses with a modest functional program, as well as those with a more developed program. Moreover, these houses belong to a certain typology of construction.

Functional node and traditional house typology in Kosovo

Plans related housing shown in Fig.6, Fig.7, Fig.8, and Fig.18 show that a good deal of these homes built in the town of Prizren belongs to a housing type with irregular shape architectonic structuring.

Irregular layout type of houses

Architectonic structuring of traditional houses with an irregular layout was conditioned by the urban context of parts of the city that were developed by a spontaneous construction and congestion. This spontaneity of the construction of neighborhoods of the city, in a broader context of urban planning, was, however, developed according to a systematic concept. Irregularity of neighborhoods as urban units, determined an irregular yard planning, and this constrained an irregular architectural structuring type of houses. Despite the fact that the traditional home contained one room, two rooms (Fig. 6), four rooms (Fig. 7, Fig. 8, and Fig.18), or more, it always in the context of functional program included a functional node with a full shape lineup. Architecture elements of the interior of these houses always excelled in a rich and rounded configuration. Urban unit architecture of this city is composed of wallpaper, light-shadow, and space. In light-shade are depicted irregular volumes of houses, with sharp lines, composed by a strong plastic creativity, thus creating an intense pace, rounded and colorful.

Houses built according to the type of an asymmetric composition concept

In the houses of this type, orthogonal layout, functional and spatial structuring is done by an asymmetric forming concept. The architecture of these homes is the product of an interactive creative process emerging out of the urban context and relationship and of the functional and spatial structuring of the house. As a result, the house built in the town of Gjakova, as shown in Fig.10, Fig.11, and Fig.12, is created in cubistic spirit. The provision of the house in the context of the plot is dictated by the approach, as well as its opening towards the yard and sun. A human usually and naturally perceives architectural creation from a height of about 1.70 m. From this height the author has photographically perceived the above-mentioned house. If closely observed, this photographic perception will result in the conclusion that architectural configuration of the house is known for a harmony between proportions and contours. Availability of home in the context of the plot, in relation to the entry in the yard, according to an online approach dictates under an angle that strengthens the perspective perception and emphasizes the three-dimensional plastics of the building. This same impression, even in a still stronger degree, is experienced in the house as shown in Fig.27 and Fig.28, as the semi-cylindrical garret (Fig.28), in the right side of the house, is depicted with its really impressive outlet. That house too is set in the same urban and architectural context as the above-mentioned house. Unlike features of other homes, created in Kosovo over the centuries, in which the preponderance of a clean and clearly defined function is evident, as in the house shown in Fig.10, Fig.11, and Fig.12, in favor of the proper configuration and outward harmony is sacrificed the functional purity of its contents. Spatial composition of the house is characterized with cubistic structuring of architectural volumes. The architecture of this house is known for an asymmetric composition of volumes, with a dynamic and harmonious rhythm. As such, this architectural work reflects a modern spirit for our time.

Creativity and Continuity

Plans related to objects shown in Fig.25 and Fig. 26, are not coincidentally given in a visual-comparison conjunction as between them there is a clear analogy. Fig.25 shows the layout of the Basilica of Constantine in Rome (308-312), whereas Fig.26 shows the layout of Sina's family home floor in Gjakova, built in 1839. Also, the layout of Basilica Urbana of Municipium DD, Fig.36, as well as the plan of the house floor of Kryeziu in Gjakova, Fig.37, have been given in a visual attachment, as the structuring of the layout of these objects carries also a clear analogy. Urbana Basilica is built in the 3rd-4th century AD, in Municipium DD, a Roman period settlement, near Socanica, Kosovo. It should be pointed out that even in the vicinity of the town of Gjakova the remains of a large Roman settlement are found. [4]. In the context of analogy between traditional house forming features of Gjakova and Constantine's Basilica in Rome, is also the home of the close semi-cylindrical garret type, shown in Fig.33. At this home we see its semi-cylindrical garret coming out of plan outlines with a main corridor axis extension. This same longitudinal extension, according to the axis of middle nave is also present in the apse in a semi-circular form of Basilica in Rome. Moreover, in the composition of the second floor rooms of the traditional house (Fig.33), parallel to the longitudinal axis, on the right of the layout, in all the length of the house, lies a narrow space ("AO"), which corresponds to the Basilica arcade (Fig.25 / "A"), which extends in all its width. From the above we understand that a good spatial structuring of semi-cylindrical garrets emerging powerfully beyond the outlines of the layout of the houses as listed in: Fig.26, Fig.27, Fig.28, Fig.33, Fig.34 and Fig.35, is a clear expression of implementation of analogy with the structure of spatial volumes of the apse of the basilica of the Roman period. If viewed in a comparative analytical context the layouts of Basilica Urbana of Municipium DD (Fig.36), and Kryeziu family house, (Fig.37), then one will see clearly that, between the morphology of these two objects an almost complete analogy is revealed. As we see from Fig.36, the spatial structuring of Urbana Basilica by a longitudinal concept, in terms of middle nave longitudinal axis on both sides, is formally concluded with two apses of different dimensions. The same concept of construction also includes the home in Gjakova, Fig.37. With this traditional home, the longitudinal corridor coincides with high nave of Urbana Basilica. Even the hallway, in a way analogous to the secondary nave of the Basilica, is formally concluded with two garrets also of different size. From the above, we can come to the conclusion that this analogy between the traditional homes of Gjakova with the Roman period basilica cannot be accidental. This conclusion is indirectly supported by the fact that, in Neolithic period, the house was not yet de-sacralized and it served as a sanctuary. Therefore, the architectural concept of the house is also carried over on sacral architecture, or in the first temples respectively, representing the home of the gods. In this context of creative continuity in time and space, we will be satisfied with the conclusions reached above, as this problem deserves a more comprehensive and deeper analytical study. It should be added that the construction of a significant number of traditional houses in the city of Gjakova of this type - with a semi-cylindrical garret, gave a distinctive character to the formation of the urban landscape of a certain part of the city.

Exterior is a result of the Interior

We see that Sine family home was built according to an asymmetric compositional concept. It is known for a contemporary forming concept. Truly, the architectural exterior of the house is an expression of genuine interior. So, in the architectural structuring of the house it is easily discerned that the exterior is always interior. Therefore, in the expressive language of architecture created by the ever popular master of architectural forms of the building one can easily read its function either as a whole or its constituent units function. In this house built by the popular master, not only is exterior architecture known for its great value, but at the same time for its interior as well, as we see from Fig.29, Fig.30, Fig.31, and Fig.32, as being very rich and known for great aesthetic values.

Houses built according to a symmetrical composition concept type

Almost the same features and architectural value, like those of the Sina family, are also included in the house shown in Fig.34 and Fig.35. Given that this home has access from its front (Fig.35), I think it should be defined as a symmetric type house. Of the same type built by symmetrical compositional concept, is the family home of Kryeziu, Fig.37, and Fig.38. The house floor presented in Fig.34 and Fig.35, and at the same time all the three floors of the house of Kryeziu, structured according to the longitudinal axis, come to a closing of garrets from both sides. Due to the structure of construction materials, the home garrets enjoy a polygonal circular layout. Meanwhile, plans related to the house floor garrets, Fig.34, are semi-cylindrical and stand for an impressive output of layout outlines of the house. This home, built in Gjakova in 1839, is depicted with its open garret positioned under the semi-cylindrical closed garret. Setting an open garret in the ground floor over the running water streamlet turns it into a very pleasant environment to stay during the warm seasons. Taken in its entirety, the house is known for its authentic architectural values. In principle, the compositional structuring of objects under a concept which applies symmetry diagram, gives an architectural work a monumental character. A monumentality spirit has depicted the Gjoni family home, built in Prizren, in the 18th century, Fig.19, Fig.20, and Fig.21. Architectural structuring and functioning of the ground floor and the floor of this house is created by a symmetrical concept with a clear functional definition. The same architectural and functional features are obvious in the Grazhda family house, built in Prizren, in the 18th century, Fig.22 and Fig.23. Both of these houses, for the past as well as today, are characterized by a rich functional program. The first house seen in the context of functional program includes 4 (four) functional joints on the floor, and two others on the ground floor. These values raise the traditional home of Prizren to a high level of residential culture in the Middle Ages. The floor plans of these houses, Fig.19, and Fig.22, show that the hallway (7) open garret (d), have a central disposition, structured along the axis of symmetry. From this hallway comes an access to all four rooms and two smaller service areas for fire ignition. The doors of these rooms, in layout positioned according to the trapezoid scheme, form two door formations, with three each. These doors, with a nice configuration and picturesque hallway depict a noble character.

Asymmetric volumes of objects forging an intense pace

In addition to the above-mentioned homes, the traditional house in Prizren as shown in Fig.15, Fig.16, and Fig.17, is also known for its great architectural and functional value and functional as well as for its very rich interior. It was built in the 18th century. In this home, the plastic composition of closed and open volumes in light-shade creates a powerful and scenic expression. Meanwhile, the dynamic structuring of these volumes has resulted in an intense pace.

Conclusions

Analytical reviews presented in the above result in a conclusion that the traditional residential architecture in Kosovo is known for a clearly defined typology. Building typology, regardless of the nature and scope of the traditional house, in its architectural complexity synthesizes the functional concept with the architectural concept in an organic harmony, thus creating a complete identity. The medieval house in Kosovo, except that it is characterized by great architectural value, it also reflects a high residential culture of the time.

Abstract

Developed almost all around Europe, following the nowadays crisis, "recycling" culture helped to revalue all that already exists to limit the expenses. There are a lot of innovative and creative initiatives often created in Europe which cross the most traditional daily object and dressing up fields, touching also the neglected architecture, as like as historical places that nowadays "live" in decay, because they've lost their previous use. The administrations too cannot help this. Not only because of the lack of resources available for restoration, but also because of the difficulties in giving them a sort of management able to give them back to citizens.

Empty places where people live and neglected churches have in common their being useless, their being not a total part of the town, their being such as an element that has lost his history. Buildings change radically in the places where they've been built: they're not considered anymore active as before, but as unavailable spaces.

By the way, thanks to some spontaneous intervention a lot of buildings can be considered still "alive" and got once again their own place in the neighborhood. The community, naturally, have to pay a lot to make it lasting in time.

San Giuseppe delle Scalze, at Salita Pontecorvo in Naples, is a clear example of the battle taken by the Forum Tarsia, an organization composed of persons able to revive such an amazing place like this. Meeting, shows, and exhibitions are the most are settled to show to the other what in 1980 an earthquake has not destroyed.

The project that we here present suggests the creation of cheap modular scenery, able to provide the church with a series of blocks, called *tancube*, to mounting shows, exhibitions and social meeting, based on the importance of the cultural place and so, always reversibly.

This work propose, the revaluation and the reintegration of the church in the urban environment, although the decay, hoping that the most complicated intervention could be planned and, finally, realized.

Keywords: Scenery, tan-cube, temporary events, design.

1. Temporary uses to stop the decay

Developed almost all around Europe, following the nowadays crisis, recycling culture helped to revalue all that already exists to limit the expenses. There are a lot of innovative and creative initiatives often created in Europe which cross the most traditional daily object and dressing up fields, touching also the neglected architecture, as like as historical places that nowadays "live" in decay, because they've lost their previous use.

Too often the administrations cannot help, not only because of the lack of resources available for restoration, but also because of the difficulties in ensuring them a sort of management able to give them back to citizens.

From empty houses to abandoned churches, a common feature of these spaces is their status, to be without any use: they are inactive elements, not integrated in the urban context, buildings whose original link with the city has been lost.

There is therefore a substantial transformation of the role played by the architecture in the social fabric which it is inserted, no longer active and functional but unknown, these spaces are not usable, even catalyst degradation in its various forms.

In the first place, the shortage of maintenance, the strong physical deterioration with the progressive decay of the building, whose quality deteriorates exponentially, makes them not only useless, but often unsafe and potentially dangerous.

All these situations affect the local quality of life: the presence of physical and environmental degradation not only make it impossible to use a space, but an abandoned building, no longer illuminated, becomes a dark space which is perceived as insecure and dangerous by local residents because can be used for a large number of different criminal activities, that need to take place in hidden locations.

However, it is remarkable that, in many cases, only through spontaneous actions of citizenship, some abandoned buildings have managed not to fall into the most absolute decay, even regaining a sense and a specific role into neighborhood: in those examples, non the Public Administration but the community ends up to take charge of the inevitable cost of maintenance.

Even without of public funds for the architectural restoration is necessary to investigate any urban residual space, their temporary uses, people who inhabit them, and observing potential strategies for employment and re-activation

Looking closely at some abandoned sites in various European cities, you can see that, in the absence of commercial development, many areas have become a field of experiments for new forms of art, music, pop culture, as well as the location of startup for social associations or for events entertaining, gardening, informal markets.....

It is important to accept their temporary nature of chance, opportunities, as places of transition from one state to another, in order to draw the attention of citizens and city authorities to the lost of city values and spiritual culture.

The revival through the attention and a new "points of growth" of urban life.

2. *The neversquare*: the Church of St. Joseph in Pontecorvo and its neighborhood

The project we we describe in this paper is part of a wider field of research on low-cost stage sets and exhibition stands for smaller theaters or abandoned spaces and is based on a work carried out at the Degree Thesis in Architecture 5UE of Simona Scognamiglio, co-tutor prof. arch. Alfonso Morone .

The singular title, *The neversquare*, connotes the social need, strongly felt by the population living in the surrounding area to have a place in which to engage cultural and urban spontaneous aggregation. Despite the proximity to the large Piazza Dante, the urban fabric of the neighbourhood is very dense and characterized by steep slopes, which make strenuous to move even in the close proximity.

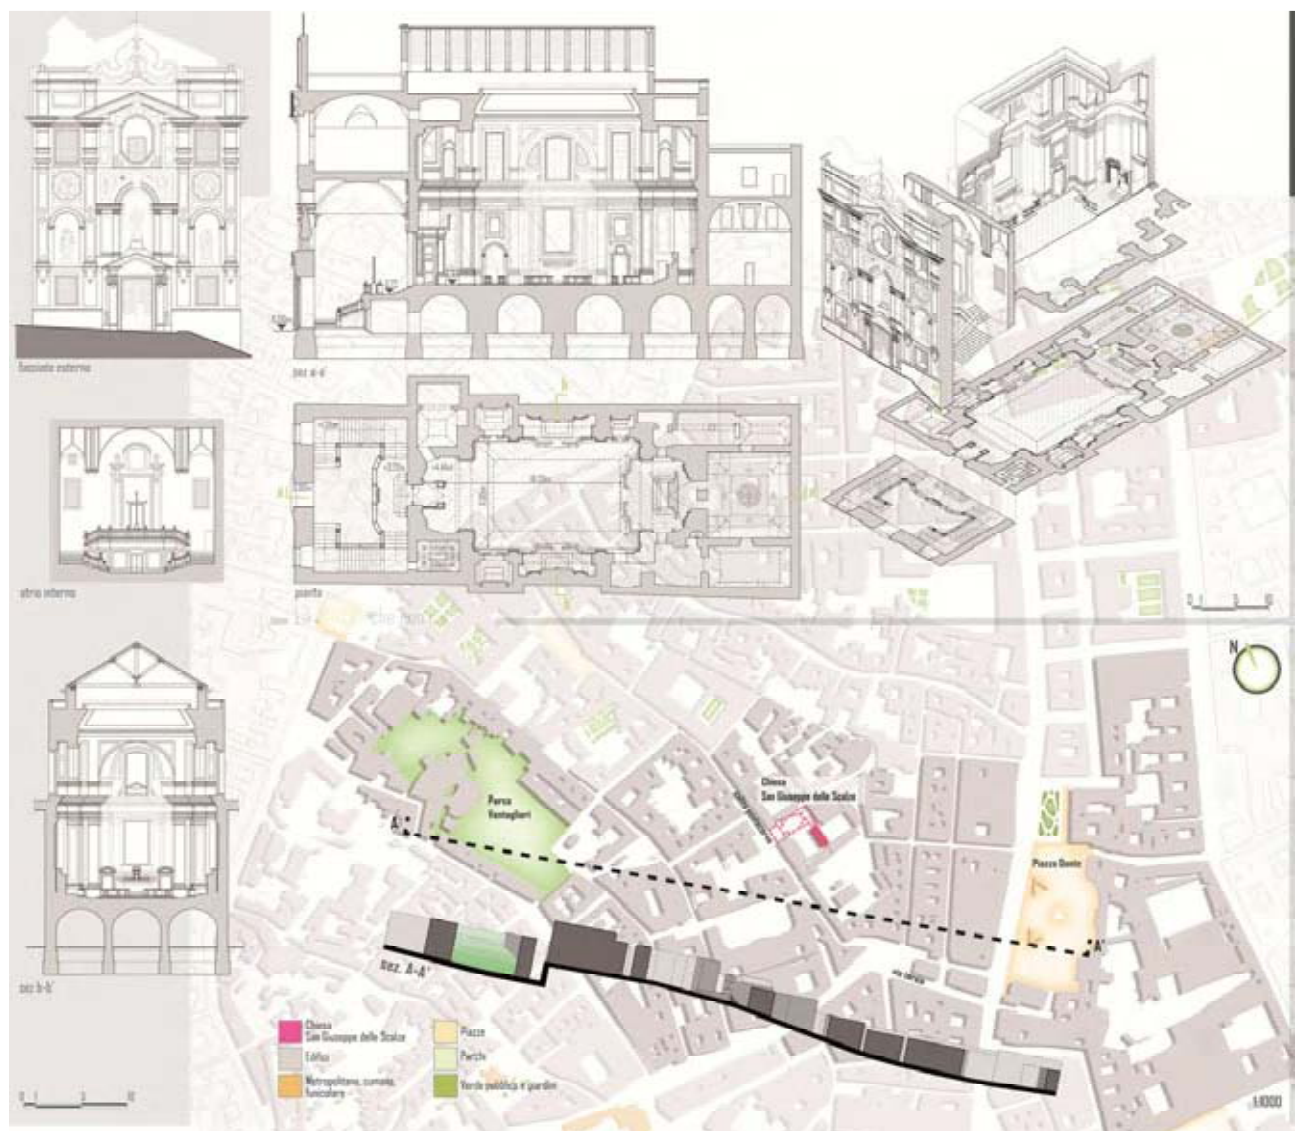

Fig. 4 – The Church of St. Joseph at Pontecorvo, Naples, drawing of S. Scognamiglio

The *Forum Tarsia* is an association of citizens residents in the surrounding areas Tarsia - Pontecorvo – Ventaglieri, since 2001 working to protect the environmental conditions and to stimulate social and cultural activities. The association - which refers to similar experiences of "active citizenship" - aims to build communication channels and gatherings among the inhabitants of the neighborhood and tries to exert a pressure on the institutions to achieve greater efficiency in services . The *Forum Tarsia* fought together with other associations in the Park Social Coordination Ventaglieri for the redevelopment of the Ventaglieri Park and, in recent years, for the restoration and re-opening of the Church of St. Joseph of nuns and other religious buildings in the area Tarsia, tying always organization of cultural and social activities for a speech redevelopment of urban public spaces. It's the leader of a small network of associations (Archintorno, Taverna East, Mammamà, etc.).

So, the church of St. Joseph has become the symbol of all these battles, in order to revive the beautiful building of Cosimo Fanzago, organizing meetings, shows, dinners, exhibitions and conferences, opening the doors of what remains of the church, whose ceiling collapsed after the earthquake of 1980, determining the progressive deterioration and abandonment of the architecture.

Figg. 4-5-6: Recent cultural and social activities in the church

3. ***Tancube: a modular low-cost scenery for events***

This project proposes the creation of a set design modular, modular, it can equip the church of flexible elements (*tancube*) for the staging of plays, shows, juggling, social dinners and exhibitions, guided by the principle of its full reversibility in order to respect the original spaces of the church and its enormous historic and artistic value. The main idea of this module is based on the fusion of the concept of *tangram*, as an object capable of generating variables schemes, and the concept of the cube as a solid characterized by the maximum degree of modularity.

Tangram is an ancient game of Chinese origin, which is obtained by dividing a square into seven parts called *tan*: a square, a parallelogram, and five triangles isosceles, two large, one medium and two small. By combining the pieces of the *Tangram*, you can get an almost infinite number of configurations and a large number of designers have recently experimented this concept in some interesting products.

Tancube is the elements we propose to provide the events to be organized in the church of a set of elements capable of taking the most suitable configuration, according to the happening to be set up. So, *tancube* can assume the shape of a chair or a table to set up social dinners, but also can provide temporary exhibitions of a flexible support to hang up panels and paintings.

In its close configuration, *tancube* can be used to create simple scenery elements for juggling shows, but its real expressive potential has been setting some theater shows to eventually take place in the church, whose emotional involvement of the audience is, at present, heavily penalized by the impossibility of setting the action in a real scene, although stylized and minimalist but engaging at a sufficient emotional level.

4. Conclusions

The present work has illustrated a moderate, but in this historical moment essential, aim consisting in the revaluation of the church, its re-integration into the social and urban environment, despite its evident state of decay; meanwhile waiting (hoping) the most complex and expansive architectural restoration, these modules of scene could be, for the activities of the cultural associations that have adopted the space of the church, an additional tool to implement the quality of the events that take place in it, allowing operations to cash flow to contribute to the maintenance of the monument.

All proposed events could be staged at the estimated cost of only € 11.000,00 and the cubes could be set aside at the end of each event, in the appropriate spaces of the building, ready to be used again.

Practice of reuse and recycle in retrofit interventions

Abstract

In the retrofit interventions, oriented to the energy-environmental rehabilitation of the existing built heritage, besides the problems concerning the specificity of the planning solutions to be adopted, for so long the delicate problem of the waste disposal by C&D is set. Waste includes not only the inactive materials of an architectural manufacture, but also its relative fittings characterized, in most cases, by a high level of heterogeneity. In fact the following improvement of the planning quality has brought to an improvement also of the energy efficiency of the fittings that have achieved a greater technological complexity. We got to a planning of the fittings, not only aimed at the energy saving, but also to the fittings recycling, referred to fittings of both traditional and innovative type such as the photovoltaic systems. The possibility of recycling materials and components, that is already examined closely enough for the building components, is examined not so closely for the fittings, because their aim at recycling finds greater planning and constructive difficulties. What it is said underlines that the real frontier of the sustainable fittings planning is that one of the design in the viewpoint of recycling (design for recycling). The adhesion to the principles of the design for recycling represents, therefore, a suitable answer, not only to the demands of sustainability, but also of energy saving.

Keywords: Retrofit interventions, C&D waste, plants reuse and recycle.

1. Residential buildings: the management of C&D waste in the "restructuring yard" (Caterina Frettoloso)

The interpretation of the concept of "waste" introduced by Law no. 178, 8th August 2002, has helped to promote policies for recovery and reuse of materials from C&D in Italy [1]. In fact, the widely opinion supported by legislation (Ronchi Decree) which considers a special waste any type of material resulting from demolition, construction and renovation, is now integrated with the contents of art. 14 (Law no. 178) in which the legislator clarifies that the definition of "waste" does not apply [1]:

a) if the same can be and are in fact and objectively reused in the same or a similar or different production or consumption cycle, without undergoing any prior treatment and without harming the environment;
b) if they can be and are in fact and objectively reused in the same or a similar or different production or consumption cycle, after undergoing prior treatment without requiring any of the recovery operations listed in Annex C of the Decree law n. 22."

In building renovations the fraction of materials from C&D, the so-called inert (concrete, bricks, scrap various), represents about 75% of waste from construction activities, in smaller quantities we find the wood (as packaging or as waste processing), and finally, plastic or paper with film (in packaging and, partly, in the pieces of plants). [2]

The identification of the type of waste, and the method of dismantling/deconstruction, is the first step of investigation if you decide to undertake a program to renovate housing unit or building in which sustainability is carried out and extends also to the dismantling phase. The evaluation of the type of waste is not sufficient to guide the choices of the designer but it should be complemented with a series of data about many aspects in order to assess the practical possibilities for reuse in technological and economic terms. The performance characteristics of the waste, before and after its removal, represent in this logic a particularly significant. To this end, the knowledge of the artifact will bring out a series of considerations on: the elements that can be reused, at the same time as, maintaining the original shape (thresholds, window frames, doors, etc.); the

waste that can be recycled by regeneration (wood, brick, stones, ...); the materials that can be recycled by waste treatments plants, not least, it is important to identify any unwanted components that should be diverted from landfills. It is now accepted that the quality of the materials from C&D is strongly influenced by the more or less homogeneity of waste fraction obtainable after a specific activity, as it is evident that the building heritage currently more subject to a maintenance/restoration was done with technologies that do not make such activities easier. They didn't design to be "dismantled" or, in some way, "deconstructed".

Therefore, at a yard restructuring the dismantling phase will require special attention and it has to be considered as a selective demolition and follow a precise procedure that, in practice, is divided into the following phases:

1. removal of the external moving parts such as waterproofing and roofing, and of all the materials classified as dangerous, starting from the top;
2. removal of the electrical systems, heating and sanitary installations;
3. removal of windows and doors;
4. removal of interior floors and partitions in wood, drywall etc..;
5. demolition of structural parts and following storage in separate containers.

Each stage of demolition activities, listed above, has effects on the organization of the yard site, especially with respect to the areas of handling equipment and storage materials. These aspects, together with the characteristics of the materials produced and reusable components from phases of construction/demolition, are open issues about the management of C&D materials. Thanks to mobile waste treatments, today more efficient, it is possible to process in the yard the inert waste fraction. This means, on the other hand, increase the complexity of the yard and, therefore case by case, it has to be evaluated the opportunity to follow this procedure.

The main phases of C&D waste integrated management are: the separate collection for fractions, as homogeneous as possible; the waste treatment and recovery; the re-use of components; the appropriate disposal of non-recoverable waste, and related control activities on the environmental impacts of each transaction. This integrated approach can not ignore the first rule of a rational waste management, in a broad sense: reducing the volume of produced waste.

After identifying waste according to the EWC (European Waste Catalogue); after adopting the principles concerning selected waste production, separate collection and environmental protection during material storage, in order to accomplish the integrated cycle of waste management, mechanisms of demand and supply (materials and components) is needed activate. On this last aspect, despite several years is passed from the experimentation of the VAMP project aiming to build an innovative information system able to manage the waste flows produced by and/or recoverable in the construction and demolition sector, it is still one of the most interesting examples.

In particular, for the disposal and supplying of materials and components, the Valorisation Decision Support System (V- DSS) elaborated by VAMP researchers aiming to *"provide support for the environmentally friendly and cost effective disposal/ supply of C&D materials and components produced by any users. This system indicates which recycling / disposal sites of C&D goods best meet Vamp system environmental requirements: economic criteria: waste management must be convenient for Vamp users. The first coefficients introduced in it are the disposal and the transport costs; environmental criteria: waste management must be 'environmental sustainable' to achieve the aim of the system. The coefficient of environmental assessment introduced in the system is defined for each activity in it."* [3]

The introduction of performance criteria to determine the quality of the material from C&D or component recovered, is a significant step in order to their life cycle does not close but, on the contrary, open to new uses and project opportunities. Above all in the case of removal of plants, required to energy saving and environmental protection recommendations, the assessment of the individual elements is needed in relation to the possibility that these be made more efficient through some technical and functional upgrade. Obviously this application will be economically sustainable.

2. Reuse of plant components (Rossella Franchino)

The adhesion to the design principles for recycling in the building sector has been extended from the first researchers, who have individualized innovative results in paying their attention to sustainability and have involved other designers in carrying out the research practically, to corporate bodies involved in the governance of constructions in important territorial areas that, with their rules and guides, have begun to impose design lines for both recycling and disassembly preceding the former and making reusable the material to be recycled. The Department of Design and Construction of New York City has been mentioned among the first most important experiences respect to all this. In 1999, with its "High Performance Building Guidelines" [4] in the chapter entitled "Materials and Product Selection", such a Department expressed the addresses for a design that, besides the other technological characteristics, should consider the possibility to recover and reuse building materials and components. In 2000 also in Canada with the "HOK Guidebook for Sustainable Design" [5] a definite change was imposed in the design for recycling.

Nowadays the possibility of a future recycling, facilitated by a design foreseeing how to disassemble materials and components for their easy separation and reuse, is being already examined closely enough for the building components, while it is being less examined for plant components because their aim at recycling meets greater design and construction difficulties unless their particular modularity, sectionability and removability are invented. Certainly recycling plant components is on one hand more complex than recycling the other building components, by now consolidated, on the other hand it is easier if the plant, even being designed as a whole with the architecture and lay-out, keeps its own recognition within the building context. The pre-requisite for planning the plant systems for recycling is, therefore, a plant setting as a functionally integrated unit in the building envelope, but physically separated. Thinking of a functional integration and a physical disconnection of a plant system means to design it so that it gives a very good performance in relationship with the function of the environment built to be either cooled or warmed or energized, but that has got links and transitory supports with it, that can be easily removed for the reuse of their components. The further effort that is required, besides, to the technical designers of the plant systems, from a recycling point of view, consists also and above all in having to reconcile the demand for reuse with energy consumption saving and use of renewable sources. In order to achieve this aim the plant system needs to have relationships with both interior and exterior environment. Architecture with a low energy intensity, submitting the attainment of the thermal comfort to the exchanges of natural heat, opportunely isolating the envelope, is its necessary presupposition. A greater possibility of recycling the plant systems happens, therefore, in the case of buildings with a low energy intensity, that is with very lower electric and thermal energy consumptions than the average and in self-sufficient buildings. Here their low consumption is given by essentially solar and geothermal renewable energy, resulting in a noteworthy simplification of both interior and exterior plant networks and allowing an easy reuse of the plant systems involved in such networks, as well. Besides, in the case of the solar energy that is the most widespread, the modularity of both thermal and photovoltaic captators must be added, that subsequently contributes to facilitation for recycling. In conclusion, the reuse of plant components and systems can be diffused, if they are conceived as simplified environmental networks, as designed by the designer as modular, repetitive and removable, that is concerning with "low-intensity" or self-sufficient models through the use of renewable energies. Recycling building materials and components is more and more diffusely considered as a factor of sustainability of architecture, especially if deconstruction is considered rather than demolition, being the former an activity aimed at separation for recycling, while being the latter a simple removal. From the considerations previously expressed, it can be deduced, however, that the real frontier of the sustainable design of plant systems is the frontier of the design from a recycling point of view (*design for recycling*). This design allows to carry out a plant system, so that the components can be recovered in their integrity and, therefore, reused with simple actions of disassemble and assemble.

Thinking of the reuse of the plant materials since the design let better carry out an eco-friendly architecture, careful to save energy uses and consumptions and to balance them with renewable natural resources, anyway. The adhesion to the design principles for recycling, achieving a high level of reversibility for the environment where the work is inserted represents, therefore, a suitable answer to the demands for sustainability. When an intervention of a building rehabilitation is carried out, they also intervene on the plant systems removing them or replacing them partly or completely with the aim at:

- either improving their performances;
- or adjusting them according to new standards;
- or replacing them for obsolescence;
- or changing their performances and their working,
- or changing their intended use,

or because it is not possible to preserve them in the building demolitions. In these occasions the removed material can be recovered and recycled, in a decreasing order of difficulty, both as a system and as a single component and as a secondary material. In the matrix the intersections have been coloured showing what type of reuse the intervention can carry out according to its aims.

object of removal	production material	reuse of component	reuse of system
performance improvement			
legislative requirements			
overcoming obsolescence			
change performances			
change destination			

Tab.1 - Matrix of removals usability

The removal for obsolescence can, for instance, allow only the recovery of materials, as components and systems, if obsolete, have not got a competitive functionality any longer.

If the plant system is removed for either its performance improvement, or a change of its performances, or a change of the intended use of the served building, it is possible instead to get production of materials, reuse of the component and reuse of the system. If the removal is determined by an adjustment to changed standards, then the recovery cannot certainly be recovery of system, but recovery of material or, at the most, recovery of components that are still in accordance with the standards.

Having spoken about a possible recovery, it is opportune to establish what it must be meant for possibility to recover, reuse and recycle the plant systems. Materials or components can be recovered singly, if the process of integration with the others allows to separate them without any dimensional, chemical or physical damage. They are also reusable when, with their separation, they have not lost their aesthetical or performing qualities and if they can be reformed or reinstated in their primitive capability of connection with other materials. Recycling can be defined the possibility to reuse the material that can be recoverable and reusable. It also depends on either the propensity or reluctance to reuse a certain material or component.

In the matrix that follows the requisites of maintenance of the plant material are highlighted according to the aim of recovery. In order to allow the recoverability in the intervention of removal of the building components, the chemical-physical characteristics of the material mustn't be altered; in the case of recovery of components, besides the preservation of their characteristics, their volume, their shape and their integrity meant as a whole of sub-components, it is made up of, must be preserved; finally, in the case of more components systems, the maintenance of the mechanical and electric connections among the components must be considered, besides what is applied to each of them.

If the aim of the recovery is the secondary material, the maintenance of the characteristics of the materials is enough; besides this, if they also try to reuse the single component it is necessary to preserve its integrity and its shape. If every possible reuse is wanted, they need also to maintain the connections among the components.

For the maintenance of the existing plant systems there are some performing and regulatory limits.

While also the old building work still offers the performances of the recent work, for instance it has got an envelope protecting from rain, warm or cold, the old heating system can't give the performances of a modern air-conditioning system.

	purpose of recovery		
preservation	production material	reuse of single component	reuse of a section plant
chemical- physical properties			
volume, shape and integrity			
mechanical and electrical connections			

Tab.2 - Matrix of recovery aim

Even more often it can happen that the plant system is not in accordance with the standards; standards always evolve quickly with the available technology and greater and greater requests of safety and reliability, for which in most cases the reuse of the old plant system is not possible.

The standards that mostly prevent the maintenance of the old plant systems are those of safety and energy and environmental performance.

3. Photovoltaic systems as a “double green” technology (Raffaella De Martino)

The sustainable design of building's plants must be aimed not only to reduce energy consumption, but also to the recycling plant systems, as well as those related to traditional or innovative type as photovoltaic systems. The exponential growth of photovoltaic installations pushes designers and manufacturers in recent years to deal with the delicate issue of the disposal of the modules at the end of life. Many components and raw materials of the panels can be, in fact, in order to saving resources, re-used through appropriate management and control strategies. Solar energy is an alternative source of energy, inexhaustible and clean as during the lifetime of a PV system, no emission of pollutants are (nitrogen and sulfur oxides) and "greenhouse gases" (carbon dioxide).

The photovoltaic energy production thus involves the undeniable environmental benefits over the traditional generation systems based on the use of fossil fuels. However, an analysis of the benefits can not be limited

to the use phase of the system, but must extend to the entire life cycle: which means to consider all environmental impacts associated with the various life stages of the product system, including the processing of raw materials, transportation, distribution, use, reuse, recycling and final disposal, using an approach called "from cradle to grave", according to the principle of the "Life Cycle Thinking".

Generally it is estimated that the average lifetime of a PV module is around 25-30 years; in theory, the lifetime of a PV system is potentially infinite since there are no moving parts, but because of the natural deterioration of materials may rupture phenomena of laminates with penetration of moisture and air within the modules and consequent oxidation of contacts and strips. These are the main causes of the decline of productivity, reduced yields and the consequent decrease in the overall efficiency of the system. At the end of its life cycle, these systems can be divested and subsequently disposed of in landfills. It is a shameful end, and especially in contrast with the main goal of energy production from renewable sources: a system in which the machine has produced clean energy runs the risk of becoming, at the end of life, in another of the many technological devices difficult to dispose of. Until a few years ago the problem of disposal was not considered, partly because of the young age of photovoltaic technology and the longevity of the modules. On the other hand, the start of the photovoltaic significant in many European countries (Germany, Spain) and the USA begins to be already "dated". For these reasons the industry, especially in Germany, has already begun to develop recycling methods thanks to the activity of PV Cycle, the European association for the voluntary collection and recycling of photovoltaic panels, founded in 2007 by industry of solar.

A traditional crystalline silicon photovoltaic module, for example, is composed of glass, used for the external and protection surfaces; of aluminium, used for the frames; of silicon and other metals, such as silver and copper, used in small amounts for the realization of the electrical contacts. Are all valuable materials that can be recovered for the production of new modules or other products.

All these considerations make it clear how important it is to close in a virtuous way the life cycle of a photovoltaic module, making this technology "Double Green", as the slogan of the PV Cycle. This way takes us to an approach called "from cradle to cradle" [6] through which materials and components recovered from the modules at the end of life (the wafers from the cells recovered intact and the high-purity silicon from broken ones) are reintroduced in a new cycle of production of the same product obtaining a considerable energy saving. In order for recycling to be truly effective and efficient it is necessary to enable such an approach from the earliest design stages of the product-system, designing the PV modules in a functional way for recycling.

PV Cycle is an association founded in 2007 to implement the commitment of the photovoltaic industry to set up a voluntary take-back and recycling programme for end of life PV modules. The purpose of this initiative was also to avoid the introduction of legislative measures by the European Community, which has, however, recently issued the new WEEE Directive. The WEEE Directive [7] on the Waste from Electrical and Electronic Equipment, regulates the proper treatment of such products and requires manufacturers and importers to secure the recovery and recycling at the end of the life cycle. In the scope of the first WEEE Directive the solar panels were not included, but from 2012 they were included in the list.

The directive does not need to be transposed by Member States until 14 February 2014. In Italy, meanwhile, manufacturers and importers of photovoltaic modules have, from July 1 2012, new precise requirements for the management of end-life phase of systems. And what a result of new application rules established by the Energy Services Operator needed to ensure the recycling of the modules. As is known, the cells of crystalline modules consist mainly of silicon, which does not lose the ability to absorb the incident solar radiation, and it is for this reason that the panels can be recycled and reused. However, this does not apply to thin films because they contain a very low percentage of silicon: their components are in fact only re-used metal ones.

The process to recycle a crystalline photovoltaic module consists of three main stages: removal of the frame and junction box, grinding and recycling in the line of processing of float glass. The fractions resulting from this process are ferrous and non-ferrous metals, glass, silicon and plastic with an average of recycling between 80% and 90%. The glass produced by the photovoltaic modules is mixed with standard glass and partly reintroduced in fiber glass or insulation products and in part in products for packaging glass. The metals, silicon and plastic may be used for the production of new raw materials.

Speech exception is made for photovoltaic modules based on materials other than silicon as the Cu(In,Ga)S_2 (copper indium gallium diselenide) and CdTe (cadmium telluride). Up to 95% of the materials used in these modules can be recovered for the use in new materials. To delaminate and separate the various components of the photovoltaic modules using chemical baths based tensides.

Among the few projects of photovoltaic systems modules with recycled it should be noted that the building of the International Solar Energy Research Center Konstanz, Germany [8]. The ISC is a research institute, specialized in the research and development of solar cells and modules with crystalline silicon, whose main goals are to make solar cells more efficient and reduce their production costs, thus encouraging the spread of a environmentally friendly technology. In recent years, the ISC also has examined in-depth research projects aimed at developing new technologies for the production of solar cells, the evaluation of new raw materials and finally the possibility of reuse and or recycling of the modules reached the end of life. This line

of research has found a practical application in the building housing the center. The southern facade of the institute has, in fact, brise soleil photovoltaic cells made of 100% recycled. Studies conducted by the institute show that the efficiency of the successfully competes with similar systems made, however, with new cells. The installation, overlapping the existing building structure, while not constituting an interesting application from an architectural point of view, is a exemplary case, particularly significant, of widespread culture of recycling in the photovoltaic field.

Drawing for the analysis of architectural language: the case of Giuseppe Palazzotto

Eugenio MAGNANO DI SAN LIO¹, Mariateresa GALIZIA,¹ Cettina SANTAGATI,¹

⁽¹⁾ Department of Architecture, University of Catania, Catania, Italy

emagnano@unict.it, mgalizia@dau.unict.it, cettina.santagati@dau.unict.it

Abstract

The research is aimed at the possibility to evaluate and comprehend, almost entirely through the disciplines of Survey and Graphic Analysis, the architectural language of a designer understanding the invariant features of his works.

As a matter of fact, in the absence of suitable historic documents and design drawings, the architectural text represents the basis for conducting the cognitive investigation.

As the subject of the research, the architect Giuseppe Palazzotto (1702-1764) was therefore selected. He was an artistic personality, a severe executor of a refined lexicon and a man of great formal coherence in the course of his long career.

A fundamental part of the research has been the creation of synoptic tables on which to start an immediate graphical comparison between similar formal solutions in different buildings, or parts of them. The drawing analysis were carried out on graphical representation obtained through careful surveys made with the same graphics rendering, aimed at an immediate comparison.

For cases of particularly complex geometric shapes we used 3D laser scanning to acquire a large number of metric information, necessary to carry out a graphical analysis based on reliable data.

Keywords: Giuseppe Palazzotto, Graphical Analysis, Drawing, Surveying, Catania

1. Introduction

Eugenio Magnano di San Lio

Giuseppe Palazzotto is one of the most representative architects of the eighteenth century in Catania. In the reconstruction of the city after the earthquake of 1693 he designed or rebuilt many buildings, from the beginning of his activity in the fourth decade of the century until his death in 1764.

He had a coherent and personal style which is recognisable during the whole period of his prolific activity.

According to classical architectural orders he developed a personal language that influenced and was influenced by the other architects working in Catania in the same period.

For instance, he was probably the inventor and was certainly the major user of the typical vertical aggregation of architectural elements which is called "candle".

In this technique a continuous line follows and defines the profile of the architectural unit; the keystone of an arch becomes the bracket of the balcony standing above and the protrusion of a geometrical cartouche between the wings of a broken tympanum corresponds to the protrusion of the underlying window lintel.

Sometimes horizontal mouldings link together windows and balconies of a facade.

In aristocratic palaces the central gate and the overhead balcony with its windows, larger than the others of the facade, becomes a single unit, a tribune.

The question is if, through architectural survey and geometrical analysis, it is possible to recognise shapes, aggregations and formal solutions that are typical of Palazzotto's architectural language.

His masterpiece is the Palazzo Valle in Catania, usually attributed to Giovan Battista Vaccarini, but, according to the testimony of a 19th century historian and especially by an analysis of the architectural style, it can be attributed to Palazzotto.

In this building the characteristics of Palazzotto's language reach their peak of perfection.

Two examples of the comparisons - carried out through both the survey and the graphic analysis of Palazzotto's diverse works in order to identify permanent features in his architectural language - are included in the synoptic tables accompanying this paper.

In particular, two main themes have been identified with some variations in various buildings which were undoubtedly designed by Palazzotto.

In the first theme the subject matter of the horizontal frame of an architectural element, which, by one line going vertically and another going horizontally, finishes at the top of a second above-lying element thus merging them in one unit, is analysed.

It is to be found again, skilfully used by Palazzotto in the side gates of the facade of the Church of San Giuliano (1740), in the big gable window in the tribune of the Palazzo del Senato (1760) and in the loggia of the Seminario dei Chierici (before 1760), although the first clear use of this formal invention in Catania has to be credited to Vaccarini who used it inside the refectory of the monastery of San Nicolò l'Arena in 1739.

Another element is that of the gable end showing vases with flowers and stone flame vases, joined through willowy lines which stand out - or were meant to stand out - against the blue skies on the top of the buildings designed by Palazzotto.

In particular, they are the playful gable ends built over the second tier of the loggia of the Palazzo dell'Università in Catania, the similar gable ends on the sides of the facade of the Church of San Giuliano, the gable end - now walled up - of the tribune of the Church of Santa Chiara and the gable end which was meant to crown the southern facade of the Palazzo del Senato in Catania; despite having never been built, it can be seen in an etching in the work of Bova taken from a drawing by the same Palazzotto.

2. The theme of the vertical frames

Mariateresa Galizia

Architecture, like all the other arts, can be considered as a text that, both in its parts and its totality, bears the signature of its author. Through a careful survey and a detailed graphic analysis of the data collected it is possible to identify both the permanent and changing features which characterise the works of the architect.

The research on Palazzotto, whose work has often been overshadowed by his close collaboration with G B Vaccarini or has not been acknowledged by many scholars, aims to provide a detailed study of the stylistic/formal features characterising his architecture, which qualified him as 'architect of the city' in 1745.

His architectural language, with its simple solutions and syntactic accuracy, was learnt from and inspired by the texts kept in the libraries of the city, as well as from the close and fruitful collaboration with Vaccarini.

Unlike the latter, Palazzotto's limited possibilities to travel to see new places which could inspire his designs held him back from achieving originality and innovation, which were the dominant features of Vaccarini's work.

His formal solutions, on closer examination, are recognisable for their controlled and cautious originality. He used traditional elements (capitals, small balusters, tympanums) 'with no innovation or amazement', but with elegance and the accuracy of their harmonious connections, which made him famous in the history of Catania.

An example can be found in some design solutions used in the Palazzo del Senato in Catania, a building whose authorship is wrongly attributed to Vaccarini. By carefully examining the blueprint of the facades, with the additional aid of archival documents, the differences are clear. Here his favourite theme is evident, the frame which bends 90° without breaking and which would become the trademark of the designer himself. the architectural element revealing the authorship of his works.

The majestic central tribune, designed in place of the Romanesque gate, occupies the whole architectural element formed by two giant flat lesenes. Unlike the large windows of the piano nobile attributed to Vaccarini, the tympanum here does not break and turn outwards dynamically, but folds on itself by lying on the same plane.

Palazzotto prefers the continuity of the mouldings finishing off the formal appearance of the architectural element. Bare and smooth impostes, slightly rotated so as to find a solution from the point of view of perspective rather than from that of form, support traditional capitals from which flat triglyphs with slightly projecting guttae hang.

A simple trabeation supports the frame with its tiny mouldings which bends 90° thus interrupting the function of the dripstone so as to leave a rectangular area which contains a marble crest of the city. The two wings of the tympanum, which hold two female figures created by G. Orlando, complete the architectural unit.

The theme of the frame which bends 90° also appears in the windows of the mezzanine. At the top, to finish the facade, there is a bare, continuous frame which surrounds the single windows, as if to join the single parts of the architectural elements in one unit. The linear and thin mouldings bend around the large windows and, with no interruption, go over the lesenes thus representing a means of "connection between the parts" which finishes the architectural structure of the facade.

A similar formal solution of a folded frame, which underpins Palazzotto's signature, can be found in the loggia of the Palazzo dei Chierici. A small room contained in the piano nobile, in which the attention paid to architectural details makes it an example of harmonious beauty between the parts and the whole unit. The quadrangular planimetric structure, with two large pilasters lying in the middle which divide the area into four parts covered with domes on pendentives and with two groin vaults, is surrounded by lavish and decorated openings, niches and large windows overlooking the inner court.

All the single architectural elements on the facades of the structure are also here "tied" by one continuous frame which bends 90° exactly where the windows lie. A tripartite lintel supports the smooth frieze which, aligned with the doors/windows, contains a modelled shield with festoons and crown, the whole unit being framed by the bare and geometrical mouldings.

The folded frame, like in the tribune of the Palazzo del Senato, supports the two wings of the tympanum turning outwards which frame a rising flame in the middle.

A signature thus belonging to Palazzotto, who very skilfully uses the frame not only as an element to finish the structure but also as a connection between the parts, as a thread which sews together the interruptions of the single architectural elements.

The same theme of the folded frame can be seen in the side gates of the Church of San Giuliano. The frame over the gate folds in a right angle giving way not to crests or shields, but to a high and soaring fanlight window which lights up the rooms for the cult.

The solution becomes a means of "connection between the parts" here as well. The two distinct elements, the door and the window, become a single unit, an architectural syntagma which vertically flings the structure towards the sky, in a single "candle-shaped" element. The bare and rigid mouldings overlap in a continuous manner with the lintel of the underlying gate. Over the frame the two wings of the tympanum rise, recurring elements supporting modelled sculptures which represent little angels.

Such similar formal solutions, found in buildings different from the point of view of type and use, have been compared through synoptic tables, in which the 90° folded frame representing the constant feature of Palazzotto's architecture appears. A recognisable signature which the architect uses with coherence and designer skill.

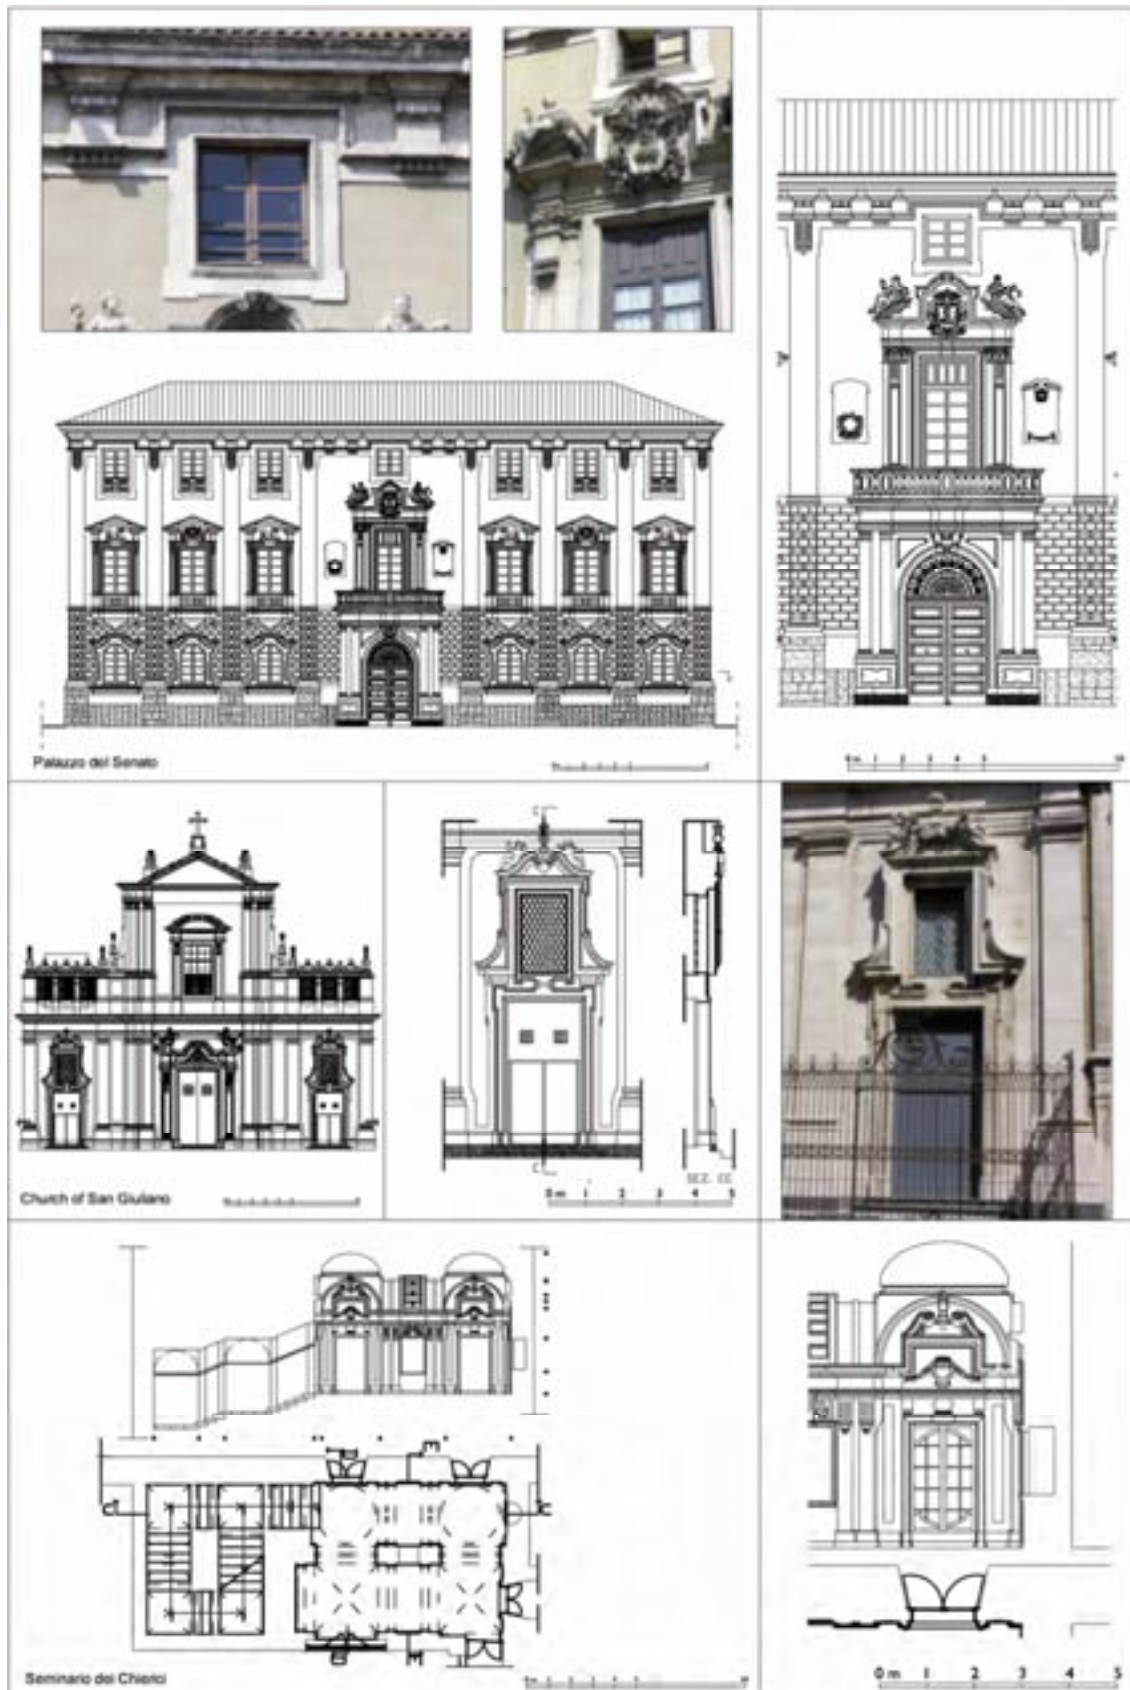

Fig. 2: The theme of vertical frames.

3. The theme of the crowning gable-end

Cettina Santagati

The methodology of study of the recurrent themes of Giuseppe Palazzotto's architectural lexicon by means of surveying, graphical analysis and documental validation allowed us to carry out an in retrospect critical lecture of its architectures and projects, thus detecting the elements that characterize its architectures and make readable its planning style.

Among those the theme of the buildings crowning gable-end stands out. Palazzotto often adopts this solution. We can find it both in civil buildings, such as the court of the Palazzo dell'Università and in the façade of the Palazzo del Senato, and in religious buildings like the lodge lantern of the church of San Giuliano and the church of Santa Chiara in Catania.

In 1747 Palazzotto replaces GB Vaccarini in the building site of Palazzo dell'Università. The first order of the portico of the cloister had been already completed and part of the second order was in a quite advanced phase of construction. To crowning the second order, Palazzotto designs a graceful and lively frieze in white stone that is rhythmic by the alternation of vases with flowers, placed in axis with underlying pillars, and soft double spirals, elegantly carved on the stone, that support towering vases with flames.

On the whole, the light and the shade effects caused by the carved stone gives a certain dynamism to the fancy and harmonic skyline of the cloister lodge.

A solution similar to the one realized for the Palazzo dell'Università is the one designed but never built for the top of the Palazzo del Senato. Indeed, it is possible to see that solution only in Antonino Bova's incision as an attachment to Arcangelo Leanti's book about the city of Catania.

Definitely, the gable-end of the Palazzo del Senato is characterized by the alternation of high verticality elements – vases with spheres – placed in axis with the underlying pilasters and lesenes that rhythmic the façade and of double spirals that embraces the entire span where they stay and support, once again, flames vases.

In this case, the greater highness of the elements in axis with the lesenes in respect to the ones in axes with openings gives more majesty to the façade layout. Furthermore, the treatment with very close horizontal lines in the frame inside the spirals creates a perceptive figure-ground effect that makes the geometric pureness of the shapes standing up.

The continuity of the frieze is interrupted at the central span where the element with double spirals enlarges itself in order to host the meridian clock and it is topped by an omega frame.

Dealing with the two religious buildings, the Church of San Giuliano and the Church of Santa Chiara, the attention of Palazzotto is mainly addressed to the dome. As a matter of fact, he experiments an innovative solution in respect to the contemporaneous realizations in Catania: the lantern becomes a lodge and involves in its inside the dome. Thus, having both an esthetic and static function. In both churches the frieze crenellations made by white stone invigorate the stability since they participate to the vertical forces resultant.

As regards the Church of San Giuliano, the gable-end solution is proposed again in the lateral sides of the façade as well as in the crowning of the lantern. Here the rhythm is more compact. The architectural element is framed between two flat lesenes and on the upper part is concluded by three mullioned windows closed by pot-bellied grills and topped by a frieze that once again alternates little flowered vases (placed in correspondence with openings jambs) and carved double spirals topped with spheres. The elegant ribs cut out beneath the openings sills balance the upper frieze.

Similarly to the frieze of the Palazzo del Senato, also in this case the double spirals are linked with continuity to the vases. However, here the ratio horizontal/vertical of double spirals is compressed in horizontal direction.

Finally the gable-end of the lodge lantern of the Church of Santa Chiara, nowadays walled in, refines the crowning to the sky of the building. Differently from the church of San Gi

uliano, here Palazzotto ties in a whole the lantern of the dome, with a dodecagonal shape, to the bell lodge in façade. Thus, the lodge and the frieze, in addition to a static function, have also an esthetic function of lightening the wall mass, otherwise it would be too much predominant.

The frieze swivels on the attic parapet alternating double spirals in the central span and slim vases in the pilasters. Compared with the solution adopted in the previous examined buildings, here Palazzotto doesn't play with light and shadow effects due to the overlapping of lightly projecting layers, but simply cuts a background inside the double spirals elements and commits the perceptive effect to materials two-colour print.

In all the examined examples we can appreciate the ability of the designer to develop, according to the needs, the theme of the crowning frieze with similar solutions but having different perceptive effects.

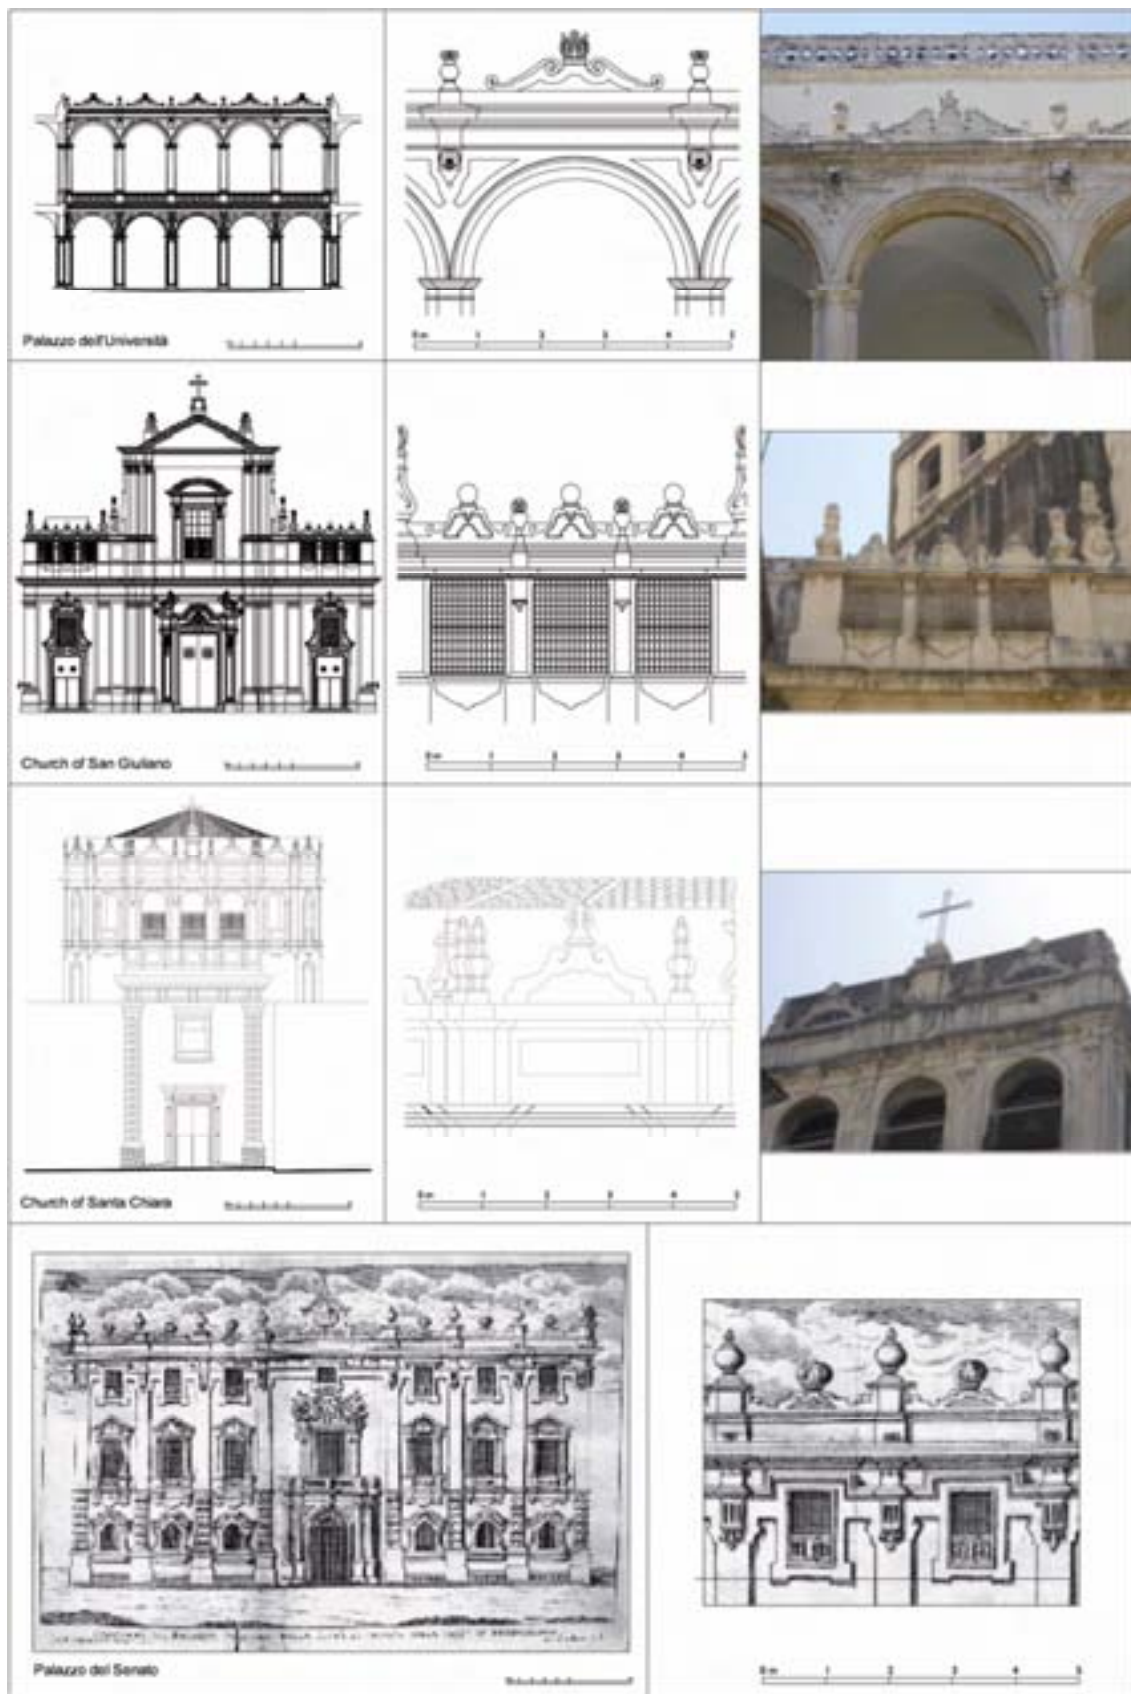

Fig. 2: The theme of crowning gable-end.

Air Movement: From the Tradition Towards Innovative Experiences

Fosca TORTORELLI¹ Francesca MUZZILLO²,

⁽¹⁾ archfo@gmail.com

⁽²⁾ Dipartimento Luigi Vanvitelli, Seconda Università di Napoli, francesca.muzzillo@unina2.it

Abstract

The consideration of air as a real building material is one of the most innovative field of architectural experimentations. The sustainable approach implies that architects should consider mutable prevailing conditions of air movement which, with its dynamic movement, connotes morphological aggregation. Different mutable prevailing conditions are given by the nature itself of air, which is dynamic into aggregation. Historical net of architecture, with relation among patios and open spaces, and with variable composition of areas and interconnections, is what reminds this sensation of thermal wellness, due to air movements.

Some ancient architectures in particular can be the historical basis from which starting for air movement innovative technologies.

With a system of design methodologies it is possible to recreate a situation similar to historic configuration of Mediterranean Architecture, with continuous alternation of entrance and exit of air.

Innovative experiences are analyzed also with methodological indications for cooling and air movement.

Keywords: natural ventilation, Mediterranean architecture, chimney, innovative ventilation.

1. Ventilation systems in Mediterranean Architecture (Fosca Tortorelli)

Technological research is now increasingly deepening the themes of innovation in the field of natural ventilation. In this sector what stands out as innovation is often closely linked to the historical tradition. Entering in the specific theme of the "chimney component", this is one of the oldest man-made "heat engines", which lends its name to the phenomenon known, in bioclimatic architecture, as the "chimney effect", associated to the natural ventilation of a building. The buildings behave like chimneys, in which inside the air circulates in function of the pressure differences, that are responsible for the natural ventilation of the building. It is fundamental for the air change of the environments and the thermo-hygrometric wellness of occupants. The use of such systems for passive cooling, and in particular for natural ventilation, has always been widespread in the Mediterranean countries just to deal with the difficult summer weather conditions.

In Italy, for example, it is possible to recognize some constructive archetypes, which use hybrid thermal control strategies, by means of the combined use of mass walls and chimney effect, enabled through appropriate openings on the building.

Unfortunately, the recent widespread building has underestimated the benefits obtainable from natural ventilation and passive cooling systems in general, relying on the system component for controlling temperature and humidity of indoor spaces.

However, it is important to know how, in different architectural references and settlements of the past, emerges the revaluation of certain environmental aspects since the initial design phase, through both the orientation of the buildings and from the atmosphere, either through an adequate internal distribution of the spaces and of the mechanisms of initiation and regulation of the flows of air and solar radiation, in order to facilitate the internal microclimate control without the use of technological systems for cooling, and in addition to guarantee the successful architectural integration of all devices to it functional.

The wind is one of the elements that represent an agent able to support the generation of the air flow, determined mainly by the fireplace effect (the hot air tends to rise upwards, creating a depression at the base that sucks the colder air from the outside). The vertical cross-ventilation system and that of the combined wind-chimney effect can coexist with obvious advantages as in Iranian wind towers and Qáa Egyptians. But back to Italy, just think of the type of construction of the Apulian Trullo, that probably began as a simple shelter, evolving over the years to become a comfortable home from the point of view of climatology / functional, economic and morphologically unique. The architecture of the Trullo has infact undergone various changes, just to make it more comfortable and functional, changing from a circular structure, to a square one (Fig. 1), until you get to form structures composed of several Trulli, with a large central room, where takes place the fireplace so you can well distribute the heat in different rooms. The external walls reach the thickness of one meter in order to obtain niches. The domed ceiling, covered with limestone slabs (the *chiancole*), has an inclination of 45 ° which promotes the drainage of rainwater and its collection and preservation through a cistern located under the same Trullo. The flooring is made of slabs of limestone (the *chiancole*), other than those used for the cover. The whole architecture of the Trullo is made according to criteria of common sense we now call "bioclimatic principles", with a single input place to the south, sheltered from the north wind, and with few windows positioned opposite one another, so as to create a natural air circulation. The thick white walls provide an almost constant temperature throughout the year, cool in summer and mild in winter

Fig. 1: Trullo structure changes.

Very briefly the Trulli offers very good terms of adaptation to climatic conditions, ensuring a high level of comfort resulting from a guaranteed good ventilation chimney effect due to the conical shape of the section and to a certain permeability of dry stone walls.

An element present on the outside of many Trulli is the bower (fig. 2) of screws to high stalk. Very often it is also the arrangement of these plants along the main front. The usefulness of the bower is to create shadow areas near to doors and windows only for the summer period.

Fig. 2: The bower

In conclusion, the Trullo can be defined as an enclosure wall controller that does not exploit the climatic conditions, but passively protects the interior from the outside.

Further examples of technological and design solutions, aimed at obtaining the best climate comfort of the interior, are found throughout the traditional Islamic architecture that goes from the ninth to the twelfth century. In Egypt, Sicily, as in all areas of the Maghreb there are buildings and residences where the constructive culture in achieving those systems, that now are commonly known as natural air-conditioning systems of buildings, goes far beyond the simple empirical experimentation. The Zisa castle in Palermo, which is halfway between the Royal Palace - placed in the center of the city - and Monte Reale, where in a few years, from 1164, with William II was built the famous Abbey of Monreale.. It is designed as a large rectangular parallelepiped perfectly symmetrical, consisting of a ground floor, where the center is a noble straw embellished with a fountain, two upper floors for housing male and female and a terrace of crowning which was originally opened in the center, allowing rainwater to fall into the impluvium of three open spaces on the second floor and then be channeled into pipes made in the soffit of the slabs. Front of the castle there is a large collection tank water from the indoor fountain (fig. 3).

Fig. 3: The main floor of the Zisa

The main facade, changed over the centuries, was open on the ground floor with three large ogival barrel vaults, the central double height, and the upper floors of single and double windows arranged symmetrically with respect to the central axis, while the rear elevation appeared on the contrary more closed.

The volume of the building, which appears today as a unique " bio-climatic machine," was completed with two building's side, jutting out from the outline of the building, containing some real "ventilation chimneys" in response to all three levels of the structure and concluded on top of what today we might call a chimney uptake.

One of the first similarities that we find the current bio-architecture, in this second example, is the importance that the designers of the Zisa have given to the orientation of the building and with respect to the path of the sun, and especially compared to the incidence of the winds. The orientation of the main facade to the north-east of this and the presence of three large openings suggests the willingness of manufacturers to maximize the benefits of sea breezes. The conditioning fresh air inside the building was obtained through a mechanism that involved the operation of the five main architectural elements and furnishings: a large fish pond in the front garden, the fountain on the ground floor, the two ventilation chimneys and the presence of large wet towels placed under the ceiling of several rooms on the upper floors. The air coming up from the port of Palermo, was cooled in contact with the water in the fish pond, which, once it enters through the large entrance porch, was

further cooled by the presence of water that flowed from the central fountain. Even today it is not clear how this fountain is nourished. Among the assumptions made, there is one that sees the fountain fed by channels descending from the upper floors. Rainwater cold, because channeled into conduits stone running in the thickness of the floors, for their conformation "Low Heat Dissipation", poured into the tank of the fountain embedded in the wall maintaining the low temperature naturally. With each new influx of rain the tank is "recharged" water cooler resulting in a replacement of the masses of cold liquid preserved.

This first system was then integrated the two ventilation stacks. Two towers perfectly symmetrical and equal in scope to the position and shape.

The air cooled as well, as they warmed, began his journey to the upper floors aided by barrel vault of ventilation chimneys that sucked the hot air from the residential environment. The air movements were facilitated by mass walls of the chimney that do not overheat from the outside with the warm rays of the sun produced the vortices of air inside. The small vortices tendencies stirred up the ascent of the air. The air circulating in this way continuous cycle in all environments. The system was helped by the presence, above each door of the room, a small lancet window. This punching allow hot air to be drawn from depression, even when the doors were closed. The movement of air masses fed itself on the principle of convection. The system is even more refined, as the builders had also thought of the amount of hot air, say residual, which continued to stagnate in the rooms farther away through the expedient of large tents wet supported by beams, the slots which are still visible to the tax of the time that, acting as cold-heat exchangers, refreshing the hot air that had layered up putting it back into circulation.

Reflecting to the present days and the many design efforts aimed at development of heating and cooling systems based on passive technologies, it is clear that sometimes the events of history repeating, experimenting with design solutions for cooling and/or heat the rooms that seem new. The modern bio-architecture uses ventilation chimneys, greenhouses for the accumulation of heat, hot and cold air ducts formed in the cavities of the walls and floors, rainwater recycling systems for use even for the purpose of cooling .

The architects who designed the Trulli or Zisa, they were not driven by the need to save energy but rather forced to conceive cooling systems to meet the needs of a better climate comfort, so that was obtained by combining the intrinsic characteristics of some natural elements such as air and water, with the forms of the architectural same. Maybe is from this point that you should start.

2. **Air movement and building shape** (Francesca Muzzillo)

The consideration of air as a real building material encourages architects to reconsider first of all the other materials from a different point of view, giving special attention to their possibility of being flexible. The most emblematic example is the system of air ventilation in Villa Baizeau in Carthage in which the architectural idea of Le Corbusier seems to be founded on air ventilation.

Contemporary architecture has taken note of this idea and over and over again the consideration of air movement is at the basis of first schemes' elaboration and there is a figurative image for shaping the building with regard to air movement. The shape of the building rises together with the preventive quantitative relation between ventilation and the conduction medium. Naturally this preventive work should be very systematic, with relation to air and the medium in which it moves, also in relation to various considerations like the possibilities of having a better internal microclimate connected with various part of the building.i A general management system of natural components should be correlated to a list of requirements codified into very carefully organised and well researched valuations.

Different mutable prevailing conditions are given by the nature itself of air, which is dynamic into its essence. And it is also true that often historic net of architecture with patios and open spaces, with variable composition of areas and interconnections, is what reminds this sensation of thermal wellness, due to air movements. With a system of design methodologies it is possible to recreate a situation similar to historic configuration of Mediterranean Architecture, with continuous alternate of entrance and exit of air. Naturally this permeability involves takes up again, in a different way, a direct and mutual action process between air and architectural forms.

While passive cooling is easily achieved through high mass performances, a lack of flexibility into massive masonry structural system does not always allow introducing new fountains and basins as evaporative cooling strategies. Most of all, some technologies of sustainable design such as solar hot water heating, photovoltaic and even small wind turbines could operate with an interference on air movement.

Peculiar to the Mediterranean architectural paradigm is the passage through the building not only of air prevailing passages, but also of perceptive and sensorial axes which are bounded, directly or indirectly, to ventilation: light and sparks of greenery, which enter the building through the openings of the envelope. This characteristic stands in opposition to the contemporary mainstream bioclimatic

architectural strategies, produced by a continual, widespread and penetrable filter. So, the emerging data suggest an idea of continue communication between open and closed spaces.

Into recovery practice, if we don't replace the voids, this lack could facilitate natural air circulation in the indoor-outdoor relationship. In fact, in our quest for an alternative to mechanical ventilation, we could improve the bioclimatic behavior of an old architecture through cross-ventilation.

Moreover, as we know that indoor air is heavier than outdoor one, a quite common practice is to drive air movements through the chimney and the voids inside the building itself is a traditional system for wellness, being these movements in a certain way similar to what we today call "stack ventilation", as they are based on the temperature difference among the various air levels, with air going upward from a higher pressure to a lower one and finally towards the open air.

Particularly seems there should be a new need for chimneys, as they have new significances and also a new evidence into architecture. Obviously there is the problem that the height of the building should not be too low in order to obtain a sufficient buoyancy force.

Sometimes in the past a different system was used and an alternative strategy let air moving into architecture from top. The air movement was connected to different typologies: ascending, descending or partly ascending and partly descending. And also this system is today studied: «downdraught cooling is an energy efficient, and cost effective alternative to conventional air-conditioning for new and existing building. It relies on the effect of gravity on a body of (relatively) cold air to create a downdraught, and thus circulate air from the source of cooling to the occupied zone within the building».

Moreover air movement into Mediterranean architecture had a different function during the day and during the night. Innovative systems, differently from the past, can be predicted exactly and air movements are knowable through dynamic thermal models with expected performance evaluations, considering during design phase alternatives among section choices, individualizing the best choices in order to encourage ventilation.

Fig. 4: Alan Short and Associate's School of Slavonic and East European Studies

Some projects descend directly from researches on air movements, as in the case of Alan Short and Associate's ones in London. In the School of Slavonic and East European Studies there are at the basis of design the passive downdraught cooled studies, with different strategies during summer and during winter. The chimneys are evident on the main façade, giving character to the architecture, which, with its thermal mass of brickwork, tends to use low standard energy.

Fig. 5: Stanton Williams' Central Saint Martins main entrance atrium

In the Central Saint Martins main entrance atrium, where the ventilation systems utilize natural air buoyancy, Stanton Williams seems to bound innovation and tradition in a space with old brick walls on one side and a new ceiling on the top. Here the presence of air vents is evident, in an effort for bringing architecture back to the origins.

The everyday and the monument, a case study of two UNESCO World Heritage sites: the wooden churches of Vilupulli and Ichuac

Constantino MAWROMATIS¹

E-mail: cmawroma@uchile.cl

E-mail: cmawromatis@gmail.com

Abstract

The tangible and intangible assets of a heritage site are recognized and valued from the disciplinary framework, nonetheless it is first local heritage and as such, a part of the everyday life. This raises an evident tension when facing the restoration of a living monument, being this the case of 16 wooden churches in the *Chiloé* archipelago, located north of the Patagonia.

In 2000 these churches were declared World Heritage by UNESCO, recognizing the architectural values of these temples as well as the cultural context they are placed in. The hard weather conditions, the scarce resources, the attachment to the land, the religion and the community ties give *Chiloé* its very own character and a special atmosphere that are part of the identity of its people, all of which has to be taken into account when restoring the temples. The task of incorporating the essential aspects of the every day life and the challenge of understanding the value of heritage in a broad sense are the inputs that have to be dealt with.

Vilupulli and *Ichuac* are two of these living temples that were restored with the mandate and purpose of recovering and maintaining the structures that had been in imminent danger of collapsing. Reconciling the material with the immaterial aspects, the humble with the monumental, and attending to the deep rooted pragmatic sense of a population shaped in the harshness of cultural and territorial isolation, were the main issues addressed.

Keywords: World Heritage – Wooden churches – Chiloé – Restoration – Woodwork

1. The archipelago of Chiloé, a distinctive local cultural setting in a global world

The particularities of a territory and a people certainly reflect onto the criteria of the restoration of a building, moreover if it is a declared a World Heritage site. Chiloé is one of those experiences that demands closer attention in this respect not only for its unique location but also for its distinct culture. It is a remote territory located over a thousand kilometers south of the Chilean capital, Santiago, just north of the Patagonia, conformed by approximately forty smaller islands and the Big Island. The archipelago is the last bastion of the Spanish colonization in Chile, and it is conformed by a rich multicultural mixture between the native peoples and the European immigrants that mingled together throughout centuries. In fact, the uniqueness of Chiloé is related to its geography and its cultural isolation, as well as to its population scattered in small rural settlements, mostly overlooking the calm inland sea, establishing a culture based primarily on the land and its resources. These conditions favored the preservation of a cultural milieu structured by small farms with subsistence agriculture that differs from the rest of the country, a reality which has been characterized by concentrated ownership in the hands of landlords, and more recently dominated by the agriculture and forestry industry.

The local population has to deal with harsh weather conditions marked by abundant rain fall, humidity and rather cold temperatures, especially during the winter season where occasional strong winds further increase the difficulties of the people in their everyday existence. Nevertheless, these

conditions have also contributed to the rich diversity of the native species of trees in a lush wooded landscape of rolling hills and winding coastlines that define the archipelago's topography of the inland sea. Wood is therefore the natural material of construction in the area. The local cultures have developed a particular building tradition based on timber, on the skills of their carpenters and on a close net of solidarity and mutual cooperation that has allowed them to manufacture a variety of wooden objects, from tools to ships, to houses, and their most significant architectural contribution, the wooden churches. These wooden churches also relate to another Chilotan historic aspect: the peoples' strong commitment to the catholic rites. With the arrival of the Spanish conquistadores and the subsequent action of the Order of the Jesuits who arrived in the seventeenth century to the area to evangelize the indigenous peoples, religion became an essential part of the local culture [1]. Current rituals and customs still in practice are related to the evangelizing work of the Jesuits, who instituted the tradition of the "circular missions" -or Jesuit Peripatetic Missions-.using the inner sea as a means of getting to all communities.

...the Jesuits organized in the course of the 18th century a fantastic spatial network with their "circular missions" which allowed them to consolidate aboriginal communities in settlements around a chapel that was visited once a year and whose religious duties were led for the rest of the year by a "fiscal" appointed from the community itself. [2]

The Chilotan church, which is typically placed in front of an esplanade, invariably appears as the main element that gives birth and direction to the villages, and the area around them. It is a site of religious ceremonies and a gathering place for the neighbors. The building itself is usually located in such a way that it can be seen from almost every corner no matter if you are inland or at sea. In fact these churches served as virtual lighthouses for the passing vessels.

Fig. 1: The town of San Juan with its World Heritage wooden church. The changing tides define the shores of the inner sea of the archipelago. (Photographed by the author, 2006).

2. The wooden churches; the constructive tradition in wood and its particularity

2.1 The material and the traditional timber craftsmanship

The constructive tradition in wood defines the timber churches of Chiloé in many ways as a unique case study. The knowledge of the variety of types of wood that conditions the construction and grants specific attributes to the diverse elements involved in a building, and the traditional craftsmanship that utilizes tools and materials in a very creative and unique manner, compensating the shortage of resources with ingenuity and joint work, are some of those aspects tightly related to the archipelago's vernacular architecture.

The richness of the native forest allows selecting different wood species that have different qualities, using thereafter, the right timber depending on the needs of construction: for example, hard timber is used for the structural elements, watertight woods for roofing shingles and exterior walls, and softer

woods for interior coatings and some ornamental elements. These woods are crafted using basic tools and are assembled as defined building elements through diverse wood joints that are originally firmly knit together by wooden anchors without the need of either bolts nor nails; joints like the so called *Cola de Milano*, *Rayo de Jupiter* and *Caja y Espiga*, are some examples of the ingenious ways of securing the timber without the need of other elements.

The building tradition also conditioned the construction characteristics of the churches. The main corpus of the temple resembles a rural shed with its gable roof and simplicity, and is usually the first part to be erected, whilst the tower represents a rather more complex configuration that is conceived as a telescopic succession of hexagonal or octagonal drums firmly embedded one inside the other in order to secure the firmness of the highest and most feeble part of the church. The entire building settles on stone foundations that typically date back to the eighteenth century, being these stones simple rocks placed on the terrain.

In spite of the ingenuity of the Chilotans in the erection of these churches, timber structures are exposed to different deteriorating agents. Profuse rain, humidity, strong winds, solar radiation and wood boring insects are a constant threat in the conservation challenges of vernacular architecture in the southern part of Chile. The locals acquired the habit of replacing the damaged parts of a church and in extreme cases letting it crumble while building a new one alongside recovering and recycling the timber from the old one. This shows a particular pragmatic attitude towards these buildings, far from the more conservative and nostalgic sentiment that is more directly related to a scholar's point of view.

Fig. 2: Quinchao, one of the 16 UNESCO World Heritage wooden churches prior to the 2011 full restoration. Exterior and interior view. The extensive and severe decay of the structure threatened the building to collapse. (Photographed by the author, 2006).

Fig. 3: The decayed elements of a church comprises the exposed surfaces of the wood, to areas usually hidden to the naked eye. The putrefaction of a timber and the presence of wood boring insects can therefore place a serious threat to the stability of a main structural element. (Photographed by the author: churches of Nercón 2009, Rilán 2006, and Quinchao 2006).

2.2 Global styles, local adaptation

Another distinctive aspect of Chilotan architecture is the ability of the craftsmen to adapt different styles and morphologies to the local capabilities given by the building materials and the existing tools available. The singular design and the image of the wooden churches in Chiloé are also directly related to the reinterpretation of an architecture that was brought from Europe, and introduced in both, civil and ecclesiastical buildings. Within the latter ones, there is a mixture of morphological influences converging throughout time with the vernacular local adaptation. In fact, a combination of the Central European tower-façade with the basilica configuration characteristic of the Latin tradition can be recognized in the Chilotan churches. There is also a harmonious combination of elements that belongs to the Gothic, the Baroque, the Renaissance and the Neoclassical among other styles that can be singled out from a rich melange of eclectic architecture. Thus, it is relevant to acknowledge certain common characteristics in the buildings' forms, materials and craftsmanship that show no significant changes over the centuries, and remain a constant regardless of the style and the sophistication in the designs, inferring that they are part of a truly Chilotan architecture.

The interior is organized by arcades that separate the main nave from the side aisles, and the exterior portico at the access, holds the tower that appears like crowning the horizontal volume. Most of the churches also incorporate a barrel vault ceiling in their central nave, a technique borrowed from the construction techniques used in the traditional wooden boatbuilding. A gallery overlooking the central nave also serves to access the inside of the tower.

Fig. 4: Achao, Chonchi, Tenaun and Vilupulli, four UNESCO World Heritage Chilotan wooden churches. (Photographed by the author, 2011, 2006, 2006, 2006).

3. The UNESCO distinction: an opportunity to share local heritage with the world

The vernacular value of the architecture in Chiloé was unknown to the rest of the nation and the world for too long. Its simple and even naïve buildings often have been unappreciated by locals and scholars for its humble characteristics. Though its value can be fully understood and appreciated when getting to know the richness of the local traditional woodworks and the involvement of a community that makes their temples be part of their everyday life. In that sense these churches are an exceptional testimony of the local customs and culture found nowhere else in the world. These wooden churches are scattered all over the archipelago, having each its own particularities but being part of the same traditional way of building.

After long years of academic work and research in the archipelago carried out mainly by the School of Architecture of Universidad de Chile with the participation of the local community, the significance of the traditional wooden churches of Chiloé has been brought to the limelight, first nationally and then internationally. In 2000, through the joint work of the Catholic Foundation of the Bishopric of Chiloé, professionals and academic faculty of the University, and the National Council of Monuments, 14 of these churches were presented and officially incorporated into the UNESCO list as World Heritage sites, on account of their heritage value and as a means of recognition of a broader family of timber structures and its relationship with the intangible values of the local people. On June 2001, two other churches were added to the list. These 16 sites were selected among about 60 traditional churches that still existed in the archipelago at the time, considering them the most significant and representative exponents of a model or type that recurs throughout the archipelago. These churches

were noted as possessing a significant artistic and architectural value of historical importance. In this selection the condition of conservation of the churches was also an aspect taken into account [3].

The official justification for the inscription described by UNESCO contemplated two main criteria:

First, that *“the churches of Chiloé are outstanding examples of the successful fusion of European and indigenous cultural traditions to produce a unique form of wooden architecture.”*

And second, that *“the mestizo culture resulting from Jesuit missionary activities in the 17th and 18th centuries has survived intact in the Chiloé archipelago, and achieves its highest expression in the outstanding wooden churches.”* [4]

The national recognition first, and later the international distinction opened a way to share the values of the wooden churches of Chiloé with the rest of the country and thereafter, with the entire world, furthering thereby an incipient but nevertheless growing touristic activity. This interest certainly constitutes an asset for local communities that can through it seize the opportunity to develop a sustainable tourist industry, while cherishing and nurturing their own traditions over the overwhelming development related to the commodities and big industrial enterprises that have been penetrating the archipelago for the last decades

Fig. 5: Interior of the church of Achao, UNESCO World Heritage site. (Photographed by the author, 2005, 2008).

4. Restoration of Vilupulli and Ichuac: two of the 16 World Heritage sites

Vilupulli and Ichuac, two typically Chilotan timber structures are part of the 16 mentioned churches which carry their own distinct particularities, but nonetheless are very similar in their construction tradition, materials and wood joints detailing; both underwent a restoration process of their tower-façade, their roofing and partially their nave in 2005, in an effort to recover their structural stability, commencing thereafter a longer process of maintenance and future further interventions that have had to be addressed considering the limited funding resources available at the time. Both churches clearly belong to the Chilotan traditional wood architecture; with their simple shed like horizontal volume and its elaborated tower-façade, they are gracefully placed in a rural landscape. Their main religious festivities seem to justify the oversized scale of both churches, located in an eminent rural area, serving not only the neighbor parishioners, but also an extended community that comes from adjacent agricultural settings. Once a year they celebrate the day of their patron saint, San Antonio in the case of Vilupulli, and Virgen de la Candelaria in the case of Ichuac, occasion when the community pays tribute to their faith.

The restoration criteria were similar for both churches, considering the technical challenges and the extension of the works first, and then the rural character of the building site.

Vilupulli is considered by many, one of the most beautiful churches of Chiloé, with its balanced proportions, its tall and slender tower -that rises up to approximately 20 meters-, and its location that is exalted by the natural conditions of the terrain and the landscape surrounding it. The very characteristic of its slim tower -its main recognizable feature-, has accelerated its structural instability, showing an advanced state of deterioration of its parts and representing a serious risk of collapse. The prolonged exposure to sun radiation, the strong winds and the abundant rain accelerated the process of wood decay and the proliferation of wood boring insects, compromising the stability of the tower's

structural system down to its foundations. The lack of appropriate insulation only aggravated this condition. Therefore, the restoration project had to consider intervening the whole tower-façade structure, dismantling it completely, piece by piece, discarding the rotten timber and reusing the elements that could be treated or recycled; mostly parts with lesser structural involvement. In addition to the tower-façade, the evident thinning of the roof and exterior wall shingles -from the original $\frac{3}{4}$ " to almost cardboard like thickness-, implied the complete removal and replacement of the roofing and some areas of the walls. Although having removed most of the shingles of the front and parts of the sides of the exterior walls, the inner wooden sidings were dismantled and reused, since they had not been significantly affected by the deteriorating biotic agents. This was also the case of the doors, the windows and their framework, as well as some minor structural elements of the tower-façade and parts of the portico area that were saved and reused. The decision of what element to discard, to reuse or to recycle was made together with the local carpenters, whose skills and experience are essential to maintain, promote and prolonge the wood building tradition over time.

A rather atypical feature of the church of Vilupulli is its flat ceiling over the central nave, that differs from the barrel-vault ceiling of most Chilotan churches; otherwise the interior spatiality and its architectural elements and ornamental works resemble the characteristic traditional wooden church.

As a way of reinforcing the sense of belonging of a scattered community, a small temporary exposition shed with the dismantled and recyclable parts of the restoration process was installed next to de church.

Fig. 6: Vilupulli, the restored church. (Photographed by the author, 2006 and 2008).

Fig. 7: Vilupulli, before restoration. Climatic factors and the wood boring insects had seriously damaged the structure of the building. (Photographed by the author, 2005).

The church of Ichuac is located on a poor smaller island and therefore represents a rather unsophisticated case in the framework of the 16 World Heritage Churches, but nonetheless it shows a elaborated ornamental work on its frontal façade as well as in its interiors. Its distinctive feature lies in the configuration of its short tower, owed to the lack of a second drum, a typical characteristic of the other wooden churches. The main problems it faced at the time, were the tilted state of the nave -due to the soft terrain-, and the extensive decay of the tower's diverse elements, the roof shingles and the wood siding of the exterior walls. The severity of the impairment and the extension of the damage represented in fact a critical case in terms of its conservation status. The structural deformations and a significant differential settlement that boded the eventual collapse of the nave and tower, had to be addressed simultaneously to the works on the tower-façade, so as to prevent further structural damage.

The particular concern *vis-à-vis* the restoration of this church, besides recovering the structural stability and improving the sealing of walls and roof, was to keep the collective memory of the community in terms of the image of the church, linking the people to the recovery effort. Due to the lack of information on the historic morphology of the church, one had to turn to the community for photographic records that could account for the buildings image, especially because of an earlier assumption that the tower originally was conformed by two drums instead of the existing single one. Finally, and after consulting with the older people of the small community of Ichuac, the decision was made to respect its actual image and proceed with the restoration project.

Similarly to Vilupulli, a small temporary exposition shed was built for the local community and for the increasing flow of foreign visitors that could get an inside of the traditional wooden craftsmanship.

Fig. 8: Ichuac, the restored church. (Photographed by the author, 2005).

Fig. 9: The barrel-vault ceiling of Ichuac, before and after restoration. (Photographed by the author, 2005).

The same way as all 16 churches included in the World Heritage sites, Vilupulli and Ichuac risk to be directly or indirectly impacted by the ongoing transformations that can be observed especially in the

bigger cities of Chiloé, changes that can also be seen on the shores of the inner sea caused by the salmon and seafood industry, that are said to affect the environment and the cultural identities. The restoration processes thus, have to reinforce the local identities in a sustainable way allowing the preservation of the intangible aspects of a heritage in such a sensible location that is undergoing rapid changes. The fact that these churches were declared World Heritage sites does not mean that they should stay frozen in time. They continue changing because they are part of a living community that also changes. The wooden churches of Chiloé are in fact the worship temples from which the entire pastoral and evangelizing activities of the Diocesan Church take place.

5. The local and the global in permanent tension

The restoration of a “living monument” faces the natural tension between the universal values of a World Heritage site and the local everyday uses; the scholastic purism and the pragmatic attitude; the global awareness and the preservation zest confronted with a living heritage that shelters the religious rites and everyday activities. This tension certainly demands paying special attention to the intangible dimensions that influence the restoration process. In fact, it is the intangible aspect of the local heritage, which has made it possible for these churches to be still standing today. This has to do with the community involvement in matters that affect their everyday life, as well as with the knowhow of the traditional wooden construction and the techniques that have been passed on from generation to generation.

The communities around the heritage churches value them not only for their significant edifices, but principally for being temples of worship and places of social gathering. This presents a dichotomy that Larsen and Marstein -citing Michael Petzet- refer to when stating that historic buildings are something more than just historic evidence; it is precisely this point where the tension between the local and the global centers. *To regard historic buildings as pure “historical evidence” is not to regard them in the full richness of their authenticity*, as pointed out by Larsen and Marstein [5]. As they recount, when considering a country church which has been carefully restored and painted, the fact that it shines and looks new, arouses the emotions of the local community who sees it as an honour to God, which should not be overlooked, but quite on the contrary, this sentiment and sense of belonging should be understood as a living value of an historic building [5]. Similarly, the wooden churches of Chiloé belong first to the parishioners and their deep religious devotion; and therefore the distinction that was given to the 16 churches that were included in the World Heritage list, should be understood as a reinforcement of the local identity and a recognition of the local traditions that ultimately will ensure the heritage permanence in time.

Fig. 10: The religious devotion of the Chilotan people and their close-knit community relates directly to their temples of worship. (Photographed by the author, 2006).

Within this predicament, the restoration process of the wooden churches in Chiloé, and specifically the cases of Vilupulli and Ichuac, seek not merely to replace a rotten timber by a new one, but also to guide the works within the traditional craftsmanship bearing in mind the delicate balance between the responsibility of intervening a World Heritage site according to the parameters and criterion suggested by the numerous international charters and specialized literature, and the very continuity of the local traditions. Therefore, it was the duty of the restoration of these churches to find a harmonious and participatory way to preserve and exalt the patina of time -wherever possible-, and at the same time to bestow a restored building that ensures its stability for a longer period of time, providing the

parishioners with a well detailed and finished temple for their rites and social gathering. Hence, it is essential to count on local carpenters that have acquired the knowledge and skills of their ancestors, promoting in this way the traditional craftsmanship, and thus preserving a fundamental part of the intangible heritage values.

Another aspect that raises conflicting points of view is related to the scale of the intervention. Unlike a monument where a permanent in house architect is assigned to carry out its maintenance and its systematic restoration -counting for it with a relatively stable budget within a given period of time-, in the case of the churches of Chiloé the scarcity of the resources and the uncertainty of being able to intervene the structural damages in a programmed way, determines fundamentally the restoration criterion. What is urgent to be addressed adds to the otherwise deferrable repairs; in this scenario the restoration project has to tackle the whole, not only the imminent, implying in some cases -like in Vilupulli and Ichuac-, the dismantling of the whole tower-façade down to its foundation, with the expected tension among some scholars. This is related to the need of responsibly ensuring the stability of a building in use, especially when the restoration project is in charge of professionals. In the case of timber structures decayed by time and by damaging agents, the damage occurs not only in the exposed surfaces of the wood but in areas usually hidden to the naked eye, affecting the critical parts of the tower, nave and roof with the consequent permanent risk of spontaneous collapse. Minor structures which present no immediate risk to the congregation and visitors can be addressed in a more conservative way, repairing and reusing parts that have no major structural compromise.

In the tangible aspect, the restoration of these churches is conditioned to their materiality and their building systems, taking into account their exposure to the harsh weather conditions. When replacing decayed timber or wooden shingles with new ones, the contrast is manifest, especially for those who are not familiarized with the local weather that speeds up the patina of a building. In fact, a newly installed timber exposed to the sun, rain and wind, blends almost totally with the older pieces of timber in a time laps of a few years. This is well known by the locals, but nevertheless places tension when harsh contrast arises. It is especially dramatic when having to exchange the roof or wall shingles that have become thinner over time needing to be completely replaced, as was the case in Vilupulli.

Fig. 11: Vilupulli after the 2005 restoration. The pictures were taken in October 2005, November 2005 and October 2009. The solar radiation, the abundant rain, the constant humidity and the strong winds accelerated the patina of time.

6. Conclusions

The restoration of the churches of Chiloé based on the local tradition of wooden buildings, presents a complex challenge that relates to the tangible and intangible characteristics of these temples and their cultural context. When facing a restoration project located in an isolated context, with a proud autonomous people who cherish their traditions, the expertise criterion and the collective imagery that the local communities have in regards to their churches not always coincides. In this context, the restoration is not driven by certain general laws, as it usually responds to the particular, not to the generic. The churches of Chiloé should not be restored for display purposes; it is not intended to exalt and recreate the old and the decaying. The objective is to restore their status as safe and dignified

temples for worship and social gathering, keeping true to their building tradition, improving poor structural aspects and seeking to do it with the full participation and involvement of the local communities, whose ancestors were the ones who gave birth to this living heritage. Hence, it is imperious to maintain and recover the skills of the traditional carpenters; only then will the process be sustainable in time. It is through this recognition of the traditional values and the skills of the carpenters that these churches will remain an intrinsic part of their communities, as well as part of the global heritage.

[The author of the present article was the architect responsible for the restoration of the churches of Vilupulli and Ichuac in the year 2005].

The quality of bridge design in the general design process

Michele CULATTI

PhD at Department of Structure Engineering, Faculty of Engineering, University of Trento, Italy
michele_culatti@fastwebnet.it

Abstract

The design has a central role in the construction of road infrastructures, including bridges, in defining the form of the work. From its conception through to the 3D graphic representation, the bridge acquires an increasing level of precision through to the final project, however in general terms there is a deficit in the representation of the two extremes of the construction process. In the first extreme, there is no *design of the need* for the infrastructure, which is still too often deferred to a political choice that is not sufficiently backed up by analytical instruments to highlight the effect on the area. At the other extreme, there is no *design of the perception* of the work, i.e. no analysis of its use: to what extent is the work perceived? To what extent can it be understood and, therefore, recognised in its formal independence? Consequently the representation deficits upstream and downstream from the technical design show a lack of reflection on the meaning of an infrastructure in a location, which tends to generate a distortion of the highly sought after *Genius Loci*.

In this report, the “gaps” in bridge project representation will be outlined (from the need for an infrastructure through to the preliminary project), and a few ways that could be adopted to fill these gaps with reflections on the methodological approach.

Keywords: design, perception, landscape

1. The “gaps” in bridge design projects

In the public image, bridges often evoke opposite effects. There is the more widespread simplification of their forms, which involves the majority of our roads and motorways in the form of flyovers, and is shown in the series and weaves of “spatial species”, as if they were gates to the city. At the other end we have the “urban scale sculptures”, the virtuoso feats of the Archistars. However, between these two extremes there are, besides various historic bridges designed by architects of great structural and aesthetic sensitivity (to name just a few Zorzi, Morandi and Musmeci), vast ranges of examples of situations that are sometimes conflicting and others consistent with the landscape. However there are numerous design approaches to conceiving a bridge, the methods, trends, cultural references (or in the worst case scenario, lack of culture), and they have to confront the technical-legislative restrictions and the experimentation with new construction materials and methods. However, the final outcome often does not come up to expectations and there are several reasons for this failure based on three macro-reasons. The first is the constant lack of transport need design: often (in our country) the decisions regarding infrastructures by the local authorities lack any rational and strategic design that is able to foresee the effects on the workings of the area, (it should be remembered that, to join two points in an area, road networks are used – which bridges are a part of – but this way areas are permanently separated and this fact is never taken into consideration). The second reason is the survey of the context and the technical design of the bridge, which is normally very precise down to the smallest detail, but also generally limited to the finished three-dimensional structure, and not extended to the area. The third reason is the lack of adequate representation of the effects of the bridge in perceptive terms.

If we consider the bridge project from the initial transport needs through to the preliminary phase, and if we trace a graph of the quality and quantity of data that should be returned through a design able to show the final result, we realise that the curve does not have a constant trend.

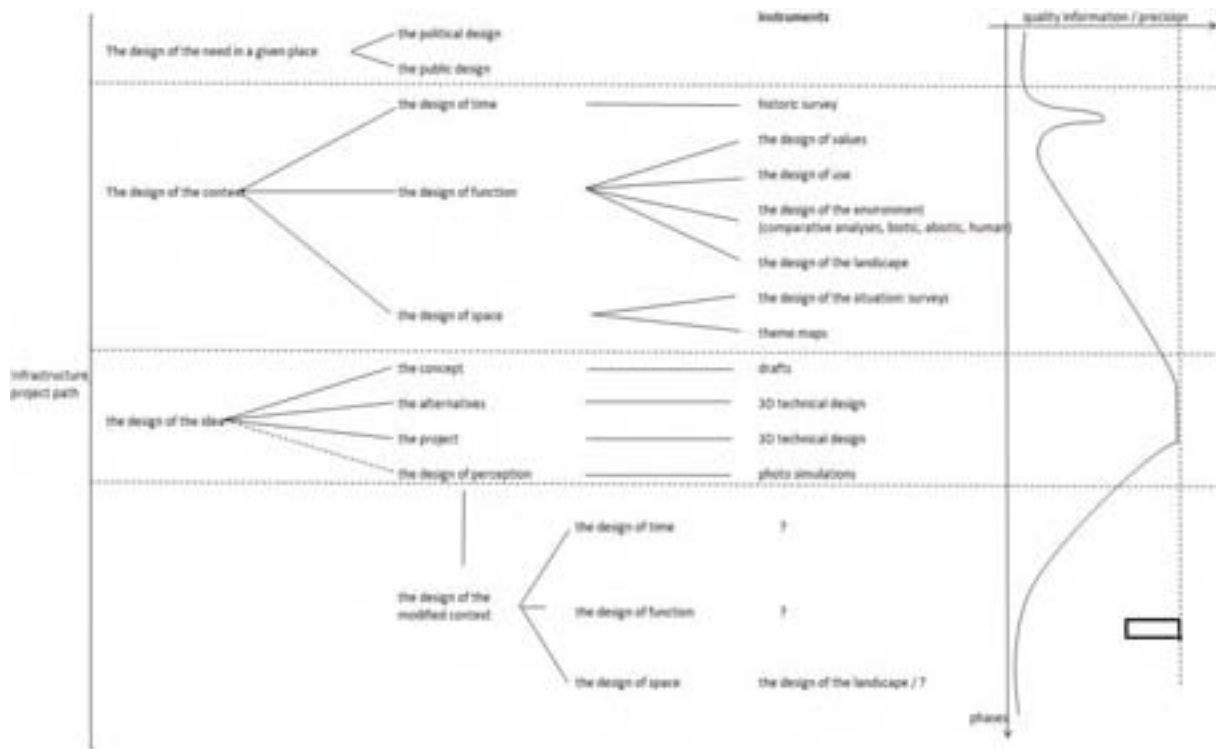

Fig 1: Graph of the survey quality trend and representation during the project phases (from the initial transport needs through to the preliminary project).

On observing the graph we can see that the political design, i.e. the modal and formal choice of the infrastructures by local authorities, basically is not represented. In fact, the political choice is rarely represented transparently through strategic maps that help understand the reasons and meaning of the choice.

However, in the graph the context has a sharp rise, in fact it is analysed in depth (even if for regulatory obligations) in its biotic components (flora and fauna), abiotic (soil, air, water) and human by means of the Public Works Regulations, with specific analysis (again imposed) of the landscape (DPCM 12/12/05, which is limited however in that it considers the relationship between designed work and context in terms of negative impacts *modifications* – if they are limited transformations – or *alterations* – if the modifications change the nature of the landscape and create “something else”, but there are no remarks to consider transformations that improve the context). There is then the need to physically introduce the bridge into the context, which requires an accurate site survey that considers the various categories of restrictions defined in the local government planning documents.

However in the representation of the context, there is often no historic study of the location and, above all, no survey of the location’s “function” intended as a space for human relationships that requires an anthropological approach.

On observing the graph, we can see the design of the idea, from the concept and gradually through to the photo simulations and 3D rendering, through to precision maximisation to then approach the *perception design*, i.e. represent the transformed context due to the bridge. Normally there is no need to consider perception apart from the theorised presumptions in architecture regarding the landscape and, in all events, leaving the final user the honour (or liability) of perception.

However, filling these survey gaps and representing unphysical facts, in particular the *strategic and perception design*, is increasingly important in the light of the growing need for quality use.

2. The strategic design

When making political choices, the decision maker’s and the architect’s cultural background are taken into account, because we have witnessed decades of scarce aesthetic culture in infrastructure design, however, special attention should also be paid to the *rationality of the choice*, because it helps determine a Genius Loci that is fundamental now to prevent that series of “gaps” of missing reflections, which often tend to reduce the idea of a quality bridge to the minimum.

All the necessary instruments are available, for example the correct use of multiple criteria analyses which, through extended analysis, i.e. beyond the geometric confines of the project, internalise the quality indicators to understand the location, exploring and evaluating the forms, functions and

meanings of the context. In this, if the context survey is returned as a graph of an organised system of signs, each sign must be correlated to the stratification of its relational, identity and historic values (according to the literature of M. Augé), moving from a graphic plane representation to a multidimensional representation. This way the context is observed from several viewpoints and therefore considered through conscience, and from its understanding both the territory, in its multiple physical and biological aspects, and the anthropological site as a seat for human relations, emerge. Cognitive maps can also be considerably useful, as they are able to explain the cause-effect relationship between the various phenomena, for example foreseeing that the introduction of a bridge, with its relative transport network, does not isolate entire villages (which instead happened recently in the Po Delta area).

Mapping the rationality of the choice on one hand and the cause-effect relationships on the other, which is translated into expressing the forecasts, can help establish a strategic design that highlights greater reflection in the consistency between designed work and its context.

3. Representing perception

The importance of representing their perception, i.e. foreseeing how the work will appear to the public, is generated by detachment between the 3D view, illusorily realistic in rendering and photo inserts, and the spatial experience where the bridge is used to varying degrees until it is actually crossed, where the perception may, in certain cases, like footbridges, be amplified and transformed from a purely visual to an acoustic and tactile experience. In this perceptive journey the environmental variables and the way the bridge is approached condition and limit a use that is only “all-round” in the virtual images and, often, in unrealistic “aerial” views.

3.1 The subject of the project

The first reflection focuses on *what* is being designed, its extension in the project. In fact, apart from a few rare examples, engineers and architects alike focus on the subject which, first designed and then given virtual form, becomes a physical object. As previously mentioned, despite the land survey techniques, 3D modelling and photo inserts are able to give good results of the final outcome, the project subject remains the *bridge* which is what attention and creative forces tend to focus on. Thus, the result is generally the *contextualised bridge*. However, with this design approach not only is the landscape, a highly discussed topic in recent years with a general growing awareness, put in the background, but, no less important, also the *overall quality* that should be queried as *how the bridge functions* realising, as already mentioned regarding the context of the strategic design, how many and which ties the bridge manages to create with its context (historic, economic, functional, local and network, perceptive, cultural and of significance). Rather in operational terms, widespread where the bridge is contextualised, there is still no idea of the *transformed context*, i.e. the outcome of a design operation that considers the characteristics and vocation of the location and the site for the project, where the continuous symbolic exchanges between the bridge and context can be recognised, until the bridge actually becomes the context, as if had always been there and to which nothing can be added nor taken away. Consequently, by focusing design attention on the bridge and specifically interrogating the context, there is the risk of altering the location, of not going beyond that fine conceptual dividing line of the passage from “Contextualised infrastructure”, where the point of view of the infrastructure dominates, to the “transformed context” where the point of view is directed to the location, to the area overall that is used and affected by the relations. The result is that the bridge often is seen as an intruder, with the resulting public protests.

3.2 The quantity of perception

There are numerous variables that affect perception: the season, the type and quality of light during the day and night, when there may be artificial lighting, the light diffusion, and its intensity during the day and night, the orientation of the bridge with respect to its geographic position, any external observation points of the bridge, the speed with which it is crossed.

So, from *how* a bridge is sculptured by time, light and shade, we move onto ***how much***. *How much* of the bridge do we perceive? Obviously the answer is subjective to each single case, and even though it is complicated to theorise analysis models that are generally valid, we can at least identify those components that come into play in perception and which enable measuring it.

One of the main aspects is *proximity*. A question of scale based on the relative position between the plane where the visible surfaces of the bridge stand and the observer's plane. This means the view of the area *from* the bridge and *of* the bridge from the area, a continuing play of marquetry where perspectives and vanishing points are dominating factors. Elevation and central perspective dominate the scene we see if we observe a bridge in the distance on a scale with the landscape, which is

amplified in the reflected image if there a river running beneath it. As we get closer to the bridge, foreshortenings and gradual progressive changes in form accompany us until we lose the perception of the structure beneath us and are able to see it in detail. But if this path, this gradual change in scale, is read as continuity it is just as virtual as the 3D graphic models we mentioned previously. In fact, the problem of accessibility of perception arises. To understand this problem, it is sufficient to take one of the most glaring cases – the organisation of the areas around the tallest bridge in the world: Millau in France. Downstream between the two riverbanks a small temporary bridge had been built to enable the heavy vehicles to work on the bridge piers. When the bridge was finally finished, the temporary bridge was not demolished but was included in the new landscape layout as a viewpoint to admire the surroundings which, in this case, is this monumental construction. Apart from the unusual view upwards, the small bridge also offers the chance of understanding the size of the tallest bridge in the world and grasp its scale with respect to its surroundings. This case leads us to reflect on the modulation of the ratio of the “quality of the work” / “number of viewpoints” to observe it. Theoretically, the poorer formal quality of the bridge, the more we attempt to deny its visibility, hiding it symmetrically and with attempts of camouflage, also considering the valorisation principles in our “Cultural Heritage Code” – the greater capacity of being a “cultural heritage” the greater accessibility to perception it should have. If we move from the landscape scale to the urban and architectonic scale, the chance of getting a glimpse of the bridge is high, and from the perception of depth given by its width, which we previously saw, we now have the perception of depth given by its length up to the point where the bridge ends on the riverbank or landfill. The regular lines are distorted, the spaces between the horizontal lines of the planking and the arch holding the bridge become “triangoloid”. There is a change in register a linguistic flexibility that should not be taken as a limitation but as expressive potential.

3.3 The everyday modellers: shade and time

Another aspect that comes into play in perceiving a bridge is *shade*, especially in our country where there are not many bridges with large or very large spans, which impose the use of suspended bridges, here the majority are deck bridges or deck arch bridges, where the structural frame is all or partially beneath the planking. Consequently, for the greater part of the day we are only able to recognise the design of the bridge, or structural architecture holding it up, in the half-light or with difficult backlights. This means that shade is also a component that gives depth and substance, but also the one that limits perception. Shade also helps to momentarily sculpture other elements in the context: the shade that the bridge throws when it is struck by sunlight, creating fascinating or invasive effects on the surrounding land.

The perception *time* is another “gap” which has been little explored. It is fundamental in the perception of a bridge and has two main ranges of variables. One is of moments, a few seconds or a few minutes we need to catch a glimpse of the slenderness of the structural weave or the convergent lines of a parapet, which, with the planking, sight other spaces and places. This is the time of the person who uses the bridge, crosses over it. The other temporal range varies from days to a lifetime, and mainly concerns those who live close to the bridge and experience, or suffer it, as part of their everyday life.

Fig. 2: Granatieri di Sardegna Bridge – San Donà di Piave (Venice) – example of an impressive bridge whose presence is softened by the colour of the arches, painted black, exploiting the shade beneath the planking.

Conclusions

In terms of perception, bridges offer *forms* of *functions* and *meanings* but, given the great variety of factors that come into play in perceiving them, a bridge should be observed in its initial design, in a cause-effect relationship not only of quality but also quantity, considering that it relates with the *forms*, *functions* and *meanings* of its surroundings. Reflect, design, survey, map and strategically plan *how many* portions of a bridge are perceived in everyday life leads all-round virtual graphic representation to a more tangible vision. In fact, *how much is perceived* helps understand the bridge. In *how much* is

perceived we can understand the formal construction-context consistency, and also *how much* (together with *what* of course) is used to evaluate the degree of interference and concentration of intruding elements in the context to determine the responsibility of architects and public authorities in altering the landscape. Therefore the amount of perception time, the play of light and shade of just a few seconds, the level of proximity and the foreshortenings that give us the measure to understand the bridge, enable us to grasp its identity and to distinguish it from other bridges.

In observing the *how much* in the distorted lines, in the *instant perspectives* a bridge gives us, we can find the true perception spaces and times of the bridge. "Times" and "spaces" that should be seen as tools to remodel and improve the initial design, governing the contraction and expansion of complex relationships between contained and container, between guest and host.

It is *how much* achieved through *what*, *why* and *how* that gives meaning to **where**, the only possible place to build a bridge. A degraded *where* hungry for improvement or a *where* in need of a new crossing or new transport symbol, but always a *where* that, in this time of scarce financial resources, requires being a *work of art* that belongs to the place.

Historical centers in seismic area: methodology for conservation, prevention and reconstruction. The case study of Villa Sant'Angelo

Davide INDELICATO¹

davide.indelicato@unikore.it

Abstract

In recent times, the recurrence of seismic events has suggested again to pay careful attention to the ways to intervene on the existing buildings with the aim of increasing their security requirements together with maintaining high levels in urban quality. In particular, it is a shared opinion that the conservation of historical city, especially in earthquake affected areas, should take into proper consideration the theme of seismic security. Nevertheless, this particular topic is confronted to operating methods which are still confused and often ineffective. This paper describes a methodology for the analysis of building aggregates of historical city, aimed at reducing their susceptibility to earthquake induced damage. This methodology has been applied to a block in the historical center of Villa Sant'Angelo, one of the towns near L'Aquila affected by the seismic event occurred in April 2009. The aim is to show that, even in situations of so high seismic risk, the deep knowledge of building constructions and of their environment is a basic condition in order to find operating solutions based on sustainability and cost saving principles. In this way, the restoration projects which spring from these principles, can find a good alternative to the easier but less sustainable solution of city delocalization. The methodology here proposed can be applied both in post-earthquake rebuild conditions and in the most advantageous prevention activities. In a period of so hard economic crisis, the lesson learned from last earthquakes imposes us to move our resources from emergency to prevention activities.

Keywords: conservation, prevention, reconstruction, historical centers, Villa Sant'Angelo

1. The research methodology

This study, based on part of a doctoral thesis, is structured on the basic concept of building aggregates. The complexity of urban historical texture is due to all its transformations, alterations, permanence, that makes hard the interpretation of constitutive nature of the buildings. The complexity of historical city is reflected on its seismic response. Buildings in historical centers, in fact, since they belong to a whole, are tightly reciprocally connected. So, the research proposes the building aggregates as a minimal unit to be analyzed and as an average component between the urban and the architectural scale. The building aggregates is defined as "a buildings group structured in time and connected by a historical self-regulation system"[1]. The components of building aggregates, by this aggregation procedure, acquire different features characterized by typical individual elements. The building aggregates is endowed with something essentially different from its individual parts which have an inner relation level permitting to consider it as a unique object. The research methodology here adopted is structured in three steps: the knowledge, the interpretation and the project. It is also developed on three scales: the urban scale (the city), the building aggregates scale (the city fragment) and the architectural scale (the building).

2. The knowledge phase

2.1. The earthquake of April 6th 2009 and the seismic history of L'Aquila

On April 6th 2009, at 03:32 AM, the district of L'Aquila was shocked by a strong earthquake with the main-shock magnitude 5.8. The distribution in plan of the shakes repetition shows that the area

involved in the seismic sequence, called “seismic crater”, is 30 Km parallel to Appennini mountain chain, in direction NW-SE. This first main-shock, on April 6th, was situated at the south-west of L'Aquila, near Tornimparte, L'Aquila and Scoppito. The stronger aftershock, registered on April 7th at 19:47 (M_L=5.3) has involved the southern area of seismic crater, near Villa Sant'Angelo, San Martino d'Ocre, Fossa, San Felice d'Ocre. On April 9th a third aftershock, with magnitude 5.1, shacked the northern area, near Barete and Pizzoli [2]. The study of the main seismic events which involved the area damaged by the 2009 earthquake, highlighted a constant and particular intense seismic activity. The strongest historical earthquakes which involved L'Aquila district (registered in Catalogo Parametrico dei Terremoti Italiani, 2004) happened on September 9th, 1349 (M_e 6.4, MCS 9) and on February 2th, 1703 (M_e 6.7, MCS 9). These two earthquakes were more powerful than 2009 events, however we can compare it whit other seismic events happened in this area in 1461 (M_e 6.4, MCS 9), in 1762 (M_e 5.9), in 1916 (M_e 5.2) and in 1958 (M_e 5.2), which damaged L'Aquila and its surroundings [3]. The goal of studying the seismic history of a specific geographic area is to recognize the hardest earthquake in relation with adjusting the consolidation project. At the same time, this study will allow to evaluate the efficacy reinforcement operations made after every post-seismic rebuilding, as a real time test.

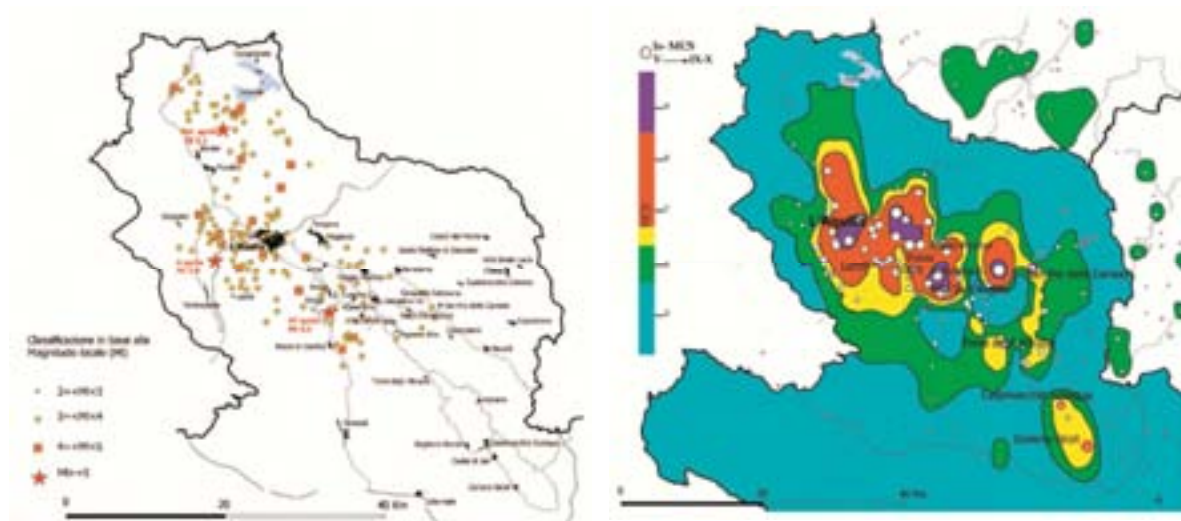

Fig. 1: Location and classification of L'Aquila seismic sequence from April to June, 2009.

Fig. 2: Plan of “seismic crater”.

2.2. Critical survey and damage survey

Villa Sant'Angelo is a typical hilly village of 5,26 square kilometres, at 570 meters above sea level. Only 436 people lived there before 2009 earthquake (ISTAT, January 1st, 2007). The village is composed of two built up areas: Villa Sant'Angelo, that is the administrative centre and Tussillo, a small hamlet. As a consequence of latest urbanization process they tend to connect themselves, but the two historical centres remain detached. The “villa” (rural area) is situated at the base of the hill; Tussillo is endorsed on the “Sant' Petr' “ mountain [4]. In this urban contest, the building aggregates considered as study case is representative of a typical damage condition of this area. This block is situated in the southern area of the historical centre of Villa Sant'Angelo, in closeness of the city entrance. The geometric survey has highlighted, amongst other things, a hard altitude gap between upstream and downstream level that influenced the architectural, morphological and typology features of the buildings. The collection of information on the structural relationship among buildings as well as on constructive techniques of each building is the so called “critical survey”, in which the buildings are examined in such a way to point out all the significant structural details, both at the scale of single buildings and in their mutual connections. The critical survey has carried out also observing the ruins with the aim to acquire information about constructive features of collapsed building to link, in the second step, at its damaging scenario. The evident collapse condition make easier the identification of constructive elements, of the walls juxtaposition, of the trace of historical passed away configuration, of historical anti-seismic aid. All this features were precisely annotated and drawn. In this step it was carried out a survey of damage and collapse status at two scales: at urban scale it was surveyed in swift way the damage and the ruins of all the building aggregates of the historical centres of Villa Sant'Angelo; at individual building aggregates scale it was analyzed the specific damage status.

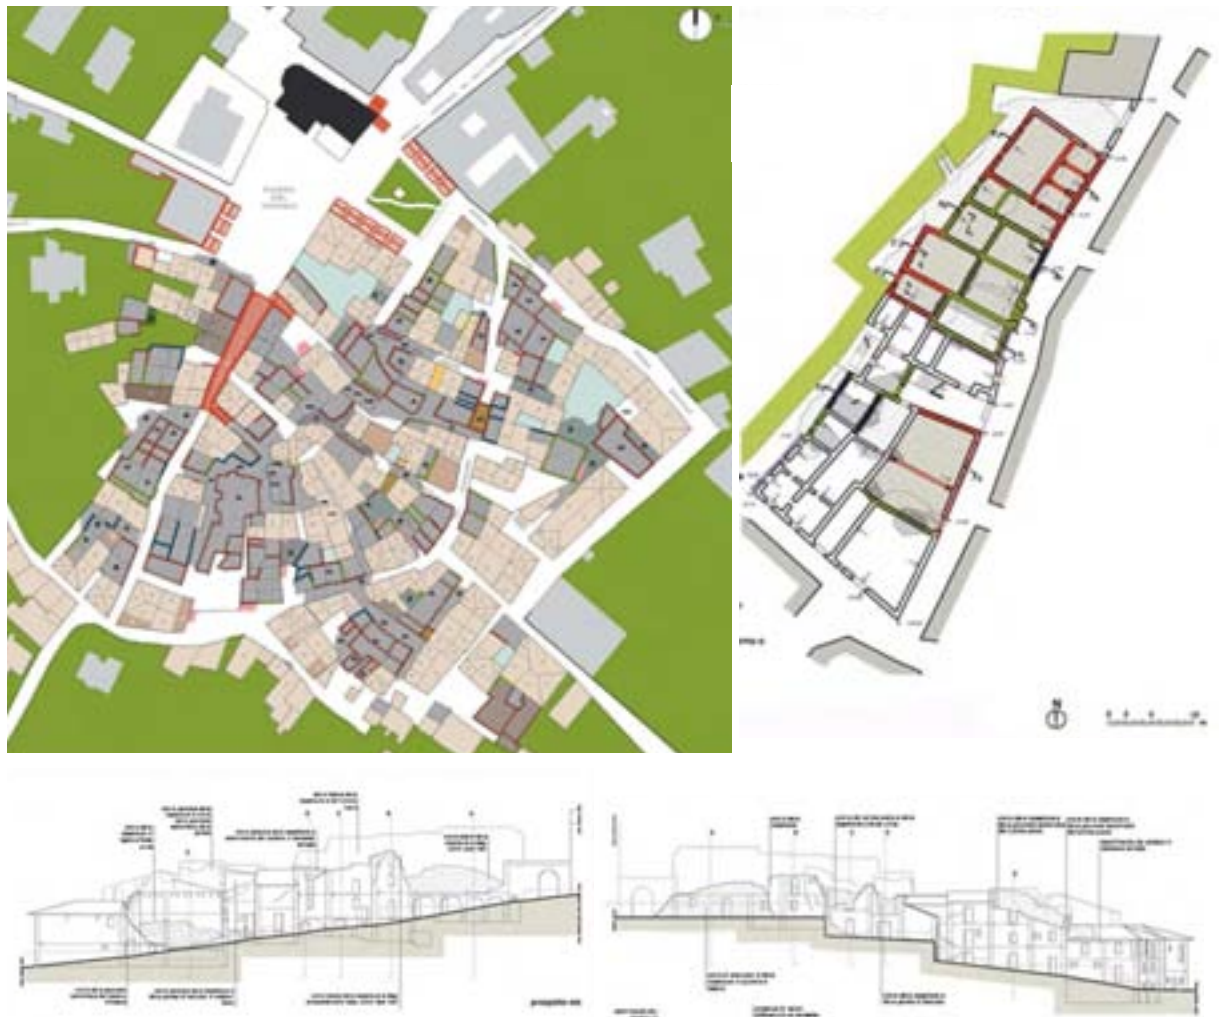

Fig. 3: Damage survey of Villa Sant'Angelo. Urban and building aggregates scale analyses.

2.3. Supposed pre-seismic configuration of the building aggregates

The critical examination of damage and collapse condition of building aggregates as well as of the ruins allowed supposing the pre-seismic configuration of the building aggregates. This hypothetical reconstruction is finalized to understand the reason of the buildings collapse or damages which can be strictly connected with their conservation status or constructive typology. Starting from the upstream area, it was supposed that the upper extremity of the architectural unit could have three elevations: two elevations were in masonry, one elevation was in concrete brick. The roof was made of steel beams, hollow clay blocks and reinforced concrete slabs. The inner buttress walls of first level didn't continue in the other two levels, so two couple of steel beams were placed in support of the roof.

2.4. Origins and development of building aggregates

Supposed reconstruction of pre-seismic configuration of building aggregates is essential, amongst other things, to retrace backwards its origins and typological development process [5]. The sequence of building process is discovered by recognition of walls juxtaposition, by assign a related date to masonry and, in consequence, to corresponding buildings. The site occupation started contemporarily from upstream buildings and downstream buildings. The upper extremity architectural unit is a one-celled building duplicated in the back. They originally had only one elevation and the cells were separated. The following elevation and unification occurred in two distinct periods: when a staircase was inserted at the upper levels and when the floor was changed. The development of the block proceeded to the south direction, by occupation of east front towards main street, then by the occupation of the back space toward the country areas. The development of downstream area started with a barn and followed by other rural underground buildings, till rejoining with residential building of northern area.

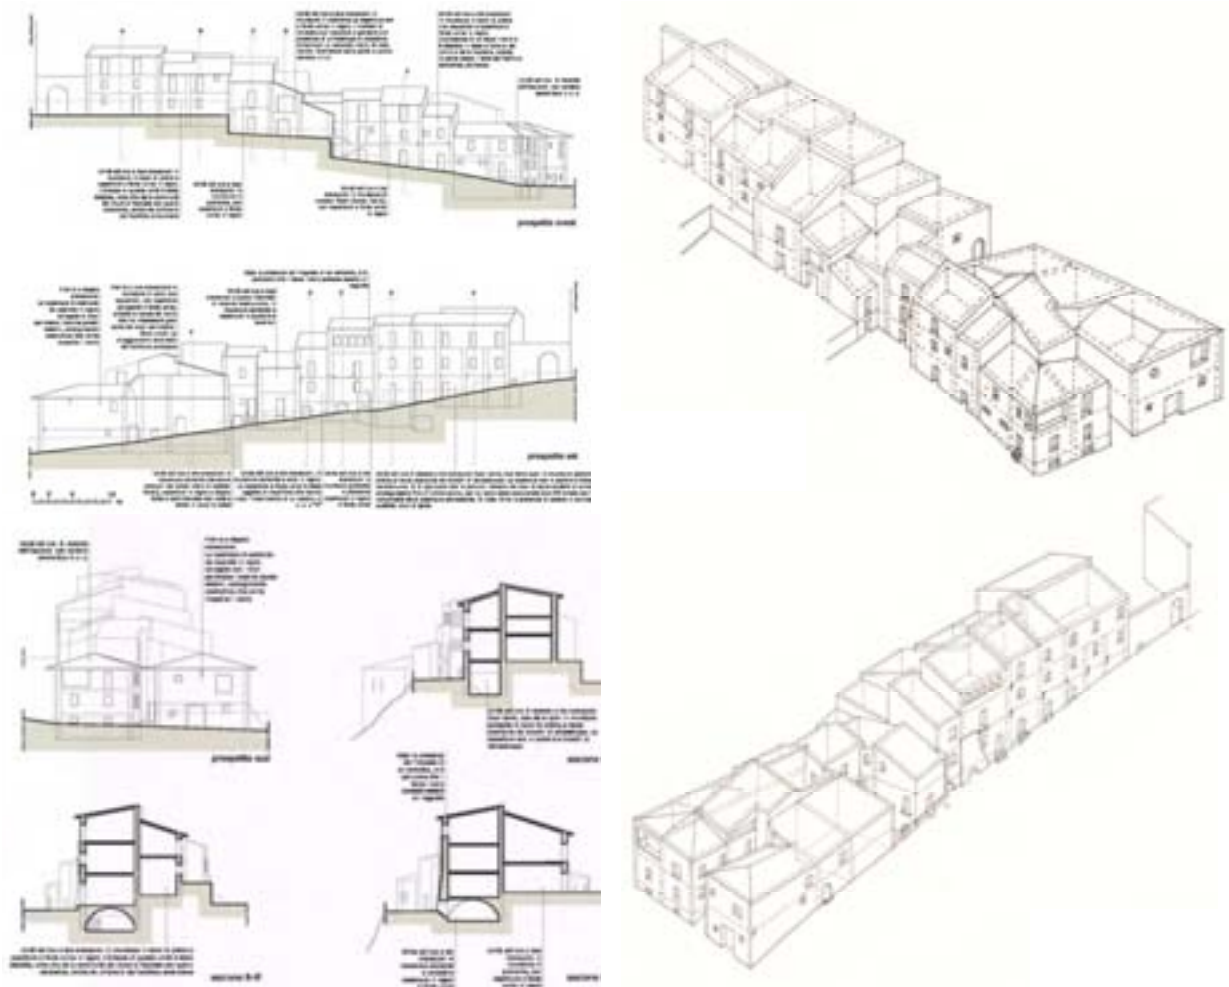

Fig. 4: Supposed pre-seismic configuration of building aggregates.

Fig. 5: Origins and development of building aggregates.

2.5. Constructive survey and local seismic culture

The Abruzzo district has been victim of many catastrophic events in all its history. So, local builder were induced to use particular devises in order to make buildings resistant to earthquake. This condition allowed to develop an historical anti-seismic constructive culture is still in progress and that we can understand by studying and careful observing historical buildings [6]. The building aggregates chosen as study case in the historical centre of Villa Sant'Angelo has many features of local constructive tradition and also the same constructive "alteration" that 2009 earthquake put to the test (for example reinforced concrete edging or roof). The evaluation of the various modern and historical constructive devises, in consequence of seismic effects, leads us to reflect both about the technical rebuilding manner and the way to reduce seismic vulnerability of the other buildings.

Fig. 7: Historical constructive culture

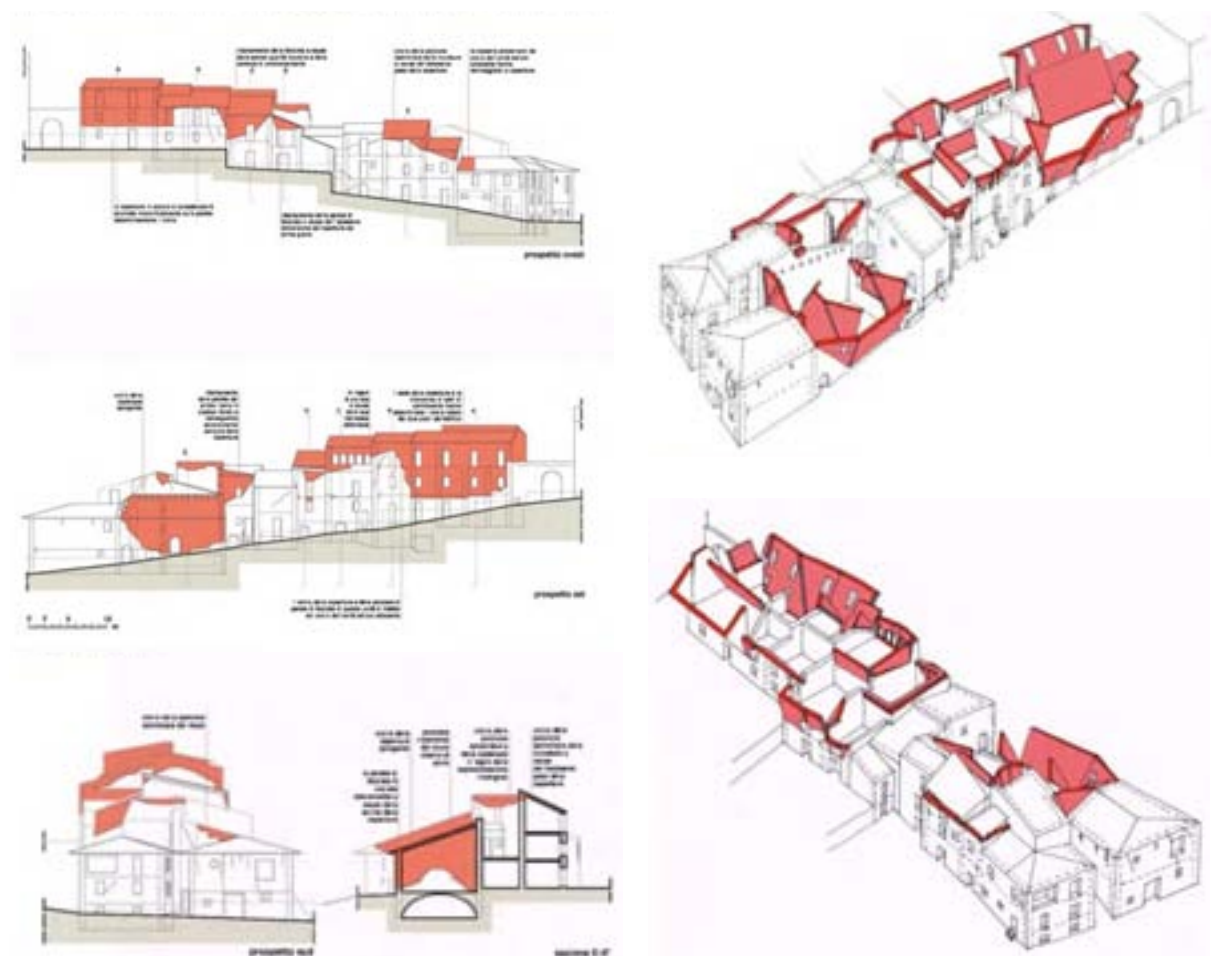

3. The interpretation: from analyses to project

3.1. Vulnerability and resistance seismic factors

In the interpretation step it was compared the reconstruction of supposed conformation of building aggregates before the earthquake with the post-seismic survey. This analysis allowed deducing the vulnerability and resistance seismic factors really existing in the building aggregates. Different kinds of vulnerability factors were identified: innate vulnerability factors (such as extreme horizontal and vertical thinness of masonry walls, pushing roofs, low quality of masonry walls...); alteration and interaction vulnerability (for instance deficiency of adjacent walls anchoring, reinforced concrete edging); position vulnerability (such as slender facade). Some of resistance factors detected in the studied block are, for example, the well anchored masonry corner, the wooden chains inside the masonry walls, the metal chains, the wooden trusses whit external anchoring.

3.2. Seismic damage scenario

Founding on previous analyses it was possible to suppose the seismic damage scenario happened due to 2009 earthquake and the individual unstable mechanisms of collapse [7]. The façade out of plane overturning collapse mechanism didn't affect the underground or ground planes but just the second levels. In lower levels there were often masonry vaults with metal chain and they resisted both when they were parallel to the façade and when they were orthogonal to the façade. Moreover the historical anti-seismic devises were particular efficient. For instance, the wooden trusses whit external anchoring in the barn prevented the collapse of external façades. Also the wooden chains inside the masonry walls and the metal chains were efficient, as we can know by observing the collapse edges. The same level of seismic protection was not guaranteed by modern anti-seismic devises in reinforced concrete. The detailed knowledge of the block and the accurate description of damages and collapses it has suffered are essential for identifying probable causes that led to the nature and extent of the surveyed scenario and, at the same time, recognizing structural solutions that could prevent even greater damages.

4. The project: safety and conservation design at urban, building aggregates and building scale

The third step of methodology is the project. It consists of a rubble removal plan and safety and a conservation project at urban scale, building aggregates scale and building scale [8]. The purpose of rubble removal plan is the conservation of what remains of Villa Sant'Angelo, avoiding widespread culling of the surviving portions, in order to not remove the traces of the ancient centre. So, the project considers some local interventions with minimal impact on surviving buildings, aiming at select what can be preserved and what we must renounce to guarantee safety and start rebuilding. The rubble removal plan combines together conservative need and safety need. With regard to the securing operations, these include various types, such as removing of unstable component of roof or balcony and the shoring walls. The need for the removal of only unrecoverable portions is motivated by the desire to minimize the loss of important cognitive elements. Some interventions are specifically aimed at the conservation of the surviving portions, for example the closing of "the edge of collapses" in order to limit the decay due to atmospheric agents, or the selection, cataloguing and storage of stones having an architectural value. This project is inspired by extremely conservative and environmental economic sustainable criterions, because it proposes the re-use of material rubble, trying to preserve what earthquake didn't destroy.

5. Conclusive considerations: from emergency to prevention

To engage a so extended damage level is a hard endeavour that could induce to considerate cursory and no social and economic sustainable solutions. The city relocation, for example, could create a great urban ruin and the establishment of new towns with no social and historical references. Also the extensive demolition is likewise inadmissible because it involves great economic resources and the removal of ancient city with no signs of the earthquake tragedy. This study proposes to intervene in gradually differentiate way to rebuilding the city, both whit creation of new architecture and conserving as much as possible.

This analyses method can also be applied in prevention way. Much consideration about the block damaged by the earthquake can be carry out in pre-seismic phase, whit prevention purpose [9].

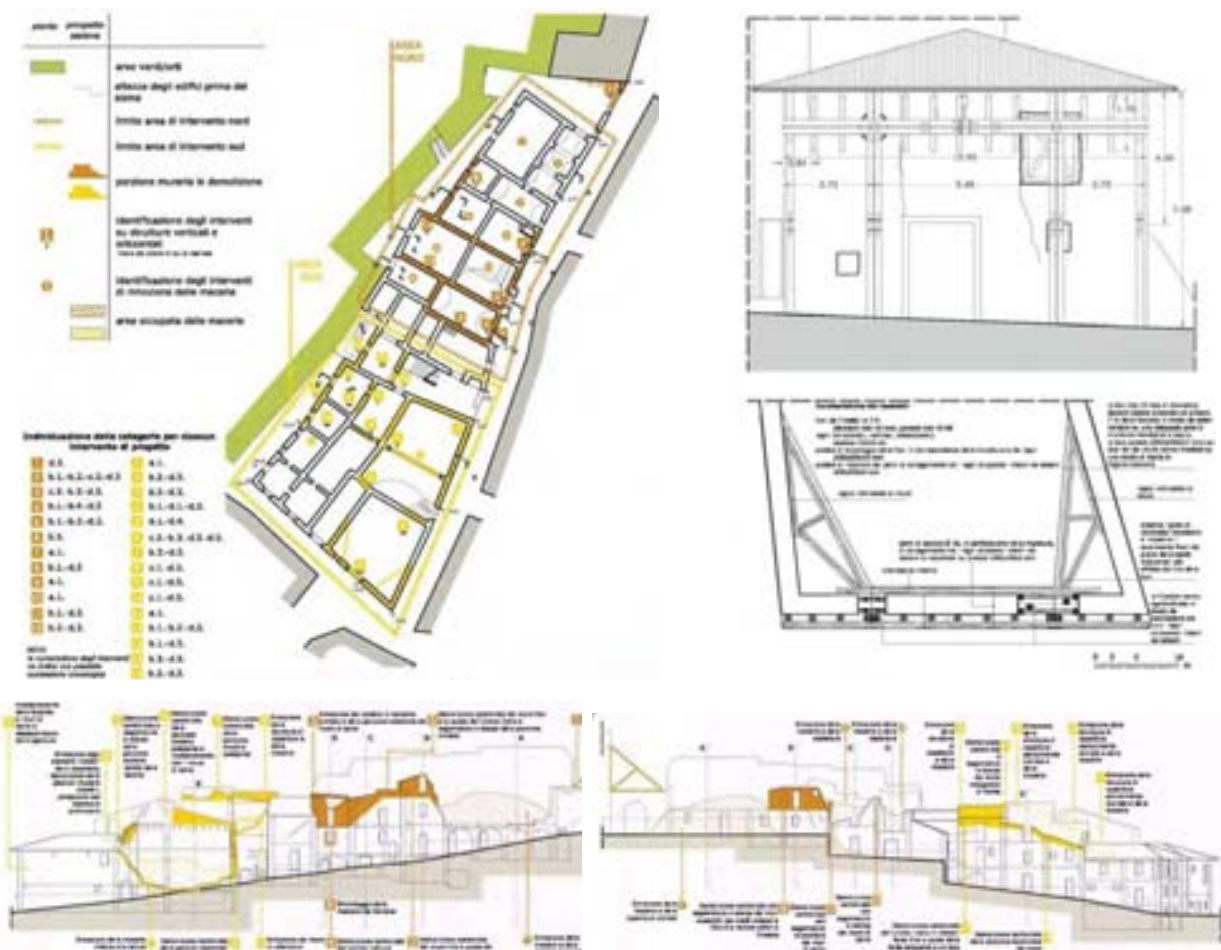

Fig. 10: Rubble removal plan and safety and conservation project at building aggregates and building scale.

The roman amphitheater of Syracuse: a forgotten archaeological artifact

«Thinking that here it's represented only the lower part of the building, that is the most narrow part in this kind of building, it's possible to imagine how much large, high, stately and impressive it had to be. [...] there is not risk to make a mistake thinking to it as one of the most extraordinary building never built». This is what Jean Houel wrote in his diary "voyage a Syracuse" (1777 – Palermo 2003). The building described by the famous traveler was re-discovered only in 1839. It is a hundred and forty meters long and a hundred and nineteen meters large, and the most part of it is dug in the rock. Nowadays it is still possible to see two ambulatories covered with a vaulted roof under the cavea, and the superior ambulatories that allow to enter in the terraces of the various parts of the cavea. The amphitheater is in the *Neapolis* of Syracuse, near to the famous *Greek Theater*, for this reason the first is overshadowed by the second. Until 2012 the building was overwhelmed by a lush vegetation that made impossible the survey work. Tourist can't visit this area because of safety problems so that only few people know its existence. Its geometrical aspects and its dimensions have never been studied before now. The following work deals with the first results of a survey work made through the scan laser *Riegl – VZ400*. This instrument and its software are able to process also those points of the cloud-points partially hidden by vegetation.

1. Historical news and survey^(a)

«Thinking that here it's represented only the lower part of the building, that is the most narrow part in this kind of building, it's possible to imagine how much large, high, stately and impressive it had to be. [...] There is not risk to make a mistake thinking to it as one of the most extraordinary building never built». This is what Jean Houel wrote in his diary "Voyage a Syracuse".

The northern part of the cavea is dug in the rock of Temenite hill, while the southern part is held up by walls.

The axes of the arena measure 69.30 and 39.20 meters, while those of the entire plant measure 140 and 119 m about. Nowadays it is still possible to see two vaulted ambulatories above the cavea, while in the superior part there are the ambulatories that allow to enter in the terraces of the various parts of the cavea.

In the cavea there are two fences that divide it in three wedges. The two main entrances were along the extremity of the longer axis, but there are also other secondary ones. In the middle of the cavea, nowadays, it is still possible to see a big rectangular basin with a pillar in the middle, linked to an aqueduct. Aldo Neppi Modona¹, in one of his works, writes that the basin was not used for water games, neither for naumachia.

Fig 1: The survey work: the first scan position

The podium wall was crowned with marble, with the inscriptions of the people to which the seats were reserved, and they date from the re-building of the 3rd century b.C. The chronology of the building is debated, and this is believed to be realized after the deduction of Augustan colony, in the last decades of the 1st century a.C. The analyzing of the used building technique confirms this hypothesis. It must also be remembered that the amphitheatre has been re-discovered in the 1839 by the duke of Serradifalco². Since the amphitheater is in the *Neapolis* of Syracuse, near to the famous *Greek Theater*, it is overshadowed by this, and until 2012 it was overwhelmed by a lush vegetation that made impossible the survey work. Tourists can't visit this area because of safety problems so that only few people know its existence. Its geometrical aspects and its dimensions have never been studied before now.

Below they are reported the first results of a survey work, not yet finished, made by a team, through the scan laser *Riegl – VZ400*. The software used for this work, is able to process also those points of the cloud-points partially hidden by vegetation.

The survey was organized in twenty-seven scan positions, for twenty-nine scans. Eleven of them were in the cavea, nine from the superior part of the amphitheatre to the center, and the other nine along the ambulatories.

During the survey, when it was possible, the used resolution points was of 1 cm for 1 cm about.

The building features implied, both in the terraces and in the superior part, the presence of noise that made heavier the file dimensions. The following steps of working and processing of data, made possible to investigate some aspects: the union of points, the building geometry, the processing of triangular surfaces and mesh.

2. Geometry^(a)

Firstly the two axes of symmetry were drawn. The major axis was drawn manually, the minor from the middle point of the first, from half, and symmetrically, for the other half, and then it was verified the relationship with the real track. Same adjustments of precision were done, consisting of a micro-rotation of the major axis, the orthogonality of the minor one, the length of the axes.

Subsequently the ellipse was drawn through the two axes. The first results showed a difference from the real track of the plant. This difference is the opportunity to make some considerations.

Fig 2: The deviation in plant between the real track, the ellipse and the arch from four centers.

The ellipse profile, faithful to the minor and the major axis, diverges around 7 degrees from the major axis and it reaches the maximum offset value of 56 cm around 24 degrees, then the track of the curve coincide with this of the plane at 70 degrees. To verify if the curve realized in the yard was due to an approximation, it was interpolated the semi-curve in the plane, having the major axis as extremes, then it was mirrored in relation to the same axis, and it was verified that the real profile mirrored coincides with the other after part of the plant. The same operation was repeated using the other axis. Also in this case the curve coincides with the profile of the plant.

So, it is possible to affirm that a double symmetry exists. It is possible to hypothesize that the plant was born from a defined geometrical operation. Now the question is what is this “geometrical will”, and how much an offset of 56 cm can be accepted, that is considered a yard approximation?

Also the oval geometry was tried. Several constructions of the polycentric from four centers were tried, with their geometric variants, but however there is an offset in the plant. This result is in line with the studies on the geometry of amphitheatres, published by other researchers³. The polycentric from eight centers was tried too. It approximates better the real track of the plant but also in this case there is a little difference from the two curves⁴. The studies are in progress and new solution are tried to find.

3. Union of the point cloud^(b)

To work on the point clouds, it was necessary to merge them into a single file *polydata* on which to perform the following editing operations.

Before that, a texture mapping and a recording have been done on the point cloud; the first to assign a color to each point; the second to relate all the clouds to the same reference system.

The texture mapping is executed automatically by the software that applies a color to each point using photographic images taken during the survey. The correspondence between points and their real colors is not always perfect because of the complexity of the object. The greatest error is referred, above all, to the points that are furthest from the laser. Moreover photographs reproduce not only the object but also shadows that change according to the position of the sun in the moment in which dates are recorded. For this reason when two point cloud, surveyed in two different moment of the day, are juxtaposed, the final object has not the same chromatic homogeneity that features the single scans.

To align all the scan, that is to refer them to the same reference system, the software proposes two different solutions that have been used together in order to obtain the best result: the *course registration* and the *multi station adjustment*.

Firstly the *course registration* was applied to two scans at a time. To make that it need at least four pair of “corresponding points”, that is easy to identify in each point cloud. The identification of these pairs is facilitated if point clouds are very dense. However density changes in relation both to the distance, and to the angle of inclination between the object and the laser.

For each alignment the software gives information about the maximum error obtained. The results have been collected and recorded.

Fig. 3: View of the cave of roman amphitheatre. It is possible to see the chromatic overlap of those point that are both in two different point cloud, and the shadow of the area in which the laser was during the survey.

<i>course registration on 29 scans of roman amphitheatre</i>	minimum error (m)	medium error (m)	maximum error (m)
	0.0067	0.0320	0.1011

Referring to all the twenty-nine scans, the medium error obtained with this process is 32,0 mm. This is a great value, considering the alignment quality, the investigated object nature, and its state of preservation when it was surveyed.

This value, however, is not meaningful of the whole project because, analyzing carefully the results, it is possible to find some values quite far from the medium one. As regard the scans on the cave and the terraces the medium error is 33.9 mm, while about to the scans on the ambulatories, it is 25.3 mm. The highest medium error is 40.1 mm and it refers to the scans on the superior part of the ambulatories.

<i>course registration on 11 external scans</i>	minimum error (m)	medium error (m)	maximum error (m)
	0.0130	0.0339	0.0547

<i>course registration on 5 of 18 interior scans</i>	minimum error (m)	medium error (m)	maximum error (m)
	0.0067	0.0253	0.0316

<i>course registration on 9 of 18</i>	minimum error (m)	medium error (m)	maximum error (m)
---------------------------------------	-------------------	------------------	-------------------

interior scans			
	0.0092	0.0289	0.0559

<i>course registration</i> on 9 of 18 scans on the superior part of the ambulatories	minimum error (m)	medium error (m)	maximum error (m)
	0.0124	0.0401	0.1011

The individuation of “corresponding points”, in archeological field, is very hard, and it is accurate and reliable only in relation to small spaces and pure geometries. Moreover the error is calculated referring to all points of the point cloud but a good portion of these is representative of the vegetation that is in the site.

The *multi station adjustment* is based on the individuation, by the software, of plane patch in the point cloud. Each patch is identified by a point that represents the center of gravity, and by a vector normal to the plane that represents its orientation in the space. While the search of “corresponding points”, which the *course registration* is based on, requires the active and selective participation of the researcher, the good result of this method is based on the correct selection of setting parameters.

Of course the nature of the investigated objects still affects the good result of alignment, but in an indirect way.

The *multi station adjustment* has been applied: to two scans at a time, after each *course registration*, to improve the alignment; to groups of scans; to the final project with all the scans.

Also in this case the errors have been recorded in relation to the setting parameters values. The medium error is only 5.1 mm but, like to the *course registration*, it is not meaningful of the whole project.

medium error (m) obtained with <i>course registration</i> on 28 scans	medium error (m) obtained with <i>multistation adjustment</i>	number of attempt	error reduction (%)
0.0320	0.0051	6	84.1%

Fig. 4: View of all scans of the roman amphitheatre

Both *course registration* and *multi station adjustment*, are two iterative methods. For this reason the operation can be replayed more times until a satisfactory result is obtained, and it is always possible to improve it anytime.

Only who gives input can decide if the quality of the operation is good or not. This choice depends on the investigated object. In this case an error of 5 mm is allowable considering that the Roman amphitheatre is a large and impervious archeological site.

After relating all scans to the same reference system, all *polydata* have been linked and a new one has been created on which performing the following operation of cleaning, thinning and meshing.

4. Mesh process and triangulation^(c)

The software used has two modes of triangulation: *Polar Triangulation* and *Plane Triangulation*. The first is recommended for closed environments, such as tunnels, because it considers the mesh consists of triangles directed to an origin defined, such as for example the position in space of a scan position. The second type uses as reference a plane which is that of the current UCS view, therefore aims to playback of land, and from more than one mesh (defined by the software 2.5D mesh) can lead to a 3D processing by different point of view. It was necessary to carry out the preliminary operations for the purpose of obtaining good triangulations. A new *polydata* was created using the filter *Octree*, in order to work with point clouds better distributed. Then it was necessary to vacate the point clouds created by the presence of trees and other disturbances. The *Terrain Filter*, designed to extrapolate from the point cloud vegetation and anomalous points, proved to be a very valuable tool to perform a more detailed analysis on the data. Several attempts were made even adopting the *polydata* filter *Deviation Gate*, but it has not managed to achieve appreciable improvements in the elimination of unnecessary points as the scene was much disturbed. For the triangulation of the entire work has made use of both types of algorithm for mesh provided, to exploit the full potential of the software.

Fig 5: Identification of bushes through the use of *Terrain Filter*

The first method was adopted for the areas of the arena and bleachers. Preliminarily it was generated a *polydata* combination of the sun scans the exterior, i.e. the scan position 001, 002, 003, 004-1, 004-2, 004-3, 006, 007, 026, 027, 028, with filter *Octree*, by setting *Increment* the value equal to 0.03 and asking to cancel the algorithm points closer than 5% of the increase: the result was a cloud of points very well defined and fairly dense, where it was lost as little information as possible. At a later stage, the *polydata* was cleaned with the help of either *Terrain Filter* or manual selection mode. From this *polydata* ready for the process of triangulation, copies were made for triangulation respectively of arena, seats in the south and in the north, in order to act on data file much lighter. For ease of working with views, triangulation was carried processing portions *polydata*, or by selecting the area to be treated and isolating it by clicking on *Show only selected area* in the menu bar. With a small set of points it was easier to carry out a more thorough cleaning of the through the use of *Terrain Filter* than the manual procedure, that is, trying to eliminate anomalous points selection by observing it from different views. Finally, the affected area was carried out by clicking *Plane Triangulation* in the menu bar. A frequent problem was to gather adjacent mesh separated by a stretch not triangulated, since the triangulations came from different views of the UCS. Consequently to saturate these spaces, the triangulation between different areas adjacent was broken up through *Remove Selected Triangles*, and then as a solution of continuity a new mesh was generated selecting the meshes with the points in the transition area. The result from the first tests with the *Plane Triangulation* was interesting:

- *Max triangle edgelen⁵ [m]*: Good results were obtained by setting values such as 0.3, 0.5 and the value 1 in the worst case, when there were large gaps to internal of the mesh. It's a parameter that has been used with caution, because the highest values allow for closing the large gaps in the cloud of points gave distorted result, relevant to areas not plotted perfectly and which hadn't precise information;

- *Max triangle tilt angle*⁶ [deg]: High values were used for this parameter, such as 150° and 160°, with which adopting a good view on to reaction from triangular, it was possible to create a mesh complete to a first attempt already, without necessarily having to change too many times the point of view for the purpose of obtaining the 3D reconstruction;
- *Min triangle angle*⁷ [deg]: Lowering in the various attempts this value, meshes always complete were obtained, consequently in the final attempts this value was usually set equal to 0.00°. In some cases, such as incomplete areas or with severe deficiencies of points, the value 5.00° was used, to avoid connecting points with other anomalous points;
- *Crop triangles outside polylines* didn't resulted very useful for our purposes because of the particular construction of the point clouds, and even with the automatic elimination of the triangles that were not enclosed by a polyline meshes with serious deficiencies were often obtained.

Fig 6: Generating a mesh of terraces by *Plane Triangulation*

The second method was used for triangulation of ambulatory and bath. For the reconstruction of the latter area a good reconstruction was obtained with the scans relating to positions 001 and 007, while the scans performed by the positions ranging from 008 to 016 were used for the ambulatories and the connecting areas with the external. Scans were generated with the respective polydata filter *Octree* and *Increment* values set at 0.01. Each polydata was released by vegetation and anomalous points using both manual selection and *Terrain Filter*. Triangulations were created using the data filter *Polar Triangulation*, imposing the following values:

- *Max. triangle edgelenlength* [m] = 1
- *Max. triangle tilt angle* [deg] = 5
- *Min triangle angle* [deg] = 25
- *Depth threshold* = 0.050
- *Depth factor* = 8.000
- *Center point* = the scan position related to scanning of origin.

The built meshes were cut profits by eliminating parts and eventually merged into a union created polydata with filter *All Data*. Completed the process of triangulation, it needs to adopt the *Smooth & Decimate* functions. The first algorithm provides for the levelling of the surfaces via the data optimization point, while the second works on the amount of triangles to maintain. The obtained tests showed the usefulness of these tools, even taking into account the necessary measures: in the first phase *Smooth* has been used simply by setting the mode of *Levelling Windowed sinc smoothing* parameters, *Iterations* 20, *0.086 Pass band* and *Feature angle 30°*; in a second stage it was possible to make the mesh more homogeneous using *Decimate* with *Target Reduction 0.1*, *0.5 Absolute error*, *Feature Angle 30°*. Much of the information contained in the original colour scans was lost, because of the necessary steps to lighten the filter *Octree*, levelling and especially decimation, so undistorted

images were created using the provided option and then texturing meshes. Now what looked like a confused cloud of points in space took a look close to real.

Fig 7: Result of the final mesh processed with the instrument *Smooth & Decimate*

The interlacing arches system in Salerno and Amalfi Coast

Barbara MESSINA

Department of Civil Engineering, University of Salerno, Fisciano (SA), Italy
bmessina@unisa.it

Abstract

In historic architectural panorama of the Mediterranean area, especially on the Amalfi Coast – also including in it Salerno – there are some built episodes of special interest: they are examples in which the recurring motif of interlacing arches draws flat or convex surfaces, with a typically taste of Arab-Norman matrix that, in the Middle Ages, strongly characterizes the architectural language of this territory.

Conceived, in most cases, to respond to some needs of structural nature, the twisted arches take on, over time, obvious aesthetic connotations, by virtue of an intrinsically geometrical coherence, capable of synthesizing, in a single physical model, reason and feeling. And so, in a gradual process of defining the architectural configuration, the pure geometric composition is transformed from abstract matrix in symbolic form.

So, starting from a reconnaissance of the Amalfitan structures in which the system of interlaced arches is used, the paper is intended to propose a geometrical and spatial interpretation to correctly understand the logic behind the conception of those forms, in which is expressed an architectural lexicon typical of the Amalfi Coast. For this purpose, using the digital modeling, and in general the graphical representation, it tries to decode the generative process of the interlaced arches pattern, thus revealing its true essence.

Keywords: Intertwined arches, geometric patterns, graphic representation, Islamic art

1. Knowledge and enhancement: architectural forms and signs in the Amalfi Coast

There are some places that leave indelible traces in memory, by imposing strongly the self-image. Places whose identity becomes a witness to a collective feeling, to the point that we identify in them, finding in their characteristic forms the familiarity of a something that has always belonged us. This happens whenever the space, be it natural or anthropic, it has a distinctive character, recognizable in its every concrete phenomenon.

This is what Norberg-Schulz summarizes into *Genius Loci*, when he states that "... the place is obviously an integral part of the existence ... [is] something more than an abstract location ... [is] a set made of concrete things with their material substance, shape, texture and color. All these things, together, define an environmental nature, which is the essence of the place" [1]. Recognize the signs and forms that contribute to define the atmosphere of a certain context, is the starting point to begin a cognitive process, aimed at awareness in the community towards an historical-artistic heritage, often overlooked. In fact, only when who live in daily contact with a variety of ordinary architectural manifestations becomes aware, it is possible to arrive at the valorisation of these shared cultural resources.

With reference to this complex issue, the present paper – that summarizes the outcomes of a wider research directed to the built heritage of Salerno and Amalfi Coast [2] – draws attention to a particularly significant territory, because rich in often unexplored episodes, in respect of which we should to start a rigorous process of cognitive appropriation.

Also, it is a reality that can explain the sense of 'represent to known': it is a unique environment in the world, characterized by peculiar aspects and signs, sometimes recurring in other cases distinctive, that connote all the built space, contributing together to define the identity of this landscape. A reality to be understood as a cultural resource to be protected and, as such, to be promoted in terms of knowledge, from the point of view of form, of geometry and of configuration. Only by providing the means to decode

the typical features of coastal architecture, it is possible to highlight this heritage, in a gradual process of awareness raising and appropriation by a community that, frequently, coexists with those testimonies without grasping the deep meaning. So, through specific graphical investigations directed to typical signs – and as such symbolic –, the study try to identify the compositive rules, and detect, therefore, the geometric and structural genesis as the pure essence, invariant and recognizable beyond the complexity of forms, with the aim of arriving at a their correct interpretation.

Retrace the logic underlying a stylistic language, today indisputably recognized as specific of investigated area, requires some preliminary considerations, necessary to identify deep and diversified cultural roots on which the coastal artistic repertoire has drawn. Just the extraordinary synthesis of Eastern and Western influences, appears as a distinctive character of the Coast's architecture, that Arnaldo Venditti not trivially defines "Norman" or "Tyrrhenian", but rather of "Arab-Byzantine style" [3]. Therefore, this syncretism is manifested in the Amalfi Coast's architecture, which properly reinterprets archetypes derived from other civilizations, even in the light of technical knowledge, and of local building practices. Leaving out a more detailed analysis of the numerous main characteristics of coastal architecture – as this is beyond the scope of this paper – is meant, instead, to draw attention to some of them, which, for elegance and evocative power, impose themselves to the observer, with greater force. This refers in particular to a number of architectural and structural elements which end up identifying with a completely original way to build, although the obvious reference to forms inspired by other civilizations. This is the case, for example, the so-called intertwined arches system, frequently used both on flat surfaces and convex, in which one sees a clear Islamic mark. Then, the chase each other's of the arches, often pointed arches, draws dynamic two-dimensional and three-dimensional wall surfaces, which reveal the propensity to the geometric shape, own of the Arab world. It is, however, a pattern that, in response to an essentially unchanged stylistic language, is both used for bearing elements as for simple decorations.

The geometry, in all its declinations, also connotes the purely ornamental repertoire of the aniconic coastal art, in general: composing elementary forms, in itself simple, we come to elaborated patterns, very strict but with strong aesthetic values. With reference to the construction techniques and to materials used for these elements, however, it appears a certain interaction of influences, derived from the Byzantine and Islamic culture. On the one hand, the use of *opus sectile* or of mosaic decoration is a clear reference to the Byzantine world, as well as the alternation of different left exposed construction materials – usually yellow and gray tuff – to chromatically embellish architectural or ornamental apparatuses. Other hand, the use of ceramics by bright and vibrant colors, that emphasize the most relevant parts for aesthetic and formal meaning – or even fully cover them – often combined with plastered and white painted wall surfaces, represents the echo of a building tradition derived from the Arab world.

In summary, the widespread and mixed use of all the described elements – both in civil and religious buildings – properly reinterpreted in the light of the skills of local workers, and based on the materials available on site, makes the built heritage of Amalfi Coast absolutely unique in the world, and lends it a recognizability that goes beyond time and space.

Among the elements that, with greater force, lay down themselves in the collective imagination as archetypes of coastal architecture, therefore, the system of interlaced arches [4] can be considered the most evocative of a built heritage, in which pure shape and symbolic meanings come together in elegant architectural compositions. In an attempt to unravel the symbolism inherent in this constructive system, of Islamic origin, and to understand the reasons which make it one of the hallmarks of coastal architecture, it is important to pay attention to the rules that govern its generative process, starting from the role of geometry, as sovereign tool that creates order.

Fig. 1: On the left: the portico of Salerno's cathedral. In the middle: a wall of the villa Rufolo's vestibule, in Ravello. On the right: an architectural element of Salerno's cathedral with mosaic decoration

2. Symbolic and ornamental values of the geometry

If, as noted, one of the most significant sources of inspiration for art and architecture of Amalfi Coast consists of the underlying Islamic culture principles, it seems appropriate, albeit briefly, to dwell on the ideological grounds inducing Islam to operate certain stylistic choices. Of course, what marks this civilization is the role played by religion, which far from being a doctrine of faith linked to the free will of the individual, rather assumes a totalizing meaning. For the Muslim faithful, the religion is the very life essence, and therefore invests the spiritual but also earthly sphere; Islam dictates the rules related to ritual practices, and at the same time establishes a set of standards of conduct that daily should guide the faithful. In this sense it is not only a religion, with reference to the technical meaning of the term, but is rather conceived as an orthopraxis, or as a set of precepts that govern the Faithful's actions, so that they are judged as correct.

Leaving aside the more specific theological considerations, it is useful to recognize that the rise of Islamic civilization, in the name of a common religion, imposes a formal collective language which, going beyond any territorial limit, can translate, into clearly recognizable signs, a universal ideological and artistic feel. So, what makes the Islamic civilization very different from the others is the role played by religion, according to which can be precisely interpreted some of the innovative elements introduced in the field of art and architecture.

From the small object to the monumental building, each product of artistic creation shows, in a clear manner, the relationship between man and God. In Islam, however, the man is not the measure of all things; his being above many creatures depends, in fact, from the benevolence of God, rather than from on its merits. Hence the attitude of ascetic contemplation, the feeling of adoration and submission to God, that involves the architecture as well as the decoration [5].

Even the iconic baggage, to which the Islamic decoration relates, is in some way influenced by religious dictates: although in the Koran lacking specific prohibitions, Islamic art uses an aniconic language, tending to an abstraction of the forms that responds the need to proclaim the superiority of God's creation than that produced by the mind and by the hand of man. In this sense we explain some decorative choices, such as arabesque, intended as natural forms' stylization, or geometric textures repeated ad infinitum, explanation of the atomistic theories, or the use of a glitzy figuration, earthly compensation of ephemeral and transitory life, or the sense of horror vacui that pushes to cover all surface without leaving any space, as if the interrupted matter betrays the doubt of our existence. All reasons that become, over the centuries, the distinctive features of that art.

Therefore, beyond each technical specificity and every stylistic variation linked to local traditions, in the field of decoration three major figurative themes stand out, all aniconic, as already mentioned: a first type related to epigraphy, a second to vegetable world forms and a third inspired by the geometry. In particular, the geometric pattern originates from earlier artistic traditions. In this respect, it should be noted as every religion, belief or philosophy has identified an important figurative source in the geometry, by virtue of metaphorical meaning often associated with the form. Thus, for example, almost always the circle symbolizes the sun, but also heaven, spirituality and soul's immortality or – if in half divided – represents the struggle between good and evil. The square represents the earth, the solidity, the security, but it is also a salvation symbol, and the rhombus indicates the man. From the square, through the golden ratio's proportions, we get the golden rectangle, expressing a deep sense of balance: the rectangle's golden section was often used by the Egyptians, as a module in the temple's architecture or in buildings for burial, such as the *mastaba* and, especially, the pyramid. And yet, the equilateral triangle symbolizes stability, harmony of life. At pentalfa (a five-pointed star with central pentagon) Pythagoras already attributed the meaning of the harmony and brotherhood symbol, recognizing the central pentagon as the heart of the universal order. The hexagon evokes the heavenly army that, as shield, wards off evil spirits. Even the octagon is of remarkable allegorical interest, especially if it considers that for Neo-Platonics and Neo-Pythagoreans, whose doctrines also influenced the Islamic culture, the world's origin would be represented by a circle generated by two overlapping squares, of which one rotated of 45° relative to each other. The originated figure is just an octagon, one of the main esoteric symbols of Christian tradition and Islamic art: it embodies the concept of spiritual regeneration, being precisely intermediate between the square and the circle. As the latter two figures – respectively symbolizing the world and the sky – so also the octagon thus possesses an extraordinary evocative value, representing the world interposed between the circumference of the heaven and the square mass of the earth, the stopping point of the event.

While, therefore, widely used before of Islamic artistic apogee, thanks to this civilization the geometry assumes an even more evident expressive force. If in the past, in fact, it had been relegated to a marginal role and was mainly used in friezes and cornices, with the rise of Islam it acquires a more complex figuration, being present both in architectural decorations and in the structural elements. The sophistication of these elements consists in the grace with which certain motifs in it simple, such as lines and circles, are combined with each other, thus avoiding the rigidity of a purely abstract composition, and loading down, at the same time, with spiritual meanings. The artists reach this result skillfully by having recourse the symmetry, which is not only used as a rigid mirror image, but also as

Fig. 2: Geometric patterns in the plan and in the space. On the left: detail of a decoration of Salerno's cathedral. On the right: a dome of Villa Rufolo in Ravello

an indefinite multiplication of modular units, able to occupy all available space, in a sort of 'global symmetry', or more often as a symmetry with respect to a variable number of axes, around which the decorative motifs can freely develop. In some cases, as noted by Oleg Grabar, the axes tend to be a form of visual imagination; in fact do not exist in itself, but only thanks to the rest of the design [6].

Regardless of the possible two-dimensional or three-dimensional applications, the theoretical principle underlying the formation of geometric ornamental effects, which unmistakable made this artistic language, is what could be called the interlaced design aesthetics. One way to conceive the architectural or decorative element that, based on support's subdivision according to precise mathematical laws, draws the surfaces overlapping lines and shapes, with a similar logic of interweaving of tissue's weft. The visual impression of extreme complexity, then, reflects an extraordinary execution's simplicity, essentially consisting of three phases: identification of a starting path, definition of a grid, twine of forms. From the flat surface to the space is a short step: it is enough to consider the thus obtained drawings as a plane projection, by a point at infinitive orthogonal to this, and give them volume, with the third dimension, to get the spatial interwoven.

The origin of this system is therefore a specific configurative criterion that, in response to the mathematical-geometrical needs, also acquires a symbolic value as well as aesthetic; the figures generated by the intertwining of simple lines, repeated ad infinitum on surfaces virtually devoid of a center and borders, according to Massignon [7], seem to respond to the atomism's philosophical view, under which the world can be conceived as an unstable grouping of atoms, individual particles from which thicken depends the definition of forms. Exceeded then the idea of a static universe, the line's dynamism and fragmentation resulting from the interweaving of geometric figures, compel the viewer to mentally follow the drawing development, beyond the physical limits of the surface. It may be that the surface is annulled, as it were, by the explosive emergence of the ornament that prevails on this.

3. The weft's drawing on the Amalfi Coast: from the ornament to architecture

If the decoration for Islam assumes a prominent role, it is mainly due to its constant interaction with the architectural structure; far from being as simple decorative element – by assigning to this term a meaning related to the pure exteriority – the decoration, in fact, actively contributes in the development of architectural forms. This aspect, which come to be a hallmark of the Muslim artistic vocabulary, it is especially evident in three-dimensional structures, such as arches and vaults, in which technical and formal aspects come together inseparably.

The idea of designing these architectural structural elements such as ornamental parts had great success in the Arab world, in general, but also spread in Christian countries of the Mediterranean area, that had come in contact with Islamic culture thanks to frequent commercial traffics. Salerno and the Amalfi Coast were not exempt from this artistic exchange, as well as commercial, and while not directly undergoing Moors' dominion, they adopted typical signs and features of the Islamic art, still recognizable in many individual elements, however, almost always incorporated into more complex structures.

As already noted, particularly conspicuous is, within the investigated architectural repertoire, the presence of the interlaced arches system which, despite the great diversity of composition – in fact the arches have various profiles and are used on surfaces from different geometry – is as a *fil rouge* that links many architectural episodes of the Amalfi Coast [2].

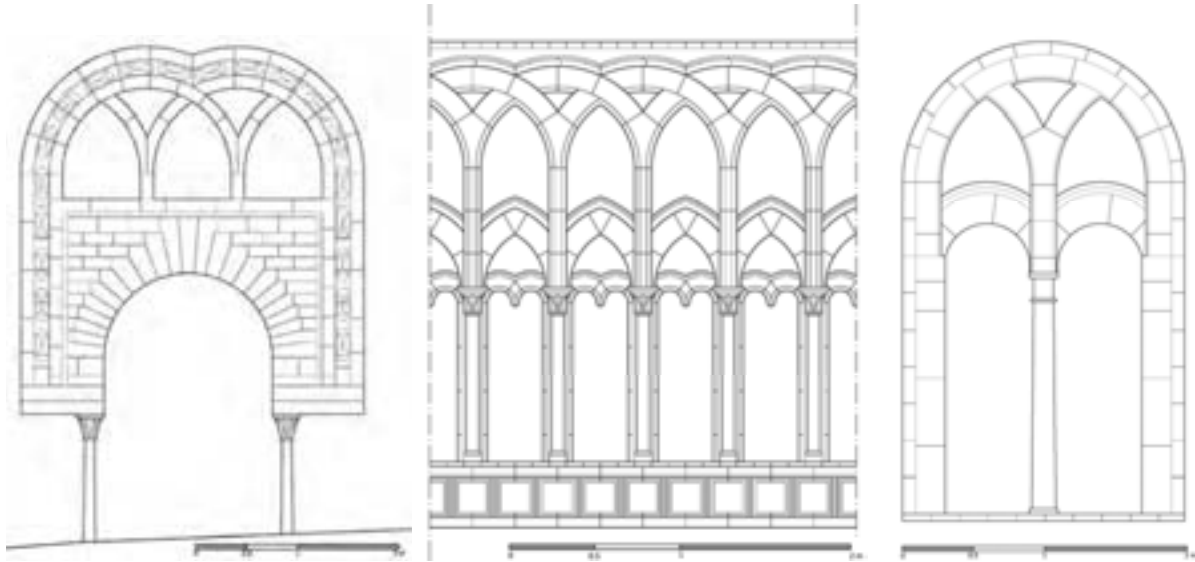

Fig. 3: Salerno, Fruscione palace. On the left: the main door. In the middle: the order of polifore. On the right: a mullioned window

With reference to the use of such a system on flat wall surfaces, interesting is the Fruscione palace's example, a building located in the heart of the Salerno historic center. The palace, built in the middle of the thirteenth century, it is surprising for the walls' formal richness; although transformed over centuries, to the point as to look, today, very different from the original, it shows clear traces of the Islamic influence, thanks to the use of that system. Firstly, the original portal of the palace, located in vicolo dei Barbuti, proposes the interlaced arches solution in the drawing of decorative frame that closes, at the top, the opening. Here a round arch, whose light corresponds to $\frac{2}{3}$ of the whole, is symmetrically repeated at both ends of the frame; consequently, the two elements overlap in the central axis of the opening. The arches are further shifted, to right and left respectively, at a distance equal to $\frac{1}{3}$ of the span, becoming generative matrices of a rhythmic sequence, virtually repeatable.

Equally interesting are the mullioned windows, now walled up, adorning both the prospectus in via Adelberga, is the one in via Santa Maria dei Barbuti. The opening's main structure is closed by a round arch that rests on gray tuff piers; the translation of this arch, in steps of $\frac{1}{2}$ of the span, generates the main pattern's twisted weave. Added to this is a secondary arches system, again semi-circular, delimiting each obtained partition walls. Even more interesting is, at the third level, an order of polifore, forming a continuous arcade of interlaced arches, today closed and fragmented due to the presence of subsequently opened balconies. The arcade proposes the solution of the round arch, supported by two underlying columns, which the arch is connected by vertical struts. The arches sequence, obtained from such basic element, is then moved so that the second theory's columns of arches are disposed in correspondence with the key of the first. The result is a superposition of elements that, at the point where these overlap, generates an ogival profile, further highlighted from a second register of minor arches, directly put on the columns' capitals.

An interesting variation on the above described theme is obtained using an arc from the ogival profile, which elementary module that generates the overall design. Emblematic, because among the best preserved examples at least in terms of architectural integrity, is the Paradise's Cloister, part of Amalfi's cathedral, built between 1266 and 1268 as a burial place of famous citizens of the city. The cloister, rectangular in plan, has a peristyle around a central opened courtyard. The space is marked by slender and elegant coupled columns – four in the corners – that support a mix of pointed arches, taste very oriental. Motif, the latter, that draws the wall surfaces both outside of the courtyard, as within the four vaulted arcades that surround it.

The rhythm of arches that follow one another along the wall surface is, in this case, far faster than in the already treated examples, and the ogival profile suggests a greater sense mystical, ascensional. Everything in the composition betrays the meaning of a space whose function is itself full of symbolic implications. This seems to be confirmed by graphical analysis that, tracing the genesis of this configurative system – however, reduced to pure geometric form – shows how, actually, the elementary unit at the base of the overall pattern is still a round arch. The span of the latter, the width of which exactly corresponds to the diameter of the circle from which originates the entire graphics array, is then divided into seven parts. This choice does not seem random when you consider that the number 7 has a strong symbolic value: six are, in fact, the days of Creation, the seventh is the break (which in the Paradise's cloister is eternal rest). Defined the basic layout, the simple shift of original form, on excluding the key brick portion, creates the complex interweaving of the arches, white as well as the walls, with respect to which emerge thanks to a slight overhang.

Fig. 4: Amalfi, Paradise's cloister. On the left: the geometrical representation of the drawing's matrix. On the right: the interlaced arches system

The lobed arch is instead the root of several other examples of coastal structures referable to the being investigated system. Typical of the Islamic architecture, and very widespread in Andalusia, the lobed arch, which fully affirms its aesthetic value with the Moors, seems to have been conceived by Oriental civilization. There is much discussion on the origin of a so complex and unusual profile, although the most accepted theory seems to be that proposed by Torres Balbás [8] and Georges Marçais [9]; according to them, this form may be generated by the intersection between the plane walls and the sculptural shells, often used in Roman and Byzantine times to cover the niches, and later taken up by Muslim artists. In the course of time the decorators, driven by the need to geometrize the designed shapes, would finally simplified the arch's drawing, subsequently evolved in numerous variants. Precisely because of their greater formal richness, these arches, twisted as a result of a translational motion, even more contribute to embellish the architecture in which they are used, sometimes as a purely ornamental decorative design, in other cases becoming real structure.

A mainly ornamental function is found in lobed arches system of the Villa Rufolo's courtyard in Ravello. Despite the many changes made in later centuries, yet it expresses that extraordinary configurative refinement born from the synthesis of different cultures that here have met. The courtyard, almost square in plan, is the focus of domestic life: in fact, overlook on it all environments that make up the real house, organized on three levels according to a schema originally with four blocks. In the upper of the east lodge, still completely preserved, a gray tuff arch from the three-lobed profile is the basic module of the system; this shape is shifted three times, in a steady and cadenced rhythm, thus defining a tangle of lines, sinuous like a delicate lace. An effect, this, made even more intense thanks to the ornamental treatment of the arch's profile, decorated with sculptural elements that evoke the drawing of leaves and natural forms.

In other examples instead, as in the church of S. Salvatore de Birecto in Atrani, the interlaced arches system defines an architectural space. In particular, we are referring to an open loggia that separates the church's interior from a space, probably an endonarthex, whose original features have been brought to light by recent restoration work [10]. This space, transverse to the axis of the church's three naves, is covered by three cross vaults, and is enhanced by the presence of what was, once, a perforated wall of Islamic reminiscence, now unfortunately almost completely walled. Its drawing is very similar to that of the Villa Rufolo's courtyard wall; in fact, a mixtilinear frame again draws a three-lobed arch, whose profile is slightly simpler than the Ravello's example. As well as simplified is the translational symmetry that marks the cyclic rigid motion described by the elementary module to obtain the interweaving of forms. In this case, the arch is moved of $\frac{1}{2}$ of the span, thus tracing a drawing less dense, but just as elegant.

4. From the plan to the third dimension: interlaced arches in space

Therefore, the geometry, if wisely used, can charge a space of profound significance that goes far beyond immediately perceived shape, especially when overcomes the limits of rigid patterns to follow, and rather becomes a broader compositional tool. This is even more evident when the interweaving of the flat shapes conquers the third dimension, often exploiting the figurative values implied in spatial compositions, generated by the elementary module for rotational symmetry around an axis.

A good many examples, in Salerno and in the Amalfi Coast, show a drawing originated from the combination of simple Euclidean geometries, that evolve from pure two-dimensionality into intricate three-dimensional structures. Despite the interpretative option exercised on the primitive drawing, the final appearance of the so obtained structures clearly displays the basic geometric principles, which constitute its strengths.

In fact, the use of interlaced arches in three-dimensional systems has its roots in a cultural background of oriental matrix that had a lot of luck in the Mediterranean basin in general, but especially in Spain; here this constructive system reached sublime levels, as evidenced by the domes of the Islamic mosque in Cordova, likely prototype of a new way of conceiving the vaulted structures [11]. The surface enclosing the space is interpreted according to the logic of the diagonal arches, which expresses the Islamic aesthetics in favor of geometric shapes, rather than of the modeling of powerful physical volumes. So here are ribbed domes supported by arches plans that, generated by the composition of two-dimensional elementary matrices, cross the space intertwined as a kind of backbone. The result is an organism in which the ribs, designed to meet the structural requirements, reveal a preponderant aesthetic value, being rather "... the three-dimensional development of an abstract bidimensional figure, whose geometric reality comes before any physical implementation"[5].

Much has been discussed about the originality of this system: examples similar to those Andalusians have been identified in the East, particularly in Mesopotamia, as well as in some European countries and in the Maghreb, yet no one is earlier than the structures built in Cordoba in the middle of the tenth century. Among the closest to the Spanish ones, for shape and material, were frequently referred to some Armenian vaults that reproduce the system of interlaced stone arches, to draw wonderful spatial geometries. Some vaulted ceilings, yet inspired at the same constructive system, are also found in Iran, where however brick's arches are preferably arranged in a radial direction. In this case, unlike what happens in the domes in Spain, the arches have, however, a maintaining function rather than structural.

While remaining well away from the complexity found in the above described ribbed vaulting, the examples in Salerno and the Amalfi Coast appear referable to the same ordering principles, clearly showing an Arabic taste. However, what distinguishes the Amalfi's repertoire, above all, is the prevalence of ornamental component with respect to the structural function, also found in some cases. The interlaced arches are in fact the key element of the decoration of a series of architectural structures, generally bell-towers of buildings scattered throughout the area, which even in the variety of materials and colors, all show a similar geometric logic: the generation of the final configuration from the rotation of a single arc around a vertical axis. In this regard, we further highlight a significant difference, in terms of geometry, than the elements that define the backbone of the Andalusian vaults. While in Cordoba, and in examples of it inspired, the ribs cross the space, describing curves from the variable profile, but always plan because released by any other architectural element unless the orientation of the vertical plane which they belong, in Salerno's examples the arches must adapt to the curvature of the surface on which the ornamental matrix is developed. That, in a graphical reading process tending to abstraction of forms, is equivalent to the intersection between cylinders, of which, typically, the first – comparable to the structure's main body – has a vertical axis, and the second –

Fig. 6: On the left: a schematic representation of a ribbed vault of Cordova. On the right: a skew curve generated by intersection of cylinders

corresponding to the arch's geometry – has an horizontal axis. Consequently, the elementary module, generator of the overall drawing, is transformed from a flat curve to a skew curve, conferring greater sinuosity to entire structure.

Among the most important examples of the mentioned repertoire is the bell tower of Salerno cathedral, built, according to documentary sources, between 1137 and 1152. Resting on a strong cubic base with a 10 meters side – of which two-thirds form the underground foundation of the entire structure – the bell tower is developed in a total height of 50 meters, by superimposing five levels.

The layers are separated by cornices, and each one has, on its four faces, a mullioned window with central column. The tower is topped by a cylindrical masonry belfry, on which it is developed the interlaced arches' motif, the first example of this kind in Campania.

The drawing's basic module is, in this case, a round arch with alternating gray tuff blocks and bricks, which later became typical of the Amalfi Coast's language. Since this element has to go along the cylindrical structure, it is transformed from a flat curve – the theoretical arch profile from which we start – to a skew curve, which is then the result of the actual intersection between the two surfaces. The thus obtained curve, turning in space according to an axial symmetry, becomes weft's matrix of the tower's decoration. A second set of smaller round arches, this time flat because laid out on the faces of a dodecagonal prismatic block, develops between the columns supporting the interlaced system, while a two-colored stone fillet with six-pointed stars crowns the cylinder.

Fig. 7: On the left: orthogonal projections of the interlaced arches of Salerno's belfry tower. On the right: digital representation of the structure (3d model by C. Desiderio)

Equally significant and well preserved is the bell tower of the Amalfi's cathedral, which in many ways follows the same structure of Salerno's belfry. The construction works started in 1180, but was completed only in 1286. Today partially incorporated in the built-up area surrounding the adjacent square, the bell tower is designed as a simple volume, but very refined from a decorative point of view. The structure is geometrically similar to a square based parallelepiped, divided into three levels; on the walls, from bottom to top, are respectively opened single-light, mullioned and triple lancet windows with round arches. The belfry's crowning is much more complex: in fact, it consists of a right circular cylinder, in axis with the underlying body. Four other cylinders, smaller both in height and diameter, are matched to the first, in correspondence of the parallelepiped's corners. The central cylinder and those adjacent to it are finally surmounted by a conical roofing.

The decoration emphasizes the bell tower's richness, expertly combining materials and geometries that give an overall effect of great beauty.

In particular, yellow and green majolicas, combined into an alternating color rhythm, embellish the belfry, drawing the frames that surround the openings, the interlaced arches that encircle the volumes – still skew curves symmetrically turned around the tower's axis – and the decorative fillets in *opus reticulatum* under the conical roofs.

Less known, but equally significant for the purposes of this paper, is the church of San Giovanni del Toro, in Ravello, a private foundation created thanks to the tribute of several local families. For its construction was chosen an emblematic area, on the highest city's site, and as such, clearly visible; the building was also placed at the point of convergence of important trades. With regard to the geometrical shape of the space, it again proposes compositional schemes, related to the most common type of the Coast's architecture: a three naves basilica, concluded by a triapsidal transept. Adjacent to the church is the bell tower, a massive square volume, decorated with twists of round-headed arches, made of yellow and gray tuff's ashlars. This motif is also repeated on the external surfaces of cylindrical apses, with the only variant represented by the transformation of the elementary module in skew curve.

The same interlacement of arches, declined in even more sumptuous shapes, is visible in what remains of the Sant'Eustachio church, in Pontone hamlet of Scala; also this building was founded on a private family's initiative. The building was built in the twelfth century on a rocky outcrop overlooking the entire valley; today it is almost completely destroyed, but a time it probably was the most majestic private religious construction of Amalfi Coast, moreover showing a certain formal analogy with the Monreale's church in Palermo. Both for features than by geographical location the church should express, in a tangible form, the political, administrative and economic power of the founding family, becoming at the same time spiritual emblem for the entire community.

Of the structure, almost certainly to three parallel aisles with apses, unfortunately remain the only traces of the outer northern wall and of the cylindrical surfaces that downstream closed the building. Particularly interesting are the apse's decorations, still visible, which, though only partially preserved, show a general scheme based on the now well-known system of interlacing arches, with alternating blocks of yellow and gray tuff. Despite the paucity of surviving elements, we can recognize a sumptuous composition that is unmatched in the Amalfi Coast's examples: here the interlaced arches system, whose profile is still a skew curve generated by the intersection of two circular cylinders, is repeated on each of the three orders of the structure's crowning.

The arches, supported by slender marble columns, revolve in space so that everyone is starting in correspondence of the keystone of the next. The same variety of matter and colours is also employed in the horizontal fillets which mark the transition from one order to the above: in this case, however, the geometric decorative motifs are obtained with a sequence of squares arranged in an *opus reticulatum* weaving.

Fig. 8: On the left: the belfry's tower of Amalfi. In the middle: the apses of San Giovanni del Toro church, in Ravello. On the right: wall ruins of Sant'Eustachio, in Scala

5. Conclusions

The brief *excursus*, albeit quickly, thus shows how ingrained it is, in Coastal area, the use of an Islamic-influenced figurative language, in which more or less complex drawings are generated the interweaving of simple elements. And this happens especially with reference to the interlaced arches system, a decorative choice which also actively contributing to the development of architectural shapes. Great attention has therefore been paid to the possibilities offered by the geometry, here as in the Islamic world understood as a fundamental tool to make order.

And facing such a spectacle, whose complex figuration is generated by simple original forms, "... it is as if a richly orchestrated symphony had been frozen in space. His themes and motifs, its dozens of

instruments are permanently available to analysis and meditation, and even the accomplished art work is always there" [6].

From the arches' interlacing on plan surfaces, to the three-dimensional evolution of the same decorative motif, everything, in the investigated heritage, shows the natural inclination for an eclectic taste, intended as an artistic translation of ethnic and cultural diversity typical of the Amalfi Coast. A reality, between East and West, in which the geometry take form through a unique language – properly Mediterranean – characterized by an extraordinary decorative strength who relies not so much to figurative expressiveness, but rather to the shape's beauty derived from a rigorous generative geometry. The use of geometry, therefore, from that which regulates the volumes to that used in the plan to guide the decor's development, it becomes the common thread in an attempt to reveal the pure essence of such a complex architecture.

Where order and beauty is, is God: and only being able to interpret the logic which governs that order we can fully understand the value of the heritage that us surrounds.

Digital reconstruction of the Maritime Theatre in Hadrian's Villa at Tivoli

Alberto SDEGNO¹

⁽¹⁾Department of Engineering and Architecture, University of Trieste, Trieste, Italy
sdegno@units.it

Abstract

The research we present in this paper is about the geometrical analysis and the digital reconstruction of the Maritime Theatre in Hadrian's Villa at Tivoli, based on the comparative analysis of the interpretations given by Francesco di Giorgio Martini, Andrea Palladio, Giovanni Battista Piranesi, Pierre Jérôme Honoré Daumet, Luigi Canina, and some other important architects, but above all the description of Mathias Ueblacker, that in 1985 published a very interesting survey and hypothesis on the initial configuration of this architecture.

Inside the great place of the Hadrian's Villa, the Maritime Theatre has a very unusual form, because of the circle in which it is collocated, but also an unknown function, as we do not know what was the finality of this space, and considering that the name was given by the people that discovered the ruins. Realized probably between 120 and 125 a.C. it has a very rich geometrical configuration, with some specific forms inside the round enclosure of columns that surrounds the water pool.

The aim of the research was to redraw either the actual configuration of it and the hypothesis of reconstruction made by Ueblacker [1], in both cases with digital technology, in order to have a comparison between the two levels of representation. A final video and an Augmented Reality presentation was realized to show, in an explicit way, the results of the experimentation.

Keywords: architecture, representation, digital reconstruction, Hadrian's Villa, Maritime Theatre

1. Introduction

The aim of this research was the analysis of the Maritime Theatre in Hadrian's Villa at Tivoli, near Rome with digital instruments in order to have the virtual reconstruction of the building and to compare the actual configuration with the one proposed by Mathias Ueblacker [1], who studied it, in the past, in a very specific way. Only few parts are present now in the original state, and for the great part of it there are only ruins (Fig. 1); despite this it was possible to investigate the architecture and propose a virtual analysis of it with new technologies of representation. The first part of the research was done at the IUAV University of Venice, as a graduation thesis by Elena Corzato [7]. The research was then developed at the Department of Engineering and Architecture of the University of Trieste.

At the same time it was necessary to analyze also some of the studies made by relevant architects on this site, who tried to give a solution to the unbuilt aspect of the Villa itself, based mainly to the geometrical design of the plan. In fact we have a lot of drawings and surveys of it, starting from XV Century. Some of the illustrations of the Maritime Theatre were made by Francesco di Giorgio Martini, Andrea Palladio, J. Laurus, Francesco Contini, Pier Leone Ghezzi, J.R. Vulpi, Giovanni Ristori Gabbrielli, Giovanni Battista Piranesi, Luigi Rossini, Agostino Penna, Honoré Daumet, Luigi Canina, H. Kahler, H. Stierlin, ending with the one already cited by Ueblacker. Among them, we have to considered in a particular way the sketches by Palladio – for the idea of invention he represented in his works – the drawings by Piranesi – for the perspective representation of the ruins – the colored watercolors by Daumet – who offered the first hypothesis of detailed reconstruction in plan, elevation and sections – and of course the ones by Ueblacker, who gave the last and more defined solution of the first configuration of the building.

During the phase of analyzing it was necessary to visit the area and also to take a photographic survey, for having a visual catalogue of every single elements of the building. As it was impossible to

have a technical and instrumental survey, we decided to verify some measures of the building with a direct survey.

At the end, this architecture was selected also for some experiments in the field of new technology of communication applied to cultural monuments, trying to verify the best way to communicate the main themes of the present investigation. So we decided to construct the digital 3D model of this building, to render with the simulation of natural illumination, to prepare a video with the walking-through technology in order to visit virtually the building, and to analyze it in a virtual way using the electronic system of Augmented Reality (AR) for the presentation in real-time and for the dissemination of information during some public events, such as conferences and exhibitions.

Fig. 1: The Maritime Theatre from above.

2. The representation of the Maritime Theatre inside the Hadrian's Villa

The construction of the complex of Hadrian's Villa started in 177 a.C. in Tivoli, on an area where a preceding villa was built in the republican period. There are a lot of interpretations on the motivations for the decision to realize this great monument, in some ways, it could be considered as the foundation of a town, in which every construction is a single solution with a strict relation with some Greek buildings. It is known that Hadrian himself decided some architectural solutions, that some architects – such as probably Apollodoro – designed and constructed. Marguerite Yourcenar wrote in 1951 the novel *Mémoires d'Hadrien*, in which she makes the emperor remembering his past, sometimes referring to the places inside his Villa in Tivoli [6].

We do not describe all the buildings of the Villa, but we will analyze only the Maritime Theatre, remembering that either the name and the function are a truly enigma for the critics and historians who studied this architecture. In fact, the name was given in 1600 and it doesn't reflect the probable function of the space. Ueblacker told that it could be considered as an "emperor's studio", a place where the emperor stayed to rest and to satisfy his spiritual needs. The circle water pool was used, probably, not only to satisfy the view of the visitors, but also for swimming, protected by the wall that is placed all around it.

A relevant part of the analysis was dedicated to the collection of the drawings that architects did for studying this architecture. Some of them allows us to understand better the initial geometrical form and its three-dimensional development.

The first one was a plan of the Maritime Theatre drawn by an anonymous draughtsman of the XV Century, and conserved at the Albertina Library in Vienna. In this case the water canal was not

represented probably because it was hidden by earth. The columns were traced as small points on the paper, in the exact location where there are the columns.

In 1465 the architect Francesco di Giorgio Martini visited Hadrian's Villa and realized some scale plans, archived now in the Uffizi Library in Florence and redrawn for his treatise now at the Royal Library in Turin. One of them is to be considered as the first survey drawing of the Theatre, realized probably on site. Also in this case the water canal is not presented for the same reason we told before. In 1547 Andrea Palladio visited the Villa and drew two drawings now collected at the Royal Institute of British Architects in London (Fig. 2). One was drawn as a sketch, not well defined graphically, and the other one was drawn in a geometric form. Both of them are quoted, and, although they did not represent a real configuration – because of the symmetry of the elements, that is not present in the actual state – it is derived by a survey created on site. In this case either the circular pool and the bridges to reach the internal island are represented. The number of columns designed by Palladio all around the pool are 81, otherwise the exact number of them is 40.

Pirro Ligorio treated this architecture in a manuscript he wrote in the half of XVI Century, but without any drawing inside, and we do not know if it was really done, or it was lost.

The first pseudo-perspective representation of the Maritime Theatre is the one realized by J. Laurus in 1612, but in reality it was an interpretation of it, because of the presence of some elements that are not present in the site. For example, there is a double porch all around the circular pool, a circular columned temple inside the central island, and some other buildings in the front.

In 1668 Francesco Contini published the first plan of Hadrian's Villa, realized thanks to a detailed survey made in 1634 by him, so we can see the development of the Theatre in XVII Century.

Another plan of the Theatre was realized probably in 1724 by the painter Pier Leone Ghezzi, and archived at the Biblioteca Apostolica Vaticana in Rome, but the drawing is not so detailed as the preceding ones. Then there was neither the water pool nor the circular colonnade, but only a simplified representation of it.

In 1745 J.R. Vulpi drew an imaginary section of the Theatre, to represent at the same time the internal and external view of it. But as the figuration is schematic, some elements are not signed, such as the pool, the bridges and the roof. All the Theatre is presented in the form of ruins, with a degradation of the walls, covered by vegetation.

In 1770 Giovanni Ristori Gabbrielli represented the complex of the Villa subdivided in single parts, as there was a subdivision of the property. The planimetric drawing was sided by plans and elevations of agricultural houses, realized to use economically the area.

Giovanni Battista Piranesi was very interested in the Hadrian's Villa, and he prepared a great plan in scale 1:1000, printed in six paper with a total dimension of three meters. It was published in 1781, by his son Francesco, after his father's death. The plan of the Theatre shows a configuration very similar to the present one (Fig. 2), with few differences (for example the number of columns all around the pool is 52, instead of 40). At the end of his life Piranesi realized some preparatory perspective drawings of the Villa, and we have some of them that showed the Maritime Theatre in the form of ruin, without the pool and wrapped by vegetation.

Some other representation of the Theatre were those by Luigi Rossini in 1826 and Agostino Penna who in his book *Viaggio Pittorico*, published in 1831-36, drew a lot of perspective views in which the building was showed in a situation of great deterioration.

In 1859 Honoré Daumet produced a detailed survey of the Hadrian's Villa and proposed a reconstruction of it, well drawn in some colored watercolors showing plans, sections and elevations of the architecture inserted in the natural context (Fig. 2).

Fig. 2: Drawings of the Maritime Theatre by A. Palladio, G.B. Piranesi, H. Daumet (from left to right).

The representation realized by Daumet were perhaps the most interesting and exhaustive about the Villa. In these documents the Maritime Theatre is shown in a comparative figuration, that presented a section of the ruins of the Theatre and, in the same paper, the probable configuration, with a high level of interpretation, so that it is difficult to identify the single elements that are present in both drawings. The drawings realized by Luigi Canina in 1872 reflected the representation by Piranesi, but he gave a personal interpretation of the Theatre, with some details regarding also the architectural order and the

capitals; a rounded monumental temple is in the center of the island with four symmetrical bridges organized along a cross.

At the beginning of the XX Century there was a scientific survey, organized by the research unit of the School of Engineering in Rome, coordinated by prof. Vincenzo Reina. The survey was executed with topographic systems and shows the actual state of the Maritime Theatre, the same that will be illustrated by Ueblacker in his drawings.

Some other representation of the Theatre were done by H. Kahler in 1950 [5] and by H. Stierling in 1984 [6]. They are basic and significant studies from which Ueblacker started for his 1985 proposal. The survey and reconstruction by Mathias Ueblacker is, without any doubt, the most precise and interesting one, because he collected all the graphical information about this architecture, did some new surveys and proposed a version of the original one that is considered the more reliable of all studies. The reconstruction was documented also with a scale physical maquette, to offer a three-dimensional visualization of the hypothesis.

3. The Geometry of the Maritime Theatre

As we told before there isn't any information about the function and the original name of this space. Probably it was a sort of shelter of the emperor where he could usually rest after his voyages, as the *ritus laconicus* required. For what concerns the proportion of this architecture, we can report the study of the module that Ueblacker identified during his research. The researcher found a module of 5 feet, that he found into the dimension of every relevant geometry of the Theatre. For example, the circumference of the exterior walls is 30x5 modules, that is 150 feet long; the circle that passes for the center of the columns is 24x5 modules, that is 120 feet; the circle of the stylobate of the peristyle is 10x5 modules, that is 50 feet (Fig. 3).

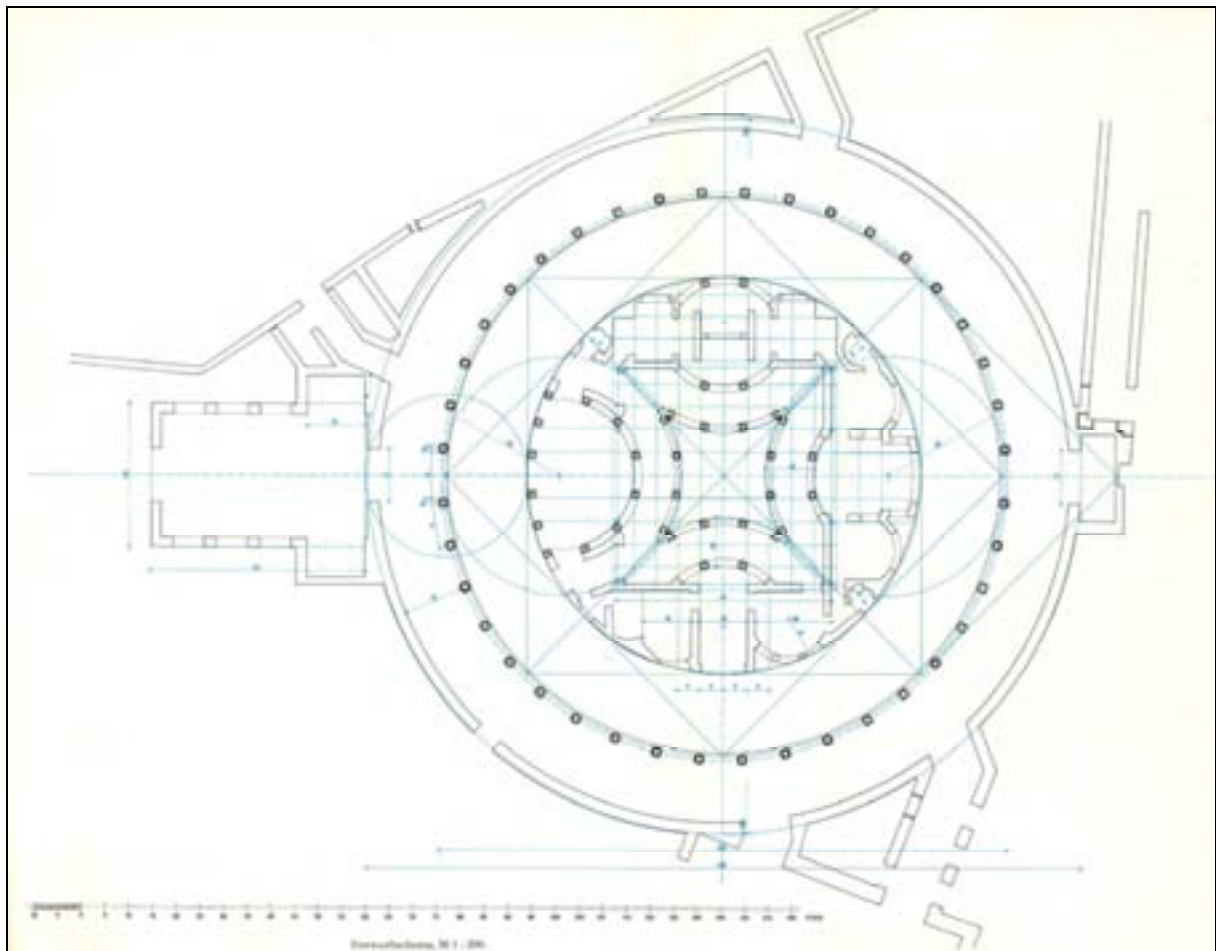

Fig. 3: Geometrical scheme traced on the plan drawn by Ueblacker (elab. E. Corzato).

So its complex geometry is based on the regular form of the circle, subdivided into a series of squares and other circles. Ueblacker described with great precision the way in which it is possible to draw the final configuration of this architecture. The first circle is the perimeter of the external wall, the second one is the circle of the axis of the columns; then you need to draw the square inscribed to the last circle, and then the circle inscribed in this square. This one is the limit of the interior island. Then the

procedure required the redesign of two circles and a squared in the middle. So it is possible to obtain the general configuration of the plan, from which we can start to draw all the other parts (Fig. 4).

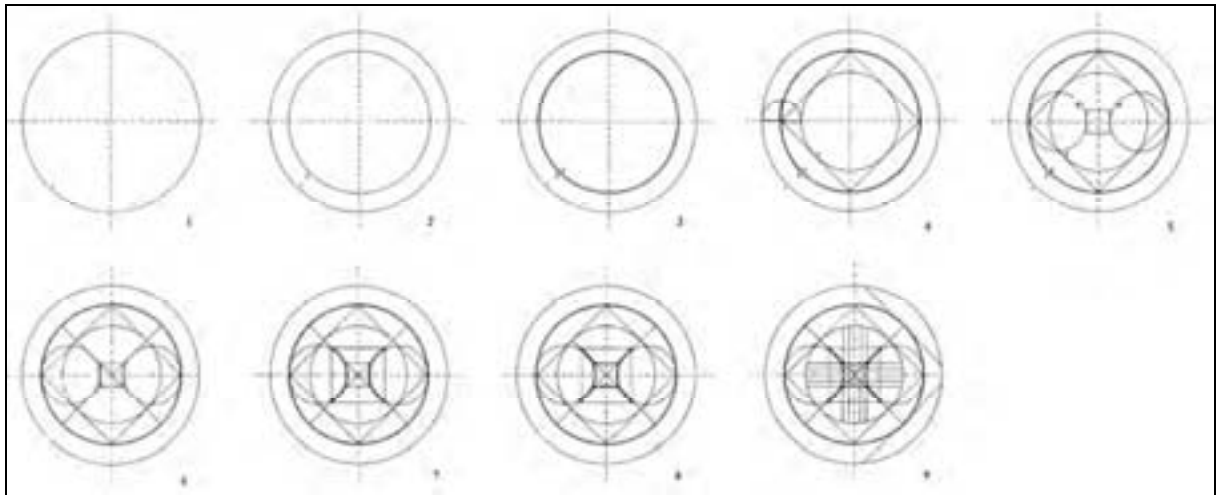

Fig. 4: Geometrical genesis of the form (elab. E. Corzato).

Then it is also very important to identify the spaces that are all around the Maritime Theatre, for analyzing the connections among this one and the others (Fig. 5). In detail they are: the Philosophers Room, the Criptoporticus towards the Stadium Garden, the Libraries' Garden, the Greek Garden, the external Exedra. This spaces are very useful to understand better the organization of the Theatre itself, although some of them are presented in the form of ruins.

Fig. 5: Digital restitution of the survey plan by Ueblicker (elab. E. Corzato).

But the principal attention was dedicated to the comprehension of the single spaces of the Maritime Theatre. A large atrium is located at north, at the entrance of the building. Near the circular porch it enlarges into two rectangular niches covered with barrel vaults. The roof of the atrium was destroyed, but it was probably a pitched one. In front of the atrium and at west side there was an asymmetrical loggia, which is 12 feet large.

After having passed through the loggia and the atrium we arrive to the round porch, that is 12 feet large too, between the surrounding wall, which is 2.5 feet large and 17.5 high, and the limit of the internal plinths of the columns. This porch is covered with a barrel vault, which is supported by the wall and by the columns. All the columns of the porch are ionic ones. Then there is a round canal of water, which is 4.90 m large and about 1.50 m deep, probably decorated with a coloured mosaic. To cross the canal there were some swing bridges, probably 4, and it is possible that the wall bridge at west side was realized upon suggestion of Hadrian himself, for the difficulties to use the swing one.

The wall inside the island were realized in *opus testaceum* (made by triangular bricks with one point inside the concrete) because it gave to the structure more solidity in an high humidity context, such as the one of the Theatre. One of the main part of the island is the exedra, limited at south with a circular row of columns, following an arc of circumference with a ray of 4.82 m., and at north with another row of them following the circle of the canal. After the exedra there is a peristyle with a mixtilinear form, a rectangle with four concave arches in the axis, doubled internally to generate a court having convex arches as sides. In the middle of the court there was a fountain. All around the peristyle there are small baths complex, with latrine, apoditerium (dressing room), frigidarium, calidarium and the heating room, where the stoker fed the fire. At the east side of the island there is the library, with some small rooms, while at the south side there is the tablinum, with two triclinia at left and right.

4. The digital reconstruction of the Maritime Theatre

After having studied the whole architecture we started the digital reconstruction of the Maritime Theatre, following the information on the book *Das Teatro Marittimo in der Villa Hadriana* by Mathias Ueblicher [1].

Fig. 6: Digital representation of the plan and section of the actual state (elab. E. Corzato).

In detail the geometrical procedure described above was at the origin of the generation of the form. In particular the aim of this research was to compare two models, the one which describes the actual

state and the other about the hypothesis proposed by the researcher; the digital models are used, in fact, as a sophisticated way to identify the relations between every single parts.

To realize the models we used a CAD software with Boolean primitives and advanced algorithms for extrude sections along a path modifying the perimeter of the section itself. These two procedures allowed us to construct every elements of the models. The first step was the digitalization of the plans, elevations and sections from the book by Ueblacker, and then we have to adjust this information with the numerical quotes in roman foot, traced by him. We have to notice that, as his drawings were done using traditional techniques, there are some simplified descriptions during the representation of sections and elevations. Due to the complexity of the building, in fact, the author decided to omit the elements in background, tracing only the parts in foreground. As in some points the sections by Ueblacker were not sufficient to understand the volume, it was necessary to use the basis of a direct and photographic survey we did to integrate the information from the book. Seeing the digital model it is possible to verify a correspondence between it and the real configuration, although it was necessary to simplify the model to represent the ruins and the state of degradation of the walls and of the columns (Fig. 6).

The second step was the digital reconstruction of the hypothesis made by Ueblacker on the original configuration of the Maritime Theatre (Fig. 7).

Fig. 7: Digital representation of the plan and the section of the hypothesis by Ueblacker (elab. E. Corzato).

In this case the main differences were based on the determination of the elevations, because in some cases there is only some information about them. Thanks to the presence of the barrel vault of the columned porch it is possible to conjecture the highness of the elements inside the island, covered with different typologies of roofs. The final three-dimensional representation gives us a volumetric visualization that allows to consider it in its real complexity.

The third step of the phase of reconstruction was the comparison of the two digital models in order to identify better the analogies and the differences between them. So we decided to use a similar

description of them - plan and longitudinal section - and a superposition of Ueblacker hypothesis on the survey of the actual state. The hypothesis of reconstruction was represented in wire-frame, while the ruins are shown with a rendering image, without materials and textures, but having only one colour (yellow) for the volume of all parts, a colour for the section (dark yellow), and a material for water (based on semi-transparent light blue), with shadows. We thought that the best visualization of this comparison was a cross-section isometric description. To complete the scheme we decided to add the drawing of the survey of the other part of the plan (Fig. 8).

Fig. 8: Isometric representation of the Ueblacker's hypothesis (wire-frame) upon the actual state (rendering) (elab. E. Corzato).

5. Advanced technology for the communication of the Maritime Theatre

The final part of the research was dedicated to the communication of the results using new technology of visualization. In particular we decided to realize a video animation and an experimental application using Augmented Reality (AR).

In the first case the video was produced with the intent to make evident the two levels of comparison, which we said before. The virtual visit of the Maritime Theatre starts from the atrium and goes forward following a possible path of the emperor who wants to show us the building. The visit was conducted into the second model, reconstructed on the thesis proposed by Ueblacker. But somewhere a double representation shows, with a progressive fade, also the actual state of the ruins. So it was possible to understand the correspondence between the actual configuration of space, and the original idea of the project. The visit continues along the circular canal, stopping in some relevant points of the path, for example near the columns, across the bridge for entering the island, and inside the internal space, and showing, at the end, the volume from the top. We decided to use models without colors and materials – only a light yellow for all the surfaces, and the simulation of the water inside – to allow the visitors to understand the volumes and spaces, simulated with shadows. The number of frames of the video is about 2000 for a duration of 80 seconds, with a frame rate of 25 fps (Fig. 9).

The second communication experiment was dedicated to Augmented Reality, that is – as we know – a sort of inverse application of Virtual Reality (VR). As VR puts man in a virtual space, making the sensation to be in another context, different from the one in which he is, the AR inverts the impression, and gives the possibility to explore a model, rotating and slicing it in real-time, as if it were in our hands. In this case the digital model of the Theatre was converted in an AR ambient, associated with a target and analyzed and explored. The use of a small camera allowed us to simulate the behavior of a

visitor inside an exhibition, that virtually has in his hands a model of the Maritime Theatre, with a lot of details and information. This opportunity could be an interesting way to distribute virtual architectural models, with the intent to create a imaginary catalogue of maquettes. We have to consider also that the peculiarity of a digital model is also in the possibility to query it, for example asking to slice the volume to analyze the internal configuration, as a traditional model doesn't have this capability and it is impossible to investigate it, but only to see walking around it.

Fig. 9: Single frames of the video animation for the comparison of the models (elab. E. Corzato).

Abstract

One object is susceptible to many representations which are different one from the other: if, on one side, these have the task of analysing the space of the referent in its forms and structures, on the other they produce images which allow to establish a relationship of cause and effect between the drawer and the user of the image.

The representation, of the object, replaces it. It allows the observer of the image to be in the presence of the object, but without the object. It is the visual surrogate of the experience which is made clear through the Methods of Representation. We are called to make a mindful but also unbiased use of each method, making them topical, in order to produce images more suited to contemporary visions. This process is implemented and resolved in the identification of points, lines and surfaces, of their mutual relations and reciprocal intersections which the action of representing allows to define in the geometric-projective space: there is a formula for each line, straight or curved, for each figure, for each surface; there is an infinitely complicated formula, or perhaps concealed in its simplicity, which describes the motion of a point that describes a line which draws a figure that generates a surface.

Keywords: Survey, representation, database

1. The Representation, the object *in absentia*

It has become a well-established fact that the transformation of the communication system in contemporary society has represented a significant moment of reflection on the potential this system offers in the analysis, knowledge and work of enhancing cultural and territorial heritage. Language is above all visual, we speak by images, data is accumulated which is each time implementable and modifiable *ad infinitum*, continuously and suddenly updated. Data which is building a large archive of the global world, where the past, present and future seem to have no solution of continuity.

In actual fact, only the tools necessary to witness and document heritage and identity have changed; heritage, on its part, has increased as physical space has amplified and it contributes to defining that new concept of space which, going back to a well known definition of Douglas Engelbart, could call itself augmented space, to be exact increased space. The proliferation of perceptive, visual, material and immaterial levels of everything that surrounds us, according to the technological process and the consequent cultural transformation, represents a sector of particular interest which has emerged in recent years with ever greater clarity: the space of every time, the space of the city, of architecture, of territory, can be expanded by resorting to an appropriate manipulation of its physical dimensions; it can be expanded well beyond its tangible boundaries if it is intimately connected with a new space of information or virtual representation which amplifies the global flow of communication. Thus, each object belonging to the real world, each trace, each expression of our heritage can be expanded with an array of information which increases its definition and comprehension.

What is happening to our culture "could be [...] the result of the normal tension between generations, the old guard resisting the advance of the new; the established order defending its stance by accusing the emerging powers of barbarism. Nothing new here, a process that has repeated itself again and again throughout history. But this time it seems different, this conflict is so profound as to feel different. Usually the battle is around the strategic points on the map, this time it seems more radical, the aggressors taking on a more fundamental stance: changing the map itself. Perhaps they have already

changed it. It must have happened that way in those blessed years which, for example, saw the birth of Enlightenment, or the time in which the world discovered itself to be all of a sudden romantic. They weren't movement of troops, and not even sons who killed fathers. They were changes, which replaced a landscape with another and founded their habitats there". [1]

It follows that the landscape, whether it be the interior panorama which defines our thought and builds our memory, or the material and external panorama which surrounds our existence and composes our space, has already changed and, with it, also the way to define, document, communicate and represent.

The most immediate sense of representation of an object refers to the imitative iconic drawing of the optical appearances of the object itself, and it goes back to the idea of graphic image traced on a flat surface to surrogate the visual experience of the observer. In its geometric codification the representation poses itself as the Albertian window or, in any case, as a putting up of many windows, all recalling the specific nature of images as they appear to the visual world. All this can be traced back to the meaning of optical projection according to which representation does not achieve signs, but rather indexes understood as traces physically determined by the referent object.

One object, in fact, is susceptible to many representations which are different one from the other: if, on one side, these have the task of analysing the space of the referent in its forms and structures, on the other they produce images which allow to establish a relationship of cause and effect between the drawer and the user of the image. Point, straight line and plane, the basics of geometry, are the functional operators used to construct the images that represent a space; while the contents of the spatial experience, translated into graphic signs, form the object of representation. It is Geometry, understood in this sense as abstract science, that provides the methods and procedures to represent the phenomena; Geometry, in fact, at least the Euclidean kind, is the set of logical and deductive consequences and graphic operations which translate geometric figures into models of spatial objects; they reveal themselves as satisfactory models which closely correspond to their physical referent, but for their formalisation to occur, it is necessary to choose a space of reference and so a method of representation which allows to realise the spatiality of the object at the level of drawing.

The representation, of the object, replaces it. It allows the observer of the image to be in the presence of the object, but without the object. It is the visual surrogate of the experience which is made clear through the Methods of Representation. We are called to make a mindful but also unbiased use of each method, making them topical, in order to produce images more suited to contemporary visions. This process is implemented and resolved in the identification of points, lines and surfaces, of their mutual relations and reciprocal intersections which the action of representing allows to define in the geometric-projective space: there is a formula for each line, straight or curved, for each figure, for each surface; there is an infinitely complicated formula, or perhaps concealed in its simplicity, which describes the motion of a point that describes a line which draws a figure that generates a surface.

2. Surveying as a search for form

If it is true therefore that the space which surrounds us has made us used to and, increasingly more often, obliges us to customs and visions that move the interest of the observer from that strictly metrical and typological to the projective and topological kind, it is also true that the cultural, conceptual and imaginative enrichment of the contemporary world offers as a deadline a qualitatively differentiated product. So, when we approach the space to understand it and reveal it, and then to communicate it in images, we have the impression that we have not just measured that space, but even invented it, as if it had become real thanks to the work of surveying before and representation later.

Where there was only matter, it is now possible to lay a web of points, straight lines, angles, numbers. To measure, means to trace a line where there has never been one. It means understanding that where there is space there are lines. And space exists where it is measured. "Space itself [...] a line from one point to the other, from the roof to the cloud, to the sun, and again to the roof. From the line points, from the surface lines and from the body surfaces, but that [is] not all. From there it is almost possible to see the subtle curve of the world". [2]

Reading and interpreting the space which surrounds us requires the use of different tools of investigation, comparison with different scales of reference, the contribution of various disciplines first among all surveying, a privileged tool of knowledge which allows to clarify a method of approach to space and an expressive language, the critical and cultural foundation of which is Descriptive Geometry.

This discipline contributes to making the observer's eye used to capturing the configurative characteristics and morphological aspects of the space in which it inserted each time, to understand the volumes and surfaces which compose space, breaking it down in the mind and putting it back together in the representation; to distinguish the intersections between the planes and surfaces which border the space; to identify geometric genesis and critically describe the significant elements.

For this reason the observer's experienced eye, the eye of one practicing the art of Drawing, the eye of who knows Methods and Rudiments of Representation, breaks down the architectural space and fragments it into representations which are often simultaneous or superimposed that help its investigation and comprehension; once the observer has taken possession of the space and its intrinsic characteristics he becomes designer and puts back together the fragments of architecture in one or more images which synthesise the space and express its forms and contents according to the logical and rigorous language of Descriptive Geometry.

The representation which follows from the survey, through the powerful synthesis of which it is able and the visual immediacy of the communication it generates, allows to obtain the object *in absentia*: in short, only the object remains, the forms of which are the sign of the place which contains it. The abstraction process which derives from it allows to interpret the object as foreign, detached, that is, from the context of which it was previously a part.

3. The placeless object

The transformation process which now influences every aspect of scientific research in the sector of Representation has led to a significant increase in technological needs, above all in terms of graphical choices. In fact, in this context, above all in recent years, numerous and diversified graphical models, able to reproduce real objects as faithfully as possible, have been experimented and assessed; in particular, the process of creating a virtual model, that is the graphic representation of a three dimensional object inside a software, has become gradually clearer over time through ever-diversified modelling techniques: from the use of primitive software which can be combined through subtraction, addition, through so-called Boolean operations, we have reached a sophistication level that succeeds in modelling objects of incredible complexity with the use of non uniform rational B-splines, or rather resorting to that class of geometric curves used to represent complex figures able to make models which are ever closer to reality and increasingly surrogates of reality.

With this type of technology geometric information becomes much more significant and precious compared to, for example, photographic mapping because it reproduces with extreme accuracy and three-dimensionally the topology of the object in a way which makes its interpretative reading extremely easy and enhanced.

By analysing the model created in this way it is possible to identify and study the object from every possible angle, be it topological or conservative, metric or type, putting forward also critical interpretations and formal readings. The great opportunity which current technology offers us is surely that of elaborating the three-dimensional model to various detailed scales, according to the type of use and goals we wish to pursue. The various levels of detail can also interact reciprocally to widen the range of possible applications. We must not forget that the software offers us the opportunity to navigate media space, examine its interconnections, to explore the model in real time; in this way, once again, there is a sort of complementarity in the representation, and this is of great importance: there is speed, convenience and interconnection, being able to access the objects in their virtual form, detached from the context in which they belong.

Experiments conducted on several examples of complex architecture, a synthesis of the results obtained to date are presented here, have led to the creation of three dimensional models of the objects which re-propose the architecture detached from its context but perfectly navigable and accessible as if the observer were in the presence of the object itself; each object-model forms part of the mosaic which will describe an open source digital archive, which is consultable by all and made available on a web platform.

To the question of the many who ask "What will remain within the visual universe of the large archive of the global world?"

Many answer History.

3.1 Database

A story through images and virtual models inspected and navigable anytime and from any location. The experiment enterprised in order to constitute the collection of placeless objects and the creation of a database: it summarizes here a sample of placeless objects created in order to make a database for the Archives of the Diocese of Sessa Aurunca that at the end of 2012 has taken the project of building a virtual museum, useful inventory of the assets of the Diocese and the disclosure of the same heritage. In this way you can see in real time the object, to assess the state of conservation, decide on actions to take, or simply to know the architectural heritage in the diocesan territory.

The images shown below are two case studies: the church of San Nicola, in the next page, and the church of Santa Maria in grotta, in the last page, both assets of the Diocese, and both explained in sequence of real image-survey 3d model-placeless object.

ingrid.titomanlio@unina2.it

giuseppe.faella@unina2.it

Abstract

This paper is aimed to providing knowledge and help in discovering types of buildings in Casale Castello, by recognizing and understanding their structural elements using B.I.M. technology.

The presented approach allows generating a recognizable digital spatial configuration of the main structural elements of buildings in Casale Castello village which is examined in this paper through the representation of its urban development. Under this perspective, analysis and representation of the city building logic and their wall types have a noteworthy interest for investigating the guiding principle of the town planning evolution through BIM methodology. It is carried out the analysis and cataloguing of masonry walls types that testifying the development and the reflection of the urban evolution based on the constructive techniques. Like for other villages Klaiber, Lavedan and Piccinato stated the difficulty to chronologically establish the various types of medieval settlement, as well in Casale Castello it's impossible to find historical documents on its develop. Using B.I.M. methodology it's easy to recognize the different structural element characterizing the buildings in Casale Castello. Through BIM method the digital representation became an efficient device for the catalogation and structural analysis of constructive elements. BIM is a building design methodology characterized by the creation and use of coordinated, internally consistent, computable information on building projects during the design and construction process. The structural elements behavior is analyzed by digital models. It is shown how, using building information modeling technology, the modern houses design has become more flexible, economic, fast and satisfying than traditional 2D drawing representation methods. The information may be refer on full life cycle building manufacturing, from design phase to that of use and maintenance, passing through the implementation phase.

Keywords: Structural elements, 3D modeling, Building information modeling (B.I.M.)

1. Introduction

Over the decades, in the fields of architecture, hand drawing has moved toward digital drawing for trying to create a more and more realistic computer simulation of designed buildings. From imagined reality it has gone to program reality drawn. The space of imagination through the drawing expresses itself, takes shape and configures the space.

The representative methods of Romanesque architecture and gothic style are different and so far from Renaissance drawings. Obviously, these latter methods are different to modern houses. Talk about the computerized drawing to describe the structural design of Casale Castello buildings means sinking tots in what has been the evolution of representative structural approach in the history of architecture.

The search of the fundamental expressive components of structural design of classicism is aimed at capturing, in modern experience some geometric-mathematical references upon which the digital design is also based. The principles used for digitizing structural drawings bring with to light the principles of the Renaissance survey.

The approach presented in this paper allows generating a recognizable digital spatial configuration of the main structural elements of historical buildings. The structural elements behavior is analyzed by digital models. It's about creating a digital model of houses capable of simultaneously contemplating various aspects of the building. This method is able to bring together building shape and structure in a single 3D model. In [Figure 1] it is possible to read a circular pattern on which is based the 3D

modeling. It starts from the knowledge of Casale Castello, through the diagnosis of conservation problems and feasibility of design buildings. So it aims to digitize the project template [1].

Fig. 1: Task sequence and analysis layout

2. Structural design: historical evolution

Romanesque Architecture is a style characterized by having similar issues that can be detected in all historical country [Figure 2], European architectures and local aspects that are typical and different from country to country. The fundamental traits of medieval religious buildings were the central nave and the lower aisles, built with very thick stone walls, cut and left on-sight. The lightening of lateral side walls of the nave was made with the endorsement of windows. The light and shade games facilities of structures were often entrusted to composite columns, cornices and niches. Cross and barrel vaults mainly dominate the aisles and different forms begin to develop, as the round ribbed vault that introduces the next Gothic period

Obviously, the structural advantage of the cross vault respect to the barrel one is evident. The loads were conveyed on four corner supports, rather than on two lines sets, allowing to reducing the wall thickness and making it to evolve more and more towards the thin lines of the next period. The houses of that period appear massive and of various typologies [2].

Fig. 2: Task sequence and analysis layout

The fundamental factor of the town's security is the town-wall, which became the main defensive system, where the towers, generally square plan, constituted the key element. However, it must be considered that in the medieval constructions type and stonework vary depending on the physical nature of materials and technical features closely linked to local materials and worker knowledge. In fact, the typological survey of masonry walls in use in western Europe during the Middle Ages includes

several stone masonries, both rubble and ashlar masonry, with different block sizes and coursing patterns.

Whatever may be the stonework, a main role in masonry strength is due to mortars. But few information and sure notes on medieval mixture are currently known. Anyhow, it is known that most mortars prepared in the Middle Ages consisted of a mixture of slaked lime, sand and water. Additionally, the medieval mortars often feature for larger amount of silica sand rather than clay that was typical of antiquity. However, although most chemical processes were based on empirical rules, the medieval workers manufactured good quality of mortar using special kilns, today almost all destroyed.

The constructive standard of foundations of medieval buildings remains virtually the same as those used in ancient time, regardless of the masonry stonework. It is very rare to find foundations constituted by masonry bed, covering all the surface of the building. The medieval builders sometimes utilized dressed blocks to build foundations, sometimes deep, but mostly made by debris mixed with baked clay and stones of different quality. In [Figure 3] it is possible to look at the collapse mechanisms occurred during the earthquake on the Casale Castello buildings.

Fig. 3: Modeling of possible damage to Casale Castello buildings

Gothic style was next to the Romanesque one. While the latter style created the dark spiritual environment opening very small windows, the gothic style opened to the brightness triggering the structure upwards. The problem of different proportion between vertical and horizontal structures required the introduction of ribs as buttresses. For private homes features remained those outlined above for the late Middle Ages [3].

The discovery of man as subject subordinated to the created, as fickle subject, consecrated the Gothic architecture expression ever upwards, towards the Divine. During this period develops an architecture that denotes height proportions much more pronounced than horizontal ones. The structural studies of sacred monuments were the first engineering experiments that experienced high inter-stories supported by slender columns. Graphically, there still was the simplicity of drawings which not only delineated very mystical decor also praised the slenderness of the buildings.

Renaissance began in the fifteenth century and inspired its principles on the Roman classical period traits, beginning a geometric, simplified and rational study, focusing on the plan distribution of buildings. Architectural perspective drawings of this era have their authorship in Filippo Brunelleschi [Figure 4] [4,5].

The courtyard houses were the recurring structural typology. Their outward appearance presented ashlar-work on ground floor. This kind of decoration heightened the structure and its contact with the ground, as a mark of strong static structure. Pilasters or architectural elements crossing throughout the high part of facade were also present [6,7,8].

Subsequently, string courses replaced the ashlar-work and gave the first signs of the presence of structures outside the building, alive and united with the formal appearance of buildings. The streets of the city were enlarged to delimit majestic palaces.

Renaissance drawings first introduced mathematical rules and correct proportions to architecture. Through the “golden section” structural elements and finishing elements were increasingly attempted to be harmonized in order not create imbalances and to make sure that coexist both within a single monument. The real mathematical rule combined with hand drawing can be found in this period [Figure 4].

Classical foundations rediscovered. Exaltation of the Greek and Roman era as a pioneer of a perfect proportioned, well calculated, with expressive capacity drawing really exciting.

The structural form of the Baroque houses preserved the courtyard house typology but extended its entry axis in longitudinal way to mark it much more, making penetrate the exterior to the interior of the court and creating the "H" plan buildings [Figure 4].

This style brought plenty of decorations that tended to cover and camouflage the architectural structure. The space was framed among leaves, flowers and statues; the sculptural traits were highlighted and the thickness of the columns was modified with precious marble facings.

Neoclassical Architecture (XVIII century) awakens the greek-roman architectural and formal principles but combines with the rationality of enlightenment. The historical period in which it arose was characterized by the industrial revolution. It was a period full of practicality and pragmatism. This current lasted many decades for its "trend" characteristic so it is not a real and defined style.

Neoclassical architecture rediscovered classics fundamentals: there was an exaltation of Greek and Roman era as a pioneer of a perfect, balanced, well-timed style and its expressive design capabilities become really exciting [Figure 5][9].

Fig. 4: Historical evolution of B.I.M.: From Leon Battista Alberti to Frank O. Gehry

3. Modern structural design

Modern movement born out of the idea and the innovative thought of world-famous architect Le Corbusier, who by his sketches brought forward the idea of his five principles to make architecture: pilotis, plan libre, garden roof, free facade and ribbon windows. His charts always show a man (“modulor”) as a proportional database. The house designed with a human scale and built on human proportions was his force point. The essential expression of the modern movement leaves the baroque plenty [Figure 6].

In this period, the exploded isometric splits used as representative methods were able to improve insight and intimate area of houses and to clear and enhance the view on furnishings. The man lives the house, in living rooms, in reading rooms. The "chais lounge" in fore guard are the frame of hand linear and clean drawings [10].

The birth of the International style and organic architecture was designed by Frank Lloyd Wright [Figure 7]. He was the most important protagonist of the architecture in the twenty-first century. He wrote "The good building makes the landscape more beautiful than it was before the building was constructed." The structural representation of his organic houses is immersed in nature and was nature [11,12].

The importance of a waterfall able to make a stunning foundation for Wright's "house on the waterfall" was the foreshadowing of what was the rediscovery of a naturalistic period.

The same trees were able to replace the house porch with their trunks. Nature takes over. The necessity of being swamped by the scents of plants. The use of construction materials such as stone brick in structural construction in the twentieth century created a very strong symbiosis between man and nature. The organic structural design dispersed in nature, became light with dividing walls made of stone. The height of buildings tended to decrease in order not to invade and not impact on the surrounding vegetation. The plants are very large horizontal lines[13,14,15].

Fig. 5: Modern application of B.I.M.

4. From hand drawings to digital Era

The transition from hand drawing on paper to drawing based on the use of technological equipment has spread faster and faster. There was no longer need to draw by hand because with the beginning of the industrial era and the design of machines for product standardization, computer equipment have opened access to the issue of the representation of architecture. Also the structural analysis had a computerization and research process that developed increasingly sophisticated structural analysis software.

Nearly ten years ago Building Information Modeling was introduced to increase the performance of traditional 2D drawing. B.I.M. is a building design methodology characterized by the creation and use of coordinated, internally consistent, computable information on building projects during the design and construction process.

With B.I.M. it can image the future by creating virtual models in economics contextualized in environment. The process relies on the creative idea of the architect, who draws materially the design solution is straightforward and very simple procedure. It lies in the operator's skill, in his intellectual and cognitive ability, to make with shadows, perspective and isometric split, the correct house structure, similar to the one imagined [16].

However, when the design project idea is entrusted to a computer and to its simulation software, the process becomes much more sophisticated. How many more are the data that is entered into the computer program, many more are the ability to create an image similar to the design idea. Being a computing machine, the computer processes the input through algorithms and determines the output.

Increasingly powerful processors and RAM memories make the structural analysis of complex architectural forms faster to analyze.

The modern architecture and the houses of 21st century strongly denounce the backbone outside buildings, becoming itself the shape house. In this case, the computer operator's ability to quantify the data input to be entered in the software becomes crucial [17].

Integrating the B.I.M. method capable of representing the structural model with a structural software, a complete view of the evolution of the structure in terms of effort, cost and energy input is allowable.

With this reliable digital representation, it is possible to follow the house project, making decision from construction planning and performance predictions to the cost estimates. B.I.M. methodology can keep information up-to-date and it's accessible in an integrated digital environment. It can immediately and quickly compute the quantities characterizing a technical element also (i.e. the surface of a plaster). The various information contained in building information modeling is: geographical location, geometry, material properties and technical elements, the phases of construction, maintenance operations.

Fig. 6: B.I.M. Process

5.XXI sec. with Building Information Modeling (B.I.M.)

The transition from 2D to 3D computer design was more or less straightforward and simple. The graphic project of houses in the twenty-first century found in many architectural software vendors a simple worldwide spread.

However, from some years there is a growing CAD develops. A new computerization of architectural design concept is spreading. It generates elements such as columns, walls, complete in all their features (geometric, stratigraphic, material, volumetric / spatial). It is a generation of software capable of drawing the building structure not as a set of lines, arcs, and polylines but as a set of comprehensive and cooperative elements. Example of this type of computerized generation of structural models is the Building Information Modeling or B.I.M. With this method, buildings are designed entirely in all their component elements. It follows the work construction with its processing costs calculation and ends the life cycle of the generated model with the investigation of maintenance costs. In the last decade, the important issue concerning the relationship between housing and energy saving is also recognized by using B.I.M. [Figure 6] [18,19].

By creating a B.I.M., it is possible to fully orient a building by entering the coordinates detectable with GPS antenna and calculate the exposure during the year. Also the calculation of the amount of a material present, for instance, on the house floor is very easy with the B.I.M. computational analysis.

This kind of digital representation is not limited on drawing simple graphics (lines, polylines, circles, arcs) but it allows designing technical drawing of the building components (walls, structures, windows, doors) that contains component data, such as geometry, constitution and spatial position. B.I.M. was promoted to reduce waste and inefficiency in building design and construction [20].

Results show the high quality of houses design in the 21th century. They have not historic importance but have more structural efficiency than traditional constructions. It is shown how, using building information modeling technology, the house design in the 21th century has become more flexible, economic, fast and satisfying than traditional 2D drawing representation methods.

The information may be refer on full life cycle building manufacturing, from design phase to that of use and maintenance, passing through the implementation phase [21].

6. Conclusions

The B.I.M. is not merely the structural representation used to digitally display the house of the 21st century. It is much more. Building Information Modeling combines the design look to the structural aspect. It is able to work together different competences on the same digital platform greatly reducing costs. For designers, to support his architectural idea by a computer software such as B.I.M. is a big step forward for the entire process of creation.

For example, in Casale Castello, in a few steps it goes from the project idea to the evaluation of the processing and production costs. A single worksheet on which bring out the preservation and create a working table on which to develop innovative and functional solutions [Figure 7] [22].

The multi - disciplinary approach that was not known during the industrial revolution (in fact during the 18th century there was a separation moment between engineers and architects), is now celebrated by B.I.M. because it is able to integrates different competences. But, what is the B.I.M. is still difficult to define clearly. Although the first scientific topics of research about it date back to about 2007, it can conclude that this mode digital structural representation of buildings is much more than that which developed in the field of industry.

The B.I.M. is both a software for digital development of architectural design, a viewer of structures, a prototyping, a simulator, making possible to calculate the cost of construction and maintenance work. The significant process of B.I.M. can be seen in the possibility that gives to the designer to know the budget and evaluate right technological choices in order to monitor in a balanced way the realization of the architectural product.

To draw the avant-garde houses structure by B.I.M. is essential and crucial to reduce manufacturing costs and to respect the original idea at the base of the project. The artistic avant-garde movements are reminiscent of Dadaism, forms of abstract art and get rid of classic lines. The buildings are also structurally forms that profess themselves ahead of the modern movement, aimed at breaking the classical geometry of canons, anarchist. Never, as in these cases, the use of information technology in architectural field enables model B.I.M. manage the unconventionality increasingly extremist forms of avant-garde architecture. The house as a political poster, highly personalized by its author and that requires a particular intuition of the B.I.M. user. The avant-garde architecture computerized helps run the genius and author's alternative[23].

The results presented in this paper are based on work developed with Giuseppe Faella, Full Professor of Structural Engineering at the Second University of Naples.

Abstract

In the last decade, due to the processes and the changes that took place in the field of industry, with special reference to the most developed countries, primary industrial activities (steel, chemical, mining, etc..) moved to countries in the developing world. This process made available a number of industrial buildings no longer used. The recovery of these buildings is a problem of great interest and importance, because of the obvious impact on the related economic and social opportunities and represents an unavoidable challenge for the sustainability of the urban development.

In this paper a methodology for the rehabilitation of buildings that fall into the disused industrial areas is proposed. It makes use of a support tool proper of the project management, the graph of logical sequence (GLS), in order to identify the concatenation and the logical sequence of activities that make up the building process of recovery.

Both the architectural and structural features are considered in an integrated way.

The proposed methodology leads to the definition and use of suitable indicators, which represent in summary the information that is transmitted between the various logical blocks that make up the graph. An example of application, consisting of the proposed recovery of abandoned industrial building, belonging to the former Falck area in Sesto S. Giovanni, helps to clarify the practical application of the procedure.

Keywords: disused industrial buildings, remediation, reallocation of use, seismic safety.

1. Introduction

In the last decade, due to the processes and the changes that took place in the field of industry, with special reference to the most developed countries, primary industrial activities (steel, chemical, mining plants, etc..) moved to countries in the developing world. This process made available a great number of industrial buildings no longer used. The recovery of these buildings is a problem of relevant interest and importance, because of the obvious impact on the related economic and social opportunities and represents an unavoidable challenge for the sustainability of the urban development. The optimal solution of this problem requires the integration of the synergistic skills coming from the fields of architecture and structural design to guarantee the satisfaction of functional requirements for the new use and the structural safety.

In some cases the adaptive reuse of older industrial buildings may not be feasible due to insurmountable structural problems mainly related to the static and seismic performance. In fact several times the seismic and structural design proved to be the most expensive part of the refurbishment project. The alteration of features and spaces that characterize a building should be avoided, as each building is expression of its time and place. Deteriorated features, finishes, along as construction techniques or valuable craftsmanship that characterize an industrial building should be preserved in their essence and properly analyzed and considered during the refurbishment activity.

This paper is aimed at presenting the first results of a joint research developed by the DATA Department of the University of Rome "Sapienza" and the Department of Architecture and Industrial

Design of the Second University of Naples. In particular, the Sapienza University dealt with the architectural and the technological issues of the study and the Second University of Naples dealt with the structural safety problems. This integrated methodology has been applied to a well known case study, the former Falck steel production plant in Sesto San Giovanni, Italy.

2. Issues related to the recovery of disused industrial buildings

The recovery of disused industrial areas today is in Italy a problem of considerable interest and importance representing an opportunity for the sustainable urban development, as it reduces the need of using new space to build new constructions.

The main issues related to the recovery and redevelopment of brownfield sites are three: the pollution of soil and groundwater, the structural safety of buildings, with particular reference to their seismic behavior, the conditions of the infrastructure and network services.

During their production the industries that were present at the site in question, such as steel mills, mines, chemical industries, etc., released in the soil and in the groundwater, both superficial and deep, contaminants, in principle harmful to the human health.

To this end the Italian Ministry of the Environment clearly distinguishes contaminated sites from National Interest Sites (SIN). A disused site is considered as contaminated when the values of the harmful chemical species exceed stipulated alert levels. The limit values of pollutants are determined by a specific code [1], which indicates the corresponding, risk thresholds, expressed in terms of concentration.

Disused contaminated sites need, therefore, a remediation procedure before they will be reused.

The National Interest Sites (SIN), however, are those areas of particular environmental value, in which the contamination of soil and water is a risk to assets of historical and cultural interest of national importance. The Italian code indicates some criteria to locate the sites:

- the remediation procedures must affect areas having special environmental value;
- the health and environmental risk derived by the exceeding the threshold levels must be particularly high;
- the socio - economic impact, caused by pollution of the area, must be relevant;
- the contamination must be a risk to assets of historical and cultural interest;

In Italy, the National Institute for Protection and Environmental Research (ISPRA), according to the above criteria, identified 57 SIN, which include brownfield sites, in progress of conversion or still active, areas affected by mining activities and production of asbestos, ports, areas that were subjected to accidents involving the release of chemical pollutants, former mines, former quarries, landfills that do not comply with legislation and illegal dumping areas.

In the case of National Interest Sites, remediation is the responsibility of the Ministry for the Environment and for Land and Sea Protection, which uses for this purpose ISPRA, Regional Agencies for Environmental Protection of the Territory (ARPAT) and National Institute of Health (ISS).

So the process of requalification is very complex, because many skills and complicated legal and planning procedures come into play.

In all other cases - the polluted sites not declared to be of national interest – the remediation, however, is in the responsibility of the author of the pollution.

The areas object of the recovery action usually contain significant heritage buildings, once used for the productive activities.

The abandoned buildings, like the areas in which they are places, have lost their original function over time, becoming only "skeletons" or shells in memory of the industries to once they belonged.

These "memories of the past" usually show structural unsuitableness, due to ageing of materials, to the enhanced requirements related to the progress of scientific knowledge in the field of structural safety and to the higher attention to the seismic problems.

Paying the proper attention to state of preservation of both architectural and structural elements and to the related restoration work, existing buildings may live and change their use in a new one, more appropriate to the new requirements of the area and the community.

Another no less important problem is the extent and status of preservation of the infrastructure system and of the networks of services networks.

In fact the area, before it was abandoned, was equipped with a connection system of tracks, water lines, sewer pipes, electric and telephone nets, which served as support to the original function.

For example in a mine the rail connections had the function of transporting raw materials to the factories that change it.

With the change in the intended use of buildings and outdoor spaces as a result of recovery, the primary infrastructures are almost always inappropriate for their new role, becoming useless even if, they can become strong points for the entire area with due attention to their refurbishment.

3. Proposal of a method for the recovery of disused industrial buildings

3.1. General consideration

The proposed methodology [2], uses a working tool taken from the project management, the flow chart or the graph of logical sequence (GLS), in which a comprehensive and assisted reading of the activities that compose the building recovery process is given.

The graph of logical succession is a tool for representing the sequence of the activities of a manufacturing process. Through the logical sequence of the various activities is shown. The tasks are represented by icons, and their logical sequence is indicated by unidirectional arrows. For example, if from the A activity departs an arrow that connects it to the B activity, it means that the latter can not be executed before the A activity is completed [3].

In the present methodology the graphic is composed of three bands of activities, each one developing in the vertical direction. The first level describes the design of the building works, the second one the site planning and, eventually, the third one shows the remediation project.

In this paper, the attention is focused on the building design.

The GLS can also be read by horizontal bands. In this case it highlights the mutual relations between the three areas of design mentioned above.

This methodology leads, naturally, to the identification and the use of proper indicators, which represent in a summary form the information that is being transmitted between the various logical blocks that make up the graph.

3.2. The indicators, as a tool for the recovery of disused industrial buildings

According to Noll [4] the tool of the indicators was first applied in the mid-sixties by the American Space Agency (NASA) in the field of social sciences to identify and anticipate the side effects of the space program on American society.

It was probably Raymond A. Bauer, the director of the project, who invented in 1966 the term "social indicators" as *"statistics, or set of statistics and any other form of data that allow to assess where we are and where we are going with respect to our values and objectives, and to evaluate specific programs and determine their impact"*. [5]

From this definition, the Author derived three classes of indicators: the first one cognitive, the second one predictive and the third one evaluative.

In this work, the indicators are applied to the field of architecture and engineering. Indicators can be classified in more macro-ambits, which contain several ambits and lower-ambits.

In the proposed methodology the macro-ambits are those that describe the condition of buildings, the objectives to reach and the performance actually achieved. The ambits include the indicators that represent the urban quality, the architectural quality and the structural quality of buildings and, finally, the lower-ambits make supply the information needed for the design phase and for checking the results of the refurbishment process.

3.3. Architectural and functional issues

The starting point of the proposed methodology is the development of an in-depth knowledge acquiring activity to gather the most extensive information as possible about the buildings undergoing intervention.

It leads to the definition of indicators related to the macro-ambit of the condition of buildings [see figure 1]. Inside it is possible to identify three different ambits: those related to the urban quality, to the architectural quality and to the structural quality. The first ambit may, in turn, be divided into two lower-ambits: the first one is related to the reorganization of the buildings and the second one to the allocation of the functional mix available in the surrounding areas.

In the lower-ambit of reorganization of the buildings two indicators can be found. One of them identifies the currently building owners (indicator 1.1.1) and the other one identifies the possible presence of public incentives, provided by the government to increase the building capacity (indicator 1.1.2).

In the second lower-ambit the current allocation of the functional mix present in the surrounding areas of interest to the building is established. It is useful to identify the requirement in terms of housing areas (indicator 1.2.1) and services areas (indicator 1.2.2).

The second ambit, the one of the architectural quality, can be divided into two lower-ambits: one that represents the general characteristics of the industrial buildings and the other that supplies their specific characteristics.

In the first lower-ambit two indicators are present. The first one shows if the building is subject to architectural constraints under the Code of Cultural Heritage (indicator 2.1.1). The second indicator specifies the quantity of occupied territory compared to the surface available in the site (indicator 2.1.2).

The second lower-ambit, the one of the specific characteristics, consists of two indicators: one that establishes the integrity of the vertical closures (indicator 2.2.1) and the other that shows the integrity of the horizontal closures (indicator 2.2.2).

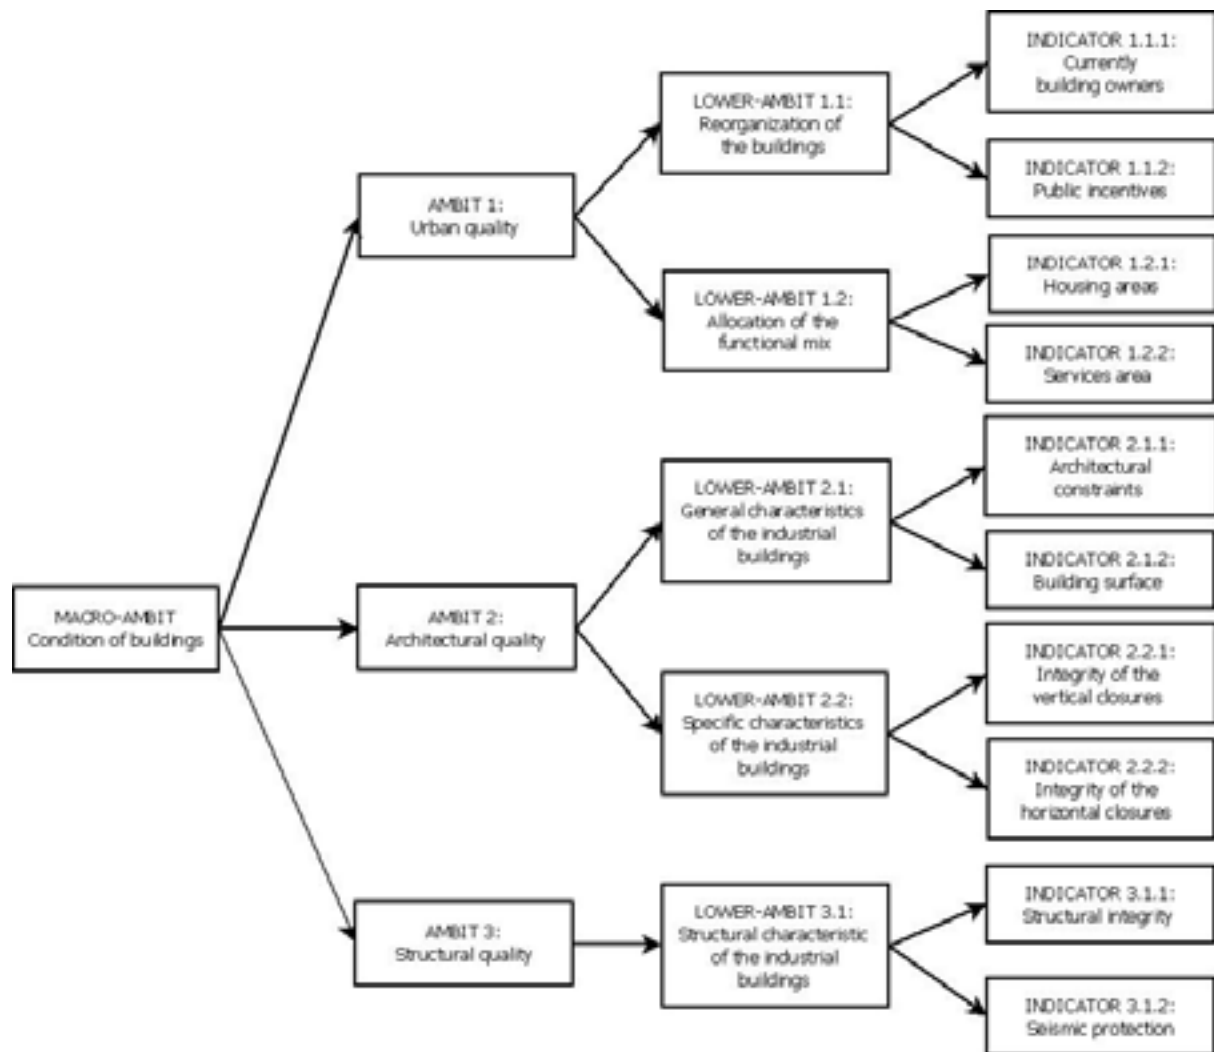

Fig. 1: Classification of the indicators used in this study.

Pointing the attention on the activities carried out on abandoned industrial buildings in Italy and worldwide, several types of functions were assigned to them. Thanks to the cognitive and social analysis the functions to be inserted in the former industrial building under study can be determined.

After having verified the actual presence or absence of the closures and of the roof, and their recoverability, the actions required by buildings are closely related to the implementation of safety both from the structural and from the environmental points of view.

There are several possible solutions for reuse. The first concerns the reuse of the building as a container of similar or different activities, like a sort of a "Russian doll" that is composed of pieces of different sizes, each one can be inserted into one of larger size. The building belonging to the industrial archeology becomes the "mother" and the function that will it will host inside will be the "seed".

Another possible solution extensively applied in the Ruhr area in Germany or in the Marche region in Italy can be considered. It is the use of buildings as museums of themselves, where their history and the area around them is commemorated and the visitor participates to the life of the former factories and can "breathe the smells" of the hard work of the industry.

The skeletons of the buildings can also act as spaces for public events, religious and sports events or they can host playgrounds for children or adults. This occurs, as an example, in the Parco Dora in Turin, where the remains of the foundations, transformed into storage tanks for rainwater, host new functions and allow for the irrigation of the gardens that have been created using the spaces surrounding the buildings themselves.

Then the historic building can be kept alive, making it become an attraction itself, only guaranteeing its preservation over time. The building becomes an attractive monument in memory of his role played in the past.

3.4. Structural issues

The structural issues form part of the status quo macro-environment, and, specifically, they are in the third area (structural quality). This field contains the sub-domain of the structural characteristics, where two indicators can be identified: the first one is structural integrity (indicator 3.1.1) which describes the state of conservation of the structure; the second one detects the level of seismic safety that the structure is capable to ensure with reference to the performances required by the Code Requirements (indicator 3.1.2).

For all the structural types of disused industrial buildings, the knowledge of their state of conservation and maintenance is a priority, as provided by the technical provisions in force.

The corresponding phase of knowledge leads to the building condition and maintenance specification. In particular, it is essential to know in-depth technologies and materials used at the building time, as well as the reconstruction of the historical transformations undergone by the building during its life.

The structural safety under both vertical and seismic loads is evaluated by applying the present methods and rules, as well as the current loadings, and not, as it might seem erroneously reasonable, the rules used at the time of the original design. In fact, the currently in force technical provisions contain, almost by definition, the latest topics and approaches concerning the structural safety.

During the study on the seismic vulnerability of buildings, the knowledge phase allows to assess the level of seismic protection that can be ensured, and then decide whether to undertake seismic retrofit or strengthening [6].

Following this method, it is possible to optimize the available financial resources through the systematic comparison between intervention costs and obtained benefits, in terms of increased building safety and, more simply, in terms of resulting lower costs of the recovery planning.

In order to evaluate the structural safety, qualified investigations that include the following activities are required:

- Analysis of foundations:
geometry survey and assessment of the mechanical properties by visual inspection and localized digs, also to identify any underground facilities, structures and cavities. In this phase, the state of conservation of the nodes between the reinforced concrete foundation and steel structure is also to be examined.
- Analysis of the main vertical and horizontal structural elements:
for metal structures, the identification of construction technology and the assessment of the status of the material conservation, verifying severity and depth of any corroded layer through in situ and in the laboratory tests. These include the evaluation of the material mechanical strength, the measure of the corrosion potential and the magnetometric tests aimed at inspecting the welds.
- Analysis of the floors and roof:
execution of static loading tests aimed at evaluating deformability and capability of floors to withstand the vertical loads without inelastic deformations.

The assessment of structural safety, under dead and live loads as well under seismic forces, can be performed according to the European or to the Italian seismic code, that require to firstly evaluate the "levels of knowledge" (LC) on the basis of the deepening of the in situ investigation, as described above. Obviously, the optimal condition, although not always reachable, is the one corresponding to the best "level of knowledge", which allow maximizing the material and structure performance.

Once the knowledge phase is completed, the subsequent one is the identification of possible restoration/retrofit project, essentially finalized to achieve structures capable to satisfy the 100% of the code safety levels at the ultimate and the serviceability state.

In order to identify the optimal structural solution from the point of view of performance, in addition to the economic one, several traditional and innovative intervention techniques must be taken into account. A preliminary analysis should compare the performance achievable by the use of different strategies, taking into account the implementation easiness, which significantly affects timing, durability and increase in expected seismic performance.

In this perspective, priority will be given to interventions characterized by a substantial decoupling function of vertical and horizontal loading resistant. Doing this, the seismic retrofit of structures is extremely easy and inexpensive, since the interventions mainly involve the seismic-resistant part only.

Finally, it has to be recalled the possibility to install energy dissipation systems, as high damping bracings, seismic isolation systems, and, more generally, system devices able to alter in a favorable manner the dynamic behavior of the structure under earthquake (passive control, active control, hybrid control systems) [7].

4. Case study: an industrial building in Sesto San Giovanni (Italy)

4.1. Introduction

As a case study is considered the area of the former Falck steel production plant, located in Sesto San Giovanni, in the hinterland of Milan. It is one of the most important National Interest Sites in Italy. The interested area is the one that until 1995 hosted the “Acciaierie and Ferrerie Lombarde Falck”, comprising a surface of about 143 hectares.

The Programme for the Government of the Territory (PGT) of the district of Sesto S. Giovanni has divided the area into two areas of strategic transformation (ATs). The first one, the ATs1 includes some buildings of the factory (the Union, the Concordia, the Plis, the Trai, the Vittoria A, the Vittoria B and the Transider areas) while the second one, the ATs2, includes the railway site [see Figure 2].

In the whole area there are still seventeen industrial archeology buildings, most of which are contained in two areas: the Union and the Concordia areas. In the first section, there are seven buildings of historic archeology, while in the second one the industrial buildings are five.

In this paper, the issue of the functional and the structural recovery of one of these buildings will be faced.

The building in question is located inside the Union compartment and it once hosted the rolling mill train [Figure 3].

Fig. 2: Plan of the former Falck area.

Fig. 3: The building "Rolling mill train" - Block A.

4.2. Architectural and functional perspective

The building under investigation dates back to the '30s. The indicator 1.1.1 informs that it was originally privately owned by “Acciaierie and Ferriere Lombarde Falck”. It hosted, in particular, the plant of the hot strip mill. Currently it is still privately owned, but by a real estate company that does not use it for any function.

It covers an extremely large space, divided into two parts: the block A still has the original roof, cleaned from Eternit (the brand name of a type of asbestos-based insulating elements), 239.44 m long x 29.70 m wide over an area of 7110 m²; the block B is smaller, it no longer has its roof, only retaining the steel columns, and is 58.60 m long x 29.70 m wide, over an area of about 1174 m². The amount of the surfaces is specified by the indicator 2.1.2.

The building structure is composed of steel frames having a span of about 28 m, placed at the interval of 13 meters, growing to a height of about 20 meters.

The block A maintains the integrity of the horizontal closures, but no longer has the vertical walls, while the block B lacks of both types of closures (2.2.1 indicator and indicator 2.2.2).

The building may take advantage of a volumetric incentive granted by the Programme for Government of the Territory, which allows increasing the covered volume by 15% (indicator 1.1.2).

The industrial warehouse is protected as an historical building by the PRG 2004 (see indicator 2.1.1).

According to the integrated program of action (PII), the function allocated to the rolling mill train building is that of sport and education container [see figure 4]. Inside the historic building will be realized, therefore, a new building, disconnected from the existing one. It will inherit all the values and requirements supplied by the knowledge acquisition phase.

Fig. 4: Recovery of the "Rolling mill train" building. Plans.

Fig. 5: Recovery of the "Rolling mill train" building. Sections.

The new building is divided into two blocks, as the existing one: the first block has the function of pre-school, primary school and secondary school, and the other one is devoted to the sporting center, including a space for the swimming activity.

The new features are developed within the existing building. The new construction reaches the height of about 10 m.

The roof of the new building is partly organized as a green roof, assuming the function of space dedicated to the football game [see figure 5].

4.3. Structural issues

The most important requirements to be satisfied, for what concerns the structural safety, are the structural integrity, that is as the ability to withstand the dead and live loads (see indicator 3.1.1) and the level of seismic protection that the building can ensure (see indicator 3.1.2). Generally, it should be noted that at the time of the design of the "rolling mill train" building, the structures were calculated using the allowable stresses method, whereas the current codes require to verify the structures at the limit state, with reference to both the ultimate and the serviceability ones.

In this regard, the fulfillment of the serviceability limit state may be more onerous than the ultimate limit state one for metallic structures, such as the ones at under consideration, because of their high deformability. This is particularly relevant if the architectural design foresees the installation of vertical closures in glass, particularly sensitive to deformations.

Regarding the seismic safety, it has to be observed that the examined building structure is located within a non-seismic area. Nevertheless, the social role that the building will play makes reasonable to obtain also a seismic protection against low seismic forces (reference to low seismicity area), mainly referring to the preservation life limit state. Furthermore, for this type of structures, the seismic action should be more onerous than the wind one, certainly considered at the time of the original design [8]. The fulfillment of the seismic requirements can be obtained by arranging high dissipation bracing in the existing structure, in order to optimally absorb the horizontal dynamic actions.

With regard to the new building structure, which will be realized within the existing one, steel material will be adopted, because it makes easier and more natural to combine the new part with the existing one. Even in this case, the fulfillment of the seismic requirements is not a minor issue, also in consideration of the large loads to be applied on the roof and of the very great ratio between building length and width in plan. Finally, the foundations of the new building will be necessarily independent from the ones of "rolling mill train" building and will have the same base level. The knowledge phase will provide the foundation type [9].

5. Conclusions

In this work a methodology has been proposed for the refurbishment of buildings falling into disused industrial areas.

It makes use of a project management support tool, namely the graph of logical sequence (GLS) or flow chart, in order to identify the concatenation and the logical sequence of activities that make up the building process of recovery.

Problems are considered in an integrated approach both the architectural and structural features.

The proposed methodology leads to the definition and use of suitable indicators, which represent in summary the information that is being transmitted between the various logical blocks that compose the graph.

the indicators relevant to the issue of rehabilitation of disused buildings are then identified and classified, critically discussing their characteristics.

An example of application, consisting of the proposed recovery of an abandoned industrial building, once part of the former Falck area in Sesto S. Giovanni, helps to clarify the practical application of the procedure.

In particular, as regards the architectural and functional aspects, the hypothesis of reuse of the "Rolling mill train" building is proposed creating inside it a building devoted to sports and teaching.

As regards the structural aspects related to the existing building, the relevant methodologies to the evaluation of its safety under both static and seismic actions are recalled and innovative solutions are proposed in both perspectives. With reference to the new building steel is adopted as construction material and solutions are proposed to guarantee the level of seismic protection require by the Italian building code.

CHALLENGES IN THE FIELD OF HERITAGE CONSERVATION IN THE DEVELOPING WORLD: A CASE STUDY OF BIHAR, INDIA

Kamini SINHA, Shailendra Kumar MANDAL

Department of Architecture, National Institute of Technology Patna, Patna, India

kamini_nitp@yahoo.com, vastumandala@yahoo.com

Abstract

Conservation includes everything starting from academic inquiry, historical research to policy making, planning uptill specific physical intervention. But, many a times the intervention becomes somewhat disconnected from this broader field of conservation. Decisions about what to conserve and why are often taken independently from those dealing with how to conserve, and vice versa.

This problem is more obvious in the developing world. The state of Bihar in India is very rich in terms of architectural heritage, its capital Patna being the site of the ancient capital of Patliputra. Their value ranges from local to international level. But integrated conservation becomes tough to achieve as the active intervention loses sight of the interconnectedness of treatment with the preceding activities.

Growing awareness of the stakeholders in the present time is resulting in various activities on the part of both Government and public. This pressure has resulted in various policy decisions on the government level. The government has created a committee under the Department of Urban Development to assist the government in taking up the activity of conservation on a war footing.

The paper analyses the efforts of all stakeholders using a combination of qualitative and quantitative research methodology. It concludes the challenges in the path of integrated conservation.

Keyword: Architectural Heritage, Ancient Patliputra, Stake holders, Integrated Conservation, Policy making

1. Introduction

Indian civilization being one of the most ancient civilizations of the world, the country, today, is one of the richest countries in the world in terms of architectural heritage. But, it being a country of 1.22 billion population with a per capita income of just about Rs 50,000/- heritage has not been able to place itself high on the priority list. Its awareness comes only after our material needs are satisfied which is tough to achieve in the given conditions.

The architectural heritage of India is of diverse nature and the cultural fabric of the settlements gives them a unique nature. But the fast pace of change due to rapid urbanization in the past few decades have placed this heritage in a problematic situation. The planning systems of India have been unable to lay enough emphasis on the heritage which could have facilitated their protection. However certain initiatives are being taken by different governmental organizations like the National Urban Renewal Mission, Ministry of culture and the Ministry of Urban Development, Government of India. The implementation of the decentralized governance enacted in the constitution in 1992 is also providing the required framework for laying emphasis on heritage conservation

1.1 Existing framework for Heritage conservation in India

The first major effort by the administration of the country in the field of heritage conservation was the establishment of the Archaeological society of India by Alexander Cunningham in 1861. The activities of ASI include maintenance, conservation and preservation of protected monuments and archaeological sites and remains of national importance. It works under the provisions of the Ancient Monuments and Archaeological Sites and Remains Act 1958 and the Antiquities and Art Treasure Act, 1972. It is an attached office under the Department of Culture. For its administrative convenience it has divided the entire country into 24 circles which together protect a total number of about 3700 heritage components. These belong to different periods ranging from the prehistoric period to the colonial period. They include temples, mosques, tombs, churches, cemeteries, forts, palaces, step-wells, rock-cut caves, and secular architecture as well as ancient mounds and sites which represent the remains of ancient habitation. Apart from the archaeological society of India, are the state archaeology departments working under the state governments which protect an even lesser number of heritage components. In certain cities even the municipalities are making some contribution in the field of heritage conservation. There are also a few number of non-governmental organizations working for the conservation of heritage. The largest organization among these is the Indian National Trust for Art and Cultural Heritage (INTACH). It is an autonomous non-governmental Indian NGO that seeks to preserve Indian Art and Cultural heritage. It was founded in 1984. Its headquarters are in New Delhi and has chapters in 117 Indian cities as well as chapters in Belgium, the UK and the United States. Some of the state governments have also established state heritage committee to further assist in conserving the heritage. Bihar is one example among them where the Heritage Development Committee has started working since 2011. Further the Universities also run some courses where the students are taught various aspect of heritage conservation. Heritage Conservation is not yet a mainstream vocation and is taught only in School of Planning and Architecture, New Delhi and Centre for Environmental Planning and Technology, Ahmedabad at the Post Graduate level. It will still take a long time to be fully established at the professional level.

The total effort of all these bodies put together has still been very little, when compared to the rich heritage of the country.

This can be explained by taking up an example of the state of Bihar which is ranked comparatively low among all the states of India in terms of development achieved so far while can be considered rich in terms of the architectural heritage that it possesses. The heritage comprises of both individual structures as well as historic areas. In the given scenario, the important task of heritage conservation becomes a very difficult task to achieve. On one hand is the infinite number of valuable heritage and on the other is the endless list of issues in the field of heritage conservation. The challenges in the field of its heritage conservation can be enumerated as follows:

1.2 Social awareness towards the cause of Heritage Conservation

The basic lacking in the field of Architectural heritage conservation is the social awareness and the emotional connection between heritage and society. Besides trained specialists, heritage conservation

Figure 1 Remains of the Great capital of Patliputra at Bihar, India

needs the collective efforts of all citizens and authorities. This is tough to achieve as the process of spreading social awareness is still in its nascent stage. There are many reasons behind its late awakening. When the western world was awakening to the cause of conservation in the 17th to 18th century, India was a bunch of small kingdoms, which were either independent or under the central rule at Delhi. The political conditions of these kingdoms kept swinging between stability to instability. This continued for a long period in history until the country became a colony of the British administration. This led to the long struggle for freedom. Under such conditions heritage could never gain importance. It was more so for the state of Bihar which ranks low in terms of literacy rate or development as a whole. The social awareness is closely linked to the literacy rate which is about 60% in the present time while it was even lower in the past decades. There has been an effort only since a decade or two towards the cause of spreading awareness. There is also a serious crunch of well trained professionals in the field. The general society is unable to connect itself with heritage conservation as most of them consider it to be the rich's hobby. For the state of Bihar, with its rich diversified legacy the task of heritage conservation is very long. As an issue of wider public and professional concern, it is still very nascent. Also there is a lack of knowledge among the people who are genuinely concerned about the heritage. Again, the initiatives that are being taken by the concerned bodies are not targeting the general public or the younger population. These programmes are generally among the researchers and people working in the field. This process will either take too long to make the state aware or it might just not be able to spread the required awareness. To get the required results initiatives at the levels of education, communication, and mechanisms for public engagement to inform people about the values of heritage places, how to care for them and how to provide for the public's active involvement in the process needs to be taken. A positive initiative in this direction has been taken by the newly formed Bihar Heritage Development committee which has involved history students from all universities to collect the initial information regarding unrecorded heritage in their own areas.

1.3 Absence of duly formed laws backing all conservation related decisions and works

Though the practice of conservation in European countries was already effectively institutionalised by law by the mid of the nineteenth century, Indian scene still lacks a properly drafted law for the field of conservation. Moreover, though quite a number of European countries were already aware and were working in the direction; this issue became an international concern only in the recent decades. India is still struggling to get a proper law in support of architectural conservation in place. But the problem is that the process is still trying to derive from the western definitions and experiences, which is somehow hampering the process of indigenous experiences. In the absence of properly formulated legal framework, the initiative taken by the concerned bodies mostly meet with failures. There is also a gap between the genuine worker of the concern and the administration which is concerned with law formulation. At the city or municipal level, mayors and political decision makers play a leading role and can potentially define and implement policies that will drive the city's approach to its heritage, its conservation, how it is interpreted, and the role conservation plays in the city's or urban area's future

Figure 2 Map of Bihar, India

Figure 3 Map of India

development. In this scene, the law which may get formulated in the near future will by all chances lack the indigenous requirements.

1.4 Insensitive Planning Actions

The threats to historic urban areas generated by modern urban planning are one of the major concerns of the field of conservation. Their conservation has so far received very little attention in urban development policy. Though, it has been addressed to some extent in the western world, it is tough to give it a priority in the developing country like India. For eg, the historic Patna city which has developed over various historic layers and which is estimated to be the location of the historic city of Patliputra, the centre from where Ashoka the Great ruled the whole of “Bharat varsha” is being dealt by the Planning Department in the same way as planning proposals for a newly developed area. Instead of giving this heritage its due importance, its conditions are rather being considered as limitations in its development. This is leading to neglect of the area contributing to its degeneration. Conserving this historic urban environment is currently one of the most urgent and challenging cultural heritage conservation issue. But in today's scenario, Conservation practices are isolated from the city's processes. The planning process of the city does not give proper priority to the aspect of conservation. The planning decisions majorly consider the size of the city to conclude planning needs and potential solutions, whereas the diverse nature of the cities needs a case to case solution. A typological categorization of the cities would have given a better understanding of the issues related to conservation and better and apt solution to the problems. There is a broad recognition by heritage professionals of the need to better integrate heritage conservation into the broader planning and city management framework, however there is a lack of knowledge about how to achieve this. Conservation is isolated or confined to the realm of monument conservation, the resulting lack of integration into the general urban planning framework limits success. Furthermore, heritage conservation professionals and departments are located at levels in municipal institutional hierarchies and so their influence is meagre as they do not have direct access to the decision-making paths necessary to influence good conservation outcomes. Conservation professionals and urban planners have been located in separate areas of the city governance. Weak or poorly implemented legislation and policy, or a lack of policy guidance is also exacerbating this situation.

1.5 Lack of inter-departmental functioning

The lack of coordination between the multidisciplinary professionals and departments is one of the major reasons behind the poor state of conservation in the state. Since there is no proper co-ordination between all the departments connected with the governance of the areas, each has their own set of rules and goals. These many a time work out to be contradictory, creating deadlocks and confusions in work implementation. Improper allotment of power and designation of areas hamper the basic aim of conservation of heritage. For Eg, while the Department of Urban Development is taking decisions for the historic core of Patna city (Capital of Bihar), the Department of Archaeology or the Archaeology Survey of India have their jurisdiction limited to individual structures. The State's requirement may be fulfilled by formulating a separate Department of Conservation under the State Government which can function in coordination with the other Departments.

1.6 Effect of Social Conditions

Bihar is still a traditional society, and the conservation of heritage or its elimination is an important issue in defining the nature of development. The past century has been one of unprecedented change in terms of impact on the urban environment. Different pattern of changes are observed in the different parts of the cities. While the comparatively newer areas are growing through rapid urban expansion and increased density due to immigration and population growth, the old historic cores are suffering from emigration resulting in obsolescence, abandonment and/or stagnation. This dual nature of change has its own sets of effects on the conservation scenario. These need to be properly managed to get the required output but in the absence of a proper management system, this is hard to achieve.

1.7 Lack of proper information Management system

The information management system of the state is another big challenge for the conservation of heritage. Since there is no transparent system, there is repetition of work at most of the sites. This is also due to overlapping of jurisdictions in the historic areas. The state also needs to assess the state of information available to practitioner and to identify the needs in the conservation of historic cities and urban settlements.

The Right to Information Act has been passed in the country in 2005. Under its provision; any citizen may request from a public authority any information which has to be replied expeditiously or within thirty days. The Act also requires every public authority to computerize their records for wide dissemination and to pro-actively publish certain categories of information so that the citizens need minimum recourse to request for information formally. But this proper management of records and their availability to one and all is still to be achieved and so poses to be an issue in present times.

Different types of information lie with different department with most of them lacking proper information management system and transparency of information. The work done by the agents are not published regularly, as a reason of which important data get lost and many a time work gets repeated. In such conditions Conservation projects are seriously hampered.

1.8 Narrow Definition

The definitions that are guiding the agents in the fields of conservation work in the state of Bihar are still very narrow. While on the international scene, the definitions have grown out from the concept of monuments to the concept of historic sites and further from the concept of conservation to the concept of management, the state still works in terms of monuments and their development, where this “Development” is many a case becomes anti to the concepts of real conservation. The need is for area rehabilitation and revitalisation approaches, which can maintain the urban tissue and the essential qualities of the historic areas and of the life of the communities residing there. It can also adapt the physical structures and activities to some of the present requirements which may otherwise get abandoned, for e.g. the various *havellies* of the *nawabs* spotting the urban fabric of the city. The monuments need to be seen as part of the conservation areas, and their sustainability and revitalisation will be most feasible if they are integrated into new concepts of use.

Figure 1 Havelli of Sir Sultan

1.9 Lack of Finances

Bihar is a state which is struggling to develop in the present times. In this state where the state is concentrating on developing basic sectors like roads, education, electricity, health and industries, the requirements for heritage conservation has taken a back stage. Fund allocation for the cause is limited which restricts the conservation related activities. In the condition of very little social awareness to the cause of Heritage conservation, funds from any other source are also limited. Attracting private investment to facilitate municipal needs is inevitably a priority for many local governments, and as national funding declines, cities are increasingly required to become financially self-sufficient.

1.10 Lack of Manpower

There is a lack of manpower who can contribute towards the conservation of the architectural heritage of Bihar. The Patna circle of Archaeological Survey of India encompasses an area which includes three states viz. Bihar, Jharkhand and Parts of Uttar Pradesh. Its manual strength is very less in comparison to the actual requirement. The total strength of resource persons that it has is very small in comparison to the duties that it needs to deliver. Similar is the case of Department of Archeology, Government of Bihar. There is no other governmental or Non-Governmental Body, neither any individual professional who is doing any serious work for the conservation of the heritage. The newly formed Bihar Heritage Development Committee is also a small body in its initial stages of working. Its members are either dual charge holders or people who are not trained in the field. This committee needs an inception period when it can be set on the right tracks of work. In such conditions, the heritage is losing time and if things do not change fast for the positive some of the most valuable heritage of the state will be lost forever.

1.11 Lack of proper designation of responsibilities

The responsibility of conserving the heritage must be shared by all. Each player has a different and specific role in the management of the historic urban environment. The relationship between the actors is also critical. Roles and responsibilities need to be clearly defined and well understood by all the actors and processes for dealing with conflict must be clearly identified.

In Bihar, it still needs to be understood as to who the main stakeholders in the field are, and who would be the main players. Decision makers are not usually trained in the field of heritage conservation and they rely on the city's various technical departments to manage urban development and conservation. Politicians often perceive heritage conservation and management as an impediment to development and economic advancement and so their commitment to the cause is much less than the requirement. Conflicting objectives between different levels of government further complicate both the decision making process and the implementation of heritage policies.

1.12 Lack of interconnection between the different players of the field of Conservation

Proper Conservation of heritage can be achieved only if all the required steps, right from academic inquiry, historical research, policy making and final intervention are properly interconnected. But this is a serious issue in Bihar as each step has a different set of player where the interconnection is lacking or quite weak.

The major agents working in the field are the Archaeological survey of India and Department of Archaeology, Government of Bihar. Apart from these Bihar has a chapter of INTACH. All these three bodies have been working on a limited list of monuments. ASI being a central government has a considerable working force and finances at its disposal. So it has been able to look after the monuments in its list in a comparatively proper way. But due to the limited resources, its list itself is quite limited.

The Department of Archaeology, Government of Bihar has a serious crunch of all types of resources, which has limited its activities to a great extent. INTACH has not been able to deliver much in the direction of active conservation of the heritage of Bihar.

The fast rate of globalisation in the past few years and the developments on international scene of conservation has together contributed towards raising the awareness in the society of Bihar. This has resulted in certain major steps being taken by the government of Bihar for the betterment of the scene of architectural conservation in the state of Bihar. But the bottom line is that in the absence of interconnection between all players, the initiatives taken do not attain the targets set for them.

1.13 Continuously changing Political Condition

The rapid cycle of change that occurs at the political level, creating and maintaining a robust and effective administrative structure becomes difficult. In the given scenario, the state requires establishing and retaining professional conservation expertise within the core of an urban area's planning and management system. Its absence is posing to be another hurdle in the path of provision of a continuous and dynamic conservation process which continues from planning to implementation.

1.14 Insufficient courses pertaining to Architectural Heritage and Conservation

Current architectural education offers little in the way of training about historic urban environment, historic buildings or conservation. Global architectural approaches currently pay little heed to local context and rarely recognize the local distinctiveness that comes from historic fabric. Moreover, the state has very little number of institutions providing architectural education. Basic education about historic building materials, building conservation practices and particularly conservation practice for historic urban areas has become a postgraduate educational activity, which at the moment is not provided in any institution in the state.

2.0 Conclusion

The general picture today is not encouraging. The scene of Conservation of Architectural Heritage in Bihar, India presently needs serious thought and quick decisions backed by devoted actions. And most important is the transparency and interlinking of all activities taken by all players devoted to the cause. In aiming for an integrated approach, however, the responsibility needs to be shared beyond the conservation practitioner. Each player has a different and specific role in the management of the historic urban environment. The relationship between the actors is also critical. Roles and responsibilities need to be clearly defined and well understood by all the actors and processes dealing with conflict must be clearly identified. What can emerge in the process is a totally Indian context in the field of Heritage conservation.

In Bihar, the act of conservation, unlike that of the west, would in fact play a central role in development processes in the coming times. It would help re-establish the identity of the state. As the conservation movement has started very late in Bihar, it has to go fast to be able to catch up with the international scene in Conservation or with the attitudes, institutions and practices that have taken several generations to evolve in Europe. But then, if the state does not act immediately, it will have to bear a drastic loss of its historic build environment and the associated cultural heritage.

Cities are living environments that must change and adapt to the evolving needs and aspirations of their inhabitant. The challenge is to manage these changes in a way that balances the seemingly opposing, but often allied forces of conservation and development. Realistically, none of the conservation community argues for total preservation of everything that is old in a city nor any one of them would be against attempts to improve sanitation and water supply, reduce overcrowding, or otherwise improve the living conditions in older housing areas. Such improvements do provide a more satisfactory environment. But a better environment also implies a satisfying of social and cultural life for those who make use of the environmental resources. It is the human inhabitants who create and constitute the socio-cultural and economic systems which give life to the physical environments.

Destruction of the historic centres, of old housing stocks and of monuments continues either by active policies of clearance and replacement or by passive policies of doing nothing to halt the slow deterioration and decline of such areas. Whatever efforts that have been made uptill now have been small scale efforts, often focussed on the most "profitable" projects, such as historic areas with tourist potential. The lower-income residents have been ignored or pushed out by existing renewal policies. With such practices there is a danger for the future that in these cities of the developing countries, only fragments of their urban heritage will remain.

The focus of revitalisation and rehabilitation of historic centres, therefore, has to be on whole areas, not just individual buildings, and on social communities, not just the physical environment. These older housing areas, typically in the inner parts of the city are often home for lower-income families and they have physical, social, economic and cultural values different from, and beyond the perceptions of bureaucrats or planners.

Advocates of rehabilitation policies emphasise the importance of a comprehensive and integrated approach to planning for older areas, and especially the need to consider complete conservation/rehabilitation areas, not just individual buildings. Of course, particular buildings of special historic and/or architectural interest should be preserved as part of the overall scheme. But the real focus is on the activities and uses of the buildings taken as a whole, and the need to upgrade selectively and adaptively.

Cultural and political awareness are the key to the battle to preserve the valuable heritage. A strong governance and legislative framework; policies that provide guidance on and trigger actions that implement the legislative framework are the need of the hour. In contrast to different players performing different task with the same goal but no interconnections, an integrated system of conservation needs to be drafted and followed. The whole circuit of education, researches, policies

and projects needs to be completed so that the state does not have to bear the irreparable damage of its valuable heritage. Economic instruments and tools that address market failures and secure conservation also need to be adopted for a positive result. What is also required is the change in the attitudes of the professionals, of economists, architects, planners, developers and the administration. It is necessary to create a changed political environment in which historic centres are rehabilitated in their true value and where policies and practice of government are modified accordingly. Institutions need to be developed, and economic and administrative instruments for control and promotion needs to be worked out.

Civic authorities need to pay attention to rehabilitation and re-use of old and historic properties which are not under government protection and use. These properties need to be listed and their rehabilitation and re-use need to be promoted. Those under public ownership can be brought to appropriate community or private-sector use.

There remains great opposition to such changes towards area conservation and rehabilitation. Landowners/landlords, speculators, government administrators, big construction companies, and many public agencies have vested interests in re-development and so, will fight to protect their stakes for modernisation. These groups have their political allies as well. Unfortunately, the people are large, and especially the people living in historic city centres, have yet not developed a sufficient sense of self-identity and community purpose to allow them to fight back. This can change, and indeed must change; if anything is to be done about the sustainability of urban heritage. But it will not be easy. And time is rapidly running out.

Priorities and interests between different levels of government are not always shared, further isolating conservation practice from the city's process. Strong local leadership is key to insuring the integration of conservation planning needs with other strategic planning demands, to establish official conservation mechanism that meet various governance requirements, to engaging with the population and other entities that can affect conservation outcomes, and to securing and directing the necessary resources to implement actions that will serve as a catalyst in the conservation process

Decoding a merchant town: photography, history and survey

Antonella SALUCCI¹

Abstract

The focus of this paper is on the cultural heritage of a small city in the Abruzzi region, with the aim to highlight the identity of a merchant town, preserving one of the first evidence in the Abruzzi residential social housing, a 'case study' especially in the field of sustainability.

The research is oriented on the knowledge of the architectural evolution of Lanciano (Ch), it was a flourishing commercial site, across an ancient main trade route, connecting Marche, Abruzzi, Puglia and Napoli; this routes have shaped the landscape and developed interwoven networks across the urban settlements.

By reading the original text documents and the iconographies, and by making a comparison with the present status – involving both the integrated use of different surveying methodologies and photography – it is possible to give an additional contribution to the documentation, preservation, safeguard and management of environmental and architectural heritage of central Italy.

By observing the city, it is possible to detect some characteristics that provide the historical centre of Lanciano with a foremost quality and uniqueness: an extraordinary harmony has been governing for centuries the adaptation of the urban settlements to the morphology of the territory, strongly characterized by relief and depressions. The four main districts are naturally arranged along the crest lines, converging in the ancient 'curtis anteana', a place of transit and stop, the market place. This urban void is the fulcrum of the city, from where, at the end of the nineteenth century, the well-organized structure of the Fiera district – the object of our study – started and expanded eastward.

Keywords: Heritage – Photography – Preservation – Sustainability – Survey

1. Objectives

The work presented here offers a summary of the results of a study of Drawing investigating the evolutionary dynamics of an Adriatic merchant town, since its ancient foundation a site of important commercial activities. As part of a cognitive investigation of architectural and environmental heritage in the Italian region of Abruzzo, the research pursued the objective of representing the urban complexity of the inland Adriatic City of Lanciano, in the province of Chieti – situated along the band of hills between the Maiella Mountain and the Adriatic coastline – through a survey of its twentieth century urban fabric, in particular the district of Prato della Fiera.

This objective was realised through the integrated use of diverse methodologies of both survey and photography, considered the privileged medium for investigating and interpreting architectural and environmental heritage.

The following notes, accompanied by a selection of images of early results, summarise a phase of investigation involving the gathering of archival documentation – graphic, cartographic, iconographic and textual – and morphological-dimensional data of the state-of-the-art.

The direct examination of original drawings of plans for the town – prepared at the end of the nineteenth century and more recently during the 1980s – and their comparison with surveys of current conditions, allow for a number of interesting reflections on the image of the city. This contributes, if only in part, to the construction of an archive of 'minor' heritage in the region of Abruzzo from the period between the two World Wars.

The observation of the city of Lanciano presents diverse elements of recognisability that render its historical centre a space of unique quality. This uniqueness is the result of a centuries-long process of adapting urban settlements to the morphology of a topographically and morphologically heterogeneous terrain of hills and valleys.

The landscape of Lanciano is comprised essentially of four principal districts – Lancianovecchia on the Erminio Hill, Borgo atop the Pietrosa Hill and Civitanova-Sacca on the Della Selva Hill – each laid out according to the natural form of the ridgeline. These urban agglomerations converge toward the ancient Corte Anteana (now Piazza del Plebiscito). This space of transit and fulcrum of the town gave rise to the ordered fabric of the Prato della Fiera district that expanded eastward at the end of the nineteenth century in accordance with a plan from this period.

The diverse buildings comprising the district of Fiera include the first examples of social housing in Abruzzo; the programme for the modern expansion and reorganisation of the city, designed in 1879 by Filippo Sargiacomo, served as the base for the “Project for the Construction of a New Social Housing Estate in Prato della Fiera” drawn up by the engineer Luigi De Cecco in 1921. [Salucci: 2011]

An important characteristic element within the fabric of Fiera – comprised of the system of historical streets developed along an orthogonal grid that reflects the structure imposed by the nineteenth century plans – is the tower-lighthouse by Aldo Rossi. The fulcrum of the pedestrian spine of the district, it was conceived by the renowned Italian architect in 1987 and constructed in 1989, in the wake of academic and professional interest in this part of the city during the 1980s.

2. Evolution

An analysis of the urban structures and buildings generated by the activities of trade that connoted the territory of Lanciano – public squares, markets, fairs, shops – reveals the complex and open vocation of a region that, during the centuries prior to Italian Unification, notwithstanding its position along the margins of the Kingdom of Italy, geographically distant from the capital of Naples, served as an intermediary with Rome and the Papal State.

While a frontier town with respect to the limits of the Kingdom, Lanciano's geographic position made it in some way central to the Italian Peninsula. The town became a space of transit, relations and communication, serving as a bridge between Northern and Southern Italy, and between the Adriatic Sea and Rome. (Fig. 1)

Investigations into the origins of trade fairs in Lanciano confirm the town's ability to configure itself over time as a multifaceted reality, a hub, a space of transit and point for the exchange of consumer products of varying types. This condition dates back to the thirteenth century when, under the protection of Venice, the town assumed the role of a threshold for the entry of its goods toward Southern Italy. [Bulgarelli Lukcas: 2006, p.11]

It is still possible to recognise diverse elements that make the historical centre of Lanciano a space of unique quality: for centuries an extraordinary harmony governed the adaptation of urban settlements to respond to the morphology of a territory of hills and valleys.

A synchronic reading of plans for the expansion of the historical centre developed over the centuries reveals an adaptation of settlements to the morphology of the terrain and a chronological synthesis of the evolution of the urban fabric. Early settlements arose on three hills: the Erminio, the ridge along which developed the axis of Via dei Frentani and the district of Lancianovecchia; the Pietrosa Hill, home to the Corso Roma and the Borgo district; the Selva Hill, with the axis of Via Garibaldi and the district of Civitanova-Sacca; the new axis of Corso Trento e Trieste developed to the south-east, in the area of Prato della Fiera. Running parallel in a south-east direction is the system of ‘Corsi’ (Boulevards) and the large public square of the Fiera district (5,6,7). The object of study includes: Corso Trento e Trieste and Via Monte Maiella (6); Corso della Bandiera (5); Via Vittorio Veneto and Viale della Rimembranza (7), which crosses the void of the Piazza della Vittoria. It is around this space that the first nucleus of social housing was developed – the first in Lanciano, and in the entire region of Abruzzo. [Salucci: 2012, pp. 97-114] (Fig. 2)

The evolution of the urban fabric from the tenth to seventeenth centuries reveals the complexity of trade relations involving the town of Lanciano, which gradually assumed an important position, even if in alternating phases, in commercial trade relations in the Mediterranean. This was due both to its peculiar geographic position, and its morphological structure (Fig. 3).

Lanciano, the ancient settlement of Anxanum, appears on the Tabula Peutingeriana. It was an important centre of trade since the era of the Frentani. Its existence as a ‘colony’ and ‘municipium’ during the Roman Era is demonstrated by the Bridge of Diocletian that consents a connection between the inhabited city and the plateau of Prato della Fiera.

The natural configuration of the Erminio Hill, situated between the two depressions of the Malavalle Valley and the Pietrosa Valley, offered adequate protection for the heart of the Roman settlement that developed along the ridge of the hill, the Via dei Frentani. This axis of connection with the Via del Mare lead to the coastal settlements of Ortona and Vasto, situated along the important Adriatic tratturo that continues south toward the region of Puglia.

During the Middle Ages the town was a Lombard gastald and in the eleventh century, under Norman control, the town expanded toward the other hills, erecting new city walls with nine new gates: S. Biagio, S. Antonio, S. Nicola, Porta della Noce, S. Chiara, S. Angelo, Porta di Pozzo Bagnaro, S. Maria la Nova and Diocleziana.

Since the fourteenth century all of the urban streets that structure the three districts converge in the area of the former Corte Anteana, currently Piazza del Plebiscito. This space serves as the political, religious, commercial and social heart of the city, the fulcrum of the settlement and a connection via the Bridge of Diocletian, toward Prato della Fiera.

The town's commercial vocation favoured the progressive definitive organisation of the Fiera district under the House of Anjou and the House of Aragon. Following the improvement of connections with the coast – in the wake of the war with the nearby city of Ortona, which hampered the use of the coastal centre of S. Vito – Lanciano gained its natural connection with the Sea.

3. Filippo Sargiacomo – Luigi De Cecco – Aldo Rossi

The current configuration of modern Lanciano – referable to the Fiera district studied here – is the work of the architect and engineer Filippo Sargiacomo (1830-1922). A native of Lanciano, he earned his degree in engineering in 1854 from the University of Naples. His professional career with the municipal government of Lanciano spanned more than ninety years.

Sargiacomo is the author of the urban expansion of the ancient city from the Corte Anteana toward Prato della Fiera: an articulated programme at various scales of urban transformation – from mobility to sewage networks to building systems – implemented in accordance with minute and detailed projects, beginning in the mid-1800s.

The expansion of the city occurred as a series of variations of Sargiacomo's plan, implemented by the municipal government. The sale of public lands in Prato della Fiera to private investors gave rise on the one hand to the modern construction of the city and, on the other hand, determined the migration of the bourgeoisie and commercial activities from the ancient part of the city.

The first Master Plan for the town dates from 1879. Its structure was based on a visual survey drawn up 70 years earlier, the "Pianta topografica di Lanciano levata ad occhio da Nicola Talli (ingegnere civile laureato) in aprile 1809" (Topographical Map of Lanciano Visually Surveyed by Nicola Talli (Graduate Civil Engineer) in April 1809), ink on paper; 27x20 cm. Archivio Storico Comunale di Lanciano (hereinafter ASCL) (Fig. 4). Using this document, Sargiacomo drew up his plan of the city at 1:2000, on a 75x100 cm page. This document was completed by a list of streets, churches and fountains.

Prior to the planning of the new district, between 1880 and 1881 Sargiacomo developed solutions for connections between Prato della Fiera and Piazza del Plebiscito; an open space, in the form of a 'saddle' closed on two ends, situated at the point of convergence of the three districts of Lancianovecchia, Borgo and Civitanova-Sacca. It was also fronted by the Cathedral and the Bridge of Diocletian, the only element of connection with the area of expansion prior to the turn of the century.

The project, which included diverse solutions, managed to reduce the level change between the two areas, facilitating the connection between the inhabited area and the space of the market.

The shifting of the new axis of the Corso with respect to the original project is evident in a plan illustrating the project for the new Corso, with respect to the plaza and the bridge: "Pianta della località del nuovo corso in Lanciano. Scala 1:100. Lanciano, 1 settembre 1907" (Plan of the Area of the New Corso in Lanciano. Scale 1:100. Lanciano, 1 September 1907). Ink on trace paper, 64x32 cm. (ASCL cat.X, b.34, fasc.757) (Fig. 4).

The urban plan for Lanciano was drawn up by the municipal administration in the wake of the laws and master planning studies developed by all large towns following Italian Unification.

On 10 August 1878 the town published the manifesto for a national competition for the "Piano Regolatore della Città di Lanciano e dei progetti relativi per la sistemazione delle strade e piazze interne" (Master Plan for the City of Lanciano and Relative Projects for the Organisation of its Internal Streets and Plazas); Sargiacomo was the sole figure to present a proposal by the established date.

The first true and proper urban planning tool for the city, this plan pursued the twofold objective of remedying the town's infrastructural shortcomings and identifying the axes of urban expansion toward the south-east.

The first axis of the Fiera district is the narrow passage alongside the north-east flank of the Cathedral: the orientation of the 'corridor' leading to Prato della Fiera would constitute the reference for Sargiacomo's development of the 1879 Plan. This document identified the two axes for the primary expansion of the city to the south-east, toward the district of Fiera and to the south-west, beyond the Viale dei Cappuccini in the Borgo district.

The report attached to the "Piano regolatore della città di Lanciano. Lanciano 31 luglio 1879" (Master Plan for the Town of Lanciano. Lanciano 31 July 1879) reads:

"The new district of Fiera will be the enlargement of the existing area along the aforementioned corso, establishing in precedence a large plaza measuring 102 by 52 m, decorated with a central fountain. It

will be formed in three parallel lines of buildings with two regular streets, one of which is precisely the current Corso della Bandiera, and two external streets, one to the north, the other to the south. It should be noted that this latter would constitute the much desired entrance from the other side of the Cathedral, in light of the insufficiency of the sole passage from the plaza, via the Corridoio, in occasion of the town's crowded weekly markets, and Fairs". [Sargiacomo: 1879].

The Corridoio (corridor) refers to Corso Trento e Trieste, realised by filing in part of the Pietrosa Valley according to the project drawn up by Sargiacomo in 1901 - "Progetto del Nuovo Corso tra Piazza Plebiscito e il Prato della Fiera. Planimetria. Scala 1:1000. Lanciano, 2 settembre 1901" (Project for the New Corso between Piazza del Plebiscito and Prato della Fiera. Plan. Scale 1:1000, Lanciano, 2 September 1901). Pen on trace paper, 74 x 400 cm. (ASCL cat.X, b.21, fasc.424). The report accompanying the project reads:

"the creation of a direct communication between the central square of the city and Prato della Fiera, the point of arrival of goods shipped by rail and transported by road from the stations of S. Vito and Fossacesia has been desired by many for some time, given the clear necessity for an immediate and comfortable means of transit from outside to inside the town and to its principal centres such as Piazza del Plebiscito, during the crowded weekly markets and renowned fairs".

Running parallel to Corso della Bandiera, the first in the system of road axes and the ancient line of expansion toward the south-east, the new Corso Trento e Trieste unites the town's two centres, both sacred and profane: the ancient city and Piazza del Plebiscito with the Cathedral on one side, and the modern city, with a large plaza in front of the railway station, on the other. [Salucci: 2007, 177-203]

These plans can be identified in a drawing by Sargiacomo from 1900, illustrating a concept for the realisation of the Sangritana Rail Line between 'San Vito - Lanciano - Castel di Sangro'. His plan – pencil, pen and colour on trace paper, 49 x 66 cm – illustrates the terminus of the new Corso Trento e Trieste and the sinuous line of the railway that wraps a large public square-park, identifiable in the area currently occupied by the hippodrome.

The new urban settlement was developed according to a regular grid of broad streets whose rational layout recognised and expressed the desire for affirmation and self-referentiality of the emerging class. The land divisions of Prato della Fiera were drawn up between 1920 and 1926. Lots were sold to private investors for the construction of new multi-storey buildings, aligned with the grid of blocks redesigned by the engineer Luigi De Cecco in accordance with Sargiacomo's guidelines on 17 November 1921 – "Progetto per la costruzione di un nuovo rione nel Prato della Fiera per case popolari" (Project for the Construction of a New Social Housing Estate in Prato della Fiera). Plan. Scale 1:1000. Black, red and blue ink on pounce paper.

De Cecco's plan consented the realisation in Fiera of the buildings owned by the Ente Autonomo Case Popolari (Autonomous Public Housing Institute, currently ATER) and the scholastic building on the large open plaza: Piazza della Vittoria, crossed by the broad axis of Viale della Rimembranza that runs parallel to Corso Bandiera and Corso Trento and Trieste, all the way to the Hippodrome; the project report stated:

"This boulevard occupies the most desirable position beginning in the north-west at Piazza del Plebiscito and running south-east to the railway station and thus all the longitudinal streets of the new district run in the same direction. Set normal to the Viale Trento and Trieste is a 270 m long boulevard that, beginning at the Sangritana Railway Station, terminates at the grand boulevard of the new District, parallel to Viale Trento e Trieste. At approximately the midpoint of this boulevard is a new rectangular plaza. All of the other streets of the new district are parallel or normal to the aforementioned main boulevards and coordinated with the existing streets". [De Cecco: 1921]

The new social housing estate featured large blocks, with courtyard types and three storey buildings atop a podium, for almost exclusively residential use. It was constructed as part of the Fascist regime's social programmes, with mortgages from the Cassa Depositi e Prestiti in favour of the Associazione Nazionale Mutilati di Guerra. (Salucci: 2011)

In 1989 a requalification and recovery plan was developed for the system of public spaces inside the Fiera district. Guided by Aldo Rossi, the design team was comprised of: C. Di Carlo, S. Di Giuseppe, S. Fera, M. Ricci, F. Spaini, M. Brandolisio, S. De Vito, C. Ghezzi). (Fig. 10)

Prior to the implementation of this portion of the plan, in 1987 the same work group participated (third prize) in the competition for the "Project for the Redesign of the ex-liceo classico, plaza and Pietrosa Valley in Lanciano". [Renzetti: 1989, pp. 35-60]

The drawings of Aldo Rossi's project presented: a site plan, perspectives, elevations and plans of the public spaces of the Fiera district. [Ricci: 1991, p. 219]

This programme included the realisation of the pedestrian complex of Via Monte Maiella, the elevated pedestrian axis that, on the one hand features the perspectival backdrop of the dome of the Cathedral, on the other presents the specific element of the unmistakably Rossian masonry tower-lighthouse with its hexagonal plan:

"The landscape and open spaces have been designed for commercial uses linked with shops or existing locales. The construction of the setting is directly linked to a system of monumental references

that include a stair set between two high walls clad in stone (main passage between the lower and upper town) and a three-tiered brick tower, conceived as a panoramic outlook and a landmark for the tourist office below". [Ferlenga: 1992, p. 90]

4. Sharing – Conservation – Complexity

Representation can be considered an indispensable medium for documenting, understanding, safeguarding, conserving and managing architectural and environmental heritage. Contemporary means of expression valorise representations of the complexity of reality and amplify the possibilities for its fruition. This consents the diffusion, sharing and above all the "open" documentation of information using interactive means of visualisation that make it easier to control and comprehend complex thematic models of reality.

The comparison between the graphic, iconographic and cartographic material discovered during preliminary studies and the urban framework and the configuration of the complex in plan and volume made it possible to fix the relationship between the object of investigation and its context, with particular reference to its particular orographic conditions.

A preliminary 'surveying project' was then developed to plan the methodologies and procedures of a more cognitive investigation. The survey of the urban setting is the result of the integrated use of direct and indirect methodologies.

The phases of indirect surveying included a laser scanning campaign using a Photon 120 scanner: range 0.6-120 m; speed of measurement: 122,000-976,000 points/sec; visual field of 360° in the horizontal and 320° in the vertical; class 3R; power 20mW; 5 sphere-scanning – coupled with a Nikon D300s camera recording on a dedicated hard disk. (Fig. 5)

Photographic documentation was gathered with a twofold and complementary objective: on the one hand as the evidence and interpretation of the principal spatial, formal, morphological and chromatic characteristics of the area's buildings in their current condition, using both general and detailed images; on the other hand, to document the instrumental phases of the surveying process (photo-straightening, laser scanning). (Fig. 5-8)

The survey of the Fiera district allowed us to retrace the principal morphological and typological elements, as well as critical elements resulting from the neglect of the area.

The geometric and architectural survey, at various scales, was accompanied by a selection of thematic analyses related to both the representation of the colour and the condition of decay of the façades, with the aim of re-tracing important values to be reinforced and critical elements to be resolved, resulting from the current state of building conservation.

The experimental quality of some of these buildings makes them examples of a specific quality of dwelling that, by embracing principles of sustainability hoped for and pursued in current building practices, become an occasion for rehabilitating traditional building materials and techniques.

Similar to numerous other examples from the same period found in many Italian cities – in the span of two decades entire districts of social housing were realised across Italy as part of social assistance programmes promoted by the Government – these building types are connoted by specific elements worth of study. These studies may be carried out by exploiting the expressive potentials of Representation, in relation to the safeguarding, recovery, conservation and sustainable development of architectural and environmental heritage. [Salucci: 2011]

Representing the complexity of this merchant town assumes, among others, a twofold meaning.

On the one hand it signifies valorising Italian architectural and documentary heritage, offering greater information about a key aspect of the evolution of 'minor' architecture in the region of Abruzzo between the two World Wars, apparently far removed from the challenges of modernity being faced at the national level.

On the other hand it signifies observing these buildings as the expression of the political and cultural evolution of an 'open' merchant town that conserves, almost unaltered, one of the first examples of public housing in Abruzzo. It is the expression of a public project with an experimental vocation, a sort of 'model district' from which to draw valuable information, above all in relation to the theme of sustainability.

Abstract

The reflection on the three sensitive topics proposed by the forum suggests considerations on the processes of transformation and evolution of architecture and the city, of the tangible and intangible "things" that make up the environment in which we live. Regeneration, conservation and innovation are issues that lead attention to a common question: whether it is necessary to modify a given condition. The city, understood as a complex and changing body, in which each architecture retains its history, is subject to constant change. However, there are places that do not seem to be subject to actions for change, parts of city so firmly anchored in themselves that appear to be immutable. The historic city is an example.

The area under study covers a portion of the historic fabric of the city of Naples, via Banchi Nuovi, which is among the old route greek to the east and the sixteenth-orthogonal structure of the spanish district to the west. This area, with its strong consolidated urban structure, has almost completely unchanged the relationship between plant and settlement, form and function, city and architecture, creating a place with a specific, and very defined, individual character.

The reflections that arise from this study are as follows:

What does it mean, and how to enable a process of re-generation in a portion of the city so layered?

How are important, within this process, the memory, the conservation and the identity of places?

Knowledge, through survey and representation, becomes a moment of research and testing, continuous discovery and confirmation.

Keywords: historic city, memory, individual character, conservation

Via Banchi Nuovi is one of the few examples of medieval structure at Naples remained almost unchanged in its morphological characteristics, despite the successive transformations during the sixteenth century. It presents a urban articulation unique within the historic fabric of the city and very different from the old route greek.

This road is part of a route - the "antico borgo di Napoli" - which connects two important streets, via Monteoliveto and via Mezzocannone and cuts the ancient center of the city in a series of open spaces and squares: from west to east, largo Santa Maria la Nova, largo Ecce Homo, piazzetta Teodoro Monticelli, piazza Banchi Nuovi, and largo San Giovanni Maggiore. The construction of these spaces has often been linked to the history of the near palaces and places of worship; some of them, far from being randomly determined, were strongly promoted by the religious orders, who planned the construction.

It is between the XXVI and XXVII century that occur the most significant changes in this part of the city. The historical maps of the period, in particular the two perspective views of Duperac - Lafrery (1566) and Baratta (1679), in fact, show the fundamental steps of such changes. Natural disasters, including floods and earthquakes, and private decisions, including sales and transfer by the ecclesiastical authorities, mark the urban settlements of via Banchi Nuovi.

This urban area is situated on a not flat land and the jump in share established between via Banchi Nuovi and via Sedile di Porto below, the ancient boundary of the lower town, is quite significant. This large "terrace", which ran through the city from east to west, linked the "upper part" of the old center at

coast. "Pennini" and "calate", usually long and narrow streets with steps, made it possible to overcome this difference. [1]

It is possible that, long before the medieval period, at the time of "Neapolis", the sea was not far from the border, which was to pass to the south of the basilica of San Giovanni Maggiore, heading west, right up to the settlement of Santa Maria la Nova. The settlements belonging to this part of the city, the formation of which originates from the topography of the area, have preserved much of the original characteristics. There is no doubt that the morphology of the insula has been one of the main components, we might say "design" component; it should certainly be added other reasons, not independent of the collective decisions, whether religious, economic, social.

Some important news concerning the history and the settlement processes that have affected via Banchi Nuovi are reported by Celano in a collection dated 1692, entitled "Notizie del bello, dell'antico e del curioso della città di Napoli per i signori forastieri" that contains interesting informations about the birth, the building and the transformations of the religious and the private building, as well as the events that saw as protagonists many important noble families of the time. By reading this text you can follow, step by step, all the street that connects via Monteoliveto and via Mezzocannone. [2]

We have to say that via Banchi Nuovi represents only a part of this route, it touches piazza Banchi Nuovi and extends to the east with via Candelora, while at the west continues with via Ecce Homo, and then bifurcates, on the one hand in via Donnalbina and on the other in via Santa Maria dell'Aiuto before, and via Santa Maria la Nova then.

It is evident that the topography of the area is strongly linked to the names of the religious complex and of the public buildings. The same applies to the public open spaces.

In head of this "y" path there are two important and ancient settlements: Donnalbina and Santa Maria la Nova. The first has been the site of a Benedictine monastery; the church, which already existed in the ninth century, was rebuilt in the seventeenth century, and was then subject to further amendments.

Fig. 1: Actual plan with the study of the street structure.

The religious complex of Santa Maria la Nova is well known since the thirteenth century, when the "new" church was built, replacing the previous church of Santa Maria ad Palatium, that was initially located in the place where it is today Castel Nuovo.

Continuing east, the route follows a bayonet, which contrasts with the regular system of the ancient city, further evidencing the medieval origin of the path.

Along this street is the church of Santa Maria dell'Aiuto, that Celano describes as "bella e bizzarra", built by Dionisio Lazzari (1673) and dedicated to an image of the Virgin that had bestowed graces during the plague of 1656.

The religious building is slightly set back from the road, this retreat has allowed the creation of a small square. On the piazzetta Ecce Homo faces "Case Alvino Pappacoda", which is separated by the Pendino di Santa Barbara from the famous renaissance Palazzo Penne.

After piazzetta Ecce Homo a short road leads into piazzetta Teodoro Monticelli. To the right is Palazzo Penne, built in 1406 by Antonio Pens - the only of durazzesca age well-preserved - and on the opposite side is Palazzo Palmarice of sec. XVIII built by Ferdinando Sanfelice.

At this point begins via Banchi Nuovi, where is Palazzo Casamassima that preserves the sixteenth-century implant; then there is piazzetta Banchi Nuovi whit the church of Santi Cosma e Damiano, the old loggia of the merchants.

Is this a case of an open public space built as a result of a natural event, the flood of 1569; at the same time, it was also open a narrow road with steps, parallel to pendino di Santa Barbara, the current calata dei Santi Cosma e Damiano, which clearly takes its name from the church. [3]

This space is very interesting because connects via Santa Chiara and calata dei Santi Cosma e Damiano, as a hinge between two paths that cross the city from east to west and north-south.

Interesting is also the functional transformation of this area: by place of trade at religious space, and today a space without function. The church of Santi Cosma e Damiano is in fact closed for years, as well as the nearby church of Santi Demetrio e Bonifacio, which has its entrance on piazzetta Monticelli.

The urban area that extends from the church of Santa Maria dell'Aiuto up to calata dei Santi Cosma e Damiano was in the past part of the complex of San Demetrio. The monastery of San Demetrio, over the centuries, was sold to various noble families, including the Orsini, who bought in the seventeenth century a part, which then became Palazzo Casamassima.

After piazza Banchi Nuovi, via Candelora leads to largo San Giovanni Maggiore where is, on the right, the sixteenth-century Palazzo Giusso (built by Sanchez de Luna, then Filomarino, now the seat of the Istituto Universitario Orientale) and, on the left, the chapel of San Giovanni dei Pappacoda, founded by Artusio Pappacoda, the noble of seat of Porto.

The basilica of San Giovanni Maggiore facing the homonymous square is one of the oldest and most important of the city. Founded around 555-560 by Bishop Vincenzo, on the ruins of a pagan temple, it was rebuilt in 1685 by Dionisio Lazzari and reconstructed again in 1872-88.

The history of the formation of largo San Giovanni Maggiore is very attractive. It consists of an area on which stands the basilica, and another to the north of via Candelora, opened to connect some parts of the historic fabric of the city.

Celano in fact writes: "Perché questa casa non haveva dritta la strada che tira alla Strada di Nilo, il Cardinale con ispesa grande fe' buttar giù molte case e ne formò la piazza, che tira su."

Going away after via Candelora, in the place where once stood the Porta Licinia, you come in via Mezzocannone, a major artery connecting the north-south direction.

Fig. 2: Study of open public spaces, churches and monumental buildings along via Banchi Nuovi.

Fig. 3: Piazza Banchi Nuovi and calata dei Santi Cosma e Damiano.

Each of these places, each of these spaces, as we have seen, has its own history, and the history of urban paths in this case is closely linked to the history of the settlements, regardless of the nature of the causes that have set in motion the processes of transformation of the urban fabric.

There is no question of urban "holes" but of autonomous places, with a specific individual character, not of residual spaces in the service of building but of autonomous entities that deserve to be treated independently, the construction of which can only be understood with a 'thorough historical research and with a careful analysis of the overall principles of interpretation, and of relationships encoded by design, and of relationships by perspective-visual and proportional. [4]

Each fragment has its value, and acquires even greater value if considered within an overall system, of which is necessarily part, and wherein the logics of the concatenation and correlations between the elements make possible to better understand the functioning of the whole system.

Each "episode" has to be studied carefully because each one is different from "other", but they are part of a path, which is not only a road network, but is a historical, perceptual, social route.

Through these spaces we can have a privileged point of view for the study of urban development, of the urban planning and architecture, of the artistic expression and of the symbols and ideology, but also of the relationship between plant and settlements, form and function, city and architecture.

Abstract

The progress achieved in the area of IT, applied to CH, hasn't always been accompanied by a proper development of the research for understanding the practical challenges that it posed. If nowadays it's possible to use 3D model as interface for the localization and querying data associated with it, the pair physical objects / documentary, sources base for the digital reconstruction, are characterized by different degrees of uncertainty and irregularity.

Within an Architectural Cognitive IS it becomes evident the need to prepare an exhaustive documentary base covering the whole process of research related to the creation of digital content within the reconstruction, that can be qualified through a full transparency of the methods of analysis, surveying techniques and the criteria used.

In this paper we present some experiments carried out as part of the virtual reconstruction of buildings just designed or no more existing. Through the semantic structuring of digital models and the use of Real-Time Rendering (RTR) techniques we attempted to develop a process of acquiring knowledge able to point out and let understandable and reusable analysis of preliminary data and interpretation criteria used in order to validate the whole process, giving the ability to visually assess our level of knowledge, with its flaws and lacunae, and to carry out comparative operations on the set of data and information held, allowing the compatibility of the digital model with alternative modes of representation.

Keywords: 3D modeling, semantic structure, architectural heritage, cognitive system

1. Introduction

Over the last year architectural representation and surveying techniques have known important evolutions with the development of new tools and methods for 3D data acquisition, documentation and dissemination of information related to architectural-cultural heritage. Such rapid progress has led to a drastic transformation of the way in which data are collected, processed, represented and spread such information. The hyperdimensionality that characterizes today's digital media, represented by their interactive nature, is not only constantly improving, but also it is transforming the way we acquire, process and spread the information. In order to describe univocally an artifact (eg. material, style, time related indications, etc.) we need more than traditional triplet of geometrical co-ordinates (x,y,z), if we wish to view the artifact as more than a purely geometrical object. Models of artifacts act as "spatial metaphors" enabling the distribution of pieces of information in time and space [1]

The development of new and more effective digital technologies, such as real-time rendering of 3D models, multimedia techniques, animations and simulations has opened the possibility of new scenarios for reading and interpreting architecture, where all the information are made available in a visual and integrated way. Digital systems introduce, in fact, the possibility of interchangeable media able to offer multiple nodes of access to a given term or object, and enable a multidimensional approach to knowledge on several levels.

The digital display allows to activate, in fact, types of surveys previously unthinkable in the fields of archiving and accessing data, spatial analysis, simulation of unbuilt projects, etc... It proposes, ie, new meanings of the concept of architectural representation, adding an extra dimension, the temporal (diachronic and synchronic), which in turn allows to know that artifact not only in its evolution and transformation during its life cycle, but also through the analysis of its composition and geometric-formal matrix.

Wide is, in fact, the series of reconstructions works of design hypotheses and drawings that, as early as 1990 [2] have used three-dimensional digital modeling techniques.

Koller et al., in the resettlement of the general framework of the challenges and opportunities offered by 3D models digital archives related to cultural heritage, recognized the need to make visible the traceability of all additions, subtractions, and changes to 3D models, in order to let understandable the calculation and display of differences between 3D models of the object/artifact [3]. Gabellone, following on the principle 7 of the Charter of Seville, has focused attention on the full transparency of methods, techniques and documentation in supporting a project of virtual reconstruction (in archeology), the only tool able to validate the results of any reconstructive study and guarantee future generations a review of the results without needing to restart the job from the beginning [4].

Within this context, a huge number of studies have resulted in order to define new protocols for processing (acquisition, manipulation and management) spatial data, resulting in the development of new methodologies for the study and openness to further research scenarios.

An important contribution in this field have come from Blaise e Dudeck who begun introducing, in example, the genesis of an informative modeling methodology [5] in which the representation of architectural objects is used for information search and visualization, letting them able to define some methodological approach in order to increase la intelligibility of 3D models' informative contents. Therefore, 3D or 2D models may distribute pieces of information in time and space, aiming to meet a dual need (a) to make architecture a spatial and temporal filter through which layers of heterogeneous information can be brought together, such as measurement and documentation, and (b) to use digital models as iterative information/visualization tools, constructed and reconstructed from day to day, and aiming to be what the map is to the representation of territories [6]. Aiming to improving the comprehension of the complex and discontinuous process of knowledge acquisition, Dudek and Blaise [7] also introduced a generic formalism of information integration that lets the researchers to gather indications step by step, and allows them to visually follow up the knowledge acquisition process. They demonstrated how graphical simulations of the morphological evolutions of edifices, produced along the investigating process, can be used as graphic interfaces in which architectural objects are located in time and space. Their objective has been to support reasoning tasks in heritage architecture with graphics enabling analysts to visualize and share their understanding of how, from a given set of information, alternative scenarios or evolution can be inferred [8].

In the field of architectural heritage, we very often faced with the combination of 3D physical objects / 2D and textual documentary sources in which both elements are subject to uncertainties and inaccuracies. The three-dimensional nature of the object itself has led, however, to seek to exploit its same representation for displaying information related to it, as well as the development of visualization techniques able to make manifest the latent uncertainties.

Zuk et alii presented an application that enables integrating and visualizing the temporal uncertainty for multiple 3D archaeological data sets with different dating. They introduced a temporal time window for dealing with the uncertainty and review various visual cues appropriate for revealing the uncertainty within the time window. The interactive animation of the time window allows a unique exploration of the temporal uncertainty [9]. Strothotte et alii proposed non-photorealistic rendering styles for encoding such additional information in a visualization of a 3D model which goes over and above the geometry. They then applied this concept to visualizations of virtual reconstructions of ancient architecture and described the prototypical system ANCIENTVIS which represents an approach to visualizing models with uncertain features [10].

De Luca et alii described a methodological approach to let usable existing iconographic corpus for the analysis and the 3D management of building transformations. The aim was to establish a relation between the iconography used for the hypothetical reconstruction and the 3D representation that depends on it. This approach relates to the idea of using 3D representations like visualization systems capable of reflecting the amount of knowledge developed by the study of a historic building [11]. In a recent paper, De Luca and Lo Buglio addressed the issue of the review of the methodological aspects concerning the collection of information that describes an architectural object in order to measure the benefit in terms of information provided by the document, with reference to the requirements and the means employed. [12.], offering an approach to the creation of representation systems that articulate the digital instance with the geometric/semantic model.

Recent work included within the series of fruitful experiences of reconstruction of an entire project from partial sketches [13], put some significant innovations with regard to:

- a) the verification of the hypothesis of drawing to be the original project for the first nucleus of a palladian villa, during the century widely reshaped) [14];
- b) the use of a semantic construction of the digital model, not only as a means to look for a building such a system cognitive;
- c) the use of interactive technical reference - typically real-time photorealistic rendering for the visualization of three-dimensional model and the use of variants snapshots managed by an iconic for illustration using the method of comparison and guided reading of model's characters of the steps taken.

In this paper we present some experiments carried out as part of the virtual reconstruction of buildings just designed or no more existing with the aim to propose new and more robust solutions to the 3D modeling from 2D drawings construction for CH artifacts. Through the semantic structuring of digital models and the use of RTR techniques we attempted to develop a process of acquiring knowledge able to point out and let understandable and reusable analysis of preliminary data and interpretation criteria used in order to validate the whole process, giving the ability to visually assess our level of knowledge, with its flaws and lacunae, and to carry out comparative operations on the set of data and information held, allowing the compatibility of the digital model with alternative modes of representation.

2. 3D modeling semantic structure

The use of a semantic structure in digital modeling becomes, not just a tool to look at a construction as a system cognitive [15] [16], but especially a technique to make clear the relationship between the architectural object and the documentation base (drawings, text and more) from which the model is reconstructed, identifying the characters, the limitations and inconsistencies of those drawings, the reconstructive conjectures adopted and not documented in the same drawings, the reconstructive solutions more likely, and the relationship between project and landscape in which it should be added, giving back self-representation to the same instrument.

Three-dimensional modeling based on structured semantic principles is, in fact, a useful tool in order to (a) obtain a decomposition of the building in various constituent elements, identified through the analysis of their geometry and aggregation between them according to precise compositional/logic rules, (b) adding to the models geometric reconstruction linguistic information related to the recognition of the signs and of a shared architectural language, (c) identifying a further connection between the three-dimensional model rendered and information stored in data-base linked to it, for the purposes of a full documentation relating to that particular architectural element.

The advantages that this type of data structure, according to the criteria of semantic organization, allow are multiple. Preserving this structure, even after the phases of polygonization and translation into interchange graphics file formats, is possible to obtain models as cognitive system, that can be used as an preferential interface for browsing between the different contents of the same DB. The semantic structure allows us (a) to manage 3D models in multi-resolution and divide them into subsets hierarchically consistent, (b) to efficiently manage the metadata related to the models themselves, and with them the ability to view and represent data relating to (c) reconstructive uncertainty, (d) the level of accuracy / precision guaranteed, (e) as well as the control of the different versions of the models, (f) to facilitate the comparative analysis between the parties or sets of architectural works, and (g) to evaluate different reconstructive or analytical conjectures, or assuming the chronological development of a building over its life [17].

Starting from the 'shape grammars' adopted one can define the tree structure that governs the 3D modeling, giving a logical and orderly structure that can be analyzed and manipulated as a whole or in parts, depending on the level of interest.

The resulting structure gives rise to a classification which is defined by a series of information which, in turn, refer to:

- the type of architectural / construction element;
- the position of each element relating to a reference system for the single artifact: level / altitude, interior / exterior, side / orientation;
- sequential numbering used to distinguish elements that belong to the same type, to the same reference position / orientation.

The semantic organization of a 3D digital model of a building can be defined taking into account the definition / identification of the nodes that make up the single element, the identification of the origin of geometric architectural elements and construction of the relationship between the elements identified and their groupings into macro-groups. The building is then decomposed by a morphological, compositional and constructive point of view, defining elements organized on several levels.

The number of typological / morphological units and elementary units depends on the criteria followed in the distinction of the minimum units and their subsequent combination, which can be identified according to the change of material, the recognition of type elements, morphologically homogeneous

Fig. 1: A. Palladio, Villa Saraceno, 3D modeling reconstructive conjecture uncertainty map

(eg. frames windows, moldings, capitals, etc..), whose boundaries are defined by geometric transitions in the presence of the same element on different levels of the building.

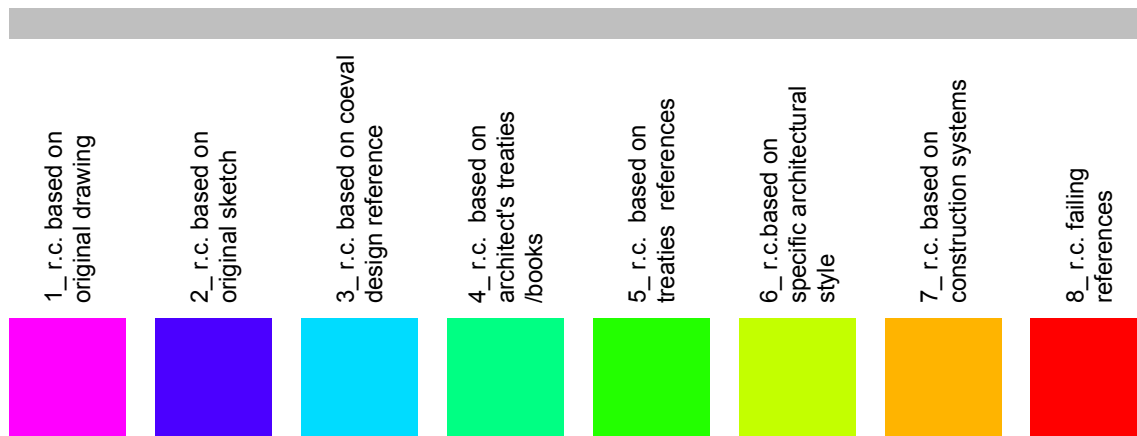

A first major example of semantic methods is the 'shape grammars' described by Stiny [18], Stiny and Mitchell [19] built of 3D parametric descriptions and rules based on full-scale materials and material assembly. These construction rules do not determine appearance; instead, they define assemblage of physical objects in 3D space. Alternatively, a design rule for a shape grammar builds shapes and shape relationships for visual evaluation; design rules tend not to provide functional or structural information for the manufacture of objects. Along the same development line Larry Sass [20] illustrated a method where rules for a shape grammar that generates physical information for machine manufacture demonstrate the need for more information and more illustration when rule building. Our method deal with Sass method; the main difference rely on the fact that ours refers to the real built object whereas his method refers to its project. Therefore, in our proposal not only the schema but also the constructive rules can be identified, highlighted and discussed. Secondly our method deals with a wider gamma of objects that range from a simple brick or bas-relief to a whole building, and not only architectural objects.

3. Displaying the uncertainty

In order to qualify and authenticate products of scientific research within the field of documentation and study of architecture, it is necessary that the 3D geometric models relating to AH - the structures of primary information to be stored in repositories 3D you want to index - will be implemented with the corresponding text metadata (catalog, commentary and bibliography) that allow transparency of information to users, in a manner similar to what happens with the notes, comments, and the bibliography in traditional publishing. A second fundamental requirement is that 3D models will be demonstrative of the solutions adopted to meet the uncertainties and the lacks.

Many of these 3D models are, in fact, reconstruction of buildings just designed or no longer existing, nor fully documented; therefore, it is inevitable that such reconstructions contain a small or large number of hypothetical elements, characterized by their specific degree of uncertainty.

This is due to a number of clear factors: the need to make up for the missing parts in the today structure, the need to implement hypothesis in the reconstruction of a 2D drawing in a spatial shape, the temporalization of the various layers to decide an original state or, most simply, the different conformations in time.

Tab. 1: Uncertainty gradient color code

The reconstruction work from a given set of drawings requires a process/pipeline of construction, of analytical type, based on a semantic system, because all the information necessary for completing the model are not always obtainable in a unique and unambiguous way from data or by drawings that we have at our disposal.

Therefore, it is necessary to define a series of preparatory and operational phases, complementary between them, in order to investigate the sources and integrative design references that are able to provide useful information to model the project, even for those parts not explicitly or comprehensively documented.

It is vital, therefore, that informative/cognitive systems facilitate the evaluation of the documents relating to the uncertainties inherent in models reconstructed, and which may be related to:

- architectural / structural elements;
- size / geometry;
- stylistic / formal;
- temporal correspondence;
- building materials.

Such type of information may be conveyed through (a) a new 3D symbology (eg. a series of glyphs 3D), (b) animation techniques / display, (c) rendering techniques or (d) a combination of text metadata and 3D visualization.

In this way it is possible to define a modelling structured procedure, based on different levels of interpretation, characterized by a progressively increasing level of uncertainty:

1. reconstruction based on original design or survey drawing;
2. reconstruction based on sketch, therefore affected by a low level of dimensional accuracy
3. design reference dated to the same period of the drawing or building studied and which have significant stylistic similarities (eg, coverage, type of roof, gutter frame, frames, roof, basement, or the openings and decorative system) with that drawing/building;
4. reference to treatises, books or architectural guideline written by the architect, author of drawing or project studied;
5. reference to treatises or manual to which the architect has or could have used as his own reference (eg measurements of the rooms, stair design, detail design and equipment, the architectural orders, if any, as well as for the definition of the height of the internal doors or types and sets the height of the time);
6. interpretative hypotheses referring to specific architectural style;
7. interpretative hypotheses more thrusts, referring to the construction systems at that time in order to achieve solutions constructively plausible and compatible with the project, by which, however, is not always possible to reach conjecture or univocal solutions;
8. reconstructive conjectures failing references.

The uncertainty display uses a density slicing color code - a variation of pseudo color - that divides the rendering objects into a few color bands, corresponding to each level of interpretation/uncertainty (see Tab. 1).

Such needs are particularly felt in the case of Palladio's work characterized by a large number of realizations or other assigned to him, but also by many studies and projects unfinished and some 'transcription' made the same architect of his most significant works, gathering them in the second book of his treatise, or to compare the fidelity or less between the theoretical assumptions, e.g. relating to the shape and size of the architectural orders, and items used in the works.

Fig. 2: A. Palladio, Villa Poiana, Cognitive graph

Beyond the analysis specifically conducted (ex-post), digital systems allow, in fact, the collection and systematization (ex-ante) of operations in order to determine the geometry of the elements that contribute to the definition of an architectural work, becoming in fact themselves explanatory values of the geometric-formal genesis of that edifice. The possibility, in fact, to examine the collection of data containing large amounts of records, such as geometric analysis and semantic characterizations of artifacts, offer new approaches to the classification and the comparison.

The research in this area should seek, therefore, to the use of data collected and processed for the purposes of their use in the areas of documentation, management, conservation, communication and dissemination of knowledge of the architectural/cultural heritage.

4. The cognitive graph and the structure of information

Systematizing geometric-formal information relating to a building with those relating to the data available that have allowed the formulation of a reconstructive hypothesis requires the need to taking into account uncertain and heterogeneous information, able to considering the evolution of our knowledge, producing 2D/3D dynamic graphics, and adapting our practices to the specific realities of the heritage field, where uncertainty should forbid graphic assertions, highlighting what is unknown, rather than hidden it.

Studying and displaying evolution of an artifact (or ensemble of artifacts) requires introduction of two additional dimensions:

- temporal;
- documentary.

Temporal dimension allows to distribute pieces of information in space and in time: in a certain position; at that time of the study; at that moment of the history.

Documentary one allows to display, or let understandable and evaluable, the methodology used in analyzing the architectural evolutions of that artifact, based on interpretation and comparison of various types of documentation.

3D model representation, as metaphor of cognitive system related to architectural corpus - the basic physical forms of the building - do not show us the “real” object, but how we understand it: different pieces of documentation in relation to architectural elements could become a browsing tool, allowing to mediate between the information to be handled and users able to investigate sets of data or information element by element.

The result is a cognitive graph, as visual metaphor of case study, which aims to restore the hierarchical structure that governs the geometric definition of the 3D model and gives access to documents about that studied artifact. Due to the relationship between each document in a data set

and its corresponding element of the artifact (edifice as a whole, parts, details, etc.) information structure could be visualized and retrieved inside a 3D model/interface that combines the metaphoric figure of cognitive system, based on a kind of "Armillary Sphere" that encompass the artifact itself, and its visualization, represented by the 3D model.

Through this structure, exploiting the semantic graphic codes, representation is able to:

- underline inconsistency in the documentation or its analysis;
- indicate the level of incompleteness concerning the investigation;
- provide an updated visualization of our knowledge on an object.

Visualization of such system by means of an arrangement using high quality RTR techniques, joint with the use of interactive consultation techniques to obtain fully 3D interactive comparison and interpretation method guided by the 3D model features and step taken, allows to let clear the interpretation of 2D drawings and its 3D shaping.

The model is made browsable in real-time according to three different reading levels, recallable indifferently at all times, that allows:

- a) comparison between the original drawing and its 3D model;
- b) analysis of the geometric characteristics of the model, through the use of patterns and diagrams that facilitate the reading of correspondence and/or anomalies detected during the analysis of the drawing, or the criteria of ratio adopted in the determination of its parts;
- c) photorealistic rendering of reconstructed project within its hypothetical/original context, as well as matching any hypotheses alternative to the shaping of some of its parts.

This solution open many doors and could introduce new and meaningful innovations to the architecture interpretation methods and techniques, along two different paths.

The first involves proposing photorealistic images obtained using simulated global illumination rendering techniques. It is, obviously, a further development of Renaissance representation advancements and a new step of the desire of fifteenth and sixteenth-century artists and intellectuals to use drawing to investigate the world and the nature.

The second concern a truly interpretative work, obtained from the simplification operation, inherent the schematism embedded in the concept of 'model'. This simplification allows to create visualizations of the real more interpretative than philological or perceptually correct. In this case reconstruction means a desire to explicitly describe and represent a whole story: not only a "re-drawing" to understand but a "re-interpretation" to communicate.

5. Case of study: BIM modeling and visualization of Palazzo Barbaran and a bottom-up process

Palazzo Barbaran da Porto was designed in 1569 by Palladio and built between 1570 and 1575. It is the only great city palace that Palladio succeeded in fully executing during his life. Commissioned by Montano Barbarano, a Vicentine nobleman, Palladio was asked to coordinate the new design and the existing houses belonging to the family of the client. Palladio contributed a set of masterful proposals with a central atrium and symmetric façade with 7 bays. Following the completion of the drawing, Barbarano acquired an adjacent house in the west, which eventually resulted in a façade with 9 bays. We applied a BIM-based modeling approach to establish a library of architectural elements cataloged semantically [21].

A basic unit that composes the façade of Palladio's Palazzo (Fig. 3) is usually articulated with four rules:

- a) a pair of pilasters whose capital could be either Ionic or Corinthian, shaft either cube or cylinder, height dominating either one floor or two floors (Chart. 1);
- b) a window with top molding's cornice either triangular or curve. (If the pilasters dominate two floors in rule one, then a rectangular window is added either above or below the window on the noble plan);
- c) a balcony with cornice and an array of balusters;
- d) two segments of entablatures on the bottom and top of the façade unit.

In this case, we set only variables in the first and the second rules, while keep the constants in the third and fourth rules. The second rule is articulated with a "If, then" sentence. The result of the first rule determines whether the part after "then" will be executed. The application of the first rule and the second rule lead to the generation of façade's unit.

If we keep in mind that the options listed in each of the four rules are in essence parameters of dimensions, visibility and substitution, we realize the Bottom-Top process from semantic nodes to the whole façade. As Revit Architecture enables interactive data transfer between the main model and database, users can create database (Microsoft Access, Microsoft Excel, or ODBC database) via DB

Fig. 3: Re-group of façade elements based on four variables including two options: Capital (Corinthian, Ionic), Shaft (Cube, Cylinder), Height (One floor, two floors) and Window cornice (Triangular, Circle)

link and modify the values of parameters. Modified values in the database would cause update of data when importing to the model. As metadata of model are cataloged semantically with optional parameters in the database, it provides user with interfaces to make modification of dimensional parameters (values with number) and Boolean (values: yes or no) parameters. In this way, the Bottom-Top process could be realized via data modification in Excel or Access.

Chart 1: Options of rule 1 applied to Palazzo Barbaran, Palazzo Porto, Palazzo Chiericati and Palazzo Valmarana

BIM's semantic structure enables multiple data enrichment and filter according to various analysis need. Also, multiple data is enriched in different levels of category, family, type and instance out of different motivations. It gave access to potential simulation by sharing data among various platforms. Therefore, the centralized BIM model serves as a sustainable dataset comprising comprehensive information, and provides access to life-cycle management and potential simulations of various disciplines. In the future, a number of works will be developed:

- Exploration of automatic generation of complicated architectural geometry in BIM.
- Integration of knowledge extracted from the treatises and real life data captured from image-based survey and range-based survey, as well as its interoperability among various platforms.
- Customize the application of BIM in heritage management via Revit API. Revit API enables users to add external command and external application by scripting in Microsoft Visual Studio.
- Establishment of web-based data repository interactive with GIS.

RTR visualization could allow quick understanding and in-depth using mainly visual categories.

6. Conclusions

The work presented here tries to combine a rendering high level of accuracy, available thanks to the current computer technologies, by means of representation form able to introduce an increase of cognitive contribution. On one hand, the photo-realistic images, obtained with rendering techniques simulating global illumination, are, of course, an evolution of the Renaissance achievements in the field of representation and, in a sense, a continuation of the desire of artists and intellectuals of the Renaissance to investigate the world and nature through drawings. On the other hand, a real work of interpretation, obtained according to the process of simplification inherent in the schematic of the 'model', allows us to create views that refer more to a vision of interpretation than an accurate reconstruction of the object created today.

The use of analytical mechanisms for reading and interpretation within a reconstructive process expresses the desire to enrich the cognitive model and demonstrate their level of knowledge with the aim of using the representation as a tool for scientific evaluation. Not only, therefore, a 're-drawing' to understand, but a 're-interpretation' to communicate, a desire that emerges in full reminiscent force also for the ability to avoid of being the final synthesis, unique and immutable, but the first step of a wider and complex discussion..

Abstract

The quality of urban reality that arises from studies made in our city can be, sometime, an indicator of environmental imbalances that tend to affect deeply human beings, causing a particular sense of disorder in them.

Understanding a place means also foreseeing suggestions for its modification; so we need to focus on an eco-sustainable development of the territory.

Adding together relevant studies on urban realities of the Mediterranean area, such as Catania, Enna and Siracusa, it is possible to trace a logical-deductive way inclined to a complex and perceptually reasoned representation able to convey the sense that the community gives to the place, giving to it a symbolic meaning and identifying it as a figure.

In this sense, cultural operations aimed at the study and deepening of the "Knowledge" and the recovery of a balance threshold – also through complex procedural systems - must be directed in harmony with an all-desired "*Charter of Protection*", in full compliance with the environmental complexity and peculiarities of a shared sustainability, which takes its cue from natural resources of the *topos*.

Keywords: Perception, Mediterranean, Urban Spaces, Stratifications

1. Introduction: A Sample Survey On Mediterranean Places

(Giacinto Taibi)

Today we look with ever growing optimism at the Mediterranean basin as a driving force for the planning of economic development with a future perspective of enhancing the vocative quality of the entire cultural heritage of the past, on the value of which the potentials of the present should be based.

The geographical area of Sicily, for its intrinsic strategic importance, is considered as a bridge between the diverse cultures of the neighbouring Mediterranean countries. These intend to promote themes which highlight common routes and strategies for the development of long-term joint projects.

Within this scenario it should also be taken into account the exchange between the urban fabric of the past and more specifically the architectures which identify cultures whose development, although different at source, can be channeled into pathways of mutual exchange.

These routes, planned with a broader scope, allow for a democratic development that involves, equally and specifically, places seemingly distant, but in fact, parts of an unsteady and ever changing equilibrium.

We are increasingly stimulated by the observation of urban sites. We venture into the maze of urban fabric and enter into its physicality in order to be able to read, understand and appreciate the most intimate significance of that particular place.

Our task usually involves defining the cultural opportunities that the urban scene offers when we attempt to read and understand areas of civic agglomeration characterised by intrinsic peculiarities. Our attention is completely drawn towards understanding the morphological complexity which deepens the intrinsic qualities of the *topos*.

Fig. 1: The survey. Places in the Mediterranean.

In a systemic framework of comparable cultural interests - referred to significant urban complexities gravitating around a broad area overlooking the Mediterranean basin - it becomes much more interesting and of great value to be able to relate, in strategic terms, urban areas which are significant for their inner vocation.

If the identity of places is the result of the processes of memory, traditions and ancient wisdom, as well as the material memories that determined their present form, then it is also true that the studies on urban agglomerates - in bringing back to light manifest or latent enactments of the past, seen through a process of optical oriented intuition – can clarify strategies of allocation of spatial volumes which are most suitable to an appropriate fruition of that particular place.

A complex task such as the in-depth knowledge of the sites which gravitate around the Mediterranean area requires a cultural commitment of a large group of operative sectors, diverse in quality and competence, which are able to secure a success through an appropriate investigation into the nature of the issues being raised.

Then it is revealed that it is the very essence of a place itself that triggers the type of analysis to be conducted, analysis and in-depth knowledge that contribute to the understanding of the place.

In this respect, the techniques presented here, aimed at the "*Factory of Knowledge*" and set up through complex procedural systems, must necessarily, in a synergy of their constituents, be part of the dictates of the "*Chart of Safeguard*", with total respect for the places that are the subject of study.

2. A Perceptual Reading Of An Urban Area Of Catania

(Giacinto Taibi)

The study focuses on an urban area of Catania part of the eighteenth century structural grid of the city which was rebuilt after the catastrophic earthquake of 1693.

It is within this Baroque grid that the research revolves around and find its nourishment, moving in harmony with synergic lines and with the whole systemic process of project intuition.

The fabric of the past, full of complex volumetric and material expressions, with obvious emotional charges, engaging and intriguing, testify the consistency of architectural and historical textures and offers, in some ways, parts of a constitutive system which is spatially articulated in a sort of cryptic form.

The volumetry of the whole urban area if put in relation to areas of planimetric expansion, seemingly simple and trivial, are such as to raise hypothesis of reasoning - in some cases latent and in others more or less manifest - which might have inspired the working mind of the architect who devised that setting.

The proposed scientific survey - if the void understood as space of manifest absence within the fabric of the city, represents more and more an opportunity for experimenting the intrinsic nature of the urban form - focuses on existing relationships between systems of the urban scene that, in some way, play a role of strategic importance within the context under scrutiny.

The work is a reflection on the meaning that can be attributed to connectivity as a means of knowledge for reading and composing an image of the spatial context which highlights its dual aspect *of place of dynamic perception and place of connectivity*.

For a survey that places particular emphasis on the return to perceptual values, it is considered particularly appropriate to focus on Via Crociferi as a privileged crossing route which aggregates and fuses together, within a Baroque context, the connection between San Francis Square and the Via Santiuliano.

This place is a centric element of particular significance as it succeeds scenically in making the visitor the protagonist of a theatrical space within an architectural backdrop in evocative tonal correlation with the Baroque layout.

It is a place where the altimetric articulation becomes a cornerstone of intuitive reasoning in essence.

Veiled architectural surfacing, stairways stretching out to the road and curtain walls, all elements defining the well-delimited architectural space, are intentional evidence provided by the designer of that spatial environment.

In reality we are faced with a number of facts that, together with the effects aroused by the intensity of the tonal context, set in motion complex sensory and emotional states.

The slow ascent, which characterizes Via Crociferi when crossed from south to north, slows down the pace as if to give the viewer the necessary time to enjoy the whole scenario of the baroque theater in which the churches of San Giuliano of Saint Benedict and Saint Francis Borgia play the role of catalyst visual elements. The scene is physically perceived in terms of heaviness of breath or breathlessness, muscle aches and sweating. As skillfully planned by the artist, the rising stretch of the road seems to intentionally delay the pace of the viewer so as to give enough time to understand that something particularly interesting is about to happen and this manifests itself within a unique temporal frame.

On the contrary, the slow declivity (the slope) of Via Crociferi, when crossed reversely from north to south, due to its intrinsic downhill nature, seems, for some intention only hinted, to accelerate the pace of the visitor whose heart quivers in great anticipation for something that is about to happen and that is being announced through:

- the steps of the church of San Giuliano stretching out onto the road;
- the surfacing of the architecture on top of pre-existing buildings, evidence of a strong cultural interest;
- the presence of well delimited architectural space, a forerunner of a phenomenal reality of particular composure.

The Supreme is announcing the complex articulation of a place that skillfully combines all parts of a well devised theatrical setting.

In such a sequence the scene defined by a short hallway leading into the enclosed architectural space, a place of convergence of various roads, implies the becoming of a space culturally full of architectural interests, not yet manifest but engaged in a mutual dialectic relationship.

A vertical boundary - delimited by the presence of the body of the building, placed transversely to the road on the arc of Saint Benedict – physically delimits this architectural space providing a meditative opportunity and an understanding of the value of the urban environment and its surroundings.

A constructed reality whose vision takes place through a cognitive process which - applying the transposition of the three-dimensional architectural reality versus the two-dimensional retinal image – triggers a mental process that can deconstruct and reconstruct data, news and information, identifiable through a set of situations and experiences acquired within its own cultural context. The chromatic quality helps to see with the eyes of the heart and the emotions. But the eye is also guided by the illusion of perspective.

In this formulation of conceptual thought, the artist continuously moves the viewer's ever evolving eye and brings into play phenomena related to the process of encoding and decoding of figures, based on well-defined rules of transformations. The images, through anamorphosis, are thus disguised and objects are deformed in such a way that the actual shape of the original can be reconstituted only from a particular view point. In this way distortions are recomposed and images assume again their original proportions.

Fig. 2: Study of timbric contrasts and tonal chords in reading Via Crociferi in Catania, in a sequence that is articulated from south to north and from north to south. (*Images of Tiziana Patanè*)

"It is, on the whole, the opportunity to bring back architecture to the notion of a controlled space but also a possible way to rediscover, through the creation and the conscious use of an unreal and oneiric space, the conjugation of type and model to ensure that form returns as form if substantiated by ideas." [1]

This controlled space is subjected to the constraints dictated by its creator who wanted to arouse perceptual and sensory effects which are decisive in shaping the expectations of the viewer engaged in the fruition of the urban scene.

Then behind the articulated planimetric geometries and long straight trajectories, a careful and wise director will have intended to put into perspective those places with an anamorphic deformation - I would say subconsciously intuitive and spontaneous - and, almost certainly, that urban scene will have been proportionate to the way in which it would be seen and perceived by those engaged and captured by the overwhelming impact of the architectural appearance either veiled or manifest.

The place that we perceive as well-proportioned is, in fact, an urban area that has been designed with prearranged anamorphic distortions, so as to make that space look harmoniously concluded.

3. A reading of an *"island within an island"*: Enna, a place in the centre of Sicily

(Mariangela Liuzzo)

Enna, founded by the Sicani in the heart of Sicily, on a rocky calcarenitic terrace that - for its central geographical position and elevation of almost a thousand meters above sea level - visually dominates the Sicilian territory in all directions, has acquired, over the millennia, the role of *umbelicus siciliae*, drawing from it the genetic identity that has always distinguished it.

Impervious by nature, for many centuries it has maintained its reputation of a sought after military outpost and unassailable stronghold, becoming subsequently, as a result of a new policy based on military-strategic coastal defense, a safe and productive centre of agricultural production throughout the region.

"Island within an island", but far from being isolated in its perched position, Enna has always been an inevitable junction and stop-off connecting, through the valley gorges of inland Sicily, the inland villages and the main city ports on the three banks of the Tyrrhenian Sea, the Ionian Sea and the Sea of Africa.

Thanks to a consequent inversion of commercial trade, the city took part in all key phases of the various rulers of the island and of the unstable relations with its neighbouring Mediterranean countries: *"for many centuries Sicily with its capital Siracusa which overlooks the Ionian Sea, had gravitated around the Greek area, from the Middle Ages onwards the island with its capital Palermo which overlooks the Tyrrhenian Sea, gravitated around the cultural area of Western Mediterranean countries"* [2]. As a result, a changing flow of men, goods, ideas and cultures from all three coastal areas and from different areas of the Mediterranean basin converged in it.

Presences and influences from the past that play an active role in the identity of the modern city, full of traces overlaid and blended together over the centuries. It is still possible to find these today in the stratification of the urban setting and in the language of architectural elements, its toponymy, its myths and traditions handed down to the present day.

If *"the city, over the centuries, instead of stratifying and expanding itself, must have been as if" pulverized "almost" blown away "by the continual erosion of many exogenous agents, wind, rain, snow and frost, that ' have flagellated it relentlessly, especially in its most exposed areas "* [3], then it becomes a priority to preserve all the physical traces of its heritage, but also to search for intangible traces, images and narratives of a past that is important to hand on.

Thus, for example, thanks to the hymns of the ancient poets and to the many images, mostly stereotypical, created by the culture of eighteenth and nineteenth century European travelers, Enna is still known, despite the absence of significant physical evidence, for being a city of ancient classical memories, the abode of the myth of Demeter, goddess of grain and crops, and of her daughter Kore, goddess of the underworld and the afterlife as well as the changing of the seasons.

A destination for cultural tourism, Enna offers visitors traditions, works of art and monuments, but also a vibrant mixture of past and present, natural and anthropogenic, that comes alive while walking down the narrow alleys of its medieval city center, and in the discovery of unexpected panoramic views onto the airy natural landscape that surrounds the city.

The ongoing research of interpretative *ad hoc* models for the articulated reality of Enna intends to reclaim the most suitable cultural and technological tools in order to detect the *unicum* of the urban and rural landscape on one hand, and to analyze, in a correlated manner, architectures, traces, elements, details, on the other, with the aim of understanding and conveying the *genius loci* of the city which is the result of a complex identity made of a number of interacting dynamics with multiple connotations, some obvious, some hidden or partially compromised.

A first significant investigation has been carried out on *Strada Maggiore*, now Via Roma, the backbone of the *forma urbis*. Over the centuries, the most important urban works have focused along its sloping path, and have appointed it as the main privileged public place as well as the military, religious and

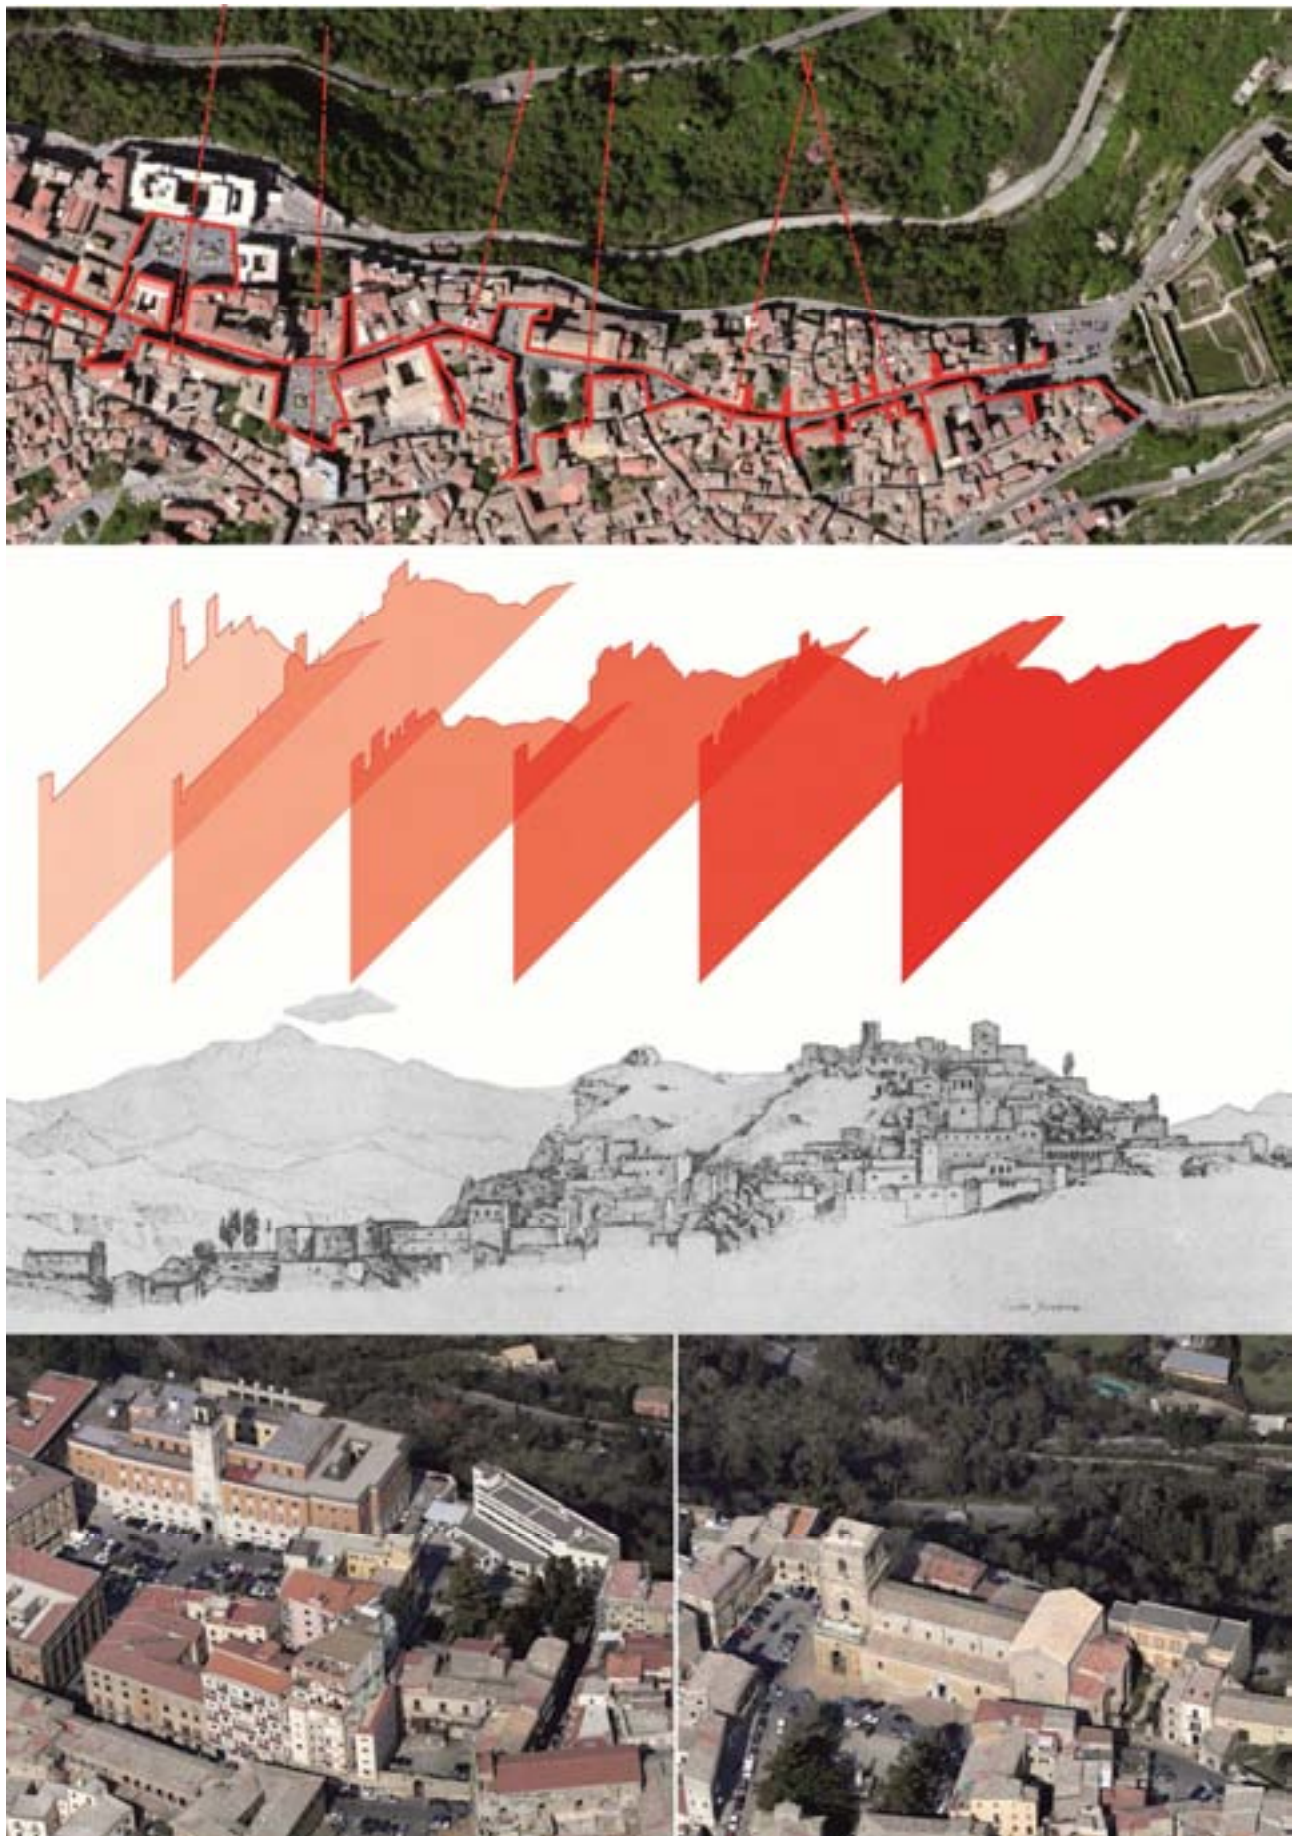

Fig. 3: Orography of the place. Spatial diagrams of the analyzed area and evolutive sections of the scenic sequences.

civic architectural landmarks of the city. In fact, the visitor's understanding of Via Roma and the surrounding urban areas coincides with taking a sedimented and responsible perspective towards that place, so as to be able to review the cultural heritage of Enna, as if browsing a fascinating book for the deep understanding of which it is indispensable to have adequate and subtle interpretative tools.

Two imposing structures of the city military defense, which mark the beginning and the end of the street, stand as primary landmarks: the castle of Lombardy, on the north-east *limen* and the octagonal tower of Frederick, on the south-west. An urban space connecting the oldest hub of the city, on the eastern ridge, and the more recent development on the western, is the square of the so-called *Balata* (from the Arabic *al Balat*, or slabs of stone), a public meeting point founded by Muslims which, for over a millennium, has retained its name and function up to the present day.

Closely connected to the axis of the main road on the north-east, is the old mediaeval town, with its meander of narrow and winding streets of clear Islamic influence, which, constrained by the irregular and sinuous boundaries of the natural precipices, seems to replicate, in the overall vision of an apical image, the orographic contours of the mountain on which it stands.

In this sense, it is of key importance the reading of the interrelations and the fabric of the place in its entirety defined by the historical context of its materic volumes and, primarily, in a reciprocal relationship of volumetric masses, if seen through significant openings onto the bottom of valley.

Over a period spanning from the fourteenth century until the recent fascist period, on the same fabric just adjacent to the main axis, great urban spaces and buildings of religious and civil power were built by remodeling new open spaces and creating completely new ones.

The spatiality of the road Maggiore has in this way progressively changed, emphasising in time planimetric and altimetric variations, within an uninterrupted itinerary, due to irregular breaks with significantly wider pauses in plazas and squares built adjacently and due to the acmes of architectural manifestations placed in crucial positions.

These architectures, remarkable for their size, architectural quality, function and symbolic meaning, over the centuries have shaped the look of the city, if seen closely, by determining the character and destiny of the urban settlement, and from the distance, by marking clearly with their towering silhouettes the urban skyline, so much admired and so cleverly described by many travelers who visited Enna from the eighteenth century onwards.

This scientific study stands as an inquisitive eye and an attentive observer of a historical document with a rich scenography and encourages, at the same time, a consideration on the value of the road as a means of knowledge and as a central figure for reading and constructing the image of the area, by placing emphasis on its dual dimension of place of dynamic perception and place of connection.

The theme of the road as conjunction and essential element in shaping the landscape provides an opportunity for an insight into the meanings of its surroundings, and a vantage point from which to observe the whole area.

This new dimension of research is inevitably enriched with different perspectives, result of the culture of *lay man* and of *higher knowledges* that must find necessarily a point of equilibrium: the descriptive techniques of the scenery then become strategic in an increasingly dynamic horizon.

The backdrops of the urban scenery in relation to the free flowing meanders of the urban margins around declare the prominence of visual perception.

The value of the past and anthropogenic-natural interactions are elements not always adequately recognized and appreciated, that today as well as in the past, identify Enna and confer to it its *genius loci*.

The process of knowledge carried out, besides being innovative, will, therefore, provide a valuable encouragement in supporting the cultural recognition that, especially in the current situation of uncertainty and crisis, must be seen as a valuable resource for the territory which must be protected and, at the same time, supported and encouraged.

Indeed, it seems more timely than ever, though still rejected, what Carmelo Severino anticipated at the end of the last millennium, *"in a context of uncertainty, Enna is heading towards its fourth millennium of existence: a huge mural [...] depicting a modern reading of the "myth of the land and the seasons," seems to communicate that Enna, linking past and present, will find in the value of its history sufficient energy to withstand, in an Europe of localisms, in a period of rediscovery and valorization of minor historical centers and their social, economic and cultural diversity, the challenges of the new millennium, recovering its raison d'être as a city, place of business, innovation and culture"* [3].

4. The Ortigia case. The reading of the place and of its semantic transformations

(Rita Valenti)

In line with the scope of this survey, Syracuse is one of three bordering areas of what is historically known as the Val di Noto.

The relationship with the place is, here as well, one of the indicators of the planning of historical sites within our urban areas. Preexisting structures, in particular, symbols of their history, represent a constant term of comparison we relate to in our daily lives. The safeguard of these areas, intended as

a synergy of conservation and development through sustainability, especially socially, reflects the quality of life in an urban area whose essence depends primarily on the quality of its public spaces (streets, squares), *the commons*. These play indeed a strategic role in a policy of regeneration.

The void between buildings has often undergone changes due to various urban interventions, more or less planned, that makes its specificity a sort of *connective tissue* worth of being investigated from both a perceptual and a qualitative point of view and also put in relation to its use and the effectual flow of life.

In regenerating urban areas, with the aim of safeguarding their past, an aesthetic approach is not enough. It is a must to seek and share visions based on assumptions that, though stemming from individual interests, are viable for the scope of a proper development. Safeguarding is in fact carried out through a kind of exploitation of the cultural and economic potential of the historical sites and plays a significant role in identifying the underlying dynamics which are expression of widespread views.

According to these assumptions, and in order to manage complex areas, the *scheme of the perceived structure* and *perceived distances*, identified by Kevin Lynch in his writing about the immature arts of City design, is of great help. [4]

We mustn't forget, however, that '*the present does not contain but the past*', so if we accept the concept of time developed by the great nineteenth century philosopher Henri Bergson, that there is a real inner duration which is an uninterrupted qualitative growth and has, as its essential feature, the emotional experience, we are able to explain the apparent paradox of *an ever changing conservation* which, in essence, highlights the significance of memory preserved in a strongly historicized anthropic-geographical landscape.

Therefore, a pure perception without support of memory is likely to return a partial knowledge of reality which can be expressed totally only through a perception, in this case particularly, which fuses matter and memory together.

With reference to the complex issues surrounding the historical sedimentation of the urban landscape we cannot disregard the polysemy of the same, in the sense that the unified perception of a stratified historical background stems from the multiplicity of symbols that the same holds in a more or less explicit manner; through their relations and intersections these symbols constitute a language in which the place is expressed and reveals itself to the researcher.

Any perceptible trace of the past in a historical urban landscape, both emotionally and symbolic as well as materially identifiable in its reference to history, testifies the crucial importance that the community has indirectly attributed to the historical and cultural value of the areas they belong to.

The decoding of signs, the semantic and interpretative reading, all belong to a field of research which sees, through observation, a shared tool of analysis capable of endorsing methods and approaches of study.

In this framework, the study applied to the urban context of the island of Ortigia, an island connected to the main island and located in the heart of the Mediterranean sea, as well as a decentralized heart of Syracuse, aims to provide a *representation*, an image of a series of perceptual relationships which arise from the ostensible signs of the relation the urban area has towards its history.

An urban landscape, in this case, layered and contaminated by various arrangements made over a period of time and considered as a single physical and emotional entity in which each part, although a fragment, contributes to the formal and functional balance of the whole. A *monumental unicum* seen as an architectural whole which has been restructured over time, a living entity whose qualitative performance cannot be investigated only as a sum of its outward features, but must include a set of tangible and intangible constituents that have determined its true identity.

In particular, the constant transformation of the city, also due to planned changes, has led in some cases to perceptual misinterpretations which, being highly subjective, have consequently implied the formation of a mental image congruent with the individual sphere.

With reference to some of the key features of the urban fabric of Ortigia we can find a peculiarity that goes beyond the pitfalls of a usual perception of an urban setting. If we assume that the *form* of a place must have characteristics of clarity and readability, so as to be flexible to the feelings of the individuals that move within it, we quickly realize that, when an urban area suffered deep lacerations, it dissociates itself from a congruent reading due to an abrupt disruption of its connection with the past.

The analysis of a specific portion of the district of *Spirduta*, with the imposing presence of Montalto palace, encourages us to reflect on the relationship between *continuity* of marginal elements, due to the works of the first half of the '900, and the unmodified nomenclature of the places which, despite the present arrangement, allows us to perceive the formation of the square element. As if memory, despite the changes made by its decision makers, wishes to preserve the clear evidence of a tissue of labyrinthine structure whose unconcealed traces can be found in correspondence with vicolo dei Tintori and whose testimony remains alive in the Ronco del Pozzo and in the name of boundary roads that do not give way to recent memory.

Fig. 4: From above:

- Dynamic perception of the flows of life;
- Dynamic perception of approach to place;
- Cartographic and photographic analysis;
- The tale of the history through its semantic expression.

As a matter of fact, the name of the district *Spirduta* is very ancient and already appears in a document of 1481. According to Dufour the name " *is, after all, very expressive of a typical labyrinth structure of this district.*" [5]

The square we perceive and that Syracusans themselves identify as a gathering space, recently renovated, in reality has no proper name; actuality has not conferred to this urban emptiness an identifying nomenclature that corresponds to the image consciously elaborated by its users.

In this context, the urban landscape presents itself, on one hand, as a gap arising from the compact tissue of the historical town, on the other hand, as a space which has been adapted to a role of public space for aggregation.

The study on the perception of the dynamic flows of life determined not only by the presence of the school complex which was built following the works of demolition, but also by everyday life, has highlighted the deconstruction of the notion of identity which can be reconstructed through a holistic process. Under these terms a methodological approach, in this key of reading, analyzes the phenomenon of formation in its semantic traits, trying to grasp the global meaning independently from the sum of physical unitary components and memory.

The sense of *place* is to be found then in the constant interaction between that which comes from the historical memory and that which comes from what the collective memory preserves in terms of matter and symbols; this is precisely the peculiar trait of this analytical introspective approach in the study on *Spirduta*. It is an interaction made explicit through a suitably organized knowledge and an attentive narration.

The stratification of the signs, due to the various urban interventions, can hybridize and confuse the flows of interactions between the parties, therefore, the complex analysis focuses its interest on the definition of new layers and new forms of relationship against the preexisting structure.

Within the same line of investigation we approach the study of the late nineteenth century urban transformation that led to the creation of the Archimede square in Ortigia, wanted by the municipality during the process of modernization and built after the fire of the Church of St. Andrew: *the elegant lounge of Ortigia*, which today has unfortunately taken on the role of road junction.

The rediscovery of its original identity passes undoubtedly through the analysis of cartographic and photographic documentary sources which confer to this planned urban void the same meaning attributed to the historical plane of the cathedral: a second large open space for the city social life that was changing its purely medieval appearance and quickly becoming modern.

The buildings surrounding this space reveal their history from the most recent to the oldest. Palace Lanza Bucci, the oldest among them, occupies an angle of the square and projects into one of the historic roads Via Amalfitana.

It is clear that in such a complex urban landscape, with deep historical roots, each process of corrosion, sedimentation and even disintegration as a result of absent interest or resources, like natural phenomena, records and interprets such choices. History, its semantic as well as perceptible unfolding, is a confrontation paradigm, almost an inner analytical necessity, in relation to the planning of a more recent future that is, in turn, destined to become history.

Abstract

Building Information Modeling (BIM) provides a framework for collaboration, a multi-disciplinary environment that brings together all the parties of the Architectural, Engineering and Construction industries (AEC). The aim of this experience (an interdisciplinary PhD course based on the BIM methodology used in the Smart Energy Efficient Middleware for Public Spaces – SEEMPubS – FP7 project) was to investigate the team work sharing and the use of interoperability between software, to test the opportunities offered by BIM process applied at existing buildings at the campus of Politecnico di Torino. Two architectural parametric models were realized (one concerning a new building –Classroom I– and one concerning a historical building recently renovated –ISBM offices–) and imported into software for energetic and management analysis using different formats like IFC and gbXML. Several lessons have been learned from these processes in order to optimize the quantity of data that pass from one software to the other ones both for type of data and for format of exchange. This indicates that actually, there is a possibility to better the BIM process, but a support from software houses is required based on the real use of common standard.

Keywords: BIM, Interoperability, Energy assessment, Augmented reality.

1. Introduction

Significant benefits to be gained from the interoperability of BIM software have generated considerable recent research interest. BIM is not only the software, but it is the collaborative process, which integrates different fields of design, construction and management to obtain the optimal result in entire process of building life cycle. It is fundamental that *bim* (building information model) are shared and accessible in open and interoperable fashion in a way enabling data and meta-data available in *bim* to be accessed, pre-processed and mapped correctly with different applications. Many researchers have addressed the problem of interoperability, but there remains a need for an efficient method that can easily transform data into different formats like IFC and gbXML for structural, energetic and management analysis. The purpose of this study is to examine and describe the teamwork sharing, interoperability between software and the opportunities offered by BIM process applied at existing buildings at the campus of Politecnico di Torino.

2. Methodology

During the course, as we had two Buildings to analyse and 12 participants from different fields and background (Architects, Engineer expert on ICT, Energy, Building and Management), we have divided all the practice activities into 5 main parts as follows:

- Building the model in a BIM software and sharing information using worksets and Central Model in Dropbox;
- Building performance and energy analysis using several software for a better interoperability;
- Feasibility of interoperable BIM and IoT system;
- Building lifecycle and management using BIM;
- Tablet application to show the different data by Virtual and Augmented Reality.

2.1 Building the model in a BIM software and sharing information using worksets and Central Model in Dropbox

For simulation and computer modeling of the buildings Autodesk Revit software was used, which is specifically programmed for BIM and provides a proper environment for interoperability by presenting the possibility of offering different workspaces, which allow each member of a group to work on specific part of modeling. Worksharing is a design method that allows multiple team members to work on the same project model at the same time. When worksharing is enabled, a Revit document can be subdivided into Worksets, where Workset is a collection of building elements (such as walls, doors, floors, stairs, etc.) in the building. Only one user may edit each Workset, all other team members may view this Workset, but are unable to change it, preventing possible conflicts in the project. Team members adding and changing elements in Worksets can save their work to a local file on the network or their own hard drive, and publish work to a central file whenever they choose. Using the Dropbox folder we attempt to solve the problem of sharing Central Model information; which worked in the beginning, but after several synchronizations from different team members at the same time, the Central model stopped responding and obviously synchronizing.

Another problem that we faced while building a model of a historical building was the complexity of the construction: former railway repair yards (OGR), freed by the railway, was behind the premises of Politecnico di Torino, this building was build between 1885 and 1895 and reconstructed in 2000 for ISMB. Although, all the parametric objects forming a building exist in Revit Databases (families), there were many difficulties to model an existing building, because to accomplish the best result, all the details and components should be modeled the same as constructed in the building. A balance between the level of the details in the central file and local file was another problem we faced during the modeling. After synchronizing the model of main trusses with the central model, elements became invisible because detail scale of default view was normal while most of the structural elements are signified just in medium or fine detail-scale view.

We have elaborated the architectural model and tested the parametric approach to typologies of elements (wall's layers, thicknesses, materials) and connections between elements itself and planes. Moreover, we have tested the interoperability using the Revit model in different software. In particular, it is possible to export from Revit to 3dStudio Max using different formats. Firstly, we tried to use *.3ds files but, even if it was possible to open the file in 3dMax, we identified several problems in localization of geometries and in number of objects per layer. Secondly, we exported to 3dMax using *.dwg format and no localization problems occurred. Unfortunately, layers and geometries were decomposed into single elements and there were some conflicts between 3ds materials and Revit ones. We also tried to export Revit geometries into Ecotect and, after several attempts, we used a *.dwg file, imported in 3dStudio Max and exported as *.3ds in order to correctly position geometries in Ecotect, but several problems occurred. Firstly, all the geometries were condensed in only one calculation zone without any reference to layers, secondly, the file was very heavy and CPU consuming, thirdly, objects and surfaces were decomposed into triangles and in some cases duplicated. Finally, we tested the interoperability with Rhinoceros 4.0 and we have discovered that using *.3ds files the geometries lose their layers and every element is decomposed into triangles. Using *.dwg files it was possible to preserve layers, but the importation could be effective only if the file would be previously opened on CAD and then imported to Rhinoceros. We tried to reduce triangles and meshes by using Grasshopper Mesh Union tools and the results were good.

2.2 Building performance and energy analysis using several software for a better interoperability

The energy performance is among the key aspects of modern building design, and the limits imposed by current regulations require a careful calculation of the heat losses and energy system efficiency. The development of this sector has led to innovative solutions for thermal insulation and increase of energy efficiency of conditioning systems. The software available for energy performance analysis is in constant progress, with an improving accuracy of calculation and the integration of 3D building design in heat losses evaluation. However, there are still some

limitations in interoperability with usual 3D modelling software, as the import of 3D-models in energy software lead sometimes to compatibility issues.

We have investigated the interoperability between the 3D model of an existing building developed with Autodesk Revit and two Energy performance tools: Autodesk Green Building Studio and Design Builder. The first is a web-tool developed for primary energy evaluation in preliminary design-stage, providing global building performance with minimum user input. The second, on the other hand, is a state-of-the-art software tool for energy and sustainability analysis in building design. The file format used for model import and export is gbXML (which stands for "Green Building XML"), which is an open schema designed to facilitate the transmission of building properties stored in 3D building information models to engineering analysis software. The export of the BIM model to Green Building Studio was completely successful, and no errors were detected during the operation. The software has calculated the energy performance of the model, but not all the parameters have been transferred to the energy analysis tool. The materials used for walls and windows needed to be re-defined by the user. Moreover, there are some possible combinations for HVAC system choice, but the user cannot define custom parameters. The main inaccuracy related to energy system has been the approximation regarding the primary energy consumption, as district heating was not included between the options listed in the software. Thus, a natural gas boiler has been chosen.

The interoperability with DesignBuilder has lead instead to major import issues, which made impossible an energy analysis. The whole building was recognized as a building block, but all the information about the components and the windows has been lost. Only the external shading surfaces were imported correctly. This issue could be related to the definition of custom building blocks, but there is a need of further investigations.

Furthermore, for the energy simulation of a Revit model Autodesk recommends to export the model to 3dStudio Max and from that to Ecotect. Since this way had already been verified by Autodesk, we decided to test new possibilities with other programs. EnergyPlus was chosen as an open source software on energy simulation produced by the U.S. Department of Energy. The only format that can be imported to Energy Plus is idf: this is a format exportable from DesignBuilder Software Ltd, a software not open source, which in fact is a graphical interface for building the model. However, there is a plugin called Open Studio that allows to run the simulation through SketchUp. So, the goal of our work in this case has become the interoperability between Revit and SketchUp. The reason why we preferred SketchUp and not Design Builder was the desire to focus on open source software. In fact, we believe that in a world where there are dozens of different software with similar functionality, file exchange between designers can be facilitated by the use of open source software as a medium. SketchUp can import three-dimensional models with the following file extensions: 3ds, dwg and dxf. When you export from Revit, it is important to be on a three-dimensional view. If you export from the plan view, only two-dimensional plan is exported. Alternatively, you need to add a façade view to the plan view. In SketchUp the model is imported with the same layers as in Revit.

The interoperability between 3D-modelling software and energy analysis tools appears to be a key issue for the diffusion of BIM technologies. The possible benefits are interesting, in terms of accuracy and modelling time. However, further steps need to be done in improving the compatibility between different software.

2.3 Feasibility of interoperable BIM and IoT system

The Internet of Things (IoT) is an emerging computing paradigm where any physical object, enriched with electronic identities, processing and communication capabilities, becomes part of a dynamic, distributed, global network of heterogeneous devices that interact autonomously with the real/physical world and participate actively in business, information and social processes. In IoT scenarios, applications become "pervasive" and must be designed to interact with digital and non-digital objects with different roles and belonging to a large number of different object classes. For such reason, applications must undergo a paradigm shift: from custom-made applications working on a "closed" set of inputs towards context-aware applications working on "open" sets of inputs. The main challenge to achieve this paradigm shift is interoperability: object must in fact be able to interact with each other seamlessly and easily retrieve information about the environment where they are deployed.

Building information models (bim) potentially represent a precious source of data for pervasive IoT objects operating in buildings. For such reason it is fundamental that bim are shared and accessible in open and interoperable way enabling data available in the models to be accessed, pre-processed and mapped correctly with IoT applications.

In order to enable IoT/BIM interoperability, the following challenges must be solved: interoperability with any available "legacy" BIM models must be possible; software interoperability between components adopted for IoT applications must be possible (e.g. remote access via web-services

or availability of library bindings with the programming language in use); interoperability with any external service useful to pre-process BIM data to serve IoT applications must be possible.

To evaluate preliminary feasibility of interoperable BIM and IoT system, a simple use case has been implemented i.e. the extraction from BIM of the topology of the walls to evaluate theoretical connectivity between different devices installed in the building. In order to achieve the results we have followed several steps: we analysed the state-of-the-art open products and selected the most suitable set tool to adapt towards the available BIM model - Solibri model viewer, BIMServer, IFCOpenShell, Blender. Conversion of the main Revit model to different formats (e.g. IFC), to assess the correctness and the conversion and identify possible issues related to the BIM format chosen for adaptation was our next step that showed that IFC format gives opportunity to validate and visualize the model through Solibri Viewer. Furthermore, the model was correctly accessed through BIM server and evaluation of its main functionalities through simple queries via web and via the SOAP interface showed that the available APIs allow simple querying on components of the model. Extraction of the Wavefront geometry via IFCOpenShell, import in Blender and verification of the IFC identifiers in the blender model, addition of connectivity "Targets" and simple evaluation of connectivity through a Python-based framework resulted in correct exportation in 3D non-BIM format; objects identifiers were kept in the 3D model, so to enable future retrieval of BIM information even if the meta-data is temporarily discarded in this phase.

Although no best-in-class solution is available yet, open BIM tools are rapidly developing, providing useful instruments to support interaction with BIM models. Such tools provide interesting advantages concerning debug possibilities and extensions through inclusion of other open components. The performed developments, although extremely simple, demonstrate through a basic use case the possibility to query simple BIM models externally, providing positive inputs about the feasibility of a BIM/IoT interoperability layer. During the work also a number of possible future challenges have been identified. Not processing operation on complex BIM models are computationally heavy, so possibly in the future, solutions will be needed to simplify and partition the models and manage more efficiently memory-heavy structures. BIM interoperability did not cause major problems, but it is expected to be more problematic working with legacy models: with more complex entities relationship queried by IoT objects might depend on the design "style" of the BIM, and thus not easily integrable with "open" applications.

2.4 Building lifecycle and management using BIM

One of the areas of greatest importance in the world of construction is the field of management of buildings and Real Estate. This sector employs a very diverse set of tools to achieve the goals. The field of Facility Management is very complex due to the many factors that distinguish it and therefore the use of appropriate information tools may allow greater control of all the variables. BIM tools can provide valuable assistance in this field; tests and analyzes performed during the PhD program have been oriented to understand how to transfer information between different applications and especially how to handle all this information inside Revit applications.

Fig. 1: Overview of scattering information.

As the information contained within Revit and about the model can be exported to other software or other databases, the question was if it was possible to add information into the model by actors not involved for oneself on the same model such as suppliers, manufacturers, insurers etc. Such information includes, for example, the production characteristics of a product or guarantees of a particular element. COBie standard, short for *Construction Operations Building Information Exchange*, a framework for organizing data developed and accumulated during the course of a building project for delivery to facilities owner and operators involved in lifecycle management. COBie is an American standard, which enables different stakeholders in the construction process; through excel worksheets extracted directly from Revit, to enter into single shared document information in their possession. The result of this operation is ability to use a single simple tool, to collect uniquely the data regarding the model. The standard is organized in 16 worksheets, containing some standardized heading information and used in the building industry, furthermore project team can decide to add any kind of information regarding design, construction, management etc. Not all COBie data are, or can be, developed within the Revit model in fact only 8 worksheets of 16 contain information that can be develop inside Revit (for instance information regarding spaces, types, zones, components, systems etc.). In this case, we used a specific tool made for Autodesk called COBie Revit toolkit (v. Revit Architecture 2012) which assists project teams to provide automated data export from Revit to COBie spreadsheet.

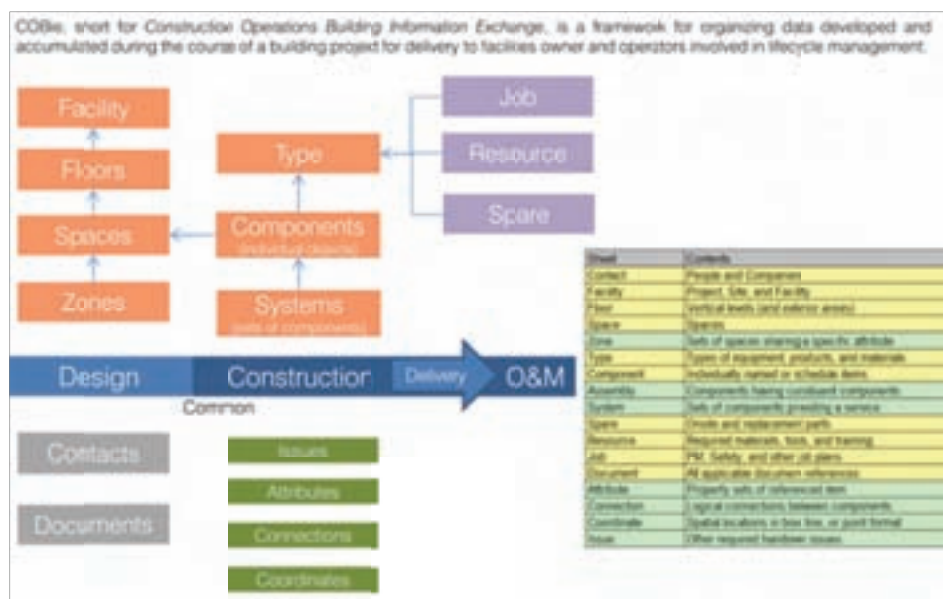

Fig. 2: Overview about COBie standard organization

The tests conducted, however, have revealed some problems related to the use of the standard, the most important of all is that the excel worksheet, containing the information, cannot be imported into Revit and consequently the final result is to have two separate operational tools. Nevertheless, this kind of approach, with precise and organized information represents an excellent way to reach the final goal to have a unique set of information without replication. In order to solve this problem (re-import in Revit) we have tested another solution: transfer information from Revit to individual operators through the adoption of DBlink that is a toolkit that allows creation of a bi-directional informational flow and can replace COBie worksheet which does not consider bidirectionality yet. This operational tool works within Revit and allows extracting, in this case in an Excel spreadsheet, the information contained in the Revit model. In this case the DBlink has been used because it is very dynamic, allowing the selection of the fields of Revit that it is necessary to extract and accordingly is very useful in case of shared parameters.

Using Revit DBlink two clear advantages are available: the first one is that extracting data in excel format allows non-expert Revit users to understand the information contained in the model and then make changes or validate it. The second one is that the excel file can be easily imported back into Revit, allowing an update of the information.

Operating in this way there is the certainty that the information remains always unique, without creating a multiplication of the same data that are difficult to manage and secondly allows a greater control on all transactions relating both to the design and the management.

The management of the building can also be enabled via 4D BIM. Its role is to add the time to a 3D CAD model, as the fourth dimension, and this allows the various participants of a construction project (from designers, contractors to owners) to visualize the entire duration of a series of events

and display the progression of construction activities over time providing an intuitive interface to project team and other stakeholders to easily visualize the assembling of a building over time. 4D modeling enables construction simulation during preconstruction to evaluate various options and identify critical aspects. Also, 4D storyboards and animations make BIM a powerful communication tool giving architects, builders, and their clients a shared understanding of project status, milestones, responsibilities, and construction plans.

Tangible benefits offered by 4D BIM are: Savings in cost and time; Risk mitigation; Conflict detection; Improved productivity; Enhanced quality.

Meanwhile, intangible benefits are: Improved communication among various division; and Visual communication to non-technical stakeholders and get their buy-in.

To investigate and verify the full interoperability of software for parametric modeling (BIM) with software for the control of projects in order to build a single 4D/5D model which can be integrated with ERP (Enterprise Resource Planning) systems and integrated platforms for management of construction and logistics like Archibus we used following software: AutoCAD Revit Architecture 2012 for BIM modeling; Autodesk Navisworks Management 2012 as 4D modeler in order to maintain as much as possible homogeneous application platform; MS Project 2010 for resource planning and control; MS Access 2010 and SQL Server 2008 as databases for data storage.

As a result of the process represented in Fig. 4 our objective was to create a single 4D model for both the control and monitoring of the project.

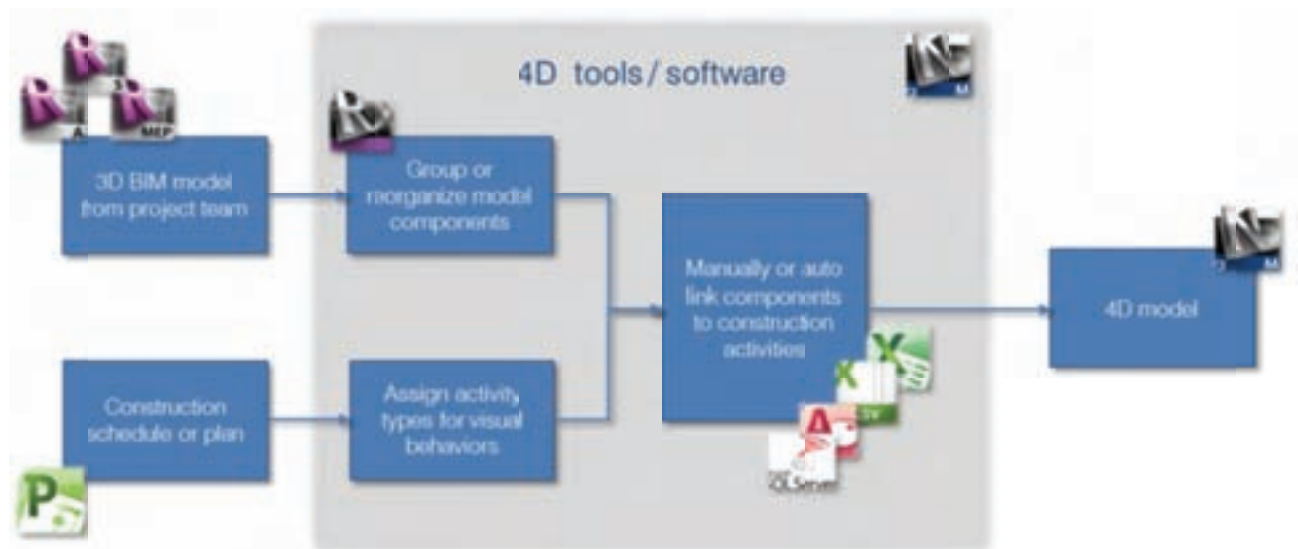

Fig. 4: The process of creating a 4D BIM.

During the import procedure of data from MS Project to Navisworks were added in the project only two attributes of all the activities, the dates of beginning and end of the project, meanwhile were not imported all other attributes such as the resources involved, precedence of the activities, constraints, project milestones and issues raised by the Critical Path Method. Also, once imported, the project is not in fact a true 4D model but only a BIM with a timing phase and the progress of the construction activities. For this reason the integration between the two environments cannot be considered a true and complete integration between the two environments because of absence of the key attributes for the control of the project. Furthermore, the exchange of information between the two environments is manual and not bi-directional: each change on the activities of the work plan (GANTT) must be turned in Navisworks model and connected to the phases of work and at the same time any change in the BIM model to be exported and connected to the working plane.

2.5 Tablet application to show the different data by Virtual and Augmented Reality

In order to increase the building awareness and to enhance any possible maintenance works, an Android application has been developed at Politecnico di Torino as task of the Smart Energy Efficient Middleware for Public Spaces (SEEMPubS) project and here tested, to provide building information exploiting both augmented and virtual reality. The end users of this application are the Building and the Energy Managers. The purpose of this solution is to overcome the limits related to the 2D visualization, presenting a 3D environment populated with building informations. To obtain the results firstly, we modeled the building using Autodesk Revit application through which architectural, structural, mechanical, electrical and HVAC models are merged to allow visualization, simulation and analysis of the building's energy performance. Thereafter the

architectural model has been integrated with sensors' models in order to allow observation of the temperature, humidity and lighting conditions of premises in real time. We modeled the parametric families of each sensor trying to make them likely, in this phase, particular attention was paid to the geometric and technical characteristics. In addition to the real sensors' modeling each room, some fictitious objects were inserted in order to allow the virtual navigation in the rooms. The next step was to export the building model created in Revit in .OBJ format and in this case, .FBX files were used because the geometry of these elements was not particularly complex.

As regards the materials, they are preserved in the passage from Revit to 3DStudio Max, however, the problems related to the subsequent conversion between .OBJ and .MLT files exist. In fact, most of them are lost and random materials are associated to the elements according to the layer to which they belong in 3d Studio Max. To overcome this drawback the materials should be reassigned to the objects through the material editor. Before proceeding with the exportation from 3DStudio Max, the geometry must be converted in mesh objects through the modifier "Edit Mesh". If this operation is not performed, the files .OBJ and .MLT do not contain any element. At this stage, it is important to verify that the exportation files do not contain geometric errors, in fact, it is possible to choose the method of approximation of the elements: triangulation, quadangulation, polygonal.

In order to ensure a fast maps loading in Android environment it was decided to perform a final files conversion from .OBJ to .JMF, exploiting the *Bonzai Engine* tool. Finally, through our application called *BIM Manager*, each .JMF file was loaded in the *BIM Server* in order to allow the virtual netsurfing of each room by tablet.

.MLT formats to be used for navigation by tablet. OBJ file contains the geometrical information of the model, while .MLT file contains the related materials. However, data exchange is not direct; in fact, the models must be imported in 3D Studio Max and exported after some modifications according to the formats required. Firstly, the model was exported from Revit using the .FBX format, subsequently, it was decided to use .DWG format due to some problems related to the geometry complexity. Using the CAD format it is possible to choose the type of solids that will be exported. In this case, ACIS geometry was used in order to drastically reduce the number of polygons that make up the various elements. During this procedure, the model has been broken down according to the types of elements. Furthermore, this choice is supported by the loading typology of the model allowed in the Android application, which specifically provides the subdivision of the model to improve navigation from a performance and methodological point of view.

The importation of the model in 3DStudio Max can be done in two ways: by creating a link to the source files through the Manage Links tool or as real importation of the source files. The link between files was chosen because with the direct importation the items were made independent from the file to which they belong. However, the second procedure, in fact, the nesting of the elements was lost voiding the process of rationalization followed during exportation. Importing .DWG formats allows to indicate the origin's source of the file while, using .FBX files, it is possible to choose the methodology for elements recognizing (depending on the material associated therewith, on the membership category or the family type, depending on not being combined entity or as a single object) and their subsequent grouping. During this process, some important information is altered: the units of measurement, the scale of representation, materials and the nomenclature of the elements. The units of measurement must be correctly set during the exportation from Revit, moreover, the option "rescale" must be checked and the units of measurement must be chosen again during .DWG files importation in 3DStudio Max.

The nomenclature of materials is automatically implemented with information related to the category of the element and the family type to which they belong. This represents a problem for the sensors and fictitious objects, which need to maintain their original encoding to be recognized.

The problem can be solved in two ways:

- By renaming the objects concerned, but this involves a double work by the operator and a quite long procedure if those elements are numerous.
- Exporting these objects by .FBX format.

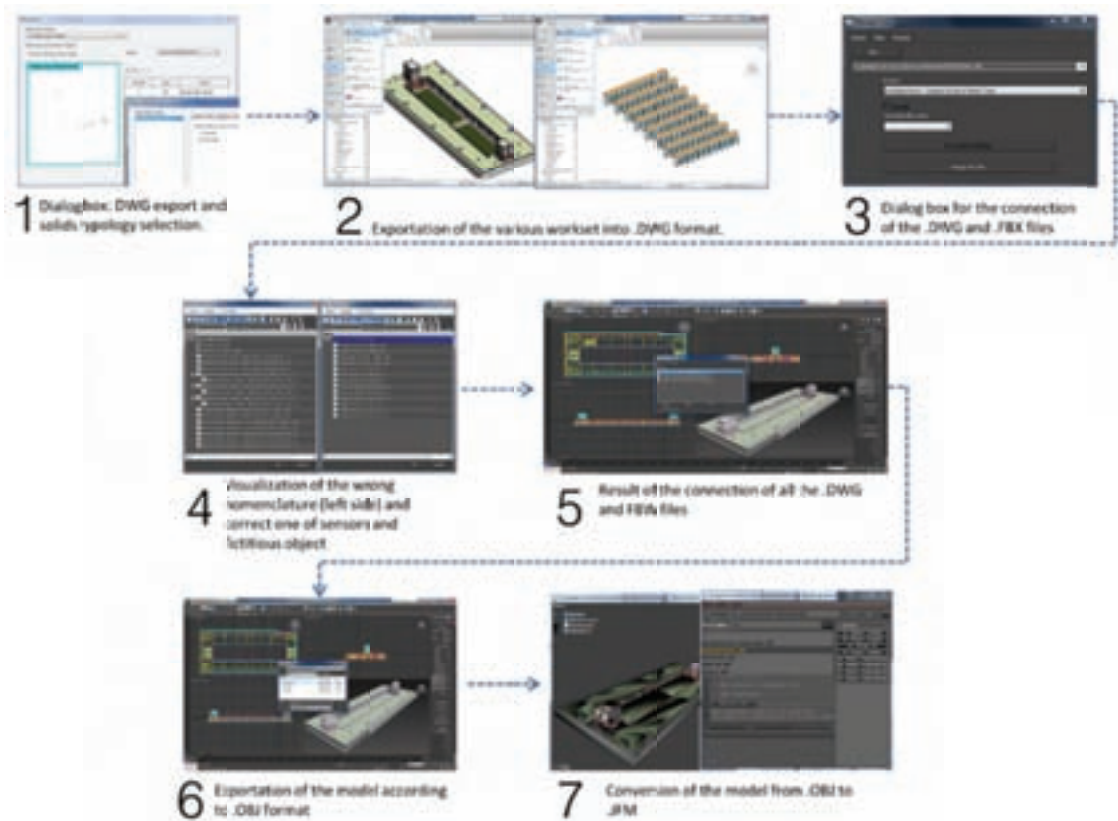

Fig.5: Operational step from Revit model to Android application.

In the following two images, there is an example of the Android App Graphic User Interface (GUI), where a 3D parametric model, described above, is shown using a tablet. The user can select information about: i) Architecture, ii) Furniture and iii) different systems such as Electrical, Heating and Ventilation. Moreover, these systems have been modeled using different colors (e.g. yellow for Electrical, green for Ventilation, etc.), as shown in figure below.

Fig.6: Visualization of the architectural model using a Tablet and of each system using different colours.

Finally, exploiting the augmented reality the Android App can provide information about rooms simply scanning its corresponding QR Code deployed into the building, as shown in figure below.

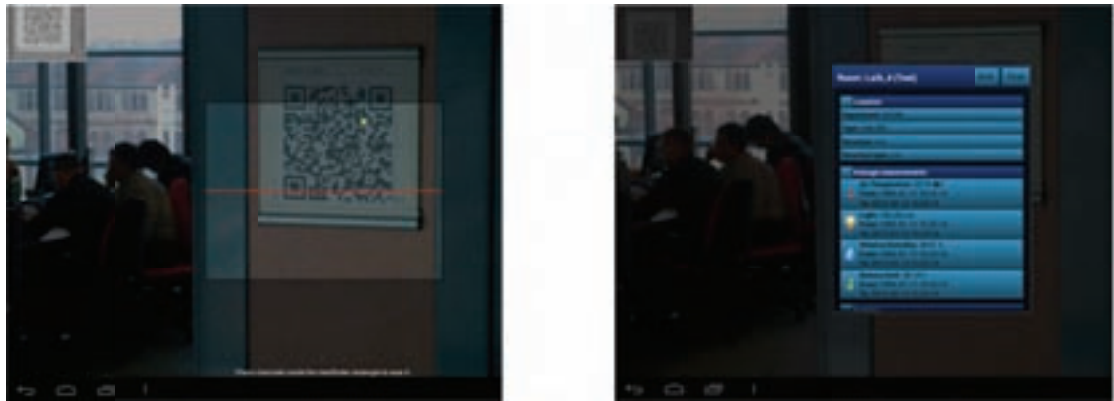

Fig.7: Example of room's information shown via Augmented Reality.

The general procedure can be summarized through the steps in the following picture summary.

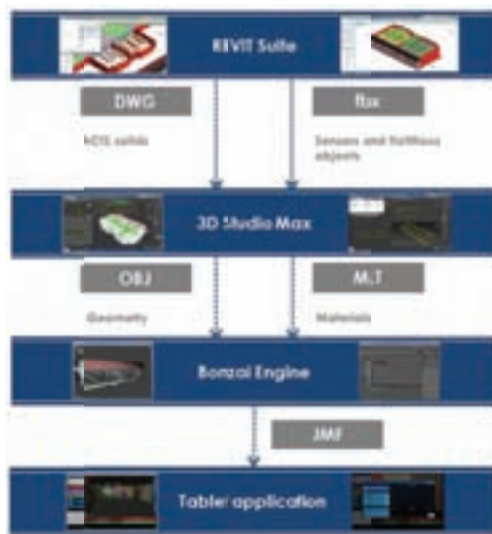

Fig. 8: Layout of the procedures followed.

3. Results

Although no best-in-class solution is available yet, open BIM tools are rapidly developing, providing useful instruments to support interaction with BIM models. Such tools provide interesting advantages concerning debug possibilities and extensions through inclusion of other open components.

The table of interoperability below is the result of the study we carried out during this course from different fields of study and different background. Of course, the table must be considered in progress as there are a lot of possibilities to use BIM software and for different compatibility processes.

Moreover, in this study, we evaluated the interoperability between BIM and tools for monitoring and control of projects with the expectation to create a single 4D model that would allow two-way exchange of information between the parametric model and the models created to monitor the progress of the project and the use of resources.

Tests have shown that, unfortunately, the full interoperability has not been achieved for a number of reasons:

- The model that is generated in Navisworks does not allow a bidirectional exchange of data and is not suitable to represent a 4D model itself, but only allows to visualize graphically the progress of a construction project;
- Data are not exchanged automatically between the software instead they must be exported and imported several times, with the risk of generating errors and inconsistencies;
- There is no integration SOA (Service Oriented Architecture) with ERP platforms like SAP, JD Edwards, Infor10, Microsoft Dynamics;

However, it must be said that there has been researched interoperability between software from different manufacturers and different technology 32 bit and 64bit; using Vicosoft software as 4D model generator and databases and software of the same by the same manufacturer (Oracle DB, BEA Weblogic, Spring, or SQL Server, MS Dynamics, MS Project Server) could be achieved a greater interoperability.

THE ARAB-NORMAN CIVIL ARCHITECTURE IN PALERMO: ENHANCEMENT STRATEGIES

Irene TRENTO¹, Liboria Laura ZABBIA¹

⁽¹⁾ Faculty of Architecture, University of Palermo, Italy

E-mails: irenetrento@libero.it, laurazabbia@hotmail.it

Abstract

This contribution aims to deepen the knowledge of a historical and artistic heritage of the city of Palermo, i.e. the Arab-Norman civil architecture, yet not adequately utilized, despite its importance as a 'World Heritage Site'.

Within the three royal parks (the Old, the New and the Genoardo), the Norman kings built the palaces of Maredolce, Zisa, Cuba and Scibene, always accompanied by water, both as a lake or as a fishpond, whose purpose was primarily hedonistic as well as productive.

The transmission of the architectural heritage to the future presupposes its promotion through the creation of an appropriate strategy helping to spread its knowledge and enjoyment. For example, Sicily has few cases of interactivity, that is virtual reality applied to the architectural heritage through multimedia resources in order to "modernize" the cultural offer and the communication with all targets of audience. In many cases indeed, a monument is soon forgotten when it is restored but not integrated into the municipal system. A new interpretation is therefore proposed, based on the relief together with the story of the restorations and the understanding of the building within its urban context, which is compromised by an idea of protection limited only to the emergency.

Keywords: Arab-Norman civil architecture, World Heritage.

1. Introduction

The study of the Arab-Norman architecture in all its forms is the research area of the working group coordinated by Professor Renata Prescia within the Faculty of Architecture of the University of Palermo. For some years, indeed, attention was paid to the Sicilian factories of the twelfth century through the research carried out in degree thesis and during conferences and study days. The project aims at a multidisciplinary cataloging of historical Arab-Norman evidences, starting from an historical-critical analysis performed on accurate surveys, with high attention to the history of the restorations integrated with the identification of authentic materic-constructive values. The aim is therefore to study such architectures no longer as a mere work of art, isolated and out of context, but rebuilding the relations between the different skills required for their fuller understanding, also with reference to the original urban surrounding (in the preserved residuals) and to the current one.

The Arab-Norman architecture can be classified into two categories: the religious one and the civil one. In particular, this paper aims to be a census of the civil architecture of public initiative in Palermo, on the basis of a renewed 'awareness' of its current conditions by the community, in order to develop a concrete proposal of multidisciplinary archiving for a "networking" of the factories. This analysis is essential in order to ensure a real enhancement through targeted communication strategies using means of knowledge able to attract the greatest possible number of users.

2. The census of the factories

Among the civil achievements of the Norman age, the Royal Park extended in the Plain of Palermo and the buildings built in it, the so-called *sollazzi*, are among the most complex and original creations of civil art and architecture. Built as places of rest and stop in the hunting grounds, they were characterized by fishponds and tanks while their typological peculiarity consisted in the presence of

In effect, the Parterre project (sponsored by the Department of Architecture in Palermo in partnership with other cultural and social components) promoted activities of intervention by residents, aiming at the enhancement of the building of Maredolce through its use and knowledge³.

The general plan for Maredolce complex is not finished to date. Expropriation measures are still being performed on buildings overlooking the edges of the fishpond, aiming at restoring the entire basin according to the plan drawn up by Palermo Superintendence of Cultural Heritage and Environment.

The basis of the proposal, certainly praiseworthy in its intent, although not fully acceptable in its final choices, is a significant attention to the close relationship between the constituent elements of the complex and the landscape, as required by the culture of Arab gardens before and Norman Royal Parks later. The presence of the garden, survivor of the massive urbanization in which the area incurred, turns out to be, in fact, something of inestimable value. The Maredolce complex therefore represents a valuable historical and environmental survival, direct testimony of the so-called "Gardens of Paradise", because of the harmony between vegetation, water and architecture.

Along with this, the single system is created by the still existing relationship between the same vegetation and the other items originally ascribed to the *sollazzo* (the arches of St. Cyrus, the church and the caves of the Giants), now separated by the Palermo-Catania motorway which has severed the former unity of the complex.

Action is, however, still required to improve accessibility, such as the pedestrianization of the area in front of the Castle and the creation of a square providing a direct view of the Castle, now hidden by precarious and abusive buildings.

Fig.3: The square in front of the Palace and Giafar street.

Fig.4: The palace of Maredolce today.

- **New Park:** built as an extension of the Old Park in a wooded area, it stretched from porta Mazzara following the trail of a dirt road, today called Via Brasa, until reaching porta del Giglio, in Altofonte, and then continuing towards the Fig valley⁴. According to the descriptions given by historians, given the presence of many wild species the park was used as a hunting reserve.

- **Genoardo Park:** latest landscaping creation, it stretched between the city walls and the mountains beyond. Made during the reign of the two Williams, it represented the point of contact between the urban gardens and the surrounding countryside. The *sollazzos* of **Scibene**, **Zisa** and **Cuba** were built inside it in the twelfth century.

The palace of **Scibene** was built as a summer *sollazzo* in an earlier period than the construction of the Zisa⁵. The plant consisted of a fishpond, the Chapel, and a pavilion on several levels in which a cross-shaped room with *iwan* served as the center⁶.

⁵ Spatrisano G., *Zisa and Scibene of Palermo*, Palermo 1982, p. 63.

⁶ The study of the Scibene has been addressed in the Laboratory of restoration of monuments maintained by Prof. R. Prescia. The contributions graphs below were made by students Guarnuto, Pirrera and Tarsia.

Fig.5: The Palace of Scibene. Plan of level I and II.

Currently incorporated within the Fondo de Caro, it is abandoned and in a state of advanced decay. The system of the front basin and the garden is, in fact, made unrecognizable by private buildings, while the structures of the upper floor, iwan and chapel, are in conditions of severe deprivation.

Fig.6-7: Aerial view and indication of the palace of Scibene.

The last restoration work on the building date back to the first half of the twentieth century, designed by Francesco Valenti in 1929, and Mario Guiotto in 1938. In the first case, the interventions involved the structural consolidation of an opening of the west façade and of the roof of the church with a single nave. In addition, following the example of Patricolo in St. Mary of the Admiral, Valenti predicted the inclusion of a toothed belt, made of more or less prominent blocks, indicating the ancient presence of the tower. The intervention of Guiotto was merely an integration, made with bricks, of gaps in the masonry of the south façade of the church. Since then, the lack of attention from the community and of a conservation planning has resulted in the state of extreme deterioration the complex faces today.

Fig.8: The palace of Scibene. Indication of restorative interventions.

The enhancement of this factory practicable from its recognition requires early action that should contain a program of interventions in three phases: prior acquisition of the palace to State ownership, subsequent restorative intervention and, finally, insertion into a tourist route allowing an easier use of the complex.

The palace of Scibene is currently part of the itinerary *Royal Art of Norman Age: The sollazzi and the royal park*, proposed in the publication *Sicilian-Norman Art* edited by the Department of Architecture of the University of Palermo in 2004⁷.

Built by William I in 1165 and completed at the time of William II probably between 1175 and 1180, the palace of **Zisa** stood near an aqueduct and a spa facility dating back to Roman times. The complex was formed by a garden and a building on three levels with a rectangular plan and two towers at the center of the smaller sides. The rooms are arranged around the central hall with iwan, whose fountain was connected to the outside fishpond through a raceway.

Used between the fourteenth and fifteenth century as a fortified farm house, it was transformed into a manor in 1635 by the family de Sandoval, undergoing numerous changes. In 1951 it was expropriated and handed over to the Regional Demanio.

Fig.9 The palace of Zisa and the park.

Fig.10: The iwan

Following the collapse of the North Wing⁸, which took place on October 12, 1971, the restoration works of the palace were initiated, and completed in 1991. What lacked, however, were subsequent recovery operations putting the building in relation with its context and especially with the elements that made up the complex of the Norman *sollazzo* (the chapel of the Holy Trinity at Zisa, the fishpond, the *gebbia*). The different properties, indeed, have not made possible a real dialogue between the parties, effectively depriving tourists of the possibility of using, and therefore fully understanding, the entire system of *sollazzo*. It is therefore desirable to design a real link between the palace and the garden, for example, through one of the *dammusi* facing the palace: and a link, according to an idea of restoration connecting modern monuments and ancient ones, with the "Cultural cantieri at Zisa", today at the center of the cultural events in the city of Palermo, thanks to the Museum for the exhibition of works especially created by young artists, called ZAC (Zisa Contemporary Art) and inaugurated last December. The "Cantieri" were set up in the Nineties in the halls of the twentieth-century Ducrot factory, south-west of the palace.

⁸ STAACKE U., *Un palazzo normanno a Palermo: La Zisa*, Palermo: Città di Palermo, Assessorato beni culturali, 1991.

Fig.11 Aerial view.

The *sollazzo* of **Cuba**, finally completed in 1180 by William II, consisted of a large pavilion at one level, surrounded by a fishpond. The small Cuba (also called Cubula), located in what remains of the garden of Villa Napoli, and the Tower Alfaina, also known as Cuba Soprana, whose Norman remains are now incorporated in the Villa, were part of the complex too. Even in the case of Cuba, as for the complex of Maredolce, the importance of the context assumes a fundamental role.

The site has been affected by many changes due to the different intended uses that have followed one another over the centuries:

Fig.12. Aerial view.

Fig.13 The Cuba.

The building was, in fact, used as an isolation hospital (1575) and barracks (1860) before being reacquired by Palermo Superintendence of Cultural Heritage and Environment (1921), which has taken care of its several restorations. It's now time for a major redevelopment of the buildings erected on the edges of the original fishpond, which don't allow the use of the monument in relation to its immediate context, and the inclusion of the monument, as already proposed for the Zisa, in a journey including the adjacent monuments of the Norman church of Victory and the Royal House of Fools⁹.

3. The Unesco application

The "Convention on the Protection of the World Cultural and Natural Heritage" was enacted in Paris on November 16, 1972, obliging the participating States (Article 4 of the Convention) to ensure the

⁹ Sgrò R. *La difesa della cultura : dalla Cuba alla Real Casa dei Matti alla Caserma della Vittoria: un percorso storico per il recupero urbano*, relatore: Prof. M.T. Marsala, co-relatore Prof. R. Prescia; Università degli Studi di Palermo, Facoltà di Architettura, A.A. 2008-2009

identification, protection, conservation, development and transmission to future generations of the cultural and natural heritage situated in the territory.

For this purpose, UNESCO (United Nations Educational, Scientific and Cultural Organization), established in 2002 that the inclusion of new sites on the World Heritage List was necessarily conditional to the establishment of a "World Heritage Committee". On the basis of the data provided by each participating State, it was commissioned to design, update and spread a "World Heritage List" (WHL), a listing of the world heritage assets considered to be of outstanding universal value. Subsequently, the Committee had the task of drawing up a list of endangered monuments, indicating the goods which needed protective interventions and maintenance works and for which a Dossier of application and a Management Plan were required.

In the preparation of the Management Plan for "Arab-Norman Palermo and the cathedrals of Cefalù and Monreale" (2012) recently presented by the Regional Department of Cultural Heritage and Environment, the instructions developed by the National Commission UNESCO World Heritage Sites and by Local Tourism Systems of the Ministry of Heritage and Culture were taken into consideration.

The knowledge of a good is the first level of protection: to know is to document and its documentation is an essential support for the protection of cultural heritage.

Therefore, the application of Arab-Norman architecture to UNESCO is undoubtedly an important tool for increasing its knowledge, ensuring its preservation, enhancing tourism and enriching the process of management of proposed monuments within the route winding between Palermo, Monreale and Cefalù.

The monuments of Arab-Norman architecture, object of the Management Plan, are twenty three but only eleven were selected for the establishment of the Arab-Norman itinerary, as the only ones fully retaining artistic and architectural components and showing good conditions, enjoying appropriate protection measures.

The choice then fell on the Royal Palace, the Palatine Chapel and the treasure guarded inside it, the Church of St. John of the Hermits, the Church of St. Mary of the Admiral, the Church of San Cataldo, the Cathedral, the Palazzo della Zisa with the adjacent chapel, the Cuba, the Bridge of the Admiral, the Duomo of Cefalù and Monreale and their outbuildings cloisters. These monuments selected according to the criteria established by UNESCO, so because of their conditions of integrity, authenticity and good preservation, marked the route nominated for World Heritage Site.

4. Conclusions.

The monuments excluded from the Management Plan, although presenting features of authenticity typical of Arab-Norman architecture, suffer from both problems of preservation and, consequently, of fruition at the same time, as we have shown above.

We believe that their "sponsorship" through the inclusion in bibliographic and historiographical routes, of which this paper is intended to be a small part, and in virtual tours, through the creation of multimedia tools dedicated to them, can serve to urge the required restorative interventions.

We also believe that thinking of fruition processes to exalt their relations with other evidences of modernity, rather than freezing them in their compromised or lost native configurations, putting them back into current socio-economic dynamics, can serve more to their conservation through the recognition by the community in a more involved use of the 'cultural heritage' as <<that complex of man's works in which a community recognizes its particular and specific values and with which it identifies>> (Krakow Card 2000).

The need to document through new distribution channels <<cognitive information useful for the management, enhancement and use>>¹⁰ of the monuments is essential to optimize the cultural offer and communication with all audiences. Despite the gradual spread of information technology¹¹, the application to cultural heritage in Sicily is uncommon. In fact, the Arab-Norman heritage doesn't have a support based on devices of augmented reality or geotagging.

Currently, on its website, the Superintendence to Cultural Heritage and Environment provides video describing the history of the factory and of the restorations of the Cuba and the Royal Palace, without giving the user a chance to interact with information. The Sicilian Regional Assembly (ARS) has created a virtual tour of the Royal Palace, where it's possible to explore environments without,

¹⁰ Fiorani D., Restoration and technologies in architecture, Roma: Carocci publisher, 2009, p.98.

¹¹ One of the first cases of computerized documentation, made during the restoration work on Michelangelo paintings in the Sistine Chapel in the Vatican, dates back to 1986. Since then, the multimedia techniques have been used both as a support to the restoration site (through the use of GIS) and with tourist and educational purposes as in the case of the main museums.

however, any historical support. Finally, the Department of Cultural Heritage and Sicilian identity, Sicily UNESCO Sicily heritage foundation, has produced a CD Rom where it's possible to find information about the application of the Arab-Norman route and charts on its monuments. These, however, while providing data on the history and indicating a territorial scope of reference of the factories, are lacking in the communication of materic-constructive values, use and membership.

Object of this paper is therefore proposing a new type of archiving of monuments, starting from the setting provided by the cataloging of the factories for the Management Plan of the Arab-Norman route, in order to put the focus on cultural values unfamiliar to the users of the service.

The typical chart presented provides an "identity card" of the *sollazzo* of Maredolce accompanied by graphics and thematic maps¹². In addition to the "standard" information such as the location of the complex, legal data or the description of the plant, special attention is paid to the history and, in particular, the history of the restorations, that historical process letting us understand the transformations of the factory such as additions, alterations or interpolations through a critical formation of a history of architecture aimed at restoration and enhancement.

Fig.14: Example of a typical chart

¹²The chart has been drawn on the basis of the processing carried out by the architect Alessia Buda.

Cultural Heritage and “Freedom of Panorama” Representing Italian Identity

Enrica Bistagnino

Department of Architecture DSA, Polytechnic School, University of Genova, Italy
E-mail: enrica.bistagnino@arch.unige.it

Abstract

What is the image of our country's cultural heritage?

Unfortunately it seemingly shows an image which is still fixed by taxonomic categories which, by forcedly separating cultural areas, products and actions, break up the unitarity that, even in local specificities, pervades our culture.

In this regard, we should attempt to provide a fresh image, trying to regenerate it in the knowledge of that transformative process which, over time and in particular productive, socio-cultural and territorial contexts, has played a role in widening the very concept of cultural heritage. It is a question of adopting a change in perspective leading to actions addressed to shaping an image with which to enhance the parts and the whole, to form a cultural panorama that depicts places in their wide range of forms, expressions and productions. This can therefore provide the people with that sense of identity from which emerges the respect for cultural differences characterizing contemporaneity.

The primary condition to depict this type of image may clearly be ascribed to the concept of freedom. Freedom to address different themes, genres, products, areas, events and so on, in a cataloguing mix that paints a picture where identity is also deduced from strong contrasts, from apparently incoherent light and shade.

“Freedom of panorama” to be able to choose, represent and interpret following the standard norms, but irrespective of field restrictions and implemental prescriptions, even the highest expressions of cultural heritage.

This paper intends to recommend some working hypotheses to paint the identity picture of some territorial areas by freely selecting, representing and interpreting the related tangible or intangible cultural heritage.

A contemporary picture that also takes into account the multiculturalism as central and unavoidable in describing cultural heritage as an open, living system.

Keywords: Heritage – Representation – Identity

1. Cultural Heritage and “Freedom of Panorama”. Representing Italian Identity

It is conventionally accepted that the complex description of a country's cultural identity must refer to the evolution of its way of thinking and the articles it produces, but also to those forms of self-expression that have delineated its image over time, often driven by representation in all of its different mediums and declensions.

In other words, according to this vision the process is less about examining only material and immaterial data that, with regards to the definition of identity, already constitute an incredibly vast repertory of elements (not always clearly linked to a unitary vision) useful to study, and more about identifying, selecting and ‘agreeing on’ diverse forms of self-reflection. Forms that, over time and as part of an incessant flow of cultural perspectives, have demonstrated the complex and often contradictory vision and attribution of meaning with respect to events.

Hence in this scenario, where, as Bauman writes, identity resembles “a cluster of problems rather than a unique question” (Z. Bauman, 2003), representation once again appears to be the privileged vehicle for attempting to trace a few signs of contemporary identity. In fact, as thought-form, representation

becomes one of the principal actions for establishing and clarifying the meaning of fragments of research. It renders them recognisable in their temporal evolution, as well as updateable, implementable, immediately accessible and available to the transformations generated by cultural evolution. Thus, in the end, always contemporary in their consistency and, above all, in their image as a source of identity.

However, if representation is the medium for attempting, between units and locales, to delineate the numerous modulations of Italy's contemporary identity, and in so doing assuming almost a dominant role with respect to real data, what forms of representation must be imagined? Toward what facts, what elements of cultural heritage must we turn our attention?

It is clear that we are dealing with a semantic question. Establishing what to include within the framework of representation and fixing a point of view comports an intentional attribution of meaning that belongs more to the elaborative than to the descriptive sphere of identity.

Having said this, if we turn our attention toward the overall image of Italy, and simplifying things to some degree, we notice that the 'genre' of cultural heritage most often considered, together with the principal means of describing them, on the one hand reflect an interest that remains strongly directed toward 'traditional' cultural heritage and, on the other hand demonstrate an attention toward diversified and up-to-date theoretical-methodological researches that, however, appear to remain substantially autonomous from one another in their language and aims.

On one side we can consider the countless 'informative' representations whose formal reference to procedures of inventorying typical of methodological unification, functional to activities of institutional cataloguing and documentation [1], propose didascalic images that substantially sacrifice an author's freedom of expression. These representations, whether graphic or photographic, analog or digital, static or dynamic, on-line or off-line (to use some of the most common antinomies able to evoke the conceptual and technical-methodological complexity subtended by the theme of contemporary representation) conserve the role and aesthetic of the documentary image: referential, informative and intentional. They can thus be considered representations 'hardened' by the analytical-descriptive model structured by classification, which transfers a schematic and hierarchical taxonomic structure to the image.

From another point of view, which observes and operates from beyond this documentary vision and within a substantially autonomous perspective, we find subjective images transmitted by an apparatus of signs that, in conceptual and technical-methodological terms, are freely defined within an incredibly vast repertory of genres and techniques. They are precious images that, despite their documentary non-intentionality and thanks to their value as a mirror of reality (György Lukács, 1963), favour an understanding of the data represented and the formation of an anthropological conscience. In other terms, a progressive aesthetic renewal allows a voluminous and powerful body of often heterogeneous images to transmit several distinctive traits of the continuous transformation of cultural identity.

One example includes photographs of architectural, artistic and landscape heritage. We can also consider the countless and often under-evaluated 'styles' of photography, such as that related to the world of tourism: by searching for themes and points of view with the intent of creating emotional suggestions, they implicitly declare a propensity, on its own positive, toward the development and management of a country's cultural and landscape resources, also in economic terms. This consideration can be extended to traditional pictorial representations that, between views of the landscape and depictions of interior spaces, reveal natural and cultural forms and speak of the public and private dimension; we can consider the signs of graphic design employed by modern and contemporary communication, whose powerful innovative importance is both technical and, above all, linguistic; we can consider all those images whose evocative dimension makes them independent of their intrinsic meaning, 'involuntary' icons of moments that have marked our history and our cultural, social and political identity; we can consider, what is more recalling the highly negative effects images can produce, the mosaic of mass media images, in some cases kitsch and stereotypical that, in a popular and pervasive dimension, distort reality and push Italy towards the grotesque; to conclude this brief and partial list we can consider the incredibly vast articulation of specialised images and, on the contrary, the marvellous myriad of representations that use different signs, forms, techniques and means to give voice to any individual or social group desiring to participate, often employing a textual and visual slang, in an emotional, intellectual, cultural process of sharing.

Hence it is immediately evident that the two fundamental macro-categories of representation synthetically listed above – tied on the one hand to institutional, codified and regulated representation, and on the other unrestricted, free and subjective – unite images that, speaking separately of cultural environments, products and actions, deeply fragment representation as a source of identity and its communication. Successively, for the codes employed, this process implicitly turns to diverse groups of spectators-actors and produces a further 'parcelization' of information.

In light of this condition it would seem important to test an updated image that is capable, between textual citations and free interpretations, to consider and indicate a renewed panorama of cultural

assets that can be deemed comprehensive, also in apparent contradiction with the very concept of the asset. In this sense, we must first of all recall how the comprehensive process of transformation generated by continuous cultural, socio-political and economic dynamics has contributed over time, in some cases slowly and progressively, in others rapidly and discontinuously, to expanding the territory of Cultural Heritage, welcoming what may have appeared lacking in dignity, value or even meaning only a short time earlier. It therefore appears important to adopt a change in perspective, extending attention from an aesthetic dimension towards an ethical dimension of the asset to generate representations inclusive of their multiple, even contradictory themes. They can be used to model a cultural fresco that uses innumerable signs, expressions and productions to speak of place. This change in perspective sheds light on values, in addition to documenting forms of deterioration, dramatic events, indifference and civil, social and cultural violations, with the objective of reading facts within their implicit dimension of memory and value.

The principal cultural asset to be protected and valorised is thus our comprehensive history, assumed integrally and without distinctions between light and shadow. The contemporary representation of Italy must be a truthful story that intends to procure a sense of identity. An identity that may later produce the respect for cultural diversity characteristic of our contemporary era. This must be a collective project, not only in its forms and 'individual' channels of management, but adopted also in institutional environments and part of instruments for the conservation and valorisation of Italian heritage. Examples include the procedures adopted by the Regional Cultural Heritage Information System (SIRPAC), which consents a participative web-based cataloguing of cultural heritage.

Thus the construction of an image as a source of identity that takes form here can be linked to two primary key themes: 'respectful criticism' and 'freedom of panorama'.

'Respectful criticism' (K. Popper) toward all that is traditional, toward the past, toward conventional forms of representation, in order to recognise material of value, but also in order to retrace the limits and, through opportune actions of research and experimentation, to seek to further develop tradition.

'Freedom of panorama' [2], in other words, the freedom to represent and re-semanticize public buildings, projects and sites, without violating an author's rights. Hence a form of representation that, while it embraces reality, is presented as an autonomous aesthetic subject of reality itself, free to reconfigure it according to intellectual visions. For certain aspects, in the field of representation the concept of 'freedom of panorama' recalls an approach to design of radical memory: an approach that interprets the "continuous movement of thought [...] in the eternal attitude of man [...] to incessantly redesign the image of the world" [3].

Thus 'freedom of panorama' is also the freedom to overcome the concept of delimiting the image and, earlier still, the concept of genre, in order to unite, or better yet integrate heterogeneous and apparently/truly incoherent themes in a single open image.

This means expanding our point of view to broaden the field of representation with the intention of 'annulling' the concept of delimitation, substituting it with a notion of continuous extension. In definitive terms this comports a fundamental conceptual leap that shifts the objective of representing cultural assets and identity from the image, as the demarcated and primary data of communication, to its elaboration, as the founding process of the search for identity.

Abstract

Set up in 1884, for collecting the eastern Sicily's antiquities, the National Archaeological Museum of Syracuse has evolved during the time following the implementation of collections and the transformations of the concept of the museum's role in society. Initially based on a nucleus composed of a few objects and some private collections, it was gradually enriched during a period of almost fifty years of intensive excavation and research undertaken by Paolo Orsi. Benefiting from the rigorous scientific requirements indicated by Luigi Bernabò Brea, the museum started a new life when it moved to Villa Landolina's area where a new structure was conceived by the architect Franco Minissi, a personality already well known in the museography's field. The building and the exhibit design were studied by Minissi to ensure the maximum flexibility. The idea was to create a museum in movement or an anti-museum able to adapt to the scientific progress and new archaeological discoveries. Conceived by its creator as a vital center for research and cultural promotion, the museum, thanks to virtual reality technologies, can today found new capabilities. Starting from a careful "reading" of the building and its environment, made by integrating surveying methods, this case study intends to contribute to the definition of a new approach to the museum visitor experiences through multimedia.

Keywords: Museography, Interactive museum, Cultural heritage, Franco Minissi, Syracuse

1. Origin and development of the National Archaeological Museum "Paolo Orsi"

Following the creation of the Kingdom of Italy, the need of conveying and reinforcing the new united nation through the recognition of a common cultural and artistic heritage, resulted in the transformation of the management of cultural institutions in the former states, placing them under its exclusive control. Italy maintained initially unchanged the homogeneous legislative body of the pre-unitary states in the field of protection of heritage, even due to the obvious difficulties dictated by the opportunity of reconciling the liberal ideology with the public interest resulting from the preservation of cultural goods. During the first years of the young Italy, the legislation in this sensitive field was therefore characterized by the persistence of a territorially differentiated discipline and by the freedom of private owners to make indiscriminate use of "their" works of art, including their alienation abroad. This, with the only exception of the Kingdom of the Two Sicilies where this practice had already been banned by the Bourbon government, also admitting the possibility to expropriate the monuments belonging to individuals, whether in ruins because of neglect [1].

More concrete protection activities in favor of artistic heritage in the new state will begin, however, only in the last two decades of the 19th century with the establishment of the *national museums*. It was the first attempt of gathering the small private collections also by virtue of an artistic and cultural heritage's legal status, by then recognized as a public good with collective purposes. We still have to wait until June 12, 1902, so that the first law of protection was promulgated and the *catalogo unico dei monumenti e delle opere di interesse storico, artistico e archeologico di proprietà statale* established. However, the Kingdom of the Two Sicilies, well in advance of the rest of the peninsula since the end of '700, had felt the need to bring together the artistic and archaeological heritage allowing its access and knowledge to the scholars and the whole community.

1.1 At the beginning of the protection of the archaeological collections in Syracuse

In the city of Syracuse, the objects that foreign travelers came to admire had, until that time, been protected by a few families, notable art collectors. One of the oldest collections was that accumulated by the archaeologist Vincenzo Mirabella, who gathered in his great building opposite the church of *San Tommaso Apostolo*, in Ortigia, a number of "endless scraps of weights, mosaics, granite and marble" [2]. It is although to 1780 that the origins of a museum institution date back, when the Bishop G. Baptist Alagona, brought a small collection together in the library-museum of the Seminary, located in *Piazza del Duomo* [3].

At the end of the century, the creation of a city museum combined with a cabinet of natural history was requested by the poet Tommaso Gargallo. He raised the issue of gathering up in a single collection "simple homelands objects, both cultural and natural value"; i.e. whether those were in possession of some collectors or those coming from the new excavations undertaken by Landolina's family [4]. For the first time, the need to establish a native museum came to light. Certainly, times were not ripe yet but this proposal became stronger following the discovery in the *orto Bonavia*, in the ancient district of Arcadia, of the statues of Asclepius (7 December 1803) and of the Venus Anadyomene (7 January 1804) by Saverio Landolina, the *regio Custode delle antichità delle due valli Demone e Noto*.

Landolina will vigorously carry forward the purpose of creating a museum. This intention seemed even more necessary in light of the fact that those exceptional discoveries have had a so high resonance to make stronger the interest of antiquarians and travelers against "Syracuse buried antiquities" [5,6]. According to his idea, the city museum would have to collect not only the discoveries of new archeological excavations but all the material scattered in private collections in order to offer to scholars and visitors, a complete overview of the archaeological heritage of the town.

In addition, the discovery of Venus, while it had increased the interest of scientists to local archaeology, on the other hand, had attracted the attention of the Royal Court, which could solicit its transfer to Naples under the pretext of the lack of a proper seat in Syracuse. A request that will be advanced several times but always been circumvented by Landolina. His frantic search for locals where to accommodate the new museum will finally succeed in September 1809 when the Bishop of Syracuse Filippo Maria Trigona will offer some rooms in the Seminary to form the first city museum. The initiative was quickly approved by the king and the museum opened on April 20, 1811. The organization of the museum was ensured by Mario Landolina (his father had meanwhile withdrawn because hit by a paresis) but it was not an easy task. The collection was made up of precious Greek and Roman monuments, ceramic materials of different nature, inscriptions, lamps, Christian's clay pots, paintings, urns and charnel houses but museum's spaces were limited. It was precisely for this reason that a discussion on its extension will be launched [7].

1.2 From the establishment of the first premises to Paolo Orsi's activities

It is following the discovery of the *sarcophagus of Adelfia* on June 12, 1872, during the research carried out by Saverio Cavallari in the caves of *San Giovanni* [8], that we can assist to a new impetus in order to give better placement to the civic valuable works of art. In 1876, an agreement was signed between the Central Government and the Town Hall for the construction of a new building for the museum that was originally supposed to rise in the place of the Post Office building. This hypothesis was therefore abandoned in favor of the church of *San Giovanni di Dio*. In the meantime, however, the civic museum, temporarily located in the premises of the Seminary, next to the Alagonian library, was declared a *Regio Museo Archeologico Nazionale*. In December 1880, the demolition and transformation work designed by the engineer Luigi Mauceri and concerning the church of *San Giovanni di Dio* and the annexed *Fate Bene Fratelli* hospital, begin [9]. The work was interrupted for two years and restarted only in the summer of 1882, under the direction of Luigi Spagna. The building was completed in 1885 and the museum officially opened on 11 April 1886.

The establishment of a state museum in Syracuse, a few years from the Italian unification, was a very important political act, also in relation to the place it stood, an area inhabited since prehistoric times, later become the center of the religious life during Greek colonization with the sanctuary of Artemis and Athena. The new structure was born in order to preserve the archaeological material coming not only from Syracuse but from whole Eastern Sicily, as had already been in Western Sicily, by virtue of the construction of the Archaeological Museum of Palermo. The first director of the fledgling National Archaeological Museum was Francesco Saverio Cavallari, who was arrived in Syracuse one year before, after having been the *Direttore delle Antichità di Sicilia*. The technical report made by Luigi Spagna on 10 July 1879, states that on the first floor was placed a small library and that the museum had five halls: the hall of epigraphy and of the Christian sculptures from the catacombs, the hall of statues, the hall of the Greek-Roman fragments, the Tribune of Venus, the hall of the ceramics. But it was thanks to the contribution of the archaeologist Paolo Orsi, that the contents were remarkably enriched with new discoveries that gave more and more scientific character and prestige to the organization of the museum. Named in 1888 as inspector of the state museum, the young archaeologist Paolo Orsi (Fig. 1) became in 1895 its director, in place of Cavallari, maintaining this

Fig. 1: The Archeological Museum in Piazza del Duomo's premises (left) and some objects from collection (right).

role until 1934. Welcomed, not without suspicion, in the Royal Superintendent of Syracuse, he was immediately attracted by the Greek origins of the city and by the charm of its many archaeological remains. He then immediately began an intense series of field investigations and collections that enabled him to draw the first systematic historical study on the original cultures of the Sicilians, the pre-Hellenic Sicily, the famous Sikeloi. The activities carried out by Orsi were not therefore only limited to the issue of island's origins. His researches on Greek civilization in Sicily, and especially in Syracuse, were highly profitable. The studies that he undertook about the Athenian still represent a real scientific breakthrough. His interest was also directed towards the discovery and the knowledge of sacred places and public buildings, such as the Greek necropolis and the Olympian Zeus of Syracuse. He personally accomplished very daring explorations to the necropolis of Pantalica, Cassibile, Megara, Castelluccio, Thapson, Licodia, Valsavoi [10].

It was the growth of artifact collections and documents coming from the large excavation expeditions mainly conducted by Paolo Orsi - in a methodical, for the time, rigorous and advanced manner - to lead to the need of designing new spaces for the museum. Already in 1916, Paolo Orsi had complained to the Directorate General of Antiquities and Fine Arts in Rome, the lack of space. The museum's collection already included in the early 20th century, numerous items concerning the prehistory of central and eastern Sicily, architectural terracottas, simulacra, small statues found in the tombs and sanctuaries, painted vases representative of all periods, ceramics, and the main pride of the museum, a large coin collection. A repertoire so vast that Guido Libertini in the introduction to his guide at the museum of Syracuse said: "*Faced with this wealth of materials we understand how space could now be lacking and therefore how the various collections, packed in different environments while waiting for a desirable forthcoming enlargement of the premises, are not always arranged in a strict chronological order*"[11]. But an extension will be possible only many years later.

1.3 The methodological rigor of Luigi Bernabò Brea for a re-foundation of the museum

At the end of 1941, when Luigi Bernabò Brea moved to the Department of Antiquities of Eastern Sicily, following a fascist measure by which the State officials from the North were transferred to the South and vice-versa, other major renovations were undertaken inside the museum, of which the archaeologist himself became director in 1942. Since his arrival in Syracuse, he had to struggle with the problem of protection of the collections from the danger of bombing, hiding them in the Akrai caves and in the Galleries of Eurialo Castle. In the summer of 1942, the museum was hit by a bomb, damaging the Christian room. The coins, however, were temporarily transferred first to Rome, then to the Abbey of Montecassino and finally to the Vatican, before returning to Syracuse. The Venus Landolina was kept in the basement of the museum. At the end of the war, he activated immediately for the reopening of the museum. Then, he began to recover the material from air-raid shelters and made a review of inventory starting, when necessary, the restoration of the pieces that, stocked in insalubrious places, had been affected by degradation phenomena. Bernabò Brea organized furthermore, an intensive program of research in the field.

In 1948, through a letter to the Ministry, he announced the reopening of the museum. To get an idea of the problems he faced, it can be cited the fact that most of the windows were shattered, and since he did not have the money to buy new ones, he replaced them with cardboard wrapping. It was only thanks to his tenacity that the problem was solved. An outstanding financement followed the visit undertaken in 1950 by the then President of the Italian Council of Ministers, Alcide De Gasperi.

Luigi Bernabò Brea also succeeded in the '40s in the establishment of the first expansion of the National Museum with the reorganization of the material from Orsi's excavations, at that time massed

in the premises of the museum. The artifacts were exhibited according to an appropriate reorganization based on the exact archaeological chronology, especially in regard to the two major Greek colonies in Sicily, Syracuse and Megara Hyblaea. He proposed, in addition, for the new rooms of the museum, a particular solution which consisted in integrating to the traditional display, underlying drawers shielded by glass in which fragmentary finds from the excavations were placed. A museological solution that reflected the desire for comprehensiveness in the presentation of the objects [12]. The most innovative aspect in Bernabò Brea's approach to the museum consisted, however, in his strong desire to transform it in a place accessible to the public, no longer a "museum temple" or an "exhibition hall" according to the conception of 18th-19th centuries, but a place changeable, adaptable, flexible on which to make the visitor, the true protagonist of the exhibition.

Despite the new museum, Bernabò Brea was aware that an intensification of the excavations in the archaeological sites of the island could lead to significant amounts of exhibits that would not have been possible to accumulate exclusively in the museum of Syracuse. So he decided to set up a series of local museums having an independent coordination and acting as "introduction" entities in the archaeological areas and working as strategic bases for the elaboration of the excavation data and the presentation of the artifacts discovered in the respective sites.

The current location of the museum of Syracuse had, however, become inadequate to host the collections and all the other functions necessary for the proper functioning of the museum. In recent years, moreover, depositories and laboratories were moved to other buildings, creating some obvious inconveniences to the smooth running of the structure. The modern museological criteria, the advancement of technology for a better use of the museum and the reduced availability of spaces not large enough for a "logic" exhibition of the archeological finds, made it necessary, in the late '50s the finding of new premises. Strongly attached to Piazza Duomo - a place which he considered as the symbolic heart of the Greek colony -, convinced as he was of the importance of maintaining a close relationship between the building and the contents, and being at the same time an enemy of the "modern", he initially proposed to purchase two historic buildings in *Piazza Duomo: Palazzo Beneventano del Bosco* and *Palazzo Arezzo della Targia*. The idea was to make them become part of an *ante litteram* "widespread museum".

To this solution, it was, however, preferred the construction of a building much larger, far from the courtyard of Ortigia: a new structure that "*would eliminate the shortage of space, giving a qualitative and quantitative answer to the update required by the scientific progress*" [13]. To this end, it was chosen an area situated not far from the Greek theater and the excavations in *Piazza Vittoria*, adjacent to the catacombs of *San Giovanni*. The new archaeological museum "Paolo Orsi" was, therefore, located in the park of Villa Landolina and the project entrusted to Franco Minissi in 1967.

2. From the design to the building of the new Archaeological Museum (1960-1988)

For the design of the new museum, Bernabò Brea had initially contacted the architect Giuliani, charging him to draw up an initial schematic diagram of which, however, does not seem to be a trace. Later, he turned to Vincent Cabianca and Franco Minissi - both well known for their work in the field of museography - entrusted them with the architectural project. He will, also, be their main contact from the initial concept to the inauguration on 16 January 1988. His role will be crucial, since it will help to provide the methodological approach of the museum, also taking care of the drawings in scale of 1:10 of all the pieces included in the collection, in order to proceed with the exhibit design. Even in 1978, when he had already left the assignment of superintendent and the work for the construction of the new museum restarted after a long break, he will contribute to the work of Giuseppe Voza and Paola Pelagatti aiming at the reassessment of the immense amount of material to be selected for the display.

2.1 The reorganization of the museum in the area of Villa Landolina

Thanks to the contribution of the *Cassa del Mezzogiorno*, the Ministry of Education took over the vast area of Villa Landolina for the creation of the new museum. The scientific program developed by Bernabò Brea for the organization of the museum primarily related to the historical and topographical background during well-defined periods, so that each section would represent a clearly defined and circumscribed historical or historical-artistic period and provide as complete a picture of Sicily as possible, for any given period. It would, therefore, have to be structured in accordance with the creation of a first section on prehistory, a second dedicated to the history of the Greek colonization of Sicily, a third to the Roman conquest of Syracuse, a fourth picturing Sicily during the late Hellenistic period, a fifth dealing with Sicily during the Roman Empire and, finally, a Byzantine-Christian section, representing Syracuse and eastern Sicily from the late Empire to the Arab conquest.

According to Bernabò Brea, some current difficulties in the arrangement of the archaeological museums derived from the two conflicting requirements necessarily had to be satisfied at the same time. The need of a rigorous selection for the general public "*with only a small number of exhibits presented in the most attractive possible way*", whereas scholars wanted to see the largest possible

amount of material in its proper setting of which it formed part being *"often bitterly disappointed when, having travelled a long way for the special purpose, they find some magnificent pieces superbly presented but have the greatest difficulty in obtaining access to study material which, for their purposes, is often also of major interest"* [14].

In the opinion of Bernabò Brea, this kind of problem would be solved by attaching to each section on the ordinary visitor's circuit, other rooms specifically conceived for specialists. These would be arranged on a completely different basis, with the accent laid on clarity and thoroughness of documentation rather than on its attractiveness layout. This would reduce, at the same time, the actual storerooms to the bare minimum, leaving them to serve exclusively for material not lending itself to the exhibition because of its quality or its excessive quantity.

The architects were so invited to plan the museum's interiors as a single space to be subdivided as the requirements of the archaeological material to be exhibited demanded.

2.2 Minissi's project for the creation of an anti-museum

The task of designing the new Paolo Orsi was certainly not casually assigned to Franco Minissi and Vincenzo Cabianca, whose role in the field of museography had already been widely recognized. In particular, the work of Franco Minissi, resulting from vast and diverse cultural relationships, ranging from the inputs of the Modern Movement and the wealth of principles, methods and criteria coming from the Italian Central Institute for Restoration, was already at that time (and still is more concretely nowadays) a reality of great importance in the framework of activities for the conservation and valorization of artistic heritage. Advocate of a rethinking of museography, which he rightly considered, as a branch of the restoration discipline, he carried out its activities according to the values of innovation, experimentation and quality, declining in architectural form the Brandi's concepts related to preventive restoration. A task that the museum must perform, creating the conditions to preserve and, in visibility, transmit the works of art to the future generations.

In the case of "Paolo Orsi", the architectural plans and the display design were studied by Minissi in order to ensure the highest ductility. The idea was to create a "museum in movement", a kind of anti-museum (as the superintendent Voza said at the inauguration [15]) able to expand with the incrementing of the collections from excavations and the progress of scientific research [16]. It was to obtain this "flexibility" - furthermore explicitly required to the designers - that a centrally-based scheme was chosen. This would allow the didactic sections to be grouped together at the center, from which - spreading out like the petals of a daisy - the sections containing the exhibits could be followed in logical sequence. Moreover, the architectural plans were founded on the modular principle of an equilateral triangular mesh, to which even the didactical equipment and the display cabinets adapted. In this way, all rigidity would be eliminated, allowing the visitor to choice of making either a complete and organized visit or a partial one during which he could freely go to any of the sections of particular interest to him, without having to follow the general itinerary.

The museum, designed to establish itself as a *"living center for research and promotion of culture"* [16], was set on three floors (including a basement) for a total area of 12,000 square meters, perfectly integrated with the surrounding natural space, showing the clear influences from Frank Lloyd Wright's organic commandment. Once again, as required by the "client", each section was composed by a historical-didactic section, an exhibition of what might be called "first selection" material, an exhibition of "second selection" material (i.e., works and references of particular interest to researchers), and a storeroom.

After several hitches, work interruptions due to the lack of funds, changes during the construction phase and unavoidable maintenance interventions, the museum was opened to the public in 1988 (even if only the sections on the ground floor had been staged), benefiting from a wide internationally resonance.

In May 2006, the pavilion D on the third floor of the museum was inaugurated in execution of a project delivered in 2001, while the set-up of E and F sectors is expected in the coming months. The area devoted to medals, the last transferred from Piazza Duomo, was opened in 2010 and is located in the basement of the museum.

3. Towards an open and widespread fruition of the "hidden" heritage

The intensive archaeological research conducted in Sicily in the last decennia, the richness of excavated sites and the large amount of discoveries, have required over time, an adjustment of the museum spaces in order to accommodate the new archeological items. The structure retains today an immense number of objects, many of which, not finding a place in the exhibition halls, are collected in the depositories located in the basement of the structure in spaces that, in Minissi's plans, were not designed for this purpose. The greater amount of the objects did not find accommodation in the glass cases exposed to the public, but are contained in "boxes" kept in rooms accessible - albeit with the understandable organizational and administrative difficulties - only to a fortunate few scholars.

This heritage discovered but still "hidden" in some cases has not been adequately studied yet (kept for many years in sometimes inadequate containers and without having verified its conservation status), but in many others, cataloged and restored, it will perhaps never find location within the permanent installation, since the integration of all elements would require an enormous amount of space and resources. In addition, the cultural purpose of the museum is the collection of knowledge and its transmission. Acts that operate through the presentation of works chosen from among the best maintained examples of greater or historical/artistic value; the exhibit of fragments and/or minor works of art, although often of fundamental importance for the scholars, is of little interest to the generic user that does not have, in general, the necessary cultural background to fully understand and appreciate their value.

The fruition and the valorization of this hidden asset is nevertheless possible - apart from the construction of new exhibition spaces (probably useless if the "physical" consultation of many minor works is of interest to a few scholars) - through the network and the use of digital technologies. Electronic catalogs, whose first applications to cultural heritage had purely documentary purposes, have experienced in the last decade an evolutionary process that promoted them from simple databases to interactive multimedia systems, turning their function as a simple tool for cataloging to efficient machine for disclosure. The network *"has become a privileged environment for the consultation and the sharing of knowledge, to facilitating the work and the integration of the bodies in charge of documentation and the protection of cultural heritage, but also for its use by a wider audience. The goal today is no longer that of cataloging the single good but also its relationship with the cultural context, while from informatics point of view there is a tendency not so much related to the definition of uniform standards, but rather to the interoperability between systems born with characteristics and for different purposes, but all useful to the increasing of information"* [17] both in a national and supranational dimensions.

The Sicilian Region, through its *Department of Culture and Sicilian Identity* has started a few years ago and through its website, an online consultation of digital publications, videos, photos, virtual and dedicated sites of the largest regional museums and archaeological parks [18]. This tool is, however, limited to a general aim and to touristic purposes, as the contents are more simple presentations of the areas of greatest interest - though widely documented - or educational projects, than a true scientific instrument aimed at the enhancement of the hidden heritage. In addition, the platform does not interface with other systems and it is closed on the outside, making it difficult to update the data and impossible to include new contributions from third parties.

3.1 From the integrated survey to the interactive and virtual museum

The case study here presented intends to show the early stages of a pilot project launched by the *Laboratory of Restoration of Architectural and Cultural Heritage of KORE University* in collaboration with the University of Bergamo. This research began with the need to answer to some planning needs that, colliding with the hard "reading" of the edifice because of the many changes and adaptations of the premises (not documented), asked for an in-depth historical analysis and the realization of a complete survey (metric, geometric and material) of the building and the area surrounding it. The acquired data, subsequently integrated with other elements of detail, also revealed themselves as an important *database* for the establishment of a multimedia platform at differentiated levels of accessibility, firstly useful to the museum's administration to the appropriate need for control and maintenance but that could easily also be opened to scholars and tourists, with a view to create an interactive or a virtual museum.

Here is that the project has been developed starting from the idea that in order to correctly understand an architectural organism, its critical observation cannot be disregarded. It is, actually, important to detect what the building generously shows but especially what it jealously hides. This twofold recognition allows making the essential breakthrough for the planning of any following intervention (restoration, rehabilitation, redesign, reuse, etc.). In particular, the survey made by integrated methodologies (traditional, advanced and innovative), led to the creation of the fully navigable 3D digital model of the museum. Organized at various levels in order to make clear the form and the architectural structure, it has allowed the understanding of the entire building: a vast system based on a hexagonal geometry that found in the interaction between the environment and the constant change of heights, its most interesting spatial character. It could, however, also offer the opportunity to "virtually" visit the museum from the park outside of the places currently inaccessible (Fig. 2).

In this study, the first approach to the sites was accomplished through free applications available on the net - such as Google Earth - allowing the view of satellite images and aerial photographs, with a very high detail. This platform, in addition to the visualization of multi-scale mapping and free access to GIS information, permits a single user to enter additional information in the form of links to be shared and made accessible to other users. Links that, in the case of "our" museum, from its geographical identification might refer to detailed information, such as the site plan and other data, connected, for example, to the altimetry and to the pathways.

Fig. 2: The 3D model of Museum "Paolo Orsi".

The combined use of GPS instrument and total station for the overall understanding of the building, even in relation to the urban environment - georeferenced both through coordinates acquired from satellite network and by means of a topographic polygonal used for the "forced centering" of scans performed with the terrestrial laser scanner - has allowed to acquire a large amount of data and useful information (Fig. 3a, b).

Moreover, it was produced, with a specific application and only by way of example, a virtual tour allowing visiting the park of Villa Landolina and the burial path situated outside the museum. This tour, applicable to the entire museum complex, could be accessible, via web or remotely, through mobile devices such as smartphones and tablets (Fig. 3c), so offering the opportunity of conducting an immersive interactive experience whose purpose is to approach the real visit of the place, both in terms of visual quality and emotional perception, especially if supplemented by the inclusion of multimedia elements (text, audio, videos, maps) [19].

Finally, the possibilities offered by the creation of "pages" containing information within shared multimedia platform, have been exploited as a tool of diffusion and dissemination of archaeological studies as well as of the activities of the museum. To this end, "dynamic" procedures have been studied in order to create models of data sheets related to the archeological objects exhibited or not, including their 3D visualization, acquired by using a high precision laser scanner and/or digital photogrammetry (Fig. 4a, b).

4. Conclusions

During the last two centuries, the concept of *museum* and its role in the society has changed dramatically. Museums are no longer sacred and untouchable. On the contrary, they have been (and still are) subjected to a wide process of rethinking, that has requested an intense examination of the values and meanings they imply, the aims and the nature of the services offered, as well as of the relationship between them and the people they wish to serve: the public [20]. The museological research has been enriched by new technical acquisitions and wider methodological horizons that have fundamentally transformed the concepts of display and collecting [21]. The vision of the museum as a static entity has definitely been overcome by a new idea based on the establishment of dynamic platforms [22, 23]. The fast development of digital technology and of computer graphics has revolutionized the visitor's approach to the museum by creating interactive experiences throughout a museum, as well as remote experiences for those who cannot get there.

Fig. 3: Images from the integrated survey: urban plan acquired by GPS (a), orthographic projections obtained by 3D laser scanning (b) and panoramic virtual tour realized by photo sticking (c).

The numerous projects already accomplished in this field (the main museums in the world have developed web sites that are more and more advanced in order to promote their collections and activities [24]) show how the virtual reality can help, for example by complementing a real visit to the place, in case it had stimulated a special interest or an intellectual curiosity; or by encouraging users to go there after having obtained through the web an overview of what the museum can offer.

This case study shows how digital technology could overcome problems dictated by the shortage of space and the presence of logistical constraints, restoring or enhancing the original spirit of the *knowledge sharing place* that Bernabò Brea and Minissi envisioned for the archeological museum of

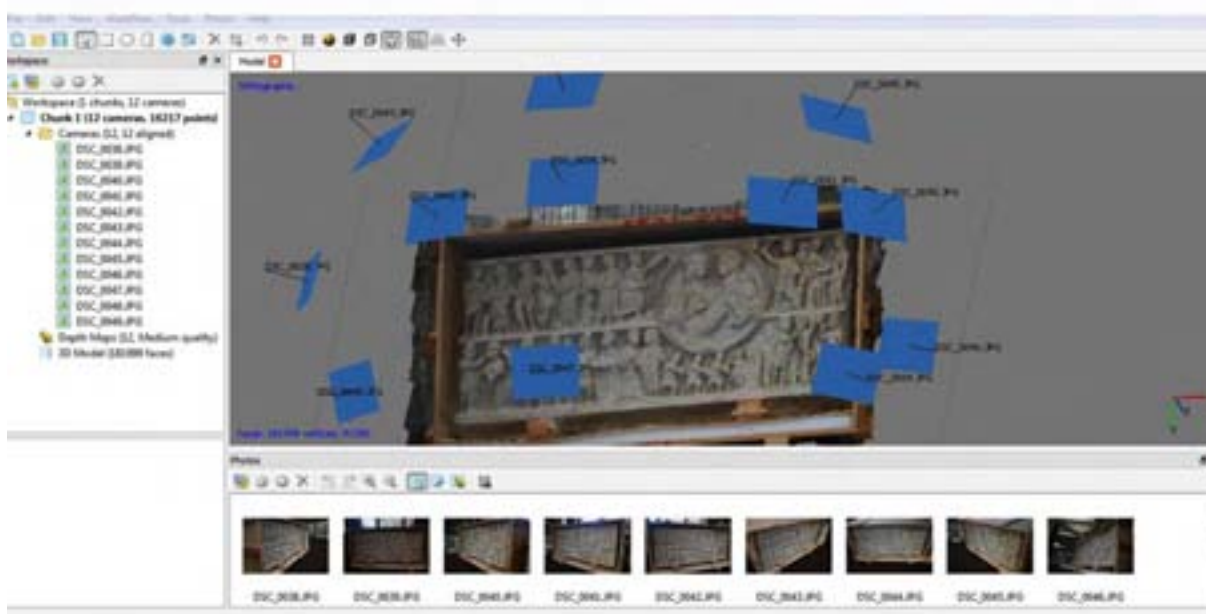

Fig. 4: 3D model of a roman head obtained using a Faro arm with laser scan head (a) and 3D model of a sarcophagus acquired by automatic image matching (b).

Syracuse. We are sure that taking the road of innovation will allow this priceless heritage to express its full potential by promoting an "open and widespread" concept of culture. The ideal thing (perhaps a utopia...) would be to establish a museum where the motto is: no doors, no guards, no wall, and no limits.

Abstract

Survey is knowledge and knowledge is the tool to decrypt messages that the past has sent us in the form of monuments.

Some, few, have maintained their own function, others changed it over the centuries. These monument crossed the centuries always equal to himself and for that little or not studied.

This work fits into the history of the monument trying to give some new answer and especially proposing a representation of it that for the first time tells something new about its life, its function, its history.

This opens a new way to the understanding, the formulation of hypotheses and testing of other through the decoding of ignored details and through the reinterpretation of the sources.

It offers a new understanding of the position of the monument in the landscape and about the role covered by this as an essential part of an ancient infrastructure, the Augustan aqueduct of the Serino.

This Work is a part of end course work about PhD in Scienza del Rilievo e della Rappresentazione dell'Università la Sapienza di Roma XXIII group 2008/2011, and explore only one of the considerations made around this ancient monument.

Keywords: Survey, Archeology, Point Cloud

1. Introduction

“Hoc est vivere bis, vita posse priore frui”

“Knowing how to live with pleasure the past is to live twice”

Marziale, Epigrammi (X,23).

This aphorism it's particularly significative to understand and describe the goals and the results achieved in this study

Knowledge, whether of the world or of themselves, has always been a strong stimulus to the research and understanding of the diverse issues surrounding the mind and human thought.

The past, which Martial calls, is itself being investigated at various scales and in various fields of interest, but with survey and analysis of what material comes from the past, it becomes conceptual and speculative for recovery of information lost in a memory that no longer retains traces of itself, but that was the basis on which to build the present or, more simply, of which this is an evolved version.

In this ancient monuments are silent witnesses of the past, but if asked, they respond by providing information that can afford to live with greater awareness of our present, fully understanding what we are delivered from the past.

From the past comes architectures, functional spaces, squares, structures that could not adapt to the changing of the culture that created them, and when they did, they have lost their initial connotations becoming something different, altering their appearance, changing substance form and function. In some rare cases, this mutation has not occurred, and this has meant that these monuments would become simply obsolete, unusable or simply forgotten.

The analysis and study of ancient monuments therefore poses special problems, requires an abstraction from modernity and a realignment to the culture that created them, we have to understand the changes brought about by time, know as much as possible the story, or listen stories that all around are told lost very often between myths and reality.

Knowing how to read a monument allows to discern on what, how and when, or at least critically framing the problem in order to find a consistent path of inquiry.

1.2 Survey as tool for knowledge

Now some questions: what are the methods and tools that should be used in specifically, which the levels of analysis and definition of the information?

From my point of view, survey is the main tool to deal with this investigation

The survey as a tool of knowledge, which does not end with the metric acquisition phase, but also includes the acquisition of all the necessary information to reconstruct the history and projectual genesis of monument that is being analyzed.

The reverse process of the project, survey, is not a linear process, and the only way for really know it, is to be able to pause, just the time to take a measure, on its surface, on the traces that time, weather, nature or man left on and that from time to time tell small fragments of a common history.

The ancient monument becomes cultural one, taking on a meaning of representative element that contains useful information for the understanding of modern culture, and this makes it even more difficult to intervene because the risk of unconsciously delete relevant information is behind the 'corner.

On it focus a number of issues ranging from operational practice to historical research, to its representation understood as choice of the most effective way to draw, in relations with the goals, and the steps of reading the architectural text .

1.2 Representation and drawing

The representation holds a fundamental importance. The act, which is basically the act of drawing, requires a discretization of the information acquired, discretization critical but limited as often related to the ability of the designer to transfer on a bidimensional plane tridimensional information and their perception. What you can imagine is often much more than what you can draw and the ability to transcribe these intuitions in design is not for everyone

The reduction to a bidimensional plane is itself limited to the cognitive possibilities inherent in the real object, and the tools available to the designer are themselves the limit beyond which no one could run. These instruments in the last few decades have seen a strong evolution, dematerializing from the paper forms which were bound and transforming itself into binary information processed by computers.

As is known, this has literally created a new world with physical space but concretely non-existent, a virtual space in which you can develop and build a model of the real object.

According to me, this world has as its current limit, but it is only a temporary condition, pattern perception still through the projection on a plane as that of the various types of monitors or viewers that once again reduce the perception of a bidimensional plan .

Obviously, this perception is now dynamic, interactive, multimedial but is based on a concept still opposed to the spatial perception of real structures, is not the observer in moving, but always the object to be rotated according to the observer meaning as observer the human user and not the virtual avatar, of course.

In turn, the instruments themselves for survey have suffered and are suffering a strong evolution, linked to the economic aspect that binds their availability.

I refer in particular to various photogrammetric techniques, which with the image digitization has opened a new and more flexible field of investigation, but also the possibility of laser scan of the real object.

The discretization by points to a real structure gives to the operator a benefit that no one else in the past has never been able to have.

The so-called "point cloud" returns immediately volumes and metric information as well as complex surfaces with very short time simplifying the metric operations and delegating the interpretation of the data which can be followed by a pluriform possibilities of representation. The model for the virtual space, or at least its structure is created immediately, the real object is deprived of its material

substance becoming immediately transmittable and accessible remotely remaining now included in a space that not existing physically can exist anywhere .

Remains separated from this operation that which at first was a necessity, the observation of the object to be displayed and the focus on specific point becomes an independent operation that is always necessary.

The fruition of the monument itself takes on a new aspect, by the necessity to touch the monuments during "Grand Tour to a remote exploration of large monuments which on one hand allows a greater circulation of information, on the other hand transmits only information filtered by the model which by its nature is not reality and not able to repeat its suggestions.

2. The Piscina Mirabilis

Object of study is the Roman monument known as the Piscina Mirabilis site north of Naples, in the municipality of Bacoli in the area known as the Campi Flegrei.

It is an ancient cistern of impressive dimensions by planimetric development of 66 x 25 m and a height at key of the coverage vault a little more than ten meters. The interior space is underground for about eight meters and is divided into five aisles longitudinal and thirteen transverse. The central one, the seventh, has a bottom surface less than about 1.50 m which is configured as a Cella Limaria suitable for the storage and expulsion of impurities in the water.

The existing access is through a staircase located on the North side of the structure, corresponding to one of two old entrances . The old access points were two, one corresponding to the present, the other corresponding to another set of stairs on the south side and currently-no longer usable due to the rising of the roadway outside.

The intersection of these spaces is identified by forty-eight pillars which cross section assumes a cruciform appearance to the height of eight meters from the bottom floor.

Actually the structure is ruled by the Central Office of Naples and Pompey that has property and maintenance.

2.1 Survey

This monument, always known but little studied, presents a series of specificity which allow to sketch a repertoire of problems which arise in similar contexts.

It's one of those monuments that are not changed their essence but that this is no longer compatible for use and function, with the modern culture.

His analysis is guided by the fact that it is configured at the same time as a cultural asset, underground and never reused.

This has led to the first problem set out above: Always known and always equal to itself, lost his memory about its purpose and its operation, so the research has tried to frame the structure in the cultural field that build it in the attempt to improve its knowledge.

Regarding the analysis by the survey, the monument presents great many operational problems related to the size, spatial distribution, elevation, relationship with the outside not easy to solve, therefore, has been a valid field of investigation for the application of the techniques relevant consolidated and the innovative ones.

The results obtained during the analysis of metric data allowed to advance a new thesis about the possible functioning of some structural parts of the Piscina as well as to test the hypothesis concerning its operativity.

The choice of laser scan of the entire monument has allowed the realization of bidimensional draw never processed before which difficulties of implementation was related to the shape and nature of the monument.

The fragmented space of the floor plan has always hindered the full understanding of the good, the horizontal layers that make up the structure had not been fully investigated as well as the reciprocal relationship between the parties not in sight, and this has been possible by creating a point cloud model and the section of the same with reference planes containing the researched information.

Hence the identification and study of significant details has allowed an in-depth, through new technologies and the creation of complex surfaces from point cloud, enables a new representation

The volts have been subject to independent investigation, has been analyzed in the structural behavior and has been created surface model designed to study the problems of static arrangement.

The individual detail have been the subject of in-depth layout , geometric, metric, material, in order to identify a repertoire of models relevant to an understanding of the overall architecture, as well as verifying possible assumptions by management of the building in its past operating conditions.

The goal was to complete a cognitive gaps, by the use and integration of acquisition technology , identifying congruent descriptive strategies for use and management.

3. A new iconographical representation

As it is logical to assume, this monument has already been represented in the past, but the novelty of this article is a new iconography that come out from the use of modern technologies of laser scanner survey and it's only one of the observation reached during the research.

The geometry of the structure and the difficulty of the measurement, have in fact significantly limited its drawing by focusing the attention of scholars on the development planimetric losing the changes in shape that occurred at different elevations.

The parallel i want to make here is the only valid metrical survey ever run on the monument that is taht's of Paoli published in 1768.

The scholar produces a plan of the Piscina Mirabilis, which was for centuries the only reference for almost all the subsequent works.

The representation of the piers has become an axiom to indicate Piscina Mirabilis inextricably linking structural and functional interpretation giving the impression that there was nothing new to say and becoming, quite by chance, a wrong tool for the study of monument.

however, Paul realized a sort of isometric cross-section of the monument, represented with the taste of the eighteenth-century picturesque rather than the metric coherence , but it is in this section that we have the point of contact between the studies.

In the section, Paoli explain the survey method used for work.

A man on a ladder stretching a tape measure using a cane until it touches the top of the vault, another men tends the tape while two gentlemen seem to check the length of the strap tight. On the ground you can see a tablet, perhaps a praetoria tablet, and a tool that could be a baculo or simply foot removable tablet.

This drawing shows the operational correctness of Paoli but also denouncing the limitations he encountered in the execution of the graph seen as difficulties in survey operations.

From here the parallel or rather the idea of a working continuity with the past beyond the limits of the survey with the technology at our disposal.

The possibility of using a laser scanner Leica C10 has allowed the creation of a point cloud of high density and so to overcome the limitations imposed by the height of the monument.

The result has been the ability to dissect the Piscina Mirabilis in all dimensions desired and then the identification of a section plane that in addition to relating the outside with the inside, allowed a new representation of the Monument.

Dissecting beyond the elevation of the sets of arcs connecting the transverse and longitudinal aisles, the shape of the monument changes, structure changes, they disappear the pillar become dividing walls and start a new way to study functional and structural monument.

The trasversal aisles are no longer connected to the longitudinal, space is fragmented into smaller rooms that are explained in the operation of the monument.

Imagining now the Piscina filled with water, it is evident that the fractionation of the naves transverse operated a mechanical filtering action to the impurities brought from the aqueduct and who remained on the water.

Once emerged within the trasversal aisles floating impurities remained blocked in the section and could be removed by normal cleaning carried out through openings in the roof .

From the structural point of view completely changes the interpretation of the monument and in particular appears now evident the warping of the covering system that was not so clearly decodable by planimetry at a lower level.

In this sense, therefore, the investigation through a new instrumentation has led to a new and more meaningful representation of the Piscina Mirabilis that arises in the logical continuation of a project begun in 1768 and supplemented in 2010 by filling the gaps left open and opening new ways to hypotheses and investigations

All the goals reached with these study, well be soon available in a specific publication around the Piscina Mirabilis.

The oval cloister of Santa Maria alla Sanità Church: a virtual representation of the original destroyed shape

Emanuela LANZARA, Roberta MONTELLA

Architecture, Federico II University, Naples, Italy
emanuela.lanzara@libero.it
robertamontella@libero.it

Abstract

Promoting the diffusion of treasures which are considered to be part of the precious architectonic heritage, not always known and, more than ever, underestimated, protects a community's cultural memory together with that of its place, increasing its value.

The aim of the intervention is the rescue, protection and the transmission of cultural value and social identity of a place.

The bridge of Sanità, named also "red carpet between two palaces", has not only destroyed some parts of the artistic heritage of the town, but is also considered to be an outsider and, at the same time, a symbol of this place.

A very important intervention that, on one hand means a division for the neapolitan town, as regards the urban and social point of view, while on the other hand, become a sort of limit helping the definitions of original contributes, by mixing old and new together.

Santa Maria la Sanità in Naples, is a church situated in a place where history and traditions are at the base of a project linked to the Paleochristian Age, thanks to the catacombs of San Gaudioso. His mannerist oval cloister, designed by Frà Nuvolo, is crossed by two piers, limiting it from its completeness.

Purpose of the survey, together with analyze and a graphic revision is a sort of communication, through a virtual regeneration of what has been lost, of the artistic heritage. This help us to obtain a major consciousness of the identity and to know the real value of places, not only clear for those who live them, but also for those who "walk" in them.

In particular the survey propose to verify the plan of the cloister: it's not sure, in effect, if it has an oval or an elliptic shape; taking it in a 3D way able to give back a complete vision of the original plan. That's just to let known, even though is not useful anymore, what's hidden back this urban intervention.

Keywords: preservation, regeneration, innovation

1. Oval/Elliptical cloister in Santa Maria alla Sanità District

Sanità, in San Carlo all'Arena, is one of the most ancient and characteristic district of Naples. It's located at the foot of the hill of Capodimonte, in the north of the old town. A lift connects two different floors of the city together: the so called bridge of Sanità in Corso Napoleone and the Sanità district. Santa Maria alla Sanità church, also known as san Vincenzo alla Sanità, is situated in Sanità Square. This second name is due to the Holy Vincenzo Ferreri, a famous Dominican friar considered the protector of the district. The name Sanità is due to the historical healthiness of that place that was located outside the city walls. In that area miracles and healings occurred near the tombs of several African bishops, including St. Gaudioso, there buried. So Sanità became a place of worship. During IX century bodies of saints were brought into the city, and these burial sites were slowly abandoned. Floods plastered the area with mud from Capodimonte hill. In 1569 a violent storm brought to light the

ruins of the early Christian church and the ancient catacombs which were after recognized as S. Gaudioso's.

Here, there was found what is still considered the most ancient image of the Virgin in Naples.

In 1577, as a result of this discovery, Dominican friars began to buy lands and decided to realize a new church dedicated to Santa Maria alla Sanità. A panel of experts chose the project of the Dominican Giuseppe Donzelli, also called Frà Nuvolo. He completed the religious complex between 1602 and 1613.

The complex of Santa Maria alla Sanità is one of the most realistic details views Baratta where parts are also represented at that time (1629) had not been completed. The image is of particular interest because it documents the complex splitting into two distinct parts, placed in two different dimensions: Church and cloister ovate in the lower, the real convent with the adjacent big cloister, now lost, at the top. Fra Nuvolo planned a second cloister, smaller than the first, giving him a very original shape, defined by the century, as oval/elliptic. Giuseppe Nuvolo is one of the most interesting authors Neapolitan XVII century, with the Church of Santa Maria della Sanità. With this project, he reveals his interest into the Bramante's project of San Pietro, trying to re-elaborate it in a more complex greek cross map, integrated in an extended square.

Inside the Church, Frà Nuvolo responds to the need to preserve the existing Paleochristian Church of San Gaudioso: he erects the chancel of the new one by setting the altar above the catacombs and the crypt.

During the XIX century, French sovereigns started in Naples some of the most relevant urban modifications which were important for the future of the town: there were made some improvements in the communication routes and in the re-organization of the already existent plans. In this way there were highlighted what is nowadays considered the neapolitan underground system.

The expected interventions faced the biggest difficulties linked to the many obstacles presented by the town, that is to say the continuous following of Posillipo, Vomero, Camaldoli and Capodimonte hills.

Expansion and development of the town included a "fan" system going through the most important areas of the town. Corso Napoleone, which now corresponds to Via Pessina, Santa Teresa degli Scalzi and Corso Amedeo di Savoia, must be considered the most difficult intervention in Naples.

Finished in 1809, the street was due to the will of Giuseppe Bonaparte, because of a sort of a faster link with the Royal Palace and the Palace of Capodimonte.

Fig. 1: 3D model representation of Sanità District. Different point of view and bridge highlighted in orange.

Closer to the social alienation, District presents a lot of potentialities and cultural and historical richness, about which residents are fully aware.

Some voluntary social and cultural associations were there formed with the intent to implement initiatives and improvements to the site, and provide citizens with social redemption opportunities, better living conditions, stimulating the civic sense. The bridge, in this revival attempt alive offers to the inhabitants of creative inspiration: became logo for the district and starting point for the realization of artistic and cultural activities. From limit, the bridge becomes opportunity, integrating perfectly with new architectural achievements: the portion of the bridge that invades the B&B of the former convent, is adapted as wall for the kitchen.

The construction of the bridge allows a different, abnormal vision of the whole, as well as the district, which can then be observed even at the level of the dome of the Church, offering an original idea for an alternative reading of the urban fabric, made at different levels and from completely different points of view.

Fig. 2: Pencil sketch realized on the bridge watching the church.

1.1 Relief and geometric survey

Two pylons of the bridge invade the cloister, dividing it into three parts. The observer loses the global perception of the original shape redefined through the relief and 3D representation. The cloister presents a curve arcade with cross-vaults surrounding an inner area defined by arched pillars with Ionic pilasters, garlands and capitals stand in piperno stone. On the vault and on the lunettes of the arcade, there are still traces of monochromes graffiti painted by Giovanni Battista Di Pino in 1624: they represents stories of the Dominican order. Transverse arches of the arcade bind internal pillars with the wall of the arcade: the pilasters, facing the environment, are on opposite sides of the stucco wall where there are niches.

The relief of the cloister is not based on mere investigation of metric type, rather on original quality analysis of global composition. The planimetric oval shape of the cloister is a singular example in Neapolitan architecture. Frà Nuvolo was the first to use this shape in Naples.

The primary output of the survey carried out within the cloister was to locate the actual geometric shape of the plans: the historical and cartographic sources show conflicting opinions by defining a plant indistinctly oval and elliptical. Ellipse and oval are both elongated circular profiles with double orthogonal symmetry: characteristics that create confusion between two different shapes and open debates about the nature of formal discovery architectures.

The pylons of the bridge break the original shape of the cloisters, allowing not an easy formal interpretation. So, was essential an accurate geometric analysis.

Fig. 3: Interior image of the arcade of the cloister.

A first step has led to critical reading of historical maps: Frà Majorino's project design, the Duke of Noja, the plan of Ferraro. All them represent an elliptical cloister in which the main axes are oriented in the same direction of the axis of the Church. The survey graphic, derived from this first reading has justified the choice of locating of the main axes, following the results derived from direct relief. Assuming the existence of a generic curved continuous profile both inside and outside the arcade, have been taken into account the points that return in the profile of the pillars identifying the inside perimeter of the arcade of the cloister. The curved profile has been verified through direct relief of the plant of the pillars with trapezoidal profile characterized by two curved sides: above all those of the interior arcade and those facing the center of the cloister, as well as the performance of the walls of the arcade. Also the profile of the pillars is indeed shrinking from the area towards the central area. The graphic check of juxtaposition of polycentric curves and ellipses on the plan, denote that polycentric curves are constructed in way to approximate their profile to that one of the ellipse. This is the demonstration that it's difficult to recognize the curved shape in question, also with the Pascal's theorem.

On the bases of the number of centres and their location, the arches of circumference which generate the curve from the oval profile can be differently compounded generating different profiles.

The interest of Renaissance architects for the elliptical and oval shapes is documented by a rich variety of iconographic sources contained within the several treatises of the time.

The discussion of the topic, argued by Ornella Zerlenga in her text *La forma ovata in architettura*, is fundamental to choose suitable geometric constructions to verify the profile of the cloister, obtained as a result of the relief operations.

Though Pascal's verification estimate the inadequacy of an elliptical shape of the cloister, the elliptical formal verification of the cloister is made. Have been verified: geometric construction published by Sebastiano Serlio in 1545 that draws the ellipse to points once the two diameters; the construction of the ellipse for three data points, considering as a starting point for the construction of three known points derived from tracking operations of pillar stands.

The same verification process was conducted for the oval shape. Targeted selection of geometric constructions is given by considering similar ovals, for formal tracking, to the profile derived from the junction of points obtained as a result of the relief. Polycentric curves built four or more centres were considered.

In book I of Sebastiano Serlio's *Treaty of Architecture* is the first treatment formulated and shown on the geometric trace of the oval. Serlio considers four different methods to draw the oval shapes.

The geometric construction published in Bosse's *Treaty* is innovative respect to Serlio's one, because it differs through the assignment of the dimensions of the axes. In this case, the object of formal research, the position of the axes is expected intuitively from a direct observation of the plant detected and therefore of its shape. Then, set the position of the axes of the hypothetical figure and its dimensions and consequently it brings, the four centres are determined by their respective arches of circumference of which the curve consists.

Then geometric construction of Breymann was chosen to draw a half oval similar to the ellipse. Formal research of oval profile is so deliberately referred to a geometric construction that was as much as possible like the elliptical one, in order to exclude any possibility to attribute a probable elliptical shape to the cloister.

It looks so interesting, as necessary, with the same size and position of the axes, compare and overlap between their formal outlines, different kinds of curves, drawn in different ways.

Polycentric curve looks definitely better suited to describe the shape. Elliptical profile have a smoothly varying curvature, while the polycentric curve presents greater variation of curvature near the point of contact between the arches of circumference. This variation is due to the intrinsic properties of the circle that admits constant curvature variable with radius. Therein the main difference between these formal profiles lies, which in this case decreed, as a result of the dispute-oval ellipse, that cloister plant profile is approximated at the oval, rather than elliptical.

Fig. 4: Geometrical check: elliptical on left and oval on right.

GEOCONSERVATION ANALYSIS AT ACKENDOWN, JAMAICA DEFINING GEOARCHITECTURE

Patricia Elaine GREEN,¹ Sherene Andrea JAMES-WILLIAMSON²

Department of Geography and Geology, The University of the West Indies, Mona Campus, Kingston 7, Jamaica, W. I. ⁽¹⁾patgreen2008@gmail.com
⁽²⁾sherene.james02@uwimona.edu.jm

Abstract

Plasters and mortars from historic buildings have been considered useful on style, formulation and cultural provenance where several transformations and stratifications have taken place over time. On the Caribbean island of Jamaica with its culturally diverse heritage holding Aboriginal, Spanish, African and English legacy, the former Ackendown Estate contains a cluster of buildings that convey this. Of significance is an 'Old Castle' that has received concurrently 16th century Spanish, 18th century British, and 19th century Scottish dating.

This paper presents aspects of an on-going Historic Structures Report for Ackendown with scientific techniques to determine appropriate analysis for mortar composition. The aim is to investigate how historic mortars and the geology of architecture may become a useful instrument, which can contribute to the identification of different building phases to establish provenance within historic periods. A comparative analysis of heritage mortar and geology across the island having established dates from archaeology and primary documentation is being developed to facilitate interpretation.

The results will inform conservation techniques and restoration principles in hot humid tectonic environments. Outcome of this work is the launch of the concept 'Geoarchitecture®' embracing the multi-disciplinary approach of architecture with the science of geology in Geoconservation.

Keywords: archaeology, geoscience, mortars, preservation, tectonics

Introduction

Christopher Columbus landed on Jamaica during his second voyage of exploration in 1494 claiming the island for Spain. He returned twice during his fourth voyage in 1503 and was shipwrecked on the north coast for one year. He encountered an Aboriginal Taino population of 600,000 although it is argued that this was an exaggeration and may have been 60,000 [1]. Within five years of his departure, the Spanish founded two towns, *Sevilla* as the principal on the north coast where Columbus has taken refuge, and *Oristan* on the south coast [2]. In the ceremonies of possession, houses and forts marked the occupation of a place or territory [3]. These Jamaican towns were established by ca.1510 with the erection of a stone fort-house, and other stone houses [4]. By 1513 the Aboriginal population had diminished and Africans were being imported into the island for enslaved labour [5]. These Spanish Jamaica towns were relocated inland from their coastal founding sites ca.1519, and a third town, *La Villa* (now called Spanish Town) was founded ca.1520 [6]. *Sevilla* and *Oristan* were officially abandoned in 1534, and *La Villa* survived as the principal and only Spanish Jamaica town [7]. The island remained as a Spanish colonial settlement for over 146 years until it was conquered in 1655 by England, and remained under English rule until it gained independence in 1962.

Whereas archaeology has established evidence of the Spanish Jamaica town of *Sevilla*, the footprint of *Oristan* has yet to be exactly defined. The 2011 archaeology report of Ackendown states that Taino and Spanish history and culture in Jamaica are still to be explored, pointing out that there are large numbers of Taino sites along the south central and south west coast that testify to their presence; further that the work on the Castle site at Ackendown gives the opportunity to examine this

issue, as this building may have belonged to a Spanish regional commander and head of the Spanish Jamaican province of *Oristan* [8]. It is highly possible that the south coast property of Ackendown may hold some clues to identify *Oristan* [9].

Research on Ackendown included a chain-of-title conducted in the Jamaica Government Archives (JGA), the National Library of Jamaica (NLJ), family memoirs of earlier proprietors; and archaeological investigations in 2011 with surface and underground work that built on previous investigations during the 1980s. This has shown that the historic name on the property titles, estate maps, and legal representation in the JGA, the NLJ, and Colonial Papers lodged in the United Kingdom is Ackendown. Yet contemporary maps call the area “Auchindown.” Therefore, this paper uses the historic property name of Ackendown.

Ackendown is situated on the south coast Parish of Westmoreland, Jamaica. The property containing approximately 116 hectares (287 acres) is bounded southerly by the Bluefields Harbour and extends northwards into the adjacent hills. Sandals Resort International (SRI) owns the property. The area containing the historic ruins is concentrated on the hillock overlooking the Harbour, with the south-coast main road separating it from the coastal stretch that has been developed into an all-inclusive beach-front hotel. SRI desires to restore the historic ruins as the ‘Ackendown Heritage Park,’ and for this, the firm Patricia E. Green Architects was engaged and conducted a Historic Structures Report. The JNHT declared one of the historic structures, the Ackendown Castle ruin as a national monument on December 21, 2006 [10].

Fig. 1: Ackendown Heritage Park Layout (©Patricia E. Green Architects, August 2011)

An area of approximately 15 hectares (6 acres) has been fenced off to offer security protection for the Heritage Park, which contains the shells of four historic masonry ruins situated contiguously on a gentle slope. These all form a quadrangle along cardinal points, termed commonly as (1) Castle, situated northerly; (2) Pimento Works, southerly; (3) Field Buildings, westerly; and (4) Cottage, easterly (Fig. 1). Colloquially, the Cottage is sometimes called ‘Overseer House.’

Set apart northerly from the Cottage is a ruin termed Block Building. This has been modified extensively during the latter part of the 20th century. Historically this would have been the original location for the kitchen, servant quarters and ‘other offices’ (latrines) for the Cottage. Adjacent to this

building on the north are the foundations of yet another structure that was used over the years as a stable and later as a garage. Archaeology during July 2011 has unearthed certain shards that suggest that a blacksmith workshop may also have been a part of this building. Analysis shows that a covered link-way would have connected these buildings to the Cottage.

The Cottage retains a cedar shingle steep-pitched hip roof, but all the other structures have no roof covering. Grey slate roofing material is strewn around the Castle ruin. A dry-bed stream meanders alongside the Cottage and separates it from the other ruins. The Cottage has landscape evidence of a sunken garden with low retaining walls contoured along the slope of the land.

In 2011, geologists at the University of the West Indies joined this work to assist in the analyses of mortar and material samples to guide conservation strategies. However, these heritage buildings have proved to be a resource for additional investigations on seismic strengthening of walls. Significantly, the geoscientific analysis has the potential to help provenance and cultural appropriation of the various parts of the historic structures. Therefore, to assist efforts to locate the buildings of Oristan, this work has now been extended to include comparative geoscientific analyses at the archaeological sites of the historic Spanish Jamaica towns of *Sevilla*, and *La Villa*.

Investigations at Ackendown and at comparative sites are on going, and have begun to assume various levels of scientific engagement. This paper briefly shares the early findings of the analyses, with an introduction to its comparative work with *Sevilla*. It is presented as an overview of the (1) Ackendown geology; (2) Natural Hazards and Disasters (3) Ackendown history; (4) historic structures; (5) geoscientific analyses; (6) geology of the heritage; (7) conservation findings; and (8) geoarchitecture conclusions.

This paper introduces the emergence of a thematic definition 'Geoarchitecture®' that combines heritage architecture with the discipline of geology. It outlines the multi-disciplinary approach being employed in the analyses of the architectural heritage using geological science, to help address provenance issues, to emphasize construction interventions for disaster risk mitigation, and to link geoconservation techniques as a support in historic preservation principles.

1. Ackendown Geology

Geologically, Ackendown sits on sections of the Montpelier Formation, Coastal Group of Jamaica. The Montpelier Formation is a white- to tan-coloured limestone with chert bands and is of Miocene age [11] (Fig. 2). The land slopes gently towards the coast with large limestone boulders strewn at the base of the property. There are two small perennial stream that take excess run-off from the slopes and drain the property. The area surrounding the Ackendown property shows karst topography, and the site itself rests on the seaward face of a rounded limestone hill.

The Heritage Park contains a diversity of geologically derived material, both local in-situ, or imported from other Jamaican areas as well as from overseas. For example there is clastic material imported from different areas in Jamaica. Imported material is found in some 'Gabian baskets,' rectangular mesh screens filled with cobbles that are strategically installed around one of the streams on the property to redress erosion. Historic slate roofing tiles found on the property are imported from overseas.

2. Natural Hazards and Disasters

Jamaica falls within the Tropical belt that historically has felt the effects of these annual seasons. From 1780 to 1786 there were five hurricanes that passed within 100 kilometres (100 miles) of the South Coast of Jamaica [12]. Additionally, the island itself is dissected by a number of faults that feature Quaternary left-lateral offsets associated with the Gonave micro-plate, which is demarcated by the Oriente Fracture Zone to the north, the Walton and Enriquillo Fault Zones to the south and the Cayman Spreading Centre to the west. Further, in western Jamaica the topography is influenced by the South Coast, Spur Tree and Montpelier-Newmarket faults that exhibit large downthrows to the south and west, respectively [13]. Historically, there was the 1692 earthquake where two-thirds of the infamous Buccaneer city of Port Royal sank into the sea, and the 1907 that resulted in the enactment of the first building laws in Jamaica [14].

"...About 200 earthquakes are located in and around Jamaica per year most of which are minor, having magnitudes less than 4.0. The most seismically active areas are the Blue Mountain block in eastern Jamaica and the Montpelier-Newmarket belt in western Jamaica. Other areas of notable seismicity include the near offshore south-west of Black River on the south coast, and offshore Buff Bay on the north-east coast..." [15]. The Ackendown heritage site on the south coast may bear testimony to these impacts, based on their ruinous condition and signs of structural movement.

There is evidence of environmental deterioration on the historic ruins, however this may be considered 'moderate'.

3. Ackendown History

The property was described as woodlands on the Early English Plat and Patent Books on deposit at the GAJ having 324 hectares (800 acres) patented to Dr. Richard Herne on August 18, 1674 [16]. By May 30, 1733 the earliest mention found to date with Ackendown is recorded in a dispute resolution document of a conveyance for 'Strathbogie' with estates or plantations called respectively 'Ackendown' and 'Retrieve' along with some uncultivated lands belonging to John Hayes and his wife Jenet who conveyed them to Peter Beckford that gives the following account [17].

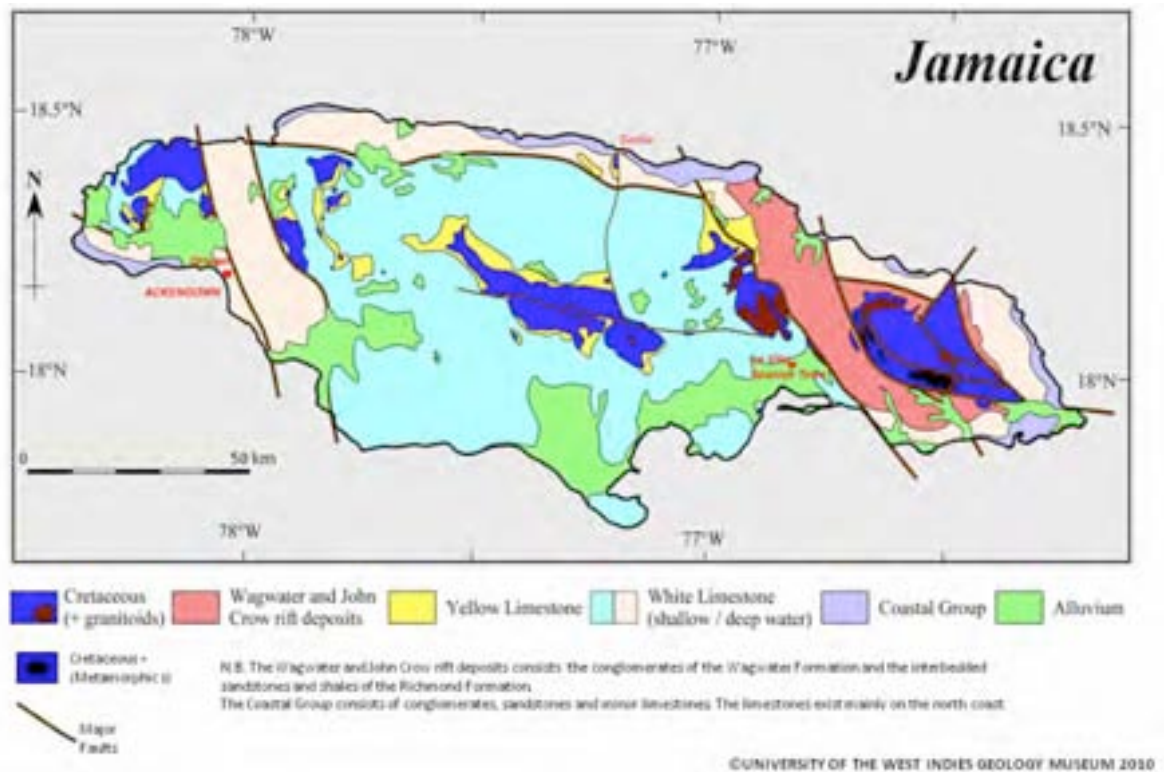

Fig. 2: Geology Map of Jamaica with insert of Ackendown, *Sevilla* (north coast), *Oristan* (south coast), and *La Villa* now Spanish Town (south central).

In 1734 John Haynes died intestate and these properties passed to the widow Jenet Hynes and her children. In 1742 Francis Sadler becomes the proprietor with his new wife, the widow Jenet Hynes. On his death in 1735, Peter Beckford passed these properties to his sons Nathaniel, William, Richard, Julines, and Francis to be equally divided between them. By January 1743 on account of mortgage entanglement, these parcels were transferred to William Beckford son of Peter. William died in 1770 leaving them to his infant son William and executors until September 28, 1781 when William turned 21 years. The Scotsman John Campbell is listed as proprietor in December 19, 1788 and attempted to convert the property from an 'estate' into a 'pen' resulting in disputes about whether this change was beneficial or prejudicial to the mortgages.

William Beckford became Lord Mayor of London, and the richest man of his time with his wealth stemming from holdings in Jamaica that passed to his son, William Thomas Beckford who was an illustrious traveller and author. Peter, William, and William Thomas were all absentee proprietors and never visited Jamaica [18]. William Thomas Beckford erected the ca.1800 mansion called Fonthill Abbey in Wiltshire, England that was designed by Architect James Wyatt and styled by the Royal Institute of British Architects as 'Georgian eclecticism' [19]. Two keystones on the Pimento Works ruins at Ackendown carry the inscription, "WB1776" and "WB1777," suggesting that these buildings were erected under the proprietorship of William (Thomas) Beckford.

Ackendown appears in the Jamaica Gazette of 1816 as belonging to John Graham Campbell with 132 'slaves' and 326 livestock [20]. After the 1834 Emancipation of slavery, in the 1837 Campbell was listed as having 331 apprentices [21]. By 1912 Ackendown was mainly rented to tenants as a cattle pen that also supplied wood, and consisted of 581 hectares (1,436 acres) in the proprietorship of I. O. Crooks and A. S. Aguilar and Brother [22]. In 1930, Crooks was removed off the title [23]. Various subdivisions took place, so that by December 2, 1971 the Urban Development Corporation owned approximately 267 hectares (659 acres) [24], from which Gorstew Limited became proprietors

in October 1992 of approximately 116 hectares (287 acres) containing the Heritage Park and the resort hotel was developed on the beach [25].

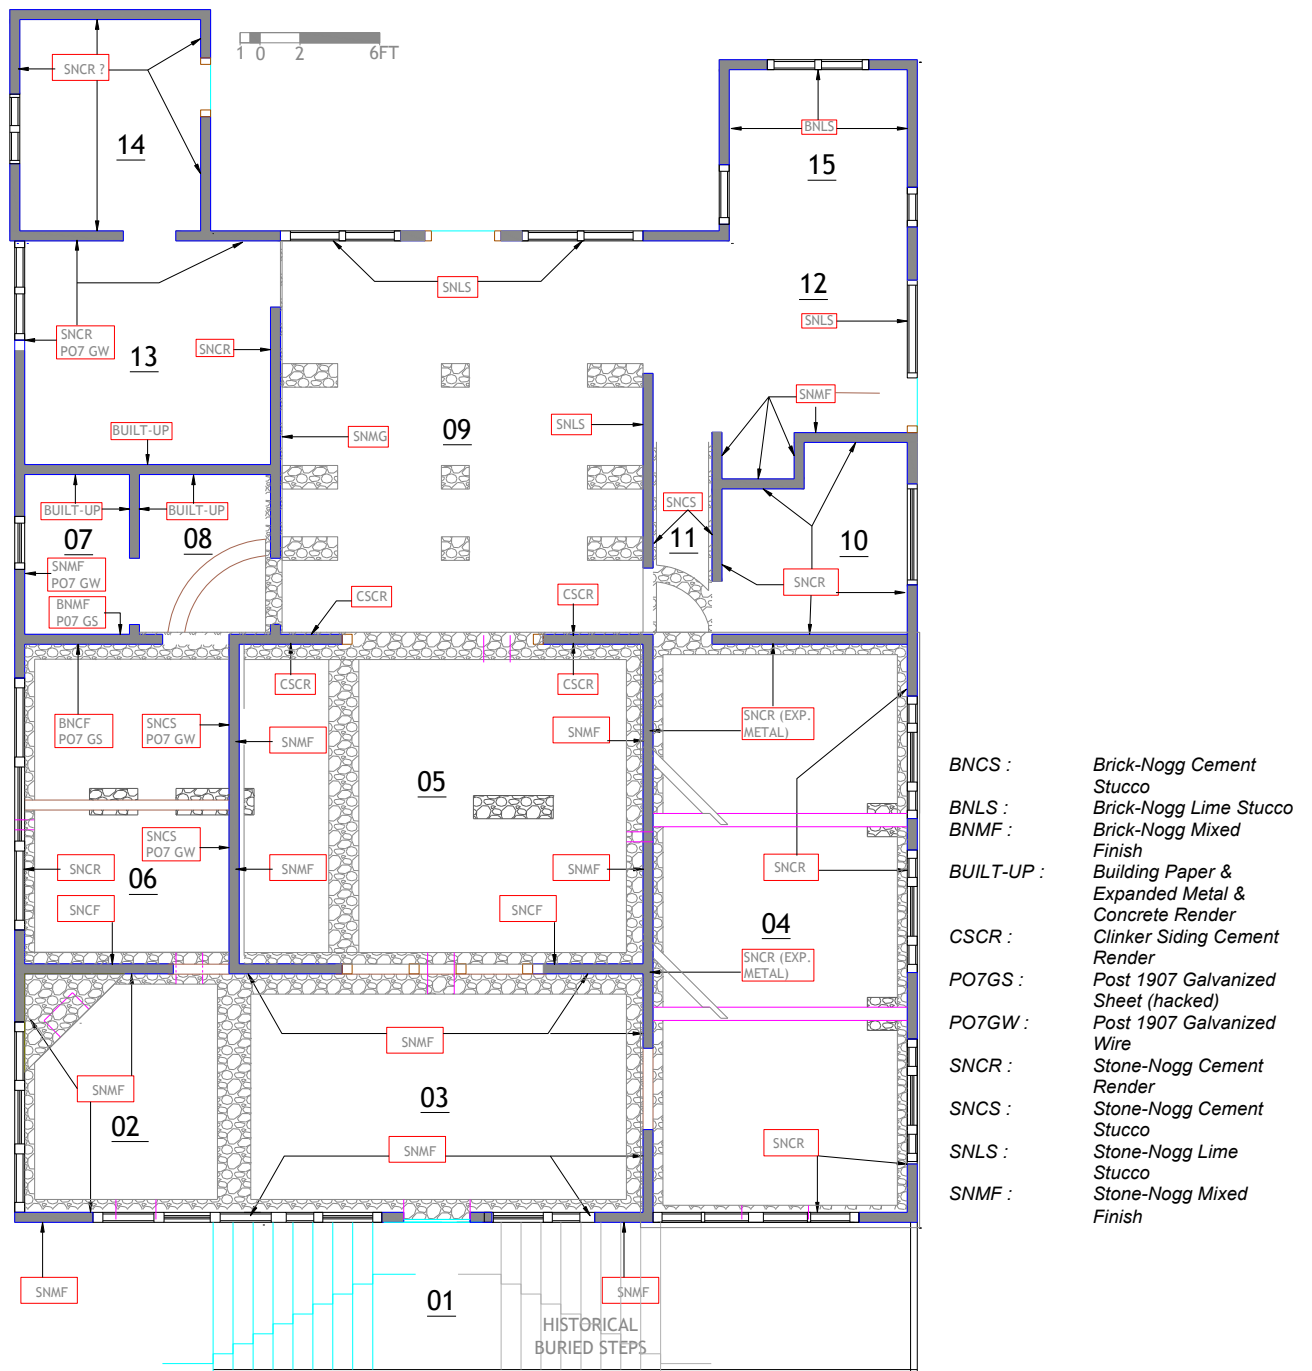

Fig. 3: Cottage Floor Plan showing random rubble foundation walls below with eleven types of upper wall construction (©Patricia E. Green Architects 2011 August).

4. Historic Structures

The Castle ruin comprises the outer walls of two double-storied Ashlar masonry 7.5 metres (25 feet) square towers with varying heights of 7.5 metres (25 feet). There are sub-floor levels on each tower. A low wall about 43 metres (141 feet) spans between both towers, with an interconnecting tunnel associated with this wall. There is evidence of upper timber flooring supports, also fireplaces and chimneystacks.

The Pimento Works are two structures each with a partition wall evenly placed. Each footprint measures 6 metres (20 feet) x 12 metres (40 feet). A five-bay barbecue with associated stone store-sheds separates each building. The barbecue overall measures 26 metres (86 feet) x 58 metres (190

feet.) The principal facade is of Georgian design with a 4-bay elevation and gable roof pitch measuring about 6 metres (20 feet) at the apex. The east structure carries two keystones over the doorways, on which is written WB1776 on each keystone. The west structure carries WB1777 on one of the keystones over the doorways, however it appears that the other doorway may have had the same but weathered. The west structure has a fireplace in the partition wall.

One Field Building has a one-roomed structure, and the foundations of the other outline two room. Both structures average approximately 6 metres (20 feet) x 6 metres (20 feet).

The Cottage contains a covered rectangular building with a veranda having an area of approximately 246 square metres (2,700 square feet). This building was occupied until about 2004, and was immediately vandalized after it became vacant, thereby revealing a wealth of geoarchitectural information. Twelve wall types are identified. One wall type is the random rubble perimeter wall foundation that provided a suspended floor. The above-floor walls are eleven different types of timber-framed construction with masonry infill. These are termed 'nogg' construction [26]. Four of the wall types are varieties of post-1907 nogg walls.

It is supposed that this building spans five centuries, 16th, 17th, 18th, 19th, and 20th centuries. On the basis of the analyses of these walls, a hypothesis was developed to ascertain the construction evolution of the Cottage (Fig. 3):

- i. The sub-floor foundations that may have been a 16th century two-roomed stone house would be sections 05 & 06. The area of this equates with one of the Field Buildings.
- ii. The sub-floor foundations that may have been 17th century are sections 02 (with a fireplace) & 03 also 09 added to 05 & 06. The area of this equates with the footprint of a Castle tower.
- iii. The 18th century alterations would have coincided with the 1776-1777 Pimento Works improvements where section 04 would be added as a foundation and the house then spanned over sections 02 & 03 & 04 & 05 & 06. An outdoor section 01, the steps would match 09 as another outdoor space.
- iv. The 19th century had the addition of sections 07 & 08 & 13 as one room, likewise section 10 & 11 & 12 as one room to the 18th century sections of 01 & 02 & 03 & 04 & 05 & 06. The outdoor space 09 would remain.
- v. The 20th century had the extension of section 14 on the east, and section 15 on the west. Also the outdoor section 09 was enclosed, and the east and west rooms were subdivided into 07 & 08 & 13 also 10 & 11 & 12 respectively to create indoor bathroom and kitchen facilities. Section 01 was integrated into a veranda.

5. Geoscientific Analyses

The techniques employed in the analyses of the building material used at Ackendown are geological methods that have found wide usage in Archaeology particularly for pottery, mortar, plaster and paint [27]. The techniques used throughout this project include hand specimen descriptions, petrography, insoluble residue analysis, neutron activation (NA) and X-Ray diffractometry (XRD). Each technique provides more information than the previous and as such a systematic approach has been taken in the study of the material. The techniques also increase in cost from hand specimen descriptions to X-Ray diffractometry.

Petrography deals with the description and classification of the rocks by microscopic examination, where thin sections are made from small slabs of a rock sample mounted onto a glass slide (~1 inch by 2 inches), and then ground to a specified thickness of 0.03mm (30 microns). In the case of mortar, the samples are first impregnated with resin, then mounted and ground. Neutron Activation is a method of identifying isotopes of an element by bombarding them with neutrons and observing the characteristic radioactive decay products emitted. Different elements produce different 'signatures' of the sample in the induced radiation, which makes determination of their concentration in the sample. X-Ray Diffractometry is one of the primary techniques used by mineralogists and solid-state chemists to examine the physico-chemical make-up of a sample.

These analyses largely form part of the provenance studies to determine the source area for the lime used in the mortar and the clay used in the brick as well as assist in distinguishing possible construction phases of the buildings.

At Ackendown, various samples of rock, mortar, stucco, plaster, brick and slate have been recorded and sampled for analysis. Thin section analysis has revealed very interesting textures; insoluble residue has indicated that the mortar is made primarily of carbonate with a small percentage being twigs and charcoal. The NA and XRD analyses are being conducted and compared with *Sevilla*, and *La Villa*.

6. Geology of the Heritage

The limestone on the historic ruins is used as cobbles or fieldstones, and block forms, as well as utilized in mortar, stucco, and plaster. It appears to have been derived from in-situ boulders on the

property or strewn fieldstones from loose blocks such as in the streams with a limestone basement, as well as from the material in-situ along the rocky coastline now housing the resort hotel development.

Constructed from hewn limestone blocks, the Castle material is also micritic, (fine-grained limestone) in texture. The tool marks can be seen on individual blocks. The tunnel is made from rounded to sub-rounded limestone cobbles. They appear to be about the same size as those used as blocks except they were not shaped into blocks.

The two primary buildings at the Pimento Works and its storehouses have a mixture of limestone cobbles and crudely-shaped limestone blocks. Red bricks are used inside the eastern building for an oven and a fireplace. Some repairs especially on the partition walls have been done using Portland / Carib cement.

The Field Buildings are composed of bits of chert cobbles in limestone cobbles with limestone blocks for the foundation and quoins.

Summary showing Geology for Architectural Masonry of Ackendown Heritage Structures

	Primary Architectural Masonry	Primary Geology	Primary Mortar
CASTLE	Ashlar	Limestone blocks	Lime (similar to that of the Cottage 2 nd phase)
CASTLE ROOFING	Slate	Overseas imported slate	None observed (slate strewn on ground)
PIMENTO WORKS	Ashlar	Limestone blocks + limestone cobbles + red brick	Lime (renovations in Carib cement)
FIELD BUILDINGS	Rubble with Ashlar quoins and foundation	Limestone cobbles + limestone blocks + chert cobbles	Lime (renovations in Carib cement)
COTTAGE	Rubble	Limestone cobbles + red bricks	Lime + Lime & Carib cement + Carib cement
COTTAGE BLOCK BUILDING	Concrete	Concrete blocks + red bricks	Carib cement
COTTAGE GARDEN WALLS	Rubble	Limestone cobbles + clastic cobbles	Lime

On the Cottage, limestone is predominantly used, and from preliminary analyses is locally derived having micritic (fine-grained) limestone cobbles in the foundation and lower walls. Red brick is found also for a fireplace at the foundation level. The rocks at this location appear to be cobbles collected and used in the construction rather than hewn rocks. The mortar on the later-staged construction is coarse-grained, and has lime as binder with limestone fragments up to 1 mm in size as aggregate. Other walls above the floor level are of various geological combinations, some only made with stone cobbles, or with timber framing filled with stone cobbles generally called 'Spanish walling', or timber framing filled with red brick.

7. Conservation Findings

Other historic material examinations for conservation included timber samples from the frames, windows, doors, and roofing as well as metal samples of nails, hinges, and straps. However the analyses for these involve other types of equipment and technology outside of geology, such as carbon dating that is envisioned. The nail analysis is assisted through the dated collection at the Archaeological Division of the JNHT.

Early stages of the geoscientific analyses have revealed the following:

- At the Castle, the mortar is medium-grained, similar to the designated 17th century hypothesis of the Cottage. It consists of limestone, wood fragments and charcoal fragments mixed in with the relatively fine-grained binder. Showing shrinkage cracks, these are indicative of insufficient burning, thereby when rehydrated and combined it would dry out quickly forming the cracks [28]. The tunnel mortar was less generously placed in this area than on the blocks of the towers. The material is firm, however may be easily scraped away from the rocks.
- At the Pimento Works, the mortar was predominantly of lime. The lime mortar was grey- to light-brown in colour, very soft, and disaggregated easily between thumb and forefinger. It shows burnt wood and charcoal fragments up to 5 mm in size. This mortar appears to have a high aggregate to binder ratio with the binder being very fine-grained with limestone fragments up to 2 mm in size as aggregate.
- At the Field Buildings, the mortar has chert and limestone fragments ranging in size from 10-15 cm used to infill the mortar between blocks. This decorative mortar is found only on the east wall, and on no other structure.
- At the Cottage, inside the sub-floor foundation level hypothesized as being 16th and 17th century, the limestone is chalky and sub-rounded in shape. These foundations and lower walls

showed a tight packing of cobbles with soft, white-grey, powdery lime mortar smeared over the rock-to-rock connections. This mortar is very fine-grained. The lime mortar appears to be created only from very fine-grained lime binder and aggregate less than 1 mm in size and used to hold small rocks in place as well as spread on the surface as stucco. There are charcoal fragments in the mortar. This application appears very crude compared to applications at other structures on the site. The arched openings within this sub-floor foundation area have been closed off with limestone cobbles, and the mortar is of similar texture and consistency. The mortar in this area is similar to that on the Castle.

Figs. 6 & 7: View of Port from Ackendown Castle with Pimento Works ruin in foreground, and hotel resort development on the beach; and one of the Ackendown Field Buildings.

8. Geoarchitecture Conclusions

The early findings of the geoarchitecture have already begun to confirm aspects of the construction dates of the heritage structures. It is recognized that the Cottage has been continuously inhabited into the 20th century, and show evolving construction techniques with developments in earthquake resistivity. The earthquake resistant construction is part of the Jamaica Vernacular Architecture [29]. It is common practice of the local community within the vicinity of Ackendown; therefore traditional restoration skills reside locally.

Parts of the Cottage compare with that of the 18th century Pimento Works carrying keystone dates of 1776 and 1777. Yet the geoarchitecture of the Pimento Works with its Georgian architectural detailing suggest that the Field Buildings with its decorated inset mortars are of an earlier date to the

Pimento Works. This type of decorative mortar is found on the 17th century Old Gaol building in Port Royal, one of the few architectural survivors of the 1692 earthquake.

Significantly, the geoarchitecture is characteristic for the Castle and the Cottage sub-floor foundations, and it may be concluded that these have the same construction timeframe. The Castle may have been a 16th century Spanish fort house and the Cottage sub-floor foundations a Spanish stone house as a part of the Spanish Jamaica town of *Oristan*. Making contemporaneous associations of the Ackendown heritage with early Spanish settlements in the Americas, the 1572 illustration of Santa Maria in Panama bears similarity (Figs. 4, 5, 6, & 7). Spanish Jamaicans helped founded Central American Spanish colonies [30]. Settlements in Panama came after those in Spanish Jamaica [31]. The 1692 earthquake may have destroyed the Castle likewise the stone house, over which the Cottage was subsequently constructed.

Geoarchitecture has far-reaching effects for multidisciplinary research. Even with these early geoscience results at Ackendown, the geoarchitecture seeks to help enhance cultural heritage tourism linkages between Jamaica and Hispanic heritage. Commonality of the geoarchitecture of the Ackendown Heritage Park with that of the wider local community would thereby engage them for sustainable conservation.

Acknowledgements

The authors wish to thank all who helped to make this investigation possible with special mention of Sandals Resort International as the proprietors and developers of the Heritage Park, the Jamaica National Heritage Trust for providing access to archaeological heritage sites under their purview for comparative analyses, the consulting firm Patricia E. Green Architects, Jamaican Archaeologist Roderick Ebanks, and the Office of the Principal University of the West Indies at Mona for the provision of a 'New Initiative Grant' that has helped to facilitate these investigations.

BUILDING INFORMATION MODELING. AN INSTRUMENT OF KNOWLEDGE FOR THE FORTIFIED ARCHITECTURE.

Luigi CORNIELLO¹

⁽¹⁾Dipartimento di Architettura e Disegno Industriale "Luigi Vanvitelli", Italy
lcorniello@libero.it

Abstract

The research is focused on the analysis of patterns of information, the creation and management of model information Building Information Modeling (BIM) applied to the study of Ticino fortified. The study proposes a knowledge and appreciation of the site of the historic and natural landscape through the relief, the representation, the reading of images and archive documents. You can define BIM process as an analysis of multidimensional models generated digitally by means of tools, a representation of a data model related to different disciplines that define it. A BIM can contain any information relating to an area and its parts. The most commonly informations collected in a BIM relate to the geographical location, geometry, material properties and elements. The development of the route is contained in the following three stages: the first concerns the perception of places and architectural presence of the landscape and the urban environment. The second segment of the research develops the comparative study of documents of different age and origin, whose expressive language offers pictures comparing the area and the current reality, both played with the scientific discovery of things and places. The third an interpolation to achieve knowledge of the first two and finaline to conserve with the necessary protection of places as a resource to be developed.

Keywords: Building Information Modeling, representation, fortified architecture.

1. The systems of fortified architecture

This itinerary offers different view of research and interpretation in the context of multidimensional methodology adopted in the various fields of investigation: from the history of architecture to landscape, from architectural design to restoration, from urban planning to archeology, from the sign to the drawing. This scientific aspect was mainly related to maps, plans, graphs, references available in archives and private collections such topics innovative research focused on emotion perception. The analysis of patterns of information about the creation and management of information BIM model applied to the study of fortified architecture of the three castles in Bellinzona. The study proposes a knowledge and appreciation of the site, historical and natural landscape through the architectural survey, the representation, the reading of images and archive documents. The development of the route is contained in the following three stages: the first concerns the perception of places and architectural presence of the landscape and the urban environment to capture these images and capture the historical value and the current reality in the visions of reality in architectural reports with the shapes and colors of the social structure. The second segment of the research develops a comparative study of documents of different ages, whose expressive language features compared images of the area and of current realities, both played with the scientific detection of the architecture and places. In addition, this course outlines a collection of visual images documented by representations analyzed in comparison. The third route to achieve interpolation knowledge of the first two is to be conserved with the necessary protection of places as a resource to be developed. The overall image of the castles of Bellinzona is mainly linked to their role in the late Middle Ages, when it served as fortifications to protect the Duchy of Milan. Residual traces of Roman and early medieval military installations are available on the archaeological plan, while other defensive works of the middle centuries of the Middle Ages are incorporated into the Ticinos' fortifications and appear in isolated form, such as the Black Tower and White Tower of Castel Grande. Those examples of

Bellinzona are military architecture, often found in the valleys of the southern alps that offered considerable differences in level topography for defense purposes, the walls and sloping connection with their narrow parapets and steep stairs.

2. The patterns of information Bim applied fortified architecture

Considering the BIM a process analysis of multidimensional models generated by digital tools, we can see that they are a representation of a model different data related to the various disciplines that define it. A BIM systyem can contain all the information about a territory and its parts. The most commonly collected concerning the geographical location, geometry, material properties and elements.

Fig. 1: The Castel Grande in Bellinzona. Plan.

Fig. 2: The Castel Grande in Bellinzona. View of the entrance.

2. The architectural presence in the urban environment. The Castel Grande in Bellinzona

The huge rocky outcrop of Castel Grande forms the natural center of the "closed Bellinzona." Of the oldest settlements (prehistoric and Roman) are barely visible archaeological traces, even the meager remains dating back to the middle centuries of the Middle Ages. Most of the factories can be placed between 1250 and 1500. These are witness of a very eventful story building, marked not only by restructuring, expansion and strengthening interventions, but also by war damage, periods of neglect and demolition. The broad summit of the hill, protected by rocky cliffs to the north and to the south by almost vertical steps less steep but difficult to access, is presented as an open space terrace with a diameter of 150-200 m. Its configuration has meant that in every epoch the defense works were to follow the natural edge of the rocky outcrop, the late medieval town still exists, therefore, rests largely on the same foundations of the Roman walls. These, found during archaeological investigations in the south wing of 1967, are made of rough stones. Today the vast inner surface offers the impression of a big empty space. Many buildings were destroyed in the fifteenth century. The nineteenth-century buildings of the arsenal, however, were almost all demolished in the course of the restoration works of the twentieth century. The sources and archaeological evidence shows that the height of the Middle Ages Castel Grande was to include a number of buildings much larger than anyone can imagine now. Several buildings were dismantled in the fifteenth century under the Dukes of Milan. Aim of the intervention is presumed was to get rid the inner surface, divided into three large courtyards, huddling for temporarily military contingent in case of need. Under Milan domination, the efforts to improve the defensive structure of the complex is concentrated on peripheral parts during the fourteenth century and especially in the fifteenth century it was provided in stages to elevate and renovate the walls, adding courtyards and auxiliary's towers of arms. The western segment also was radically restructured with the connection to the wall. In the late Middle Ages, it was entered in Castel Grande from the south through a gate in the city walls located halfway up the hill, after passed about 100 yards of arms embattled south of the city, we finally reached the main gate of the castle, which is open in the southeastern part of the walls. Since the fifteenth century, as said, the interior of Castel Grande is divided into three large courtyards with walls arranged radially from the Black Tower. This square tower, located more or less in the center of the castle, was built in the early fourteenth century and probably raised up in the fifteenth century. Further in the east lies the complex of buildings at the center stands the tallest building of Castel Grande, the slender white tower, probably built in the thirteenth century. As evident from the preserved parts of the city in the northern court there had to be buildings as well. In this area, defended by the sheer rock, the need to build a protective wall was warned between 1300 and 1400. In the years 1982-2000 the fortress was the subject of a major restoration and transformation project of the architect Aurelio Galfetti, aimed to the revitalization of the castle. The project, conceived on a regional scale, emphasizes the public nature of the complex, strengthening its ties with the city and the landscape. A striking passage in concrete, carved into the rock, at the square of the Valley to the south-west of the square of the Sun, is a new direct access to the castle and its park. The southern wing of the fortress now contains the museum spaces divided into two sections. The historical-archaeological, accommodates several archaeological finds in site and a valuable collection of coins sixteenth century. In the historical-artistic section there are a series of drawings in tempera, the Body of factory west of the castle, built in the 1820s as arsenal, has been completely restored and turned instead to new uses.

3. The architectural presence in the landscape. The Castle of Montebello in Bellinzona

The impressive complex of Montebello (also said in the fifteenth century Castel Piccolo) stands on a rocky outcrop to the east of the town center of Bellinzona. Its origins date back to the thirteenth century. The castle was probably built by the Rusca's, relevant family from Como, and from them it passed to the Visconti's in the fourteenth century. After an initial phase of expansion (in the middle of the fourteenth century), at the beginning of the fifteenth century there was a period of decay. Around 1460, the buildings do not satisfied the technical - defensive "closed Bellinzona." Successive enlargements between 1462 and 1490, transformed the old building two - fourteenth century fort complex that characterizes the castle today. Left to decay in the nineteenth century, the work of consolidation and completion, completed in 1903, we read in the interventions in site, clearly readable, in courses of red tiles that separate the new parts from the original ones. The access to the hill where the castle stands is relatively easy from all sides, but especially from east. Unlike in Castel Grande, to prevent the enemy to approach it was necessary to dig deep ditches. The plan of the building looks like a rhomboid, obtuse angles are connected to the arms of the northern and southern walls of the village. The present building are readable the three main stages of the development of Montebello: the original and the two fortified city walls that surround it, built respectively in the fourteenth and fifteenth centuries. It dates back to the founding (XIII century), the main fortress: a fence uneven, slightly oblong, divided internally by more walls. It is not clear if the buildings that exist today on this website correspond to the original plan: open windows in the wall, now facing one of the two courtyards, would indicate changes in the structure plan. It is not excluded that the bunk, covered by a hipped roof and situated in the northeastern part of the fortress, is a reconstruction due to the restoration in 1903: the old illustrations show here only a building of four floors, with a pitched roof only inward. The overall plan of the fortress follows a pattern common in southern alps valleys: a high and robust wall huddled, inward, residential buildings and commercial vehicles. Part of this scheme the entrance to the fortress at the top on the west side and today reached by an external staircase. Presumably in the middle of the fourteenth century the fortress was built around a fortified by irregularly shaped, 7-15 m away from the original complex and crowned, straight flush to the wall, with battlements Ghibellines. The reveal of the remains in the boundary is constructed in a second time (fifteenth), both in a smaller building west of the central core. To the east, the castle complex thus expanded is protected by a deep moat, over which was thrown a drawbridge and the door - opening round arches in the southeastern part of the city walls - is set in a fifteenth-century tower. As shown in the oldest parts in the city of the fifteenth century, even then the plateau east of the outer moat had to be included in the fortifications. Massive interventions between 1462 and 1490 mainly interested the perimeter of the fortress: Harnessing the fourteenth-century walls it erected a new one, more robust, which in essence still determines the external profile of the castle. In the east land of the moat is a ornament terminating at an acute angle with the outer door, adjacent ditch and parapet fitted with trap doors. The moat oldest is closed to the north by a parapet, to the south by an auxiliary pentagonal tower, open at the back, which is the starting section of the junction with the southern arm of the walls of the village. On the site of the port in fourteenth-century the city is a port-projecting tower, with supportive function. The corners of the boundary rise auxiliary towers, open towards the interior and free of platform; at northeastern part is instead leaning on the inner side with a construction platform. An open door in the southern section of the city, with a drain reflects the original situation of the fifteenth century. The walls includes various service rooms for the use of sentinels; slits and gratings of the wall and towers were designed for crossbows, muskets and mouths of small caliber. The terrace is bounded to the west of Montebello, on the side facing the city, by a crenellated wall with semicircular auxiliary turret. In the fifteenth century Montebello was considered among the castles of Bellinzona, the most suitable to the defense all over the field in case of war. The free space within the main fortress and advanced fortification works could meet the need of sudden accommodate troops and war material. The keep houses the Civic Museum and archaeological, built in the years 1971-1974 by the architects Mario Campi, Franco Pessina and Niki Piazzoli.

4. The architectural presence in the natural environment. The Castel of Sasso Corbaro in Bellinzona

Approximately 600 m southeast of the city, at the highest point of the rocky outcrop where are located the fortifications of Bellinzona, stands the fort of Sasso Corbaro. Unlike other works of defense, integrated from the thirteenth to the fifteenth century in a single defensive system, this castle stands in a completely isolated. In the second half of the fifteenth century it was fortified the summit, to fill a void in the defensive system of Bellinzona. Work began only after 1478, before he built the rugged northeast corner tower of the future complex, then ran to the other parts. The work continued until around 1481-1482. In times of peace, the fortress was used as a prison. Repeatedly damaged by lightning in the sixteenth and seventeenth centuries, around 1900 Sasso Corbaro was a ruin. The consolidation work did in this century have made substantial architectural remains unrecognizable. The rock forms a square of about 25 m per side, from the north-east and south-west corners where rise four-sided towers of different heights. The fortress - whose walls have a thickness between 1.8 m to the east (front of attack) and about 1 meter elsewhere - it was designed for a defense on all fronts: on all sides developed a parapet with embrasures and battlements Ghibellines, also present in the watchtower on the south-west angle. The entrance to the courtyard of the fortress - on the west facade, facing the valley - it still shows traces of a gate made of bars, the south and west sides of the courtyard are occupied by two floors wing housing, along the wall boundary, a time covered by a gable roof that began under the parapet walk. The powerful bunk on the northeast corner, evidently built before the other parts, now comprising four floors. To the south and west of the core are the remains of arms of courtyards and minors buildings. The last restoration took place in the years 1998-2006 by the architect Paola Piffaretti.

5. Images of the area and the reality aimed at the preservation and protection of places

Knowing a city and its territory means to review the history of its people and its urban fabric or acquire social structures and architectural features of the present and the past, and with more attention to what remains of the architectural heritage to be protected as a powerful sign of knowledge. The research, based on the action of protection and enhancement of the fortified structures, cannot be separated from an activity based on the discretization of multidimensional knowledge and measurement of assets through the use of BIM systems. The study consisted of the reading of the territory, aimed at the understanding of all the complex aspects that contribute to determining the form, not only as the outward appearance, but also as a carrier of tangible and intangible assets related to the history, culture and traditions which over the centuries have marked their signs to the environment. The investigation is focused on the knowledge of fortified Ticino's architecture, focused on the study of the chromatic inscribed in the UNESCO World Heritage site since 2000. To outline a possible path of observations for urban environments is useful to focus on some general considerations with thoughts based on multidimensional study starting from the perception of the elements of the environment related to their spatial position and the synergy with the intervention of BIM knowledge on the site.

Control and reuse of the rainwater in the urban context

Rossella FRANCHINO,¹

⁽¹⁾Department of Architecture and Industrial Design, Second University of Naples, Italy
rossella.franchino@unina2.it

Abstract

Within a correct and sustainable urban development, the control of the flows of rainwater to the ground is particularly important. When the balance of the rainwater at a territorial level is meaningfully altered because of the ground changes, implementations of infrastructures of water collection are often necessary and they are expensive from both the economic and the environmental and landscape point of view. It is evident, therefore, the necessity to check the process of water collection at the origin replacing or placing side by side to the traditional infrastructures the so-called "green infrastructures", as suggested by the United States Environmental Protection Agency.

The aim of this research concerns the use of the principles of the nature as a model of management of the rainwater stimulating the hydrological potentialities not developed by the site. The final result consists in the individualization of "green" technologies both passive, only natural, and active with small engineering, allowing to carry out an urban micro-basin self-ruling the meteoric waters picked up to the ground in the area that is object of study according to the logic of "design for water conservation".

Keywords: infrastructure networks, rainwater, water conservation

1. Introduction

In the last decades the environmental worries have been prior among the greatest worries of the contemporary man. The environmental issue has conditioned in a very marked way study, application and management of both innovative and simply evolutionary new technologies. That's why the analyses of convenience, only oriented by the necessity to save resources, have become analysis of compatibility that have added to the purpose of saving also the purpose of mitigating the environmental impact, both seen in their incidence on the residual availability for the future generations and on the possibility to still enjoy a not completely degrading habitat, even having it submitted to repeated transformations.

Currently one of the most important environmental problems consists in the territorial management of the infrastructural networks that, in some cases, has produced situations of real emergency. Within a correct and sustainable urban development, the control of the flows of rainwater to the ground is particularly important.

2. Water-use integrated cycle networks

At a territory scale, the integrated cycle of the waters se provides different phases. From its point of origin, water reaches individual users through primary and secondary distribution and after whatever use it is put to, is discharged as waste water into the sewage system, which conveys it to where it will be finally treated [1] .

Since any intervention within a territory gives great importance to the correct environmental design of a water-supply network, examining the network as a whole, instead of looking at its single elements, will provide a more general overview that will then allow us to make recommendations as to the re-use

of this resource. Water is, in fact, an extremely valuable resource and therefore the over-riding aim of the entire cycle of use must be how to save and how to recycle it whenever possible.

The typical water-cycle is made up of: procurement, storage, use and disposal. Procurement may be from a spring, ground-water, freshwater supplies (rivers, lakes), and only in a few cases also rainfall and seawater. The latter two resources are used in special cases and for isolated areas of use, being constituted by holding-tanks for collecting rainwater and desalination processes for seawater.

In the other, more commonly-known cases there are collecting tanks and drainage channels for obtaining water from springs, artesian wells or wells for groundwater and plants which use river water and lake water from source. Once having collected the water, a fundamental element for its use is naturally its quality, from an organic-oriented, chemical-physical and bacteriological viewpoint.

Depending on the eventual use of the water, in most cases it is absolutely necessary to resort to a series of drink ability measures, which might consist of neutralising certain pollutants that may be present, reducing their strength, modifying their pH value, disinfecting them etc ... The water that has been drained off is collected in special holding devices where the necessary treatment takes place and it is from here that the flow begins for the various uses of water, which has to be supplied proportionately in order to satisfy current and possible water needs.

Generally this phase of the cycle consists of a process of heat transfer to the water which is mainly channelled, under pressure, but also in some cases, in the open air, to holding tanks situated in the proximity of end-users. These holding tanks have differing sizes and typologies in relation to the type of use, the topographical features of the catchment area and the type of function required.

The most common types are buried or above ground, depending on whether the area to be supplied contains natural elevations or is completely flat. The size of the tanks, besides being obviously dependent on the number of users, is also determined by the characteristics of the community and flow-rate coefficients required. From the holding tanks a distribution network is developed which must deliver punctually the necessary quantity of water required by individual users. This network is usually a mesh type since it is subjected to considerable variations in flow-rate and with this type it is possible to ensure the greatest flow to specific points. It would be pertinent to note the difference between the heat-transfer network which is proportional to average flow-rate required by users. The function of the holding tank is precisely that of receiving water constantly at an average rate of flow and delivering the required flow rate instantaneously.

Subsequent to water use is the discharge of waste water, in quantities conventionally set at 80% of that supplied, which takes into account those amounts of water which are not discharged into the sewage system but used for irrigation or external flushing. It should also be noted in the water balance that water supply is generally equivalent to a maximum of 60% of the water that is drained since a considerable amount is lost in the conduits or from pump overflows and tanks. The waste water is transported through sewage conduits which take it to its final destination, following purification treatment. The sewage system may be of a mixed or separate type, depending on whether it collects rain water. The network elements should allow for, whenever possible, not only the discharge of waste water from all possible users, but also the distinction between runoff water and sewage water so that runoff water may be reused after treatment for watering green areas and street-cleaning, while sewage water is transported to purification plants where it is thoroughly treated.

In some cases, once the principal pollutants have been neutralised, the recycled water may be delivered to homes, through a system which is separate to the drinking water system, and used for WC flushes. It is also important that rainwater, which contains dust and pollutants of various kinds in solution, is separated from this recycled water through overflows and sent into the sewage system for subsequent purification treatment.

The final purification treatment takes place in plants which deal with the neutralisation of the main pollutants contained in the waste water so as to enable it to be sent to a final body of water. In order to protect the delicate equilibrium of the aquatic eco-systems of the receiving body of water it is important that the effluent from the purification plants does not contain residual pollutants. Traditional treatments for purifying water are of a physical kind (sedimentation), of a chemical-physical kind (adding chemical reagents) or of a biological kind (active mud) and produce the so-called "purification mud" which has to be specially processed (in the past in special waste disposal sites but now in incinerators).

The location of these treatment plants is also of great importance since they represent sites of high environmental impact. This impact may be reduced through the use of tunnel plants or covering the tanks and taking steps to treat the air through deodorising scrubbers. Where possible, this deodorising treatment can also be carried out with deodorising aerosol systems.

Traditional purification systems, in small-scale cases, might be bolstered or even replaced by natural treatments which greatly reduce the content of artificial elements and the amount of energy consumption. For example, instead of constructing concrete holding tanks, particularly in naturally, humid areas, water flow can be, to all intents and purposes, implemented by gravity.

Such natural treatments can, in certain cases, be sandwiched between the pre-existing purification system and the final receiving body of water, in such a way as to neutralise the residual organic content and to protect the environment in case of malfunction of the pre-existing system.

To achieve purification of water without resorting to mechanical means, which have high environmental impact, purification systems can be used, in small-scale cases, which are based on natural processes such as reed-bed purification.

3. Controlled process of rainwater management

In the previous paragraph the integrated cycle of use of the waters has been analysed starting from the point of water sampling up to reach its depurative treatment and its reintroduction in the final delivery. Just because the water is a very precious resource, the whole cycle of its use has been analysed from its saving point of view and all the possibilities of its reuse have been considered.

Beyond these considerations, in addition, the territorial scale is very important to check its origin the process of collecting rainwater through a controlled management that can be done by determining the contribution of rainwater and their possible recovery and reuse, infiltration in the soil and the entries in the natural water bodies.

In the urban context the continuous increasing of impermeable surfaces has often determined great problems of erosions and flooding besides altering the hydrologic natural water cycle damaging the balance among precipitation, evaporation, groundwater recharge and surface outflow. It is evident that it is imposed, therefore, a change of attitude in the water management in urbanized territories that must follow the natural cycle.

The study of the hydrological balance at the regional scale, involves the characterization of the flows of precipitation, runoff, infiltration and evaporation.

When the balance of the rainwater at a territorial level is meaningfully altered because of the ground changes, implementations of infrastructures of water collection are often necessary and they are expensive from both the economic and the environmental and landscape point of view. It is evident, therefore, the necessity to check the process of water collection at the origin replacing or placing side by side to the traditional infrastructures the so-called "green infrastructures", as suggested by the United States Environmental Protection Agency according to the logic of the Low Impact Development (LID) [3]. It is an approach to the development of the territory that uses principles tending to recreate characteristics of the natural territory in order to carry out a functional drainage of the site, so that the rainwater can be considered as a resource and not as a waste. There are many systems that can be used for adhering to these principles such as: drainage systems and permeable pavements, rain gardens and green streets. They are "green" technologies both passive, only natural, and active with small engineering [2], allowing to carry out an urban micro-basin self-ruling the meteoric waters picked up to the ground in the area that is object of study according to the logic of "design for water conservation".

For implementing the LID principles, the water can be managed so that they can use the principles of the nature as a model of management of the waters, stimulating the hydrologic potentialities not developed by the site. Applied on a wide scale, the LID systems can contribute to reinstate hydrologic functions and, with particular devices, also ecological functions of the whole aquifer. The interventions of transformation of the human-made territory, in fact, must be interested, among the other aspects, also in the ecological aspect for the maintenance of the biodiversity in order to protect the natural processes that are at the basis of the ecosystems survival.

In the United States of America there are many important experiences of implementation of green infrastructure according to this logic as the experiences of: Seattle e Olympia (Washington), Portland e Wilsonville (Oregon), Philadelphia (Pennsylvania), Emeryville, Santa Monica e San Jose' (California), Chicago (Illinois), Alachua County (Florida), Stafford County (Virginia) e Lenexa (Kansas) [4].

The following are two examples of green technologies for the recovery of rainwater particularly significant. In both cases the water is collected from the roof of the building.

In the water reuse cycle, the building represents the central element of the network: it is able, in fact, to join the resource use exigencies with the same reuse ones, in an optic of sustainable environment.

In the first case the water collected from the building is sent towards a rain garden (passive system), in the second case to a system consisting of tank, pump and filter (active system).

The rain garden is a depression in the ground where rainwater collects. The top layer of soil, which are also planted the plants, making a natural filtration of rainwater before returning to the underground stratum (Figure 1).

Fig. 1: Schematic rain garden

A system for recovering and re-using rainwater for buildings (Figure 2) is set up in such a way as to allow for the collection of water from roofs, terraces and pavement gutters and to re-use it, after appropriate treatment, for various uses such as: WC, car washes, washing exterior pavement areas, watering kitchen gardens, lawn and green-area irrigation, reintegration water for anti-incendiary use and even for some electrical appliances like washing machines, appropriately fitted.

The system involves several phases, the first of which is collection. All impermeable surfaces are suitable as areas for collecting rainwater. Obviously, the greater the area for collection, the greater the amount of rainwater that can be collected for re-use.

The next phase is that of filtration. A filter is fitted that permits the removal of those elements which deteriorate the quality of the water in the water-tanks. After this, storage is required for the water in tanks.

Some of these are fitted with a system that slows and regulates input flow in order to prevent the disturbance of sediment that collects on the bottom. The tanks can be positioned below ground outside the building or in basement spaces or storage spaces inside the building. Those tanks which are placed outside have the advantage of being hidden from sight and protected from accidental damage while, those placed inside have the advantage of not requiring any tampering with the external system for their positioning and therefore eliminating the risk of damage to the main system apparatus. The system also includes a pump, which through a control unit passes the water into the recovery system.

Fig. 2 : System for recovering and reusing rainwater for building

Standardisation of the design process using BIM software

Saverio D'AURIA¹, Davide BARBATO²

^(1,2)Department of Civil Engineering, Faculty of Engineering, University of Salerno, Salerno, Italy

⁽¹⁾sdauria@unisa.it, ⁽²⁾dbarbato@unisa.it

Abstract

The progress of computer technology applied to the architectural, structural and MEP design is revolutionizing the working methods and the relationships between the various stakeholders in the construction industry.

As in the 80s of last century, the diffusion of CAD software changed the way of drawing (considerably speeding up the phase of realisation of the technical drawings) so does nowadays the increasingly widespread of parametric and multi-functional programs – such as BIM – that are revolutionizing the design and realization process of the work. With them, working groups with different skills and experience are able to interact minimizing misunderstandings and disturbances that are always cause of low productivity and poor quality.

However the BIM software and methods are still not adopted by small and medium design studios and by the vast majority of construction companies, especially in Italy. One of the reasons for this scepticism is the lack of guidelines and standards that would make it easier to approach the building information modeling.

This paper intends to present the international state of the art of BIM design process standardisation, making reference to Finland, Canada and Australia, leading countries on these issues; it, additionally, introduces with a case study a workflow of a structural design realised complementing one of the most common BIM software with a software for modeling and FEM structural analysis highlighting its potentiality and criticality.

Keywords: building information modeling, BIM standards, parametric design, interoperability, BIM workflow.

1. Introduction

The traditional way of design is rapidly transforming - or, in some cases, it has already completely transformed - thanks to changing of socio-cultural scenarios, to the always more demanding clients, to the new technological frontiers and to the renewed possibility for the architectural, structural, engineering and energy sectors project. If on the one hand the construction industry is going through a period of decline due to the stagnation of the economy that involves almost all industrialized countries, on the other hand this phenomenon is one of the promoters of the renewal of the entire construction industry. The demand for high quality works in the shortest time possible and with very low budget, has led designers, builders and owners to establish different relationships, based on a high degree of specialization and on the rapid and correct exchange of information between the involved parts. In such a context of continuous and rapid transformation it is no longer possible to look at design in the same way it was done in the last century, when a single team was able to manage large projects, because of the long time and the favorable economic conditions they could count on.

Nowadays, it is essential to work with an heterogeneous team made up of at least one expert for each areas involved in the project. They can no longer exist spatial and temporal boundaries that slow down the creative and constructive process. Big architectural firm hire structural engineers living thousands of miles away, as well as mechanical and electrical engineers who speak different languages or manufacturers with different know-how.

Communicating, in the technical field, without misunderstandings and loss of time, allows to maximize the productivity while minimizing costs and interferences still not compromising the high quality of the

project. Like in a chain of causes and effects, this architectural planning 'revolution' is supported and nurtured by computer science that, for more than thirty years, has been speeding up and improving many of the design and technical calculation (structural, engineering, energy, etc..) procedures. One of the last outcome of this research is represented by the BIM (Building Information Modeling) software. They are changing and improving greatly the design methodologies.

The latest BIM software for architecture and engineering have, in fact, allowed a significant improvement by methodically organizing and simplifying the integration of the different skills required in the design process. The new computer science tools, in this way, are able to easily integrate the different roles and skills of designers, manufacturers and builders. This is possible because this software creates parametric three-dimensional models with all kind of information needed (physical-mechanical specs, energy, materials, economy, maintenance, etc.). Therefore, the infographic model is not just a simple virtual rendering, but it is a manipulable system that it is able to simulate the hypothetical real behavior of the building during its definition process.

The diffusion of BIM is not being as fast as it was, for example, the one of the CAD. This is basically because the CAD was a change in the instrumentation. It consisted in the switch from the drawing table to the so-called 'electronic drafting machine' with immediate results in terms of productivity of the drawings. For the BIM, instead, we need a change in the entire structure of the building process, as well as in the relationship between the participants in it. That is why only the major architectural and engineering firms and the biggest construction companies are totally 'converted' to BIM and exploit its full potentiality. The change was possible for them because they had the adequate economical resources and the courage to make such a great change in the professional method. It should also be noted, however, that in many cases, there is a very limited knowledge on this issue, and there are no guidelines and protocols that facilitate the approach to this new design methodology.

The change should be encouraged by the institutions, public and private, involved in the world of construction. Countries that invest more in research, development and dissemination of the BIM methodologies are also those that invest more in big infrastructure projects. They are the United States, Canada, United Kingdom, Scandinavia, Australia and a few other. After ten years the BIM was presented, there are still few nations equipped with organizations (governmental or not) who bet on the new technology of building information modeling. Over the years, these countries provided themselves with vademecum, guidelines and standardisation protocols; in some cases they made mandatory the use of them, in order to reduce errors and especially misunderstandings in the delicate stage of the data transfer between the technicians.

This paper will first provide an overview of the spread of the BIM in the world by analyzing the technical documents compiled by the different countries using the new methodology; then it intends to deal with the degree of interoperability that a BIM can have with a software for the structural analysis. To this end there will be proposed a pertinent case study and an appropriate workflow.

2. BIM standardisation protocols

There are several European and non-European countries that invest in the spread, in the use and in the development of BIM methodology, applying them to the entire construction industry. Public and private organizations, universities, professional associations and companies show an increasing interest in this issue that, in some cases, as we shall see, affected considerably the efficiency of the design, production and construction process. The saving, both in time and economic terms, is remarkable if you consider the significant reduction of errors and misunderstandings in the sharing of information between the various participants in the building process. The National Institute of Standards and Technology (NIST), the U.S. Federal agency that works with the principles of the industries to develop and apply new standardisation protocols, estimated that nearly \$16 billion is the annual cost the building companies pay to cope with the lack of coordination and with the errors made in the design composition (Fig.1) [1].

Stakeholder Group	Planning, Design, and Engineering, Phase	Construction Phase	Operations and Maintenance Phase	Total
Architects and Engineers	1,007.2	147.0	15.7	1,169.8
General Contractors	485.9	1,265.3	50.4	1,801.6
Specialty Fabricators and Suppliers	442.4	1,762.2	—	2,204.6
Owners and Operators	722.8	898.0	9,027.2	10,648.0
Total	2,658.3	4,072.4	9,093.3	15,824.0

Fig. 1: Costs of inadequate interoperability by stakeholder group, in \$millions (Source: GALLAHER, Michael et al. 2004).

European excellence in the field of BIM (Fig. 2) are the Scandinavian countries and the UK. Presently, they are high sensitive to the concepts of building information modeling and interoperability. For several years in Norway, BIM has been using for the entire lifecycle of public buildings. Thanks to the thrust the Norwegian Directorate of Public Construction and Property puts in this standardized methodology, they have reached very high levels in this field. To the point that, from 2010, it is always required the use of an 'open BIM' parametric software for the design and the management of any public building. This result in the use of a singular IFC file, importable without interference in the most common BIM software on the market, that make easier to manage and maintain the buildings. This was possible thanks to the publication of the *Statsbygg BIM Manual* [2]. It became a reference point for all the agencies and the designers who want to adhere to standard BIM demanded by the public corporation of management of the building.

The approach provided by the Norwegian manual is based on all levels of planning in order to optimize the flow of information between designers, the customer and the public administration. Uniformity of the data, an higher quality of the products and of the materials used, plus a significant reduction of the management and realization cost, are only some of the overall benefits.

In Denmark, the first attempt to introduce the BIM dates back to 2006, when the *3D Working Method* and *3D CAD Manual* were published. They focused on how to create, exchange and reuse the three-dimensional models in the different project phases. An additional contribution to the spread of the BIM method has come from three public corporations that own immovable property: the Palaces and Properties Agency, the Danish University and the Defence Construction Service. They imposed the use of the parametric design with the IFC format, consequently affecting the entire real estate market.

Finland is one of the first European countries to widely experiment the BIM for big public works. The Senate Properties is its government corporation that, from 2001, deals with these issues. It recently published the series *Common BIM Requirements 2012* [3], that is the result of an extensive research project on the topic of BIM, strongly demanded by building contractor associations and by building materials producers. This in fact helped to standardize design processes and, above all, to encode the data exchange method between the various participants in a project.

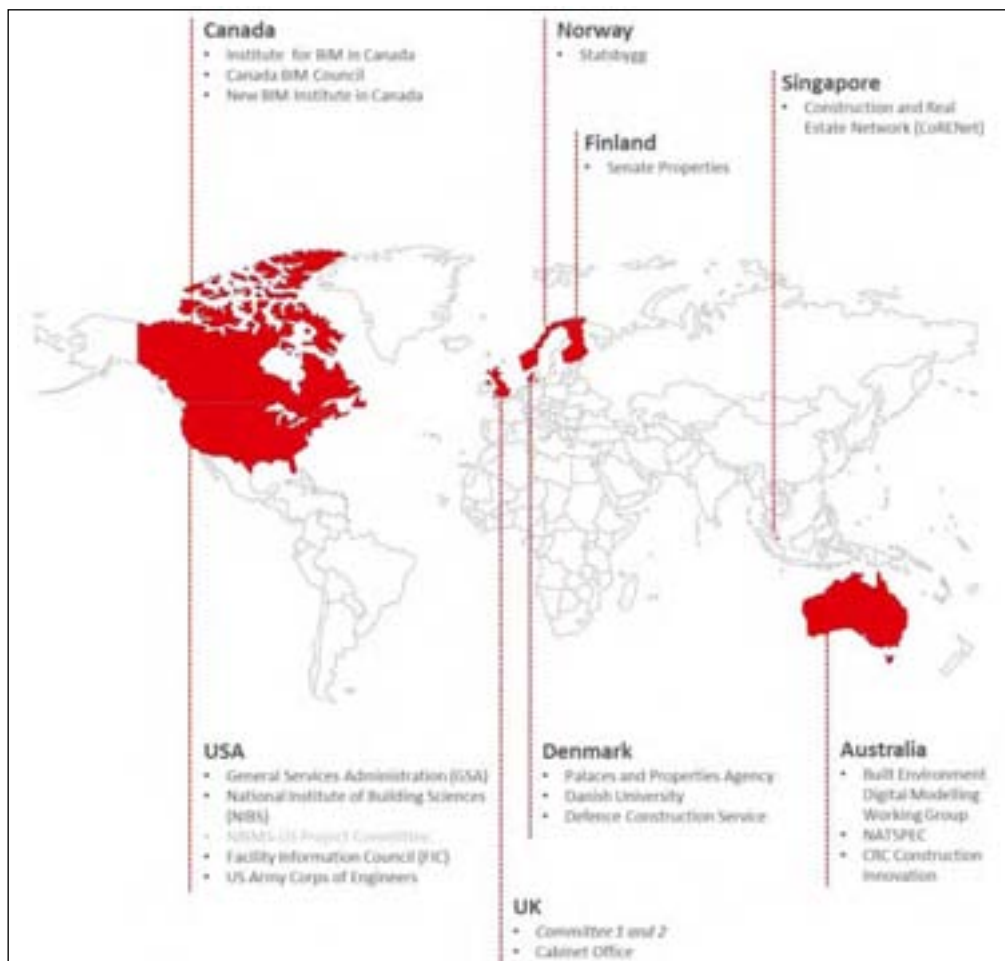

Fig. 2: The main entities involved in BIM development and standardisation (Source: OSELLO, Anna. 2012).

Fig. 3: Some of the most important documents about the spread and standardisation of BIM methodology in the world.

Since May 2011, the British Government has launched a full program of works on the organization and the management of the entire construction industry in order to obtain not only a significant saving of resources, but also an increased quality of the products and of the services generated by the parts involved in the construction sector and in the related fields. The National Building Specification (NBS) is a UK-based system of construction specification used by architects and other building professionals to describe the materials, standards and workmanship of a construction project. One of the initiatives promoted by the corporation is related to the development of a database of BIM objects for the construction industry, with free access for all professionals in the construction industry. The *National BIM Library* contains thousands of IFC files (windows, walls, partition walls, foundations, boilers, etc.).

They were put online by the producers as a means of advertisement. This give exposure to the products and at the same time facilitate the work of the designers who can avail of computerized model of the architectural objects having all the features of the real objects.

Overseas, the United States of America are a point of reference also in the field of parametric modeling, so it is not by chance that there lies one of the largest software companies in the world that produces programs for the AEC.

For more than ten years, various government and private organizations have been involved in the spread of the new BIM methodology thanks to the drafting of guidelines and standards. Some examples are the General Services Administration (GSA) that since 2003 regularly update the *BIM Guide For Spatial Program Validation* [4], and the National Institute of Building Sciences (NIBS) that has developed the *National Building Information Modeling Standard* [5].

The aim is to improve the process of planning, design, construction and maintenance of the buildings by using a standardized computer model containing all the useful information for the entire lifecycle of the construction that is readable by all those involved in the building process.

3. A case study: interoperability between BIM and structural analysis software

In the habitual professional practice the data exchange between the different participants in the design process can cause inconsistencies, loss of information and misunderstandings that lead to loss time, unproductiveness and, in the worst cases, to design errors.

Traditionally, the workflow is sequential - architecture-structure-systems - and involves professional figures working mainly on bidimensional computer elaborate created with the CAD software. When you need to make changes to the plan, no matter how small they can be, a considerable amount of resources (in terms of time, energy and money) is required. Consider, for example, the case where we have to rotate a pillar and, as a consequence, to move a window, a hole or a partition wall is necessary. What may appear to be a quick correction operation becomes, instead, a complete revision of plans, sections, views, schedules, estimates, etc.

The use of the BIM software would nip this problem in the bud because all the informations regarding physical, constructive, computational characteristics of the computer modeled elements would be stored in a single database, so that the change of only one of these elements would automatically cause the change of all the other, directly or indirectly, connected to it.

Unfortunately, it is very unlikely that engineers and architects will work with the same software. However through the interoperability between BIM software and traditional software and with the implementation of a correct workflow it is possible to improve the quality of work in terms of time and precision, drastically reducing errors in the coordination stage and, later, in that of realization.

The examined case study, the design of a small house, shows how to work with a BIM software (in this case Autodesk® Revit Architecture 2011) plus a software for the FEM analysis (in this case the CDSWin, 2010 release, by STS®) used to calculate the reinforced concrete structure. The intent is to show the workflow used to made both tools efficiently communicate, under the architectural and structural aspects, thus ensuring a profitable interaction between different professionals who do not use the same software.

To ensure interoperability between the two examined programs is essential to follow a design 'protocol' so as to ensure, on the one hand, the data input speed and, on the other hand, probably the most important aspect, a reduction of redundant elements. Working with Revit Architecture 2011, the building is three-dimensional modeled from the architectural point of view: you define the type and the quality of materials, the physical and mechanical properties, the colors and everything is essential to realise, for example, schedules of environments, schedules of window frames, energy assessments, economic estimations, etc. (Fig. 4).

For the modeling of the structural elements and for the realization of the architectural model, always using Revit, you need to define grids and levels: the grids allow to identify unambiguously the position of beams and pillars in the horizontal plane XY, the levels set the quotas of Z of the floors. The intersection between the grids and the levels generate the nodes that, within any FEM software, represent the points of connection of the pipes and, therefore, the basic elements of the matrix analysis.

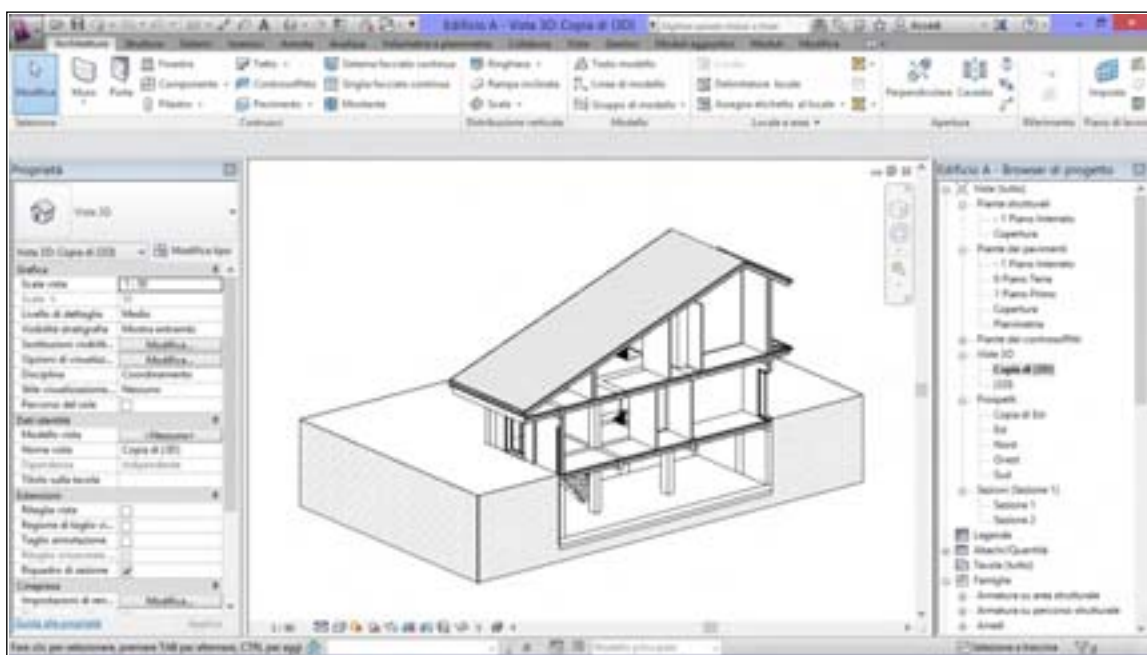

Fig. 4: Axonometric section of the architectural model in Revit.

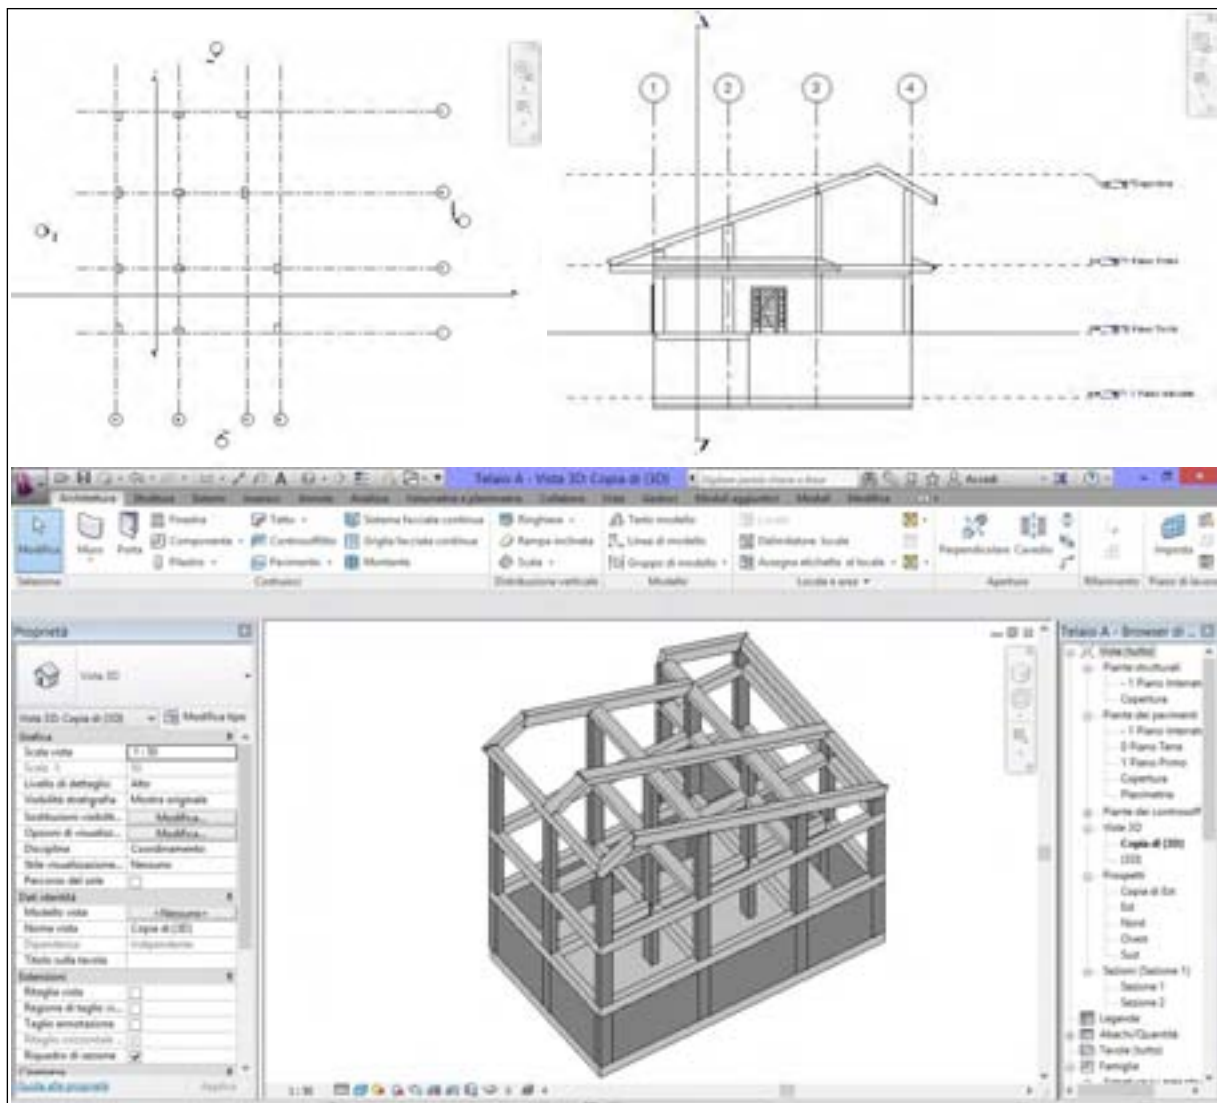

Fig. 5: Input of grids (at the top left) and levels (at the top right) for the structural modeling (on the bottom) in Revit.

Since this stage it is possible to notice any possible interference between structural and architectural choices that can be easily and immediately solved. The following step consist in the three-dimensional modeling of the structural elements (columns, beams and floors): in the case of traditional structures, it is advisable to proceed by levels because often the joists of a building are repeated identically at every floor, and to speed up the input, you can proceed with simple copy and paste operations (Fig. 5).

In this way we obtain a complete 3D model both from the architectural and structural point of view. Although there are several Revit plug-ins to make the calculation and the analysis, we preferred to hypothesize a workflow to make interface two different software and exploit their dialogue ability based on BIM language. They are, as said before, CDSWin by STS® and Revit Architecture 2011 by Autodesk®. The STS® produced some plug-in that are able to import files from BIM software and, from these, to generate the structural scheme suitable for the calculation program.

When exporting, Revit generates a .txt file. that CDSWin is able to implement and discretize because it recognizing all objects with a structural function used in Revit. The technician can filter out the desired elements through a very intuitive window for the data interchange. After this step, CDSWin automatically generates the structural model, retaining the quotes of the floors and the dimensions of columns, beams and joist without loss of data. From this point, the step of real calculation can start (Fig.6).

The flexibility of this design process lies in the fact that the designer can, at any time, make changes to the new model that is imported without any constraint. He can insert or delete elements, or can make other modification to the sections or to the materials. This method turn upside down the traditional approach but the effort made to cope with such drastic changes is well balanced by countless improvement such as an easier and clearer exchange of information and a reduced possibility of error.

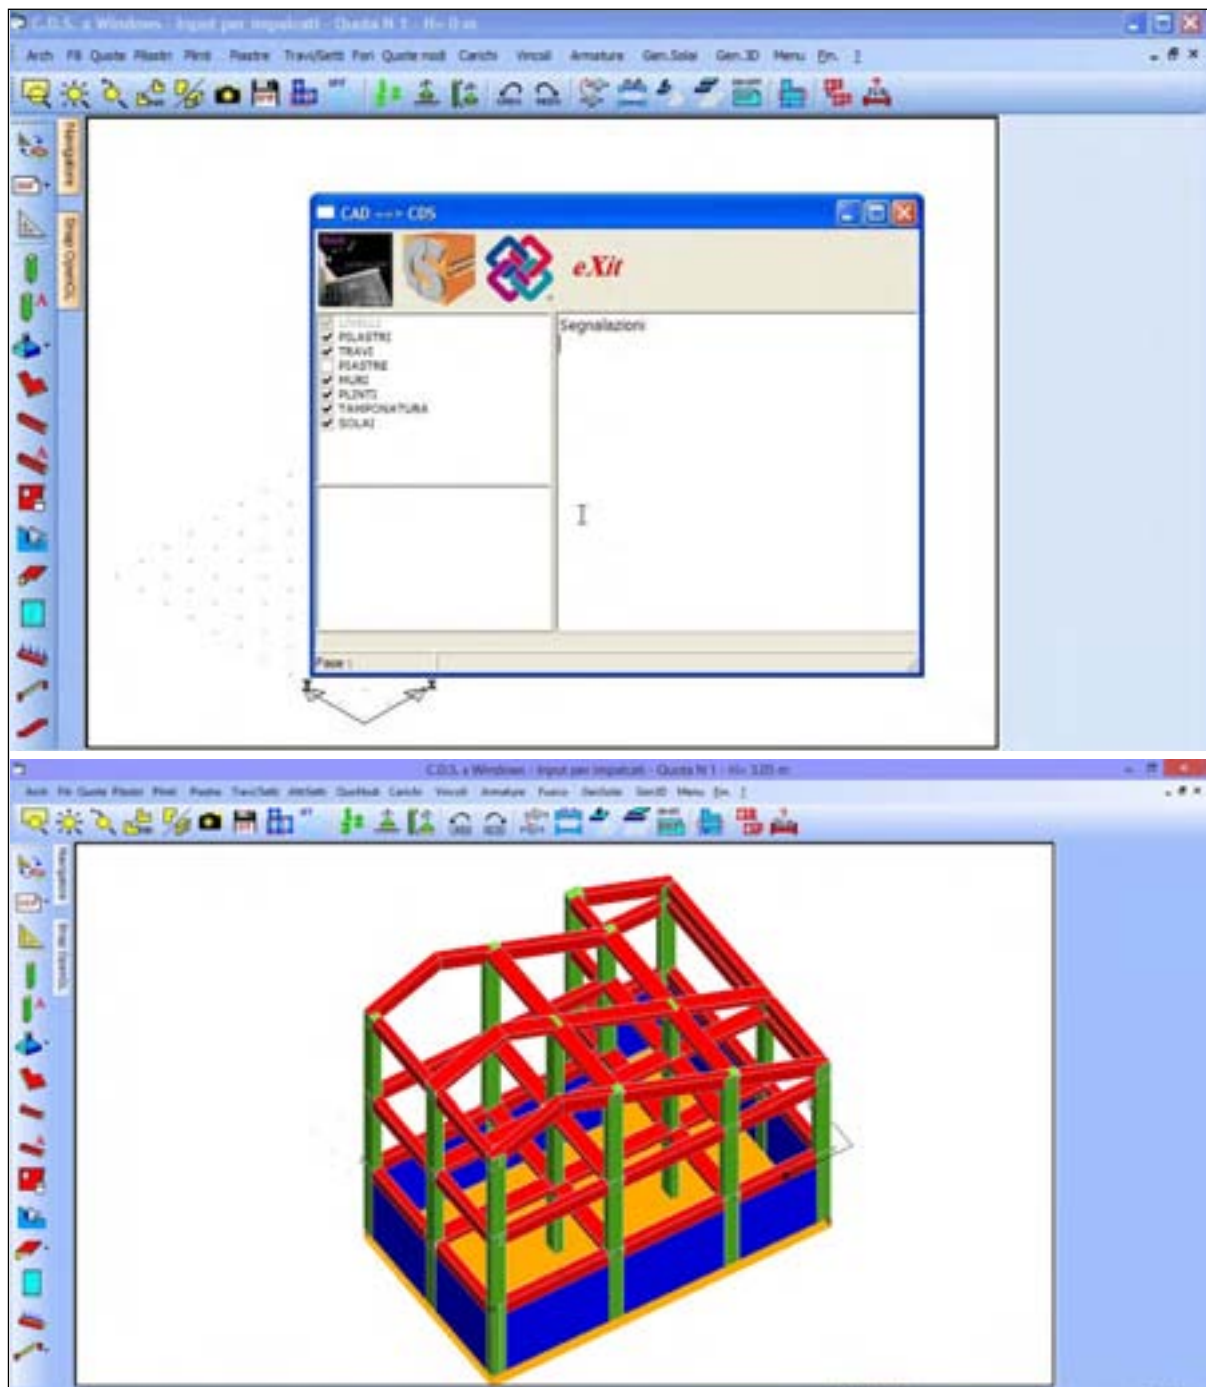

Fig. 6: Import of the structural model from Revit to CDSWin.

The traditional process, instead, involves a preliminary step of design and analysis based on the reading of the architectural design. This means, inevitably, the creation of multiple and uncoordinated models that affect the productivity, the efficiency and the quality.

4. Conclusions

The growing worldwide adoption and implementation of BIM for its powerful data-based modeling, visualization, analysis and simulation capabilities represents the start of a transition to an integrated digital information infrastructure that will ultimately revolutionize almost all aspects of the construction industry [6]. For this reason it is essential to identify specific actions: the construction industry have to become the driving force for the diffusion of BIM methodology, the institutions have to adopt new softwares, the software house have to simplify the interoperability between the different commercialized products and research institutions have to sensitise students and professionals. A radical reform is needed.

The proposed case study shows that even small projects can be treated with the BIM method and it also shows how it is possible to make professionals with different know how interact. Unfortunately, the spread of BIM through small and medium design company is limited by several factors such as the initial onerous investment in buying the software license and the long time needed for the professional education of the team). Due to the economic crisis we are undergoing, the inclination to make changes and innovations is lowering. It is clear, however, that the transition to this method may turn out to be just the solution to this stagnation as it can be seen as an important opportunity to work with high profits and shortly regain the initial investment thanks to the high efficiency that this method would ensure.

Rural and urban courtyard houses in Campania region- Changes in the education and planning of architecture in public and private sector

Massimiliano RENDINA

Department of Architecture and Industrial Design "Luigi Vanvitelli", Second University of Naples, Italy
massimiliano.rendina@unina2.it

Abstract

In a few years the edifices built at the edges of the countryside and close to downtown have been transformed from a series of demolitions and reconstructions. The thick buildings, which took the place of the rural courtyard houses, are very close to each other at times, other times are distant like they staggered in the skyline of the roads in the city suburbs. Straight roads are full of two floors tuff stone houses, which often include old courtyards. This have create a wide variety of ideas, which were never or badly used in the current building practice, and which can and must become the basis for a reflection on the construction of a new kind of urban suburb. Using first, as source of inspiration, some pictures which underline some critical issues of the cities and then using as source the results of a PhD research and a model of a project in the same field, we tried to draw the attention on the environmental problems about which society is more and more concerned. Furthermore, we carried out two lab tests on the same subject, which outline the didactics from the 80s till today (1_ many patio houses together in little districts, 2_ one single house with a courtyard made by putting together different pavilions). Finally, we made two buildings responding to the theme of the courtyard space and of the peristyle in Campania. Briefly: if people slowly become aware of the importance of the environment, builders must safeguard both.

Location of the three places object of the project in the area of Caserta

1. Build up anew

This part of the work is intended to be a short study on which kind of houses, cottages, apartment houses and settlements are more common in the rural and suburb areas in Campania. The study has been carried out by sampling, using the logic of the single event or even through tests on a little piece of land, heritage of old methods and of urban planning in renovation. The result is that nowadays residential buildings and new built-up areas, filling empty spaces or improperly replacing existing ones, are unconsciously writing the chapter of the 'real estate speculation', which has spread settlements everywhere in almost sixty years [1]. Reinforced concrete and innovation, as well as the demand for new houses, have contributed to the consumption of the territory, which today means 'wildfire' construction.

Besides, the responsibility for the choices that were made, improperly described as strategic and shared between politicians and planners, has made the action of time irreversible. The settings chosen for the examples and which are illustrated through pictures, drawings and sketches, focuses on suburbs and countryside areas in the province of Caserta, which were ruthlessly rebuilt or just analyzed in studies. The first place we studied was S. Maria Capua Vetere and the edges of the Sant'Erasmo district. The area is full of big tuff stone houses with a central courtyard alongside narrow streets where generations of hemp farmers (then tobacco farmers) used to live and where newly built two floors houses are slowly replacing the old buildings. Many state that these are very sporadic cases, but they actually know that dozens of new concession will soon be approved, some others justify the buildings staying way behind the street line by claiming questionable regulations on the distances; there are even those who wish the spreading of the phenomenon so that streets will at least be bigger. The truth is that everything happens without a proper urban planning, or at least an idea of the appearance the city should have. Even though it's necessary to impartially assess the demand of the real estate market and recognize that multiple houses in small towns are almost built using terraced houses and in-line houses, the general description provided from the following pictures is almost worrying and predict a chaos which would barely be controlled.

Insertion of reinforced concrete on one side of an old building along a road of the rural suburb in S. Maria C.V

(1_partial view of the road; 2_close view)

Example of a break in the row of rural tuff stone courtyard houses with a new building standing way behind the street line – three floors reinforced concrete apartment building with in-line constructions – S.Maria C.V.

New building with no reference to the location – piece of land with terraced and in-line houses overlooking a green space between Capua and San Tammaro-Santa Maria C.V.

The second stage of the study was made on an old street in Casagiove, which lead to a little part of the city that some years ago was the topic for a study on the urban characteristics of middle cities the area of Caserta [2]. This area, which is made of a series of courtyards iso-orientate [3], was chosen for a study of urban analysis and which inspired a study for completing the edge of a town, along the axis of the old city of Capua. The results of the study were quite interesting, but even more interesting was a project of modern courtyards, adapted to the dimensions of the old ones.

2. An in progress research

966

Service module and aggregation of the patio house.

Arch. Luigi Fratini – extensible house
from Domus 214/1946

The roots of the patio of the modular home go back to some thousands of years ago when it rapidly spread into the Mediterranean area and in Greek. It is intended as an outdoor extension of the indoor (living room, bedroom, etc.), a kind of filter between the street (or small balcony) and the house, which can solve the problem of light of the buildings, allowing to blend the outdoor with the indoor. The courtyards, around which the pavilions of the second study are installed, have the same origins of the patio in the first study, however very similar to the peristyle in Pompei and the abbey's courtyard. In the first type the parts are assembled together, living area, service module and patio. In the second one, which has a big court yard at the center, three buildings are put together, each with a different aims and different dimensions. The first one has only one floor with a living room, the second one it's a two floor house with outdoor stairs and with a sleeping area and the third one with the kitchen, indoor stairs and basement.

Outline of the three pavilions
dell'esercitazione di laboratorio

study model of a pavilion house
(allievo Gianluigi Zarro a.a. '98 - '99)

We carried out three lab test, one for each pavilion, plus one for the entire final composition of the house. As in recent years the researches concerning the functional potentials of the house with its own courtyard has made progresses (see Le Corbusier's Immeuble Villas made in 1992, or Ludwig Hilbersaimer, who in 1931 writes: "we can give the possibility to live in an open space area even to those who doesn't want or can't have a little house with a garden") till the vertical forest of Stefano Boeri, today we need to carry out new studies on the districts full of big courtyards in the rural periphery which are going to be dismantled. Besides, we should find new solutions to a new kind of building which feet the demand of the real estate market without distorting those parts that are typical of urban spaces.

3. Two coutyard houses in Campania

The following images show the results obtained by realizing small plastic models set between tradition and contemporaneity and which were compared to each other. The topic is quite the same of the previous studies: a central empty space, with colonnades and pavilions defining the dimensions. The first one it's a private house in the countryside, while the second one it's a communal space for young and old people in a public garden in the popular district in Sant'Agata in Capua.

The museum of the territory. Notes for active conservation

Ef시오 PITZALIS

Dipartimento Architettura e Disegno Industriale Luigi Vanvitelli, Seconda Università di Napoli, Aversa, Italy

E-mail efisio.pitzalis@gmail.com

Abstract

Recent contributions, efforts and programmatic indications have identified in the heritage of archaeological sites and monuments of our country, one of the most extraordinary “outdoor museums” in the world. It is becoming increasingly urgent to make an ongoing commitment to environmental protection and conservation, but also useful to consider the enhancement and development as an authentic cultural resource and economic importance especially for the South and the islands.

In this projection, one of the main themes, which focuses the activities of the various sectors concerned, is the provision of planned infrastructure projects and services necessary to develop the territory, according to an economic impact with a tourism/cultural application. In this sense, some Community action programs – such as the Treaty of the Union – aim to reconstruct the complex mosaic of goods considered essential to Europe in order to reclaim a common cultural heritage. Similar programs, envisaged under the cooperation between States, promote an exchange of knowledge both from a technical point of view as well as with regard to the use of human and financial resources. An interchange between research institutes is responsible for cataloging the most appropriate use of the different technologies as well as considering employment opportunities in the field of restoration, rehabilitation and preservation.

Keywords: heritage, monument, museum, archaeology, resource

1. Section

The main purpose of scientific research in the preservation of archaeological and artistic contexts consists in the formulation of a useful vocabulary to verify the consistency of the project interventions in areas of particular historical value. Through the paradigmatic works, the different technologies of intervention are compared, from the technical, structural, and linguistic aspect, with the aim of establishing a classification tool of the techniques and materials used in the various European realities. Thus, reference is made to issues that have as their main objects:

1. the adaptation of new structures on pre-existing monuments and archaeological sites;
2. the problem of discontinuity between “new” and “old”;
3. the question of an integrated intervention but recognizable.

Elements are therefore aimed at promoting an active use of the archaeological remains from a pedagogical and museum point of view, in order to correspond the demand for tourism and culture, more and more present, especially in Mediterranean area.

The Italian tradition of museology.

Since World War II, the museological phenomenon marks the national and international architectural debate through the experiences of Albini, Gardella, Scarpa and BPPR. A phenomenon in Italy - in contrast to what occurs in other European countries (for example in Germany, where the museum is a real typological paradigm) - is accompanied by the restoration of parts of great archaeological value. In the modern conception of the kind of museum, it is worth remembering the important distinction

between collecting and active experience. A distinction introduced in Italy in 1949 by Giulio Carlo Argan recalling concepts of English and American origin expressed by Herbert Read and, in particular, by John Dewey in *Art as Experience* (1934). Concepts that have an idea of museum activity oriented according to a pedagogical perspective and according to a civil and democratic engagement able to counter the pure and ecstatic contemplation of the object. A teaching vocation which is accompanied by the issue of a restoration that should not distract from the contemplation of the museum subject.

Problems and methods of intervention.

In the speeches of protection and preservation of the archaeological remains, it is important to verify the figurative, formal and technical methods to find the solution of the main problem: the coexistence of the old and the new. This verification must consider some issues related to the finding of the typological remains. The main issues include the following:

1. the problem of a more appropriate architectural language (historicist, domestic, impersonal);
2. the structural issue: timely elements, continuous elements, elements in suspension, moving parts;
3. the theme of the base in relation to the variation of the different historical stratigraphy;
4. the way of overlapping in relation to the physical discontinuity;
5. the issue of large roofs and transparency;
6. integrated intervention but recognizable;
7. the modeling of the topography in non-urbanized areas;
8. coexistence with the urban structure.

Case-Study

The project, presented as a demonstrative example, is a thesis developed by Marco Russo within the Planning Workshop at the Department of Architecture and Industrial Design Luigi Vanvitelli. It is a "Centre for Underwater Archaeology" located in Baia (Napoli), and is constituted by a volume of coverage place as protection of archaeological underwater remains.

Design of multimedia archaeological park in the Mediterranean area. Survey, modelling and communication. The case of Leptis Magna.

Chiara SCALI, Andrea MANTI, Domenico TOSTO

Department of Architecture and Territory, University Mediterranea, Reggio Calabria, Italy
E-mail chiara.scali@unirc.it – andrea.manti@unirc.it – domenico.tosto@unirc.it

Abstract

Presentation of an overall project of reutilization the archaeological site of Leptis Magna (Libya): virtual reconstruction, design and communication of the archeological park for entertainment and a guided tour of the site.

The project is an integrated action program for the revitalization of one of the most important Unesco sites in North Africa, result of an extensive study on archaeological sites in the Mediterranean area conducted in the Final Laboratory of Degree in Architecture.

The study of these sites was the scientific and methodological basis for a two years Master's program in "Design of multimedia archaeological sites in Mediterranean area. Detection, modeling and communication."

The aim is to develop knowledge of an interdisciplinary nature with the specific objective of merging different experiences and skills for the design of multimedia archaeological parks.

The research aims to form a common language between archeology, architecture, computer science and environment, in order to achieve better coordination in the professional field between different disciplinary expertise, in reference to the knowledge and enjoyment of the vast archaeological heritage settled throughout the Mediterranean basin including through new systems of education and communication media and virtual.

Keywords: Architecture Survey, 3D Modeling, Visual Communication, Archeological park, Web App.

1. Design of multimedia archaeological park in the Mediterranean area. The case of Leptis Magna.

(Chiara Scali)

A deep transformation in the cultural heritage has produced in recent years a gradual opening and a different consideration to the places of culture, considered not only as an heritage to preserve but also to highlight and revitalize. In this perspective, new trends in architectural and urban regeneration have been oriented to the use of innovative methods and instruments in the fields of conservation and reuse, as well as demonstrated by the argument of the General Forum.

According to these themes, the studies conducted for several years by the research unit of Prof. Francesca Fatta are focused as part of the survey aimed at re-use and enjoyment of archaeological sites. In particular, the research examines the multitude of historical sites in the Mediterranean area, and especially in North Africa, whose historical importance is in some cases underestimated and enjoyment by the public remains often superficial.

To this end we conducted more in-depth analysis on the ancient city of Leptis Magna, Libya, studying new possibilities for the use and knowledge of an archaeological itinerary.

The ancient Leptis Magna, founded at the beginning of the first millennium BC, was one of the oldest Phoenician colonies in Africa and established, together with Oea and Sabratha, one of the main ports of the ancient region of the "Emporia", also known under the greek name of Tripolitania (just "three cities"). Declared as UNESCO World Heritage Site since 1982, Leptis Magna is one of the most important archaeological sites internationally known, especially famous as the largest and best preserved Roman city in the world.

Encouraged in all its history by its geographical location in the past for the ease of access from the sea and the possibility of docking thanks to the river Lebda running through it. and, over the centuries, thanks to the sand that has submerged and protected, and then give it back to us almost intact. Leptis that preserves Punic and Roman ruins, is an exceptional testimony of Roman history, particularly the high point and the architectural brilliance that goes back to time of Septimius Severus who was born in Leptis in 146 BC, who promoted the city growth and monumentalisation.

Walking through the ruins of the monuments is like enter onto a path backwards in time, where it's possible observe and understand the typical composition and organization of urban of a Roman colony.

Fig. 2: Leptis Magna, an integrated system of fruition and communication.

Despite this, the archaeological site of Leptis is largely untapped: currently the only existing service for visitors consists of a small museum pertaining to the archaeological site. The lack of pathways between the different monuments, the insufficient services for tourists, the total absence of a communication system, leading to reflect on the importance of integrated redevelopment interventions in archaeological sites such as this one.

We thought therefore to propose a reuse project of the whole site, that starting from the survey and from the virtual reconstruction of spaces and monuments, arrives to encode an integrated system of fruition and multimedia communication. A project that, in this case, does not result only in tangible objects but also in a complex grid of "immaterial architecture".

Nowadays, the design of an archaeological park can and must go through the new possibilities offered by the web and new technologies of communication and information instant sharing, to a new and more current understanding of entertainment and increased participation during the guided tour.

In addition to "physical" design of paths and main systems of green, lighting, services and exhibitions we planned the design of a system of intangible paths that guide the user within the equipped areas during his visit. Through a multimedia system that uses GPS technology and web-apps, the visit becomes interactive and the whole archaeological site becomes a virtual museum in the open air in which every real monument corresponds to its virtual counterpart, complete with historical information, curiosity and virtual reconstructions.

In this process the graphic project plays a role of primary importance: in the exact identification of the individual thematic areas, in the park internal communication, through the development of signage and corporate communications and also acquires a fundamental role in the next, immediate, identification of places and monuments through the creation of *ad hoc* icons, shared and used then interactively on the web-app.

The appearance of virtuality is increasingly one of the most immediate and effective forms of promotion and attraction for the facilities - museums and archaeological sites - inserted in a logic of cultural tourism ever more demanding and competitive. The ultimate goal aims at the creation of an archaeological park whose design results the least invasive as possible, in accordance with the evidence of the past, which demonstrates how there can be an exchange common ground between archeology, architecture, information technology and environment.

Fig. 3: The archeological park: tangible objects and immaterial architecture.

2. From real model to virtual reconstruction

(Andrea Manti)

The project phases of the virtual museum inside the Leptis Magna archaeological site, contemplate that the various types of data are collected and processed using different methodological approaches, to eventually then be integrated into a single interactive environment.

In recent years is emerging within the international community of archaeologists a strong interest in Virtual Archeology. The term "Virtual Archaeology" was founded in 1990 when Paul Reilly (pioneer in Virtual Archeology) first proposed it in reference to the use of three-dimensional models of monuments and objects.

This discipline is capable of giving access in a visual and interactive way to data that are otherwise would be difficult to control. Through the construction of 3D models and simulations it is possible to create a cognitive process of the past and make it accessible to users through an interactive display system.

We can therefore affirm that virtual archeology is a process of acquisition and simulation, as well as a tool to rebuild something that is no longer visible.

Modeling and three-dimensional reconstruction of the whole territory of the ancient city of Leptis Magna with its major archaeological monuments and the online publication of processed data were two of the main aims of this project. To achieve these objectives has been planned a phase of *in situ* data acquisition and another one of processing in laboratory starting from historical, architectural and archaeological sources.

Finally the 3D models have been optimized and rendered in order to be included in a web platform accessible through an App installed on mobile devices such as smartphones and tablets.

Concerning the realization of virtual models we have followed two different approaches:

1. metric data acquisition of the site and the archaeological monuments through techniques of integrated architectural survey, aimed at their graphic restitution and representation;
2. create, using the software Autocad, a three-dimensional model of the city, in its landscape, and of the most important buildings with its appearance in the ancient times.

Fig. 4: Sample of virtual reconstruction: model of the Theatre and Market area.

Fig. 5: Bird's-eye view of the three-dimensional model.

2.1 Architectural survey of the archeological site Leptis Magna

One of the first problems encountered during the development of the project was the choice of a correct acquiring technique of the monuments metric data in regard of the size of the site. The communication and promotion of cultural heritage require an extensive documentation in terms of location, shape, color, geometry and also historical and artistic characteristics. The disciplines of the architectural survey have honed in time the techniques of data acquisition in step with technological development. The greatest expectations in the sector of Cultural Heritage are aimed at 3D laser scanning techniques; this system is able to operate quickly and give the opportunity to access to the data in real time. The ancient Leptis still presents a wide variety of very complex cases and situations because of its urban plan.

Currently inside the archaeological site there are ruins of important monuments. Some of them have the original structures almost intact.

This has been possible thanks to the fact that they remained protected for centuries under a heavy blanket of sand that in some places reached 10 meters in height.

The used methods are photogrammetry and architectural surveying through Laser Scanner 3D.

These two methodologies have provided all the elements necessary for modeling the analyzed object and their integration has provided the best results in terms of reliability and completeness.

The architectural survey through the terrestrial laser scanner CAM2 Focus3D generated in a few minutes dense clouds formed by millions of 3D points. The point clouds obtained were combined and filtered through the software SCENE and provided detailed and accurate images of detected objects.

In some cases we used more traditional techniques of survey to complete the acquisition of the data.

2.2 Three-dimensional modeling

Once finished the *in situ* survey operations we got on to the next stage of data processing and three-dimensional modeling in laboratory.

Starting from the metrics data originated from the acquisitions we have reconstructed the entire urban system in order to contextualize in the best way the ancient monuments and to create virtual tours in the archaeological park. We proceeded to virtually reconstruct the ancient urban plan modeling quickly the entire built-up area with a good level of definition of full and empty spaces.

There has been a complete control over the entire scene structuring in a hierarchical manner the various elements thus obtaining a large amount of structures all different from each other.

Because the ultimate aim is the online use of the 3d models we decided to represent with simple and schematic forms the buildings of the town, while for the monuments have been used different levels of detail. The virtual reconstructions are very useful in the understanding of ancient architectures. This is even more true when the aesthetic perception of the structure is ensured both in architectural entirety as in the decorative system. For this reason it has been adopted a manual technique of three dimensions modeling to reconstruct the ancient phase of monuments such as the theater, the thermal

baths and the arches, and to make them usable in real time. All reconstructions have been verified by archaeologists in order to ensure philological and scientific accuracy.

The 3d models were constructed with the software Autocad starting from the data obtained from the survey operations. To use 3D models within a virtual reality application we had to work on different levels of detail.

To create the more complex objects, such as capitals, we used surfaces made up of several polygons in more detailed versions and a smaller version for minor variations.

For the texturing of the 3d models has been assigned to the surfaces a neutral color material with the intention of giving a plastic effect to the object, therefore virtual, with the full intention of putting more emphasis on the spatial structure of the model.

2.3 Communicating the site through the Web App

The project didn't end realizing and rendering virtual models, but all the research material and virtual reconstruction was collected in a web-app available on the Internet at <http://leptismagna.altervista.org>. The web-app created can be used like an interactive and multimedia guide as a navigator in the archaeological park.

Through a dedicated Wi-Fi network visitors can always know where they are, to be guided in their itinerary and get detailed information about what they are seeing. The park planned is designed as a virtual museum at the open air. Various paths connect different thematic areas and each area is like a museum room that exposes something. The most important rooms are those containing the monuments where will be placed a QR code. The QR Code (Quick Response Code) is a kind of bar code that is associated with the visible contents on mobile devices, the latest generation of smartphones and tablets.

Generally these codes connect the device to media content contained in a web page.

In this project through a QR code reader installed on the mobile device, once launched the application, simply frame with the camera the code and immediately will activate the visualization of the virtual reconstruction of the monument we are visiting, with a panoramic view of 360°.

The code must be placed on a pedestal that, once scanned, will allow to have the exact correspondence between the real and the virtual perspective.

We wanted to transform real space in virtual space where the individual monuments are displayed in their original form. Many museums have a website where the monuments are displayed in virtual space. In Leptis Magna the site becomes a virtual space.

In this way the monument is not taken out of context from its original site and the visitor also has the chance to see the actual state where there is a monument (real) and its reconstruction (virtual).

Fig. 6: QR code solution.

Fig. 7: Virtual tourist guide solution.

3. Multimedia archeological landscaping in Mediterranean area. Survey, modeling and communication.

(Domenico Tosto)

The main element of the research project carried out in recent years by the team coordinated by Prof. ssa Fatta, is its interdisciplinary character, whose ideal conception is the planning and the fulfillment of a master.

The specific aim of the master consists in comparing precise academic specialities, such as Archeology, Architecture, Engineering, Town Planning, Design and all the different academic field within Cultural Heritage, in order to succeed in developing expert researchers able to work in a competent manner and high standards in "Virtual Heritage" field.

The vast archeological heritage particularly in regard to the archeological sites and areas in the Mediterranean, will be the implementation and the interaction of all the different knowledges and disciplines involved in the development of a common language and a better coordination among the professions.

The organization of the master will provide a new course of study, both combined and coordinated, in order to give students the basis classical knowledge together with all specific competences on understanding and employing the modern technologies to value Cultural Heritage at its best.

The new profile of researchers will be able to understand, analyze and deal with cultural heritage and above all they will have every planning and program skill to create multimedia archeological parks.

The course involves students to get in-depth analysis of specific topics in areas of historical, archeological, and basic representation of architecture and archeology.

Procedures and specific protocols about different methods of survey will be investigated: manual, instrumental, topographic and photogrammetric.

The course also provides the use of specific softwares which are designed to perform various tasks, starting from the documentary research of the study area, the integrated management, the subsequent processing of all the collected data and the preparation of representative models designed for thematic or dynamic representations.

Computers and technology provide knowledge and essential aids to the "Virtual Heritage" field and are getting more and more important nowadays.

Today the most relevant aspect of interventions in cultural heritage involves the creation of a database, a data repository that can be used both as a historical memory, the DNA of a past whose traces have been survived up to the present days or they can be processed for the realization of digital models which become the basis for the creation of museums and archaeological parks built among artifacts, landscape, and communication.

They are specific tools to study the deep relationship that links tourism, local development and cultural heritage legislation.

Smart communities and local company museums: two new concepts for the Mediterranean Museum System of Design and Applied Arts

Claudio GAMBARDELLA,¹ Jochen SIEGEMUND²

⁽¹⁾ Architecture and Industrial Design Department "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Aversa, Italy

claudio.gambardella@unina2.it

jochen.siegemund@c-i-a-d.de

Abstract

The idea of creating a "Mediterranean Museum System of Design and Applied Arts", as an extension of the "Officiamuseum" originally planned for the Campania region and will be based in Pompeii, intercepts many important issues affecting the arts and sciences: the development of artidesign capable of giving a voice to the material cultures of the euro-Mediterranean area and successfully establish itself within the global market shaken by the recession; the possible interaction between museums of specialized craft, applied arts and design to enter into cultural energies in the necessary process of revitalization and modernization of existing artisan production activities; the management of a complex system that seeks to involve various countries, culturally, politically and economically distant from each other, inspired by the concept of Smart Cities and Communities.

The local company museum project should be representative of a "productive landscape" such as the Museo Casa Enzo Ferrari resulted in a public competition by the Municipality of Modena that wanted to celebrate the many brands in the field of cars and motorcycles established themselves in the area.

The aim is to treat these two issues in order to explore and characterize the idea of the System, in this initial phase generated by contributions from the Cologne University of Applied Sciences, Okan University in Istanbul and the Second University of Naples.

Keywords: System – Mediterranean – Company Museums – Corporate Architecture – Artidesign

1. Introduction (Claudio Gambardella)

The project of the Mediterranean Museum System of Design and Applied Arts, following the 2012 edition of this Forum with our friends from Turkey and Germany, is becoming increasingly popular body. The "System" consist of numerous artistic and scientific themes, which include: the development of artidesign – as a third genre between design and craftsmanship – capable of giving a voice to the material cultures of the Euro-Mediterranean basin and, at the same time, establishing itself successfully in the global market shaken by the crisis and crossed by a thousand considerations of growth, post-growth and decline; the possible interaction between specialised craft, applied arts and design museums to insert cultural energies into the necessary process of revitalization and modernization of existing artisan production activities; the draft Company Museums of the territory that, unlike the corporate museums tout court, must be representative of a "productive landscape", and finally, the management of a complex system that aspires to involve more countries, culturally, politically and economically distant from each other, inspired by the concept of Smart Cities and Smart Communities.

Fig. 1: strategic scheme of Regional Museum System of Design and Applied Arts – Officiamuseum (graphic design by Mariacarla Panariello).

2. The idea of system

The idea of system, widespread in the scientific world, has a chance of being implemented even in architecture. It is worth highlighting some basic points that have provided suggestions for subsequent considerations contained in this paper. The famous book *Uncommon Wisdom* by Fritjof Capra [1] tells of important meetings with important members of the worlds of physics, biology, psychology, economics, politics and culture of the 1900s, that the author, a former “flower child”, had when travelling to every corner of the globe. However, it is in another book, *The Turning Point* [2], that Capra develops the scientific content discussed in those meetings, such as the studies of the American physicist Geoffrey Chew (1924). In contrast with the “quantum field theory”, Chew launches in 1961 the manifesto of the “S-matrix theory”. The central core of this theory is the “bootstrap” concept that indicates a system of “self-consistent” relations between elementary particles. In this perspective, a particle is no longer an entity ontologically determined in absolute terms but is defined only in terms of its relations with the entire corpus of all the others. Despite the new theory having been surpassed by further developments and experimental confirmation of quantum field theory, its influence on the construction of the contemporary world was notable. According to the bootstrap theory, Capra argues that “nature” is not understood as a composition of elementary entities with certain basic properties, but rather as a dynamic fabric of interconnected events in which no part is more important than another. The reduction of nature to elementary components comes from Greek philosophy, which is dominated by the dualism of spirit/matter, while the conception of the universe as a dynamic fabric of relations is typical of Eastern thought and has always fascinated Capra, leading him to write his most famous book, *The Tao of Physics* [3]. The theory of Chew is a philosophy of the “canvas”, “network”[4], a philosophy based, therefore, on a structure of relationships. In fact, the *bootstrap* theory is very close to a general systems theory. It insists on relationships rather than isolated entities and, as the vision of systems theory, it perceives these relationships as inherently dynamic.

All that the worlds of science, culture and art produce, can and should flow into the world of design, periodically triggering the crisis of its doctrinaire systems, allowing fresh air to enter into the closed rooms of the disciplinary apparatus. If it were possible to apply the concept of network and system to architecture, it would be possible to get nearer to the essence of historic centers, for which the phrase “urban fabric” has been coined. It is worth considering cities like Siena or Palombara Sabina, 10th century historic centre, as well as the very different Corricella, an ancient fishing village on the island of Procida, “architecture without architects” that developed over time. It is easy to see that the chorus of these centres is not the result of a mortification of formal pluralism and that the differences do not affect the substantial unity of the buildings. These three paradigmatic examples could also include some of the considerations made by Gregory Bateson [5], dealt with in the books by Capra and summarized in the imperative “to shift the focus from objects to relationships”. Perhaps the Middle Ages, is therefore the most modern era of our time? Perhaps the way of designing and building in the past, even with the construction of towers, cathedrals and ducal palaces, anticipated a “systemic” vision that is more advanced than what, in the globalized universe, we are able to produce today? It is not a question of construction methods, functions, architectural language, but of ability to see the land as a living network within which to create a dialogue with a new architectural intervention or a simple re-use of an existing building, such as in Procida.

Fig. 2: Procida island. The village of fishermen, Marina Corricella, is an example "work in progress" of "architecture without architects".

An example of how to apply systems thinking to contemporary architectural design and what the transition from objects "architectonic" relationships could mean is the Nelson-Atkins Museum of Art by Steven Holl in Kansas City [6], the United States, completed in 2007. The project consists of five interconnected structures as opposed to a single large existing building. The five buildings give rise to new spaces and new points of view. Steven Holl fused architecture, art and landscape into a unified experience. The project was part of a larger project that led to the annexation of more than 15 thousand square meters of new exhibition space to expand the old structure, expanding the "Sculpture Park" as well as a new exhibition of the permanent collections. "The annexation – said Steven Holl – does not translate into an object: we envisioned a new model that fuses architecture and landscape. In contrast to the stone building, the lightness of the new architecture in glass lens meets the surrounding landscape that takes form in the sculpture garden". It was as if Steven Holl wanted to renounce an architecture of individualism in favour of the idea of fabric between new buildings, old buildings, art and landscape, focusing on the design tension of the interconnections rather than on individual buildings, simple translucent glass blocks.

This is obviously just an example of how architecture can buy sobriety, without losing in creativity. Designing architectures as systems, rather than an alternative absolute to traditional design, stands as one of the possible ways to give new meaning, new features and new resources to the many empty and uninhabited buildings located in the rural Italian countryside that is crossed by highways, as well as to historic buildings located in small towns that are unmanageable due to their size, and entire ghost towns, with no inhabitants. A design that repairs the wounds inflicted on the territory, which heals wounds. Italy, unfortunately, bears all the hallmarks of this devastation. Nowadays, the discipline of Architecture of the Interior cannot only deal with the internal spaces of buildings and cities, but also the creation of new relationships "between architectural objects" existing within a system to be founded on its strategic and economic variations.

3. Smart Cities, Smart Communities, Smart Countries

By 2020, the EU will have invested about €11 billion on the European project that promotes e Smart Cities; medium-sized urban realities – with a population between 100,000 and 500,000, a catchment area of less than 1,5 million people, but with at least one university - that a study carried out in 2007

Fig. 3: Steven Holl, the Nelson-Atkins Museum of Art, Kansas City (Missouri - U.S.A.), 2007.
<http://rsteins.wordpress.ncsu.edu>.

by the Polytechnic of Vienna, University of Ljubljana and Polytechnic of Delft estimated about 600 (hosting nearly 40% of the entire urban European population). Now, the projects that are being developed, funded and, in some cases, created relate to interventions to improve the lives of citizens in the six areas identified by this study: Smart Economy, Smart Mobility, Smart Environment, Smart People, Smart Living and Smart Governance. Europe is, therefore, encouraging the “intelligent” community that go towards solutions “integrated and sustainable offering clean and safe affordable energy to citizens, reducing consumption and creating new markets in Europe and elsewhere”; a consideration, in line with the requests contained in the Communication “Europe 2020”, that indicates by that date the five EU targets which will guide the process and will be translated into national targets. They relate to employment, research and innovation, climate change and energy, education and the fight against poverty. They are, in essence, interventions on the existing city, primarily aimed at the production of intangible goods, such as the provision of new services to citizens, or the implementation of a network of connections between people.

With the smart cities, there is to a new myth. It is in the intelligent city that contemporary man puts all his trust and entrusts the resolution of his fears. Salvation with the help of technology, he wants to put things right, remedy a serious situation culpably caused by his behaviour, convert a hostile territory into a livable habitat became, rejecting the idea of a tragic fate, inexorable where the air, land, water are scarce or polluted. Man wants to defend his right to create new realities. Starting from the “smart” city and the new relationships that can sprout in them, rebuilding at different scales pieces of society (smart communities) so as to interconnect clusters of smart communities, also located in distant geographical areas, but held together – as in the case of the Mediterranean Museum System Design and Applied Arts – by the common thread of a creative and productive culture welded to tradition and local excellence.

4. Designing systems: The Motorway of Art

An example of a system is the “Motorway of Art. A museum 100 kilometres along”.

This a project produced by the Department of Design Culture at the Second University of Naples [9] on behalf of the Board for the Architectural Heritage of Salerno. It could be called a territorial marketing project for the A3, an Italian motorway, well-known all over Europe for the problems it has had since its beginning in the 1960s. Its layout, extremely tortuous in the Calabrian part, was designed by the Ministers and MPs of the time, which entailed very high costs due to the presence of several structurally complex viaducts. For several years, this important infrastructure of Southern Italy has been undergoing major works to be brought up to European standards, with motorists – and the tourists who want to reach seaside resorts in the summer – being stuck in endless queues. These

works are about to be completed. However, some still believe that this motorway will remain an inter-regional infrastructure to link the regions and towns it runs through, rather than provide a fast connection between the North and South of Italy.

The crucial point along this motorway, the place where to start to put in place a major project, is Padula, with its Charter House (one of the most important in Europe) – with its perfect conditions, its recently-acquired ability to attract international art and culture experts and quality tourism. For several years, the Soprintendenza has been promoting Contemporary Art (Exhibitions and Days) and Landscape Architecture (Hortus Artis) events curated by the art critic Achille Bonito Oliva. In these events, artists and architects have tried to give a new meaning to the monks' homes and gardens, turning the Padula Charterhouse into a Contemporary Art Centre. However, Padula, which is very far from the main city – Salerno, is not important enough to survive over time and become a real tourist attractor, due to it not having a living soul. At the same time, the areas through which the motorway runs cannot benefit from this prestigious presence. The idea, therefore, is to re-think this infrastructure as a *motorway of art: a 100km long museum*, a prestigious tourist itinerary to rediscover historical places and cultures, art, landscape, food and wine and handicraft, exploiting the benefits produced by these Contemporary Art events in the tourist-cultural sector. The project may also support any future contemporary art events at the Charter House, which will gradually lose its isolated nature of "cathedral in the desert".

Fig. 4, 5: Padula charter house. The big cloister and a contemporary art installation into a monk's house.

The project has involved 12 exits along the A3, and has also filed the small villages which can be reached from those exits for a total of 26 municipalities. The Petina exit has been selected because of the former Sant'Onofrio Convent, a standard-type container which is particularly suitable to house temporary exhibitions, with a bookshop and a design café. The product, which at the moment is only a ruin, is located in the area of Petina, two kilometres from the exit, but away from the town, which is further up. The ex-convent has become the subject of an exhibition design project to serve as a sort of "demo" version, or prototype, to re-propose other historical containers along the motorway within 5 kilometres of any of the 12 exits considered.

In addition, imagining the motorway of art as a company, whose legal nature will be determined in due time, a *Corporate Identity* project has been set up including signs, posters, banners, stationery and museum merchandising products which will reinforce the idea of a single system and increase its visibility. A Communication project along the motorway and the Municipalities that are part of the "System" (not only those located nearest to the exits) with the setting up of information totems in museums (one has already been designed), public buildings, refreshment stands and restaurants, info points, stores and productive companies characterising the various places, etc.

To give significance to the project, I am continuing to explore the specific issues relating to the various motorway exits. In particular, until now, there have been two theses in Interior Architecture which have dealt with a very interesting aspect: the recovery of a number of farms, located at the exit of Battipaglia, understood as a subsystem of the so-called "Highway of Art". They are very unique farms, from the point of view of architecture and construction, which are almost all in ruins. Their decline, of course, began with the decline of the agricultural economy, in part also caused by the creation of the motorway itself. How can these farms be recovered? What direction should be taken? How can this project to recover the farms be linked to a more general "Highway of Art" project? The Battipaglia exit is of great tourist value, especially for anyone coming from Central and Northern Italy and going to the seaside resorts of the Calabrian coast or further south, to Sicily. It may therefore be a viable alternative to the nearby motorway service station in Pontecagnano, offering more services, including

the “non-global” restaurant, as well as a place to stop to rest as well as stop over-night. It is for this reason that we have thought of a real “community of farms” with multiple functions that can represent one of the major nodes of the “Highway of Art”. Tourists, for example, can visit the “museum of the motorway”, tasting wines and local products, listening to the “audiobooks”, borrow the books, as you do with cars or bikes rented in many European cities, returning them to other centres of the “Highway of Art”.

Fig. 6, 7, 8: .The “Motorway of Art”. General map and project of renovation of Sant’Onofrio Convent (Petina motorway exit). Rendering of the exhibition space and café design.

At the same time, the Battipaglia exit is strategic because it leads to the prestigious archaeological site of Paestum and, further on, the seaside resorts of the Cilento, almost all awarded the “blue flag”. For this reason, the subsystem of the farms, thanks to its geographical location and its architectural features, may attract Italian and foreign investors working in the food industry (think, for example, the activities promoted by Carlo Petrini Slow Food), or publishing, such as Feltrinelli. At the same time, it becomes of strategic interest for those who want to promote the productive activities of the dairy and agricultural sectors, with there being businesses many along the road that leads to Battipaglia, Paestum and the Cilento. All the resorts located at the A3 Motorway exits, from Salerno to Padula, have their own specific characteristic building, and through the reuse of this historic patrimony, currently disused, create parts of a great museum spread over one hundred kilometres. A museum that, like its contemporaries, is constituted not only by exhibition rooms, but also spaces for the so-called additional services.

It is clear then that the presence of a motorway, even when it is a poor infrastructure such as the A3, may be an indispensable factor for the creation of the system – in this case, the museum – which by its very survival. In fact, the entire structure of a motorway and state provincial, municipal roads, becomes the circulatory system. In other thesis, it is not a motorway, the backbone of the system, but a railway line that is underutilized or completely abandoned. In particular, the thesis by Gaetano Auricchio, “Live Platform”, the stretch of the railway line between the towns of Nocera Inferiore and Mercato San Severino, due to the freight and passenger traffic has declined over the years reduced to a few hours within a week, brings out an area that can easily be destined to a rural park in the service of the people who gravitate around the stations involved in the project. In the thesis (in preparation) by Fabio Carbone, more specifically related to the issues of *business museology* [8], “Irpino Wine System Museum” will have in the future the company museum of Feudi di San Gregorio as its main driver. In this case, the railway line Avellino-Rocchetta Sant'Antonio, now abandoned, is the necessary factor that can encourage the emergence of the system with 28 stations, linking a selected number of wineries in Irpinia, according to a sustainable model. With a section in Avellino of the Department of Agriculture of the University of Naples “Federico II”, where there is a degree course in Enology and Viticulture, the business system of some of the best producers of wine from Campania can be treated as a Smart Community, crossing university education, tourism, gastronomy and production activities. A renewed railway line, in fact, in addition to returning an important service to the inhabitants of the area, can be an effective non-polluting infrastructure within the system.

Fig. 9: "Live Platform", the railroad station becomes new nerve centre of relationship between city and park. Project of degree thesis in interior design of Gaetano Auricchio; Claudio Gambardella supervisor - Bachelor of Science in Industrial Design, Faculty of Architecture /S.U.N., 2011.

5. Designing systems: the University Smart Community

The project [10] deals with the creation of a Smart Community in the province of Caserta, between the art cities that are the venues of the various Departments of the Second University of Naples and the

four municipalities of the Domitian Coast. Firstly, the project aims to exploit an underlying tourism that already exists and affects the university population of students and professors, both Italian and foreign, operating in the five locations of the Departments of the Second University of Naples, within an area that is strongly characterized by historic-architectural, artistic, archaeological and landscape features, with Caserta being the “great attractor”. In addition, the Smart Community extends to all the areas of the Domitian coast, within the province of Caserta, which, due to the presence of a large number of hotels, could be future “decentralized SUN guest accommodation”, with it being a good standard and economically convenient, and not only providing beds and meals but also services related to the organization of events, scientific conferences, seminars and workshops typical of university activities.

The project also includes the promotion of a relationship between the university and the African community that lives along the Domitian coast with the creation of a “museum of African Culture”, physical and virtual, and a meeting point in one of Municipalities of the Domitian coast and distributed in the form of museum fragments for scientific thematic areas in the different venues of the SUN. This could possibly help in the fight against organized crime and illegal employment, through the support and affirmation of a renewed cultural identity of the African Community.

Finally, the University Smart Community uses the environmentally friendly and sustainable services of car and bike sharing with electric vehicles that can easily meet, with reduced costs, the chronic lack of transport links between the different locations involved in the project.

6. Conclusions

As we have seen for *Officiamuseum*, it will be necessary to envisage the creation of a visible center of the “system” of *Officiamuseum*. What should it be like? What requirements should it have? Although we are in the scientific context of Company Museums or Corporate Architecture (which is mentioned later by Jochen Siegemund), the architecture of this “museum” should not express a company’s brand (like corporate museums) but the “brand” of an entire productive landscape and, therefore, of more companies within a territory with construction methods, materials, techniques related between them and the same “tension” design belonging to *artidesign*[11].

A paradigmatic example is the Museo Casa Enzo Ferrari. “It is a museum that celebrates the role of Modena in the evolution of Italian high-performance cars: the home not only of the Ferrari, but also of the Maserati factory. Modena is one of those special places where the tradition of Italian craftsmanship has met engineering, giving rise to a series of cars charismatic that, with irrepressible beauty, united a unique power performance”[12]. With these words, Deyan Sudjic talks about what he calls “[...] a monument to the vision of the project by Jan Kaplický” in the book entirely devoted to the museum[13]. Not a corporate museum but of companies, those between Parma and Bologna, producing cars and motorcycles, sports and racing cars (Lamborghini, Ducati, Maserati, Ferrari, Bugatti and De Tomaso) for a lifetime and that represent Italian excellence in these two areas.

The last work of Kaplický, who with David Nixon in the late 1970s founded Future Systems, was inaugurated in 2012, three years after the laying of the first stone, and his death [14]. For the purpose of the speech, we should highlight some important aspects that are inseparably related to architecture and the symbolic value/strategy of this museum: the goals, the client, the place in which it arose, shape and colour as well as the use interior spaces. The purpose was stated above. The museum was not to be dedicated to a single car, the Ferrari (which incidentally has its corporate museum in Maranello), but had to express a corporate culture that is the flagship of a territory. It is for this reason that the work was commissioned by the Enzo Ferrari Birthplace Foundation, a mix of public and private organizations which is part of the City, the Province and the Chamber of Commerce of Modena, the ACI and Ferrari SpA and chose the instrument of the international competition to decide who to entrust the project to. The site is of high cultural value and symbolic. The museum, in fact, is built next to the nineteenth-century birthplace of Enzo Ferrari, in an area rich in dealerships and factories of car parts, not far from the centre of Modena, from the Piazza Grande, the Cathedral and the Ghirlandaia Tower, all UNESCO World Heritage Sites. The work, then, could not but be strongly characterized. The form – the description of which is conveniently summarized by Sudjic: a “high-tech bulb encircled by grass” that like “a protective hand” cradles the birthplace of Enzo Ferrari - enclosing the dual need for mythical roots to an exemplary company story, with a strong and innovative affirmation, respectful but without submissions. Even the colour is the result of a reasoning that is attentive to the meanings. Not “Ferrari Red” that would end up favouring one company, but rather the “Modena Yellow” more connected to the place in which they all could be recognised. Finally, the structure of the museum: a permanent exhibition of the life of Enzo Ferrari, organized in the restored product and a space for temporary exhibitions in the new building can accommodate up to seventeen cars that Kaplický imagined placed on rotating rectangular platforms mushrooms with thin stems.

What the Mediterranean Museum System Design and Applied Arts would be like is hard to imagine, at least in the details *Officiamuseum* is taking shape as a scientific project through a Summer School aimed at German, Turkish and Italian students of the three partner universities [15], aimed above all at

understanding the similarities and differences between the different territories and creating a first international station with which to operate in the future. A project that aims to be practical, with it being realized in the coming years. In fact, the difficulties are immense. Consider a future extension of the "system" to other countries in the Euromediterranean (over 35 EU countries, North Africa and Asia-Mediterranean), with it being very difficult, perhaps impossible to create. Moreover, Officiamuseum in Campania, as a set of companies and museums, has been blocked for about ten years, even if a small temporary museum in Pompeii is being realised as the centre of the system. The opening of an initial location in Turkey might even give new impetus to the project in Campania. Perhaps, this is a utopia, a dream that takes on the contours of a feasible international grouping of universities, museums and local small businesses for excellence to build a huge creative community, open to dialogue, focusing on local diversity, on the one hand, and on the matrix artigianal-design, on the other. The Summer School will be able to develop a possible and flexible model, carrying out a small scale experiment, on only two territories, in Italy and Turkey with only three initial partners. The scientific collaboration between universities has already been tested successfully. It will also try to create a dialogue between companies and their museums as well as convince the various operators that this is a great, cultural, economic and productive opportunity. As with the other systems, it will have to take into account the connections that, being all virtual but physical, will ensure maximum speed and ease and be, of course, sustainable, smart.

7. Corporate Architecture - Corporate Museum (Jochen Siegemund)

Tradition is the trend of brand management. Awareness of the value of a carefully prepared and presented appealing history has won in recent years increasingly importance. Not only the big industries, the so-called global players have come up with their corporate museum created a permanent place for their brand heritage and brand culture, and small to medium sized companies recognize in an increasing the possibilities of spatial presentation space for communication and interaction with their own traditions and core brand offers. Companies invest in spatial communication, such as industrial museums, exhibitions and corporate brand worlds.

The motivation and the reason for this entrepreneurial activity is obvious, on the one hand exists in the company an ever more extensive pool of corporate history, was suitable to present themselves, on the other hand offers a museum exhibition and brand world the chance of positioning the brand in our global, fast acting world. It is not limited to, the provision for displaying individual exhibits, it's about the permanent placement of intergenerational processes that have shaped our industry today and everyday culture. In view of the high turnover of company shares and brand names, corporate "Built identity" are museums, so symbols of continuity.

Corporate museums are not only as museums, they are a new building typology, a hybrid between the museum and brand world. Here, the corporate museum is a little different from the "classical museum" in public ownership. One thing they have in common, both preserve the society from the loss of their history and provide space for identity and history. This is not a new development, the latest at the beginning of the industrialization of large corporations have begun to collect art and cultural heritage and to present in foundations and museums. For industrial museums is not just a matter of preserving the history and issue, but rather active and forward-looking work essentially with the own collection, so to speak, to position itself as tradition-conscious businesses and to explore trends.

The term corporate museum refers to the association of the industrial museums to the field of corporate identity. The corporate museum takes in the corporate architecture of an enterprise, often a central, mostly experimental - strategic - function. While public museums reflect the educational mission, are additional aspects, such as research, brand management and brand image building communication is the priority here. Corporate museums are located at the interface between scientific and economic claims. Next to the branding of a company's corporate museum offer promising new potentials and synergies in a creative business management, between the poles, historians, cultural managers, engineers, up to business managers and marketing experts.

Companies are challenged to act smart and sustainable. Corporate museums offer these forward-looking company the necessary and meaningful place for future transdisciplinary learning and experimental laboratory situation of a forward-looking company. Corporate museums are an integral part of corporate culture. A trend that can be observed recently, are smart museum networks of corporate museums. Industry museums form are thematic, smart and strategic alliances and thus expand its international positioning in the competition globalen Museums and brands.

Measurement, Representation and Rural Architecture Exploitation: Knowledge through Historical Maps from Mills to Hydropower Stations

Fabio Converti

Department of Architecture and Design, Second University of Naples, Aversa (CE) City, Italy
fabio.converti@unina2.it

Abstract

Belonging to a place (geographical and cultural area) is decisive, mainly for certain territories, in order to fix forms and technologies of the built heritage, both as specification of stylistic peculiarities and as method of approach to the project's process.

"*Striving to give new life*" and preserving coincide with an acquisition and knowledge process that represents the revival of roots from the historical tradition.

Sources, as investigative tool, allow us to enhance and innovate forms and construction technologies, but above all to gain a theoretical model that is the basis of architectural works of our lived backgrounds.

The objective of the quality of the landscape shows itself as relationship and feedback for any project on punctual and spatial scale, secondary targeting on it territorial modification interventions, in the direction of economic and social ambitions, through a shared planning for a multidisciplinary integrated enhancement.

In peri-urban and suburban area, topics of knowledge, recovery and enjoyment of the rural architectural heritage, also seen regarding their production of multifunctional values, play a fundamental weight. The agricultural environment, as result of continuous relationship of interdependence with the man, must not be perceived as an environment that produces only commodities, but especially "landscape", full of peculiarities, in which it is possible to read traces of the historical memory of settled communities and landscape identities.

Keywords: Representation, Heritage, Rural, Landscape

1. Introduction

Cadastral mapping, where thematic of possession is represented, is an essential tool for management of territory. Extended to entire national territory, it is made of 80% at 1:2000 scale mainly in Cassini Soldner mapping system and refers to several centres of emanation. The Land Agency has now maps in vector format in the native system effectively throughout the whole country and "original plant" maps in raster format are being in acquisition representing, even not up to date, "the most precise" basic metric criterion we have.

Landscape's representation - "traditional" or digital one - must inevitably take its origin from the problem of reduction of natural variety to an objective and transferable picture, because of its codification: this is a need providing scientific rigor to the possible graphical, analytical and descriptive model of landscape shape, which, according to theoretical approach of complexity and "multi-dimensionality" of knowledge of world, can never be reduced to mere measurement and extension, neither it is ever entirely attributable to "exact" rationality of map or vector path, nor to fascination of view or satellite photographs.

In 1965 George, for example, showed an important method perspective about criteria for reading rural territory, detecting in characteristics of soil use, in land ownership structure and in average size of

cultivated fields, some data collectors of prevalent agrarian type in a certain area, considered as the result of historical plot among socio-economic factors and local physical ones.

2. Research field

Socio-economic and structural modifications, occurring in agricultural sector in the last decade as consequence of EU policies with the reform of the Common Agricultural Policy (CAP) and the launching of Agenda 2000, imposed a reposition of Italian agriculture in the way that it seems better to give up the traditional concept of *agricultural* world by extending its meaning to that of *rural* one. This is the main effect produced by changes of company structure and organization, become more and more market oriented and integrated into socio-economic context.

Landscape reflects the "sense" of territory outlined in itself: it offers in a photographic and synchronic way its ability to reveal a form of identity regulation of its own order.

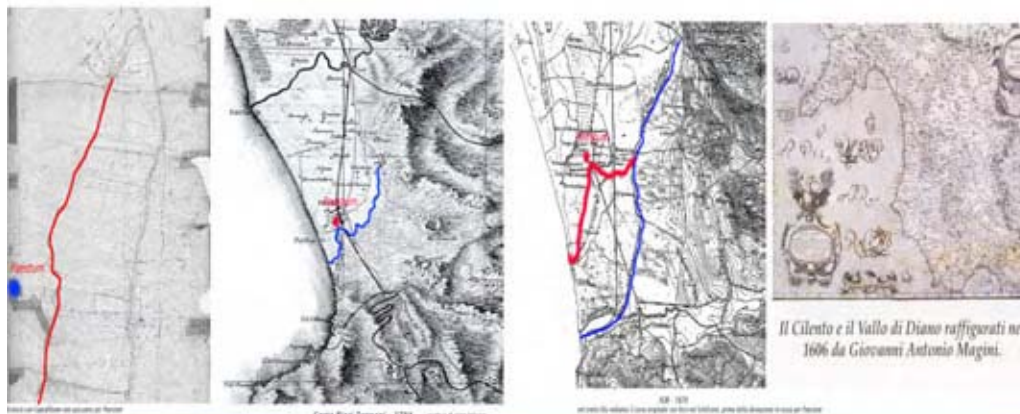

Fig. 1 Geodesic plant of Molini Capo di Fiume with respective sources and its surroundings in Capaccio (Salerno) in 1857, Designer and Surveyor Michele Caccavelli (State Archives of Salerno).

It exhibits signs of diachronic becoming told by the evolution of inner phenomena and more or less by the integration including elements arising from outside, inevitably exchanging models and phenomena with. *Landscape's shape is direct consequence of forces acting on it: forces, in appearance independent, are in fact strictly dependent on each other. Therefore, it is not only important to analyze each component, but also, and especially, all possible elements of connection among various forces* (Benedetto Croce).

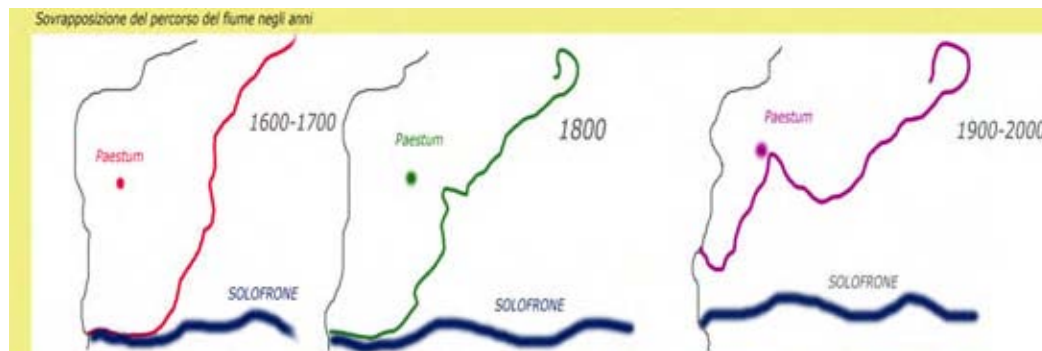

Fig. 2 River course through historical cartographies

The human living is in fact always a co-inhabiting, which is to say a social construction of sense (Bronfenbrenner 1979).

Rural traditional building, centuries-old sign of agriculture of place, is going to disappear, responding to a phenomenon more related to time than to space. Starting from Trulli in Puglia to Lombard farmhouses, from German Bauernhäuser to English barns, nothing seems to escape from silent and constant phenomenon of dismission.

Fig. 3 From mills to hydropower stations in Piana del Sele

The law of 1922 wanted by Benedetto Croce conjugated the notion of historical truth of landscape, in the broadest sense of environment including its natural and geographical specificities and its historical and literary proofs, with social and national sentiment.

3. Objectives

Century-old farm buildings do not seem suitable, or adaptable, to perform any nowadays function: owners are uninterested because of high costs for restoration, following the trend to build new productive structures, more functional and suitable to need production and Community directives and, finally, also because of numerous constraints.

Prescriptive contradictions contribute to discourage even more owners.

In other words, learning to understand landscape is a necessary step to "*comprehend the territory*" (Corna Pellegrini, 1997) and to decode it also in many cultural identity values; perhaps the most important purpose of this practice of research is the application, being the aim to raise awareness to local communities of the importance and often the specificity of values expressed by places and areas, and thus also to "*orient projects of government of landscape-territorial modifications/changes, because they will be anchored in line with concepts of protection, upgrading and enhancement*" (Castelnovi, 1998).

To catch elements fully, snatch their meaning and contextualize them, it was necessary to build a coherent and comprehensive interpretive trail, able to make identity of places recognizable, assigning membership, and revealing subtle links and fragile balances. Therefore, the study of the Piana del Sele landscape not only brings out critical phenomena arising from consumption of free soil, but also focuses attention on the need to make the best to increase in value both historical and cultural potentialities of built environment and environmental ones with all concrete and possible connections.

Figure 4 Complex Le trabe of Capo di Fiume

The strong agricultural character of regional territory refers to the centrality of multifunctional role of agriculture and its actors - farms - which, from classical conception of goods "producers", become protagonists of preservation processes, through actions of management and of care. These actions, in particular geographical foothills areas, are irreplaceable contributions to functions of supervision and protection of territory.

Socio-economic mutation occurred over time have profoundly affected relationships, creating small particle properties and changes in cultural or territory abandonment.

The unbroken expanse of lands of ancient feud first was replaced by the plot of enclosed plots of land, and then, in some areas, by the further fragmentation of funds in smaller properties, till their definitive abandonment.

Therefore, the protection of rural areas should be considered a target since the beginning of planning and design stages, through knowledge of their current socio-economic, environmental, landscape tissue and of an "agricultural project" to which to guide them.

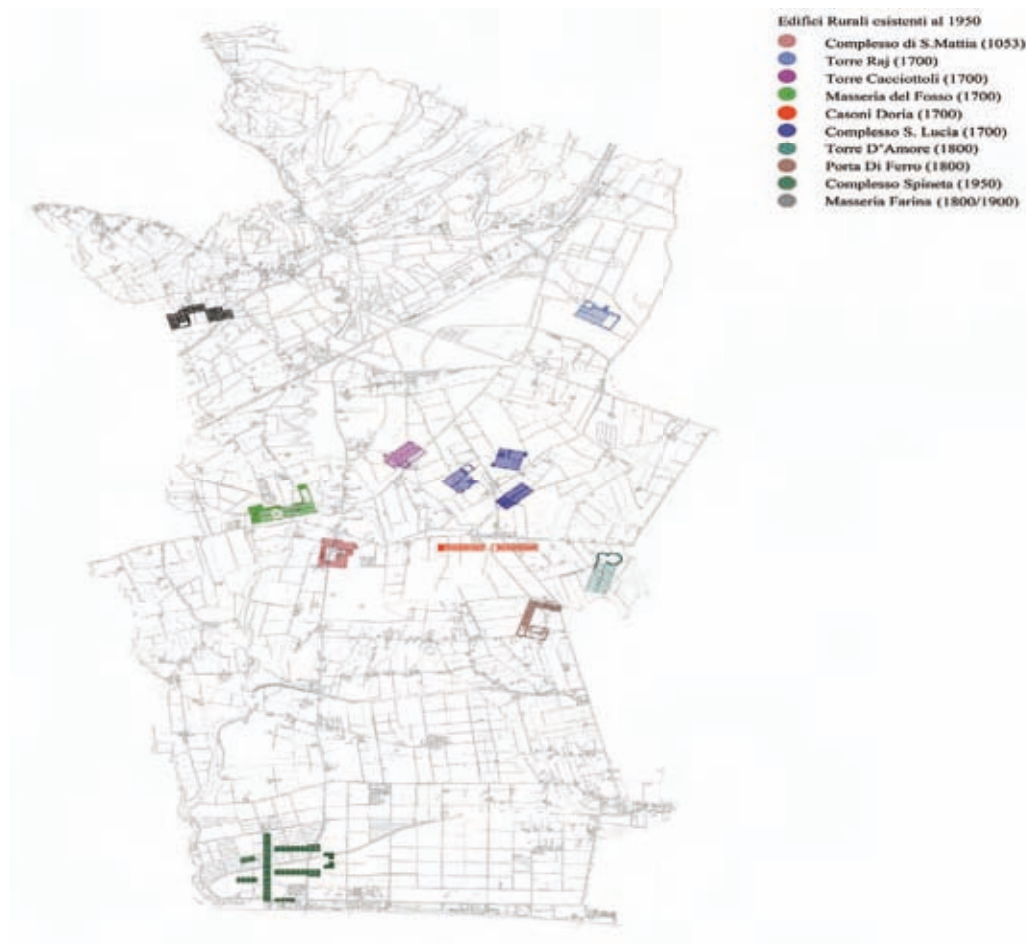

Fig. 5 Farms Network Plan of Piana del Sele

Not underestimating historical and documentary value of these assets, it would be necessary to give answers to problems still leading to the abandonment of rural buildings.

Fig. 6 Rural productive architecture (Bufalara) Capaccio

Each rural construction expresses manufacturer ability in relation to used materials, locally available. Rural housing contains a clear connection to identity of places where it was built and also with function and social level of the owner. In this field these motivations are essentially enhanced by predominance of one of these components: the function. In fact, on this simple but specific factor, the history, the evolution and the reason to be of rural building are based on.

Fig 7 Raj Tower (Battipaglia)

The continuous research of typological elements, the need to shelter for living and also protect animals and products of the earth, inspired and then refined over time the symbiosis form-technique building.

Fig. 8 Sketch of Raj Tower (Battipaglia)

In Italy each rural building is totally interdependent with landscape where it is inserted in. The historic settlement of rural matrix is a key component that helps to characterize traditional rural landscapes. It can take various forms, types and functions in landscape, being related to different cultures, techniques of building and local economies.

Fig. 9 Axonometric view of Raj Tower (Battipaglia)

Fig. 10 Exploded axonometric view of Raj Tower (Battipaglia)

"Even at legislative level rural environment develops concepts of multifunctionality which are also entering into vocabulary and agenda of Italian politics" (Di Iacovo, 2003): the recent guidance law for the modernization of agricultural sector (Legislative Decree 18 May 2001, no. 228, Orientation and modernization of the agricultural sector, in accordance with Article 7 of the Law of 5 March 2001, n. 57. (published in Ordinary Supplement no. 149/L to the Italian Official Gazette no. 137 of 15 June 2001) is obviously moulded on a set of multifunctional type, and it is in this context that Article 13

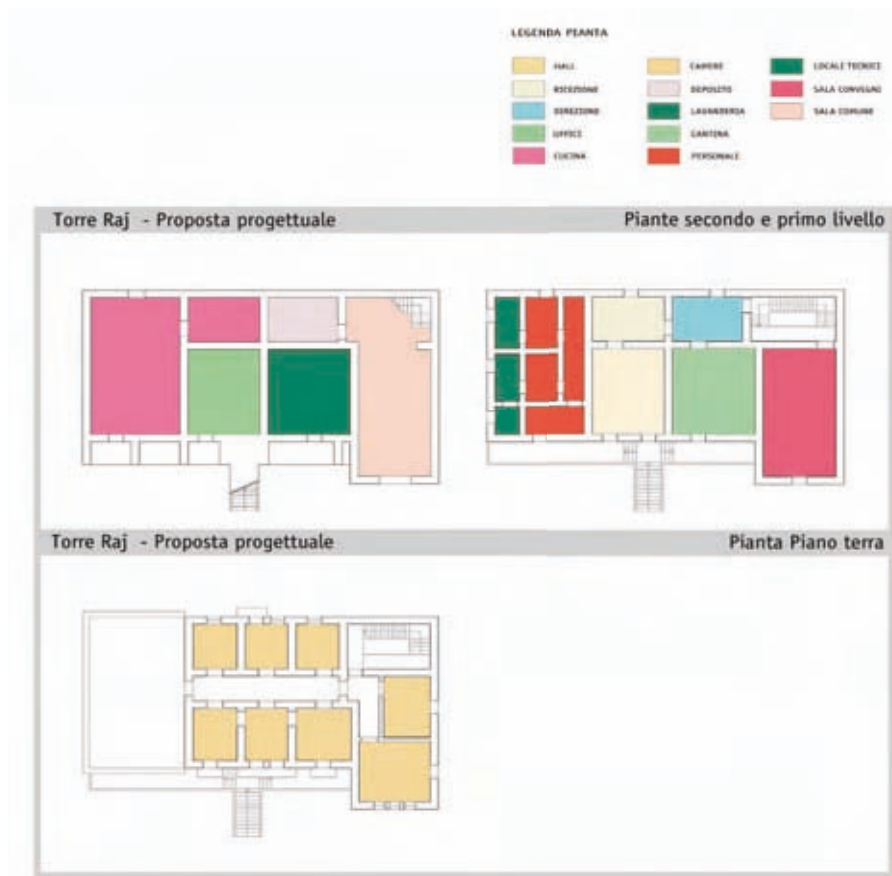

Fig. 12 Plans of Raj Tower (Battipaglia)

Fig. 13 Farina Farm (Battipaglia)

Analyzing traditional rural aspects of the Piana del Sele area, it is only right and proper to mention the water system: a landscape marked by “gore” (so called canals to irrigate fields and to bring water to mills driven by hydraulic power) by mills and by oil presses, also representing the terminal ring of farmer or landed dealer attention to issues related to hydro-geological instability and to floods caused by irregular fluvial regimes and by difficulties of water endorheic basins. A dedication to territorial maintenance often need to be remedied.

Fig. 14 Sketch of Farina Farm (Battipaglia)

5. Methodology

It is possible to improve a good by acting directly on it or by operating indirectly on its surrounding environment: an action for the better intervening on territory can not ignore the inclusion in process of enhancing those places where the construction of agricultural landscape starts which is to say rural areas.

Fig. 15 Axonometric view of Farina Farm (Battipaglia)

Rural settlements, located in districts of Battipaglia and Capaccio, show themselves as a schedule of buildings of different periods, added to the basic core, depending on evolution of activities and on changing trends of cultivation.

Buildings themselves, in their typological structure, highlight this ongoing transformation made of new additions, adaptations, expansions.

Briefly we could define them as settlements constantly evolving, because they are intrinsically related to the execution of agricultural work.

Fig.16 Exploded axonometric view of Farina Farm (Battipaglia)

Many contemporary buildings were not designed to be integrated architecturally with other ones and with landscape. Unlike ancient times (until early 1900s), recent farms do not help to give a positive image of agriculture in modern society.

After inspections analyzed buildings may be classified as follows:

1. Types of historical rural architectural heritage

Buildings of cultural, environmental, historical-monumental value and bound buildings or complexes included in dictates of Legislative Decree 22/01/04 n. 41 "Code for Cultural Heritage and Landscape" under Article 10 of the L.06/07/02 n. 137 and historical and architectural environmental elements present in aggregates themselves.

2. Types related to culture and local identity

Agricultural complexes and buildings retaining traditional features and types particularly identifying the site, and rural settlements of ancient formation having significant importance as evidence of culture and local identity.

3. Types of significant value for conservation and enhancement of agricultural landscapes

Handmade and rural buildings of environmental interest representing a typical factor and essential part of agricultural land.

4. Types of rural building of modern production or recent insertion

Buildings characterized by presence of structures of modern construction not of particular interest.

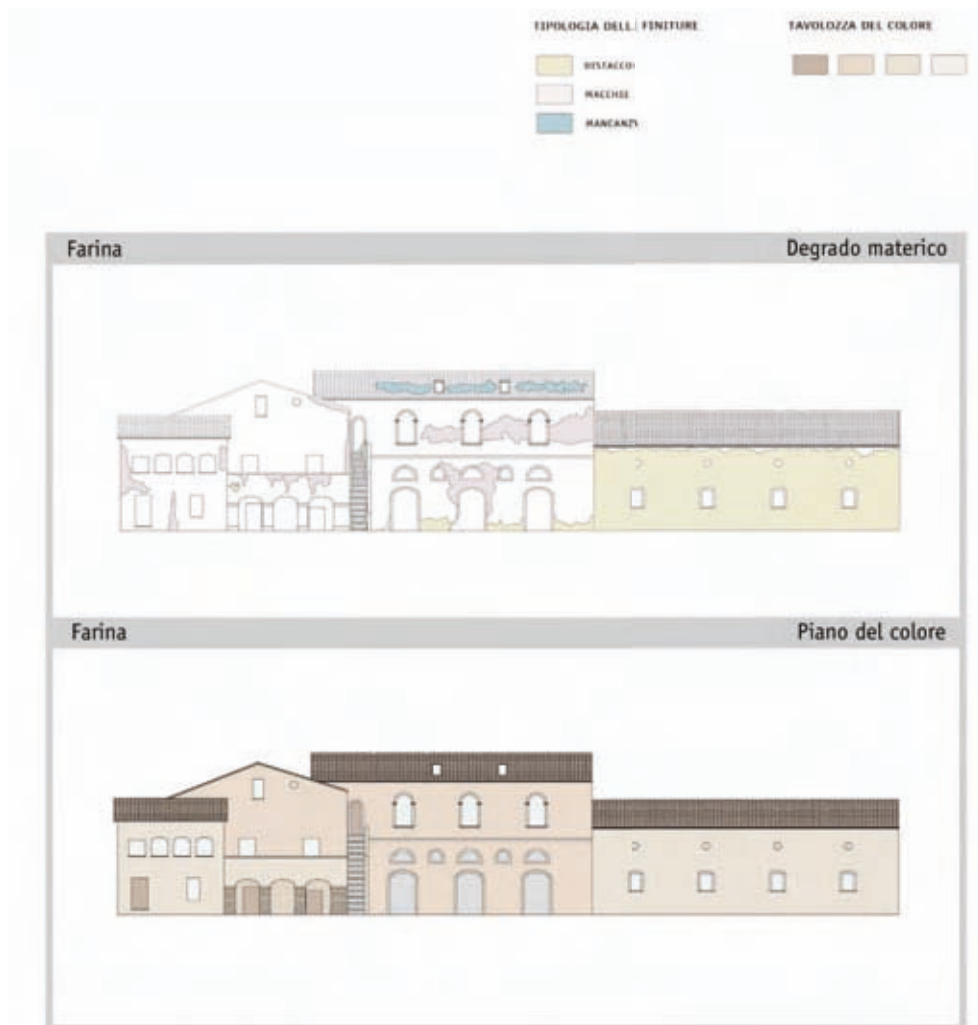

Fig. 17 Overview of Farina Farm (Battipaglia)

6. Conclusions

The conservation project is preceded by a preliminary feasibility assessment aimed to verify normative restrictions, compatibility of intended use in relation to structural characteristics, topographical, technological, dimensional aspects, to cost/benefit evaluation.

The conservation project consists of a preliminary fact-finding phase divided into different levels: historical-critical analysis, geometric survey, materials and structures survey (furnished with stratigraphic analysis), degradation and collapse survey, diagnostic tests (for chemical, physical and petrographic characterization of materials).

On the basis of achieved results in survey it can be developed the proposal of restoration, enhancement and conservation of materials (also including reclamation actions for dampness) and the project of preservation of structures, aimed to stop causes of degradation and disruption through the use of specific techniques for repair.

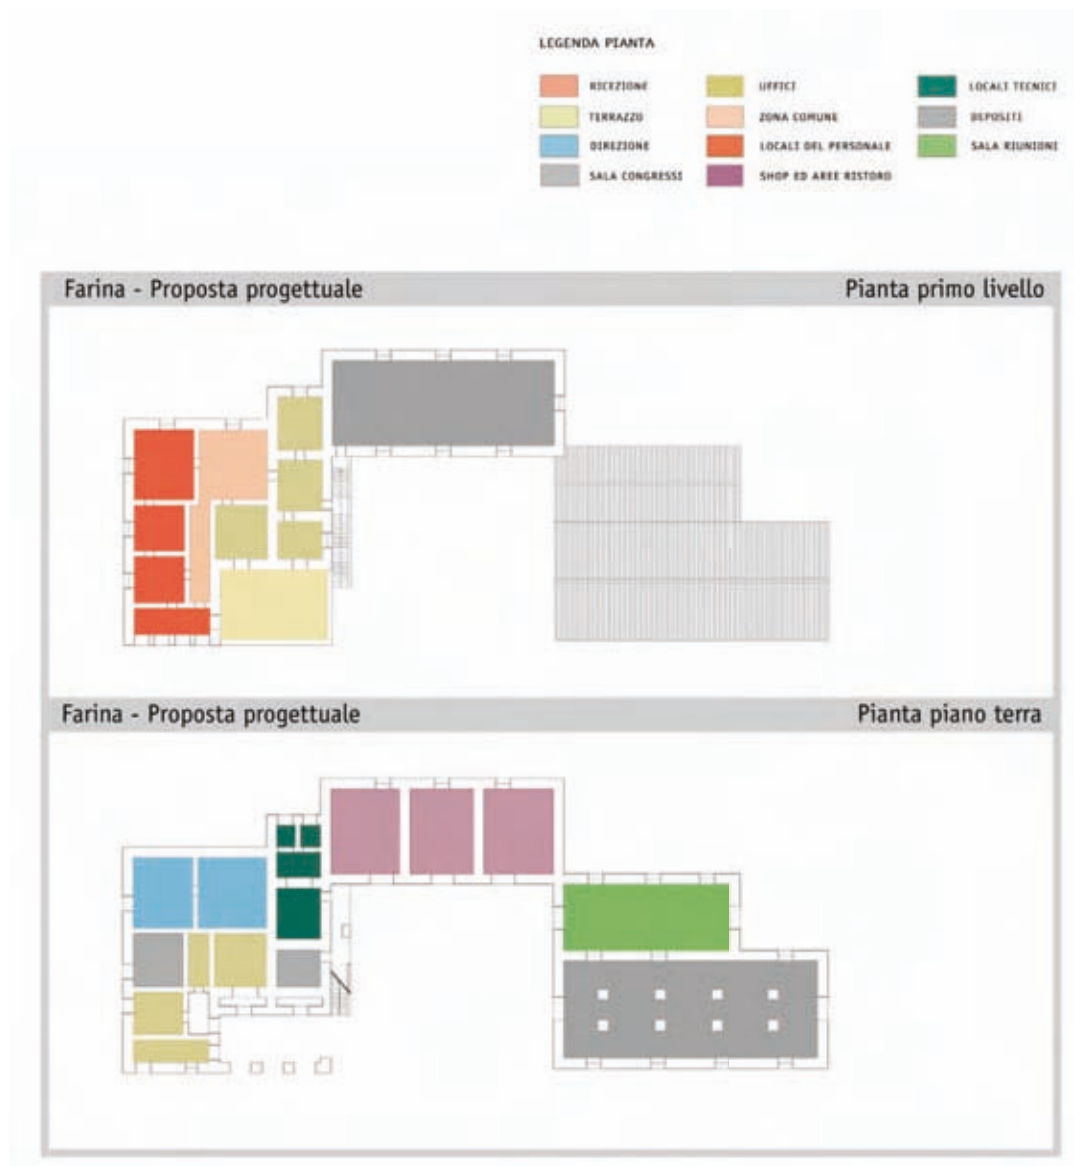

Fig. 18 Plants of Farina Farm (Battipaglia)

Ensuring preservation of material consistency of building, then architectural design will be consciously able to face issues related to built handmade use, as necessary condition for its preservation in time: from the adaptation of systems, to distributive, functional and spatial aspects and the possible inclusion of new architectural elements that will stratify on material structure of building. This theme of relationship between old and new concerns not only a single building, but also, more generally, the construction of new buildings in a historical context.

Sprawl Repair. Site-specific tools for Neapolitan sprawl town

Fabrizia IPPOLITO

Dipartimento di Architettura e Design, Seconda Università di Napoli, Aversa (CE), Italia
fabrizia.ippolito@unina2.it

Abstract

A collection of researches on Neapolitan territory (Ippolito, 2013) is the starting point for a reflection on the topic of repairing the residual landscapes of urban sprawl, focusing on the relationship between their generic and identity features. In a time when urban sprawl faces everywhere abandonment and waste, in a place where these phenomena are in part side-effect of unexpected economical and social mutations, or disobeyed future expectations, in part natural effect of the recent history of the place and its strongly connoted landscape, regenerating Neapolitan sprawl town requires a re-valuation of its peculiarity within the present debate on urban regeneration and site-specific tools of action.

Field of inquiry is the valley between Naples and Caserta, inland and sea, where a landscape of both natural-archaeological excellences and environmental-social alarms is the ground of a sprawl building process and of great infrastructural works which, from the 80s, have been answering on one side to the inhabiting and expansion's demand of Naples metropolitan area, on the other side to the construction's demand of an often self-fed cement cycle, swinging between emergency urbanism and everyday urbanism. Here the great works coming from extraordinary emergencies and from national and international growth funds, together with the products of a progressive, mainly residential, urbanization, face a tendency to abandonment which testifies the original vices and the failed promises of Neapolitan urban sprawl. Among the wastes, features, dynamics and peculiarity of the Neapolitan landscape re-emerge.

Key words: urban sprawl, Naples, residual landscape, repair/recycle, generic/identity

Sprawl Repair. Site-specific tools for Neapolitan sprawl town

Looking at Neapolitan sprawl town as a significant sample of inquiry for an urban debate which is nowadays engaged in reinterpreting, some years after their apparition, urban sprawl phenomena, in light of the abandonment and shrinking events which it is more and more involved in, and which suggest a reparation oriented design attitude, maybe useful for many reason. Because it is a territory where sprawl urbanization has developed in a very extended form, depositing piles of constructions and infrastructures over a manipulated soil; because here abandonment and shrinking phenomena arise with great evidence and frequency; because here the conflict between generic and specific, which concerns every town, but particularly sprawl town, representing an unavoidable issue for its regeneration, comes to evidence in a peculiar way. Most of all, because here sprawl town, showing an anomaly in its construction and a vocation to discard, particularly demands reparation. A look at the events of the construction of this territory and a sampling of its landscapes, taken from the infrastructure that make this town work, can be the occasion for highlighting these peculiarity and for searching for opportunity of intervention.

Chosen as a field of inquiry, the valley between Naples and Caserta, inland and sea, where the Neapolitan sprawl town appears at its extreme, is emblematic of the matters related to urban waste and is characterized by an accumulation of infrastructures – highway, freeways, high speed railway, hub, port, airport – at various degree of completion – completed, interrupted, under construction, designed, programmed – mingled with a spread of constructions – houses, boxes, residential buildings – at various stages as well - often interrupted

or abandoned -. Hereabout a land and a coast of both natural-archaeological excellences and environmental-social alarms are the ground of a sprawl building process and great infrastructural works which, from the 80s, have been answering on one side to the inhabiting and expansion's demand of Naples metropolitan area, on the other side to the construction's demand of an often self-fed cement cycle, frequently oriented by occasions rather than necessities. Hereabout emergency urbanism and everyday urbanism intersected each other within a massive change of the territory, consuming it by constructions and manipulations and by both evident and clandestine dynamics. Hereabout the great works coming from extraordinary after-earthquake interventions, being extended for decades through an infrastructural turn, and from national and international growth funds, mainly addressed to infrastructures, together with progressive, mainly residential, building interventions face a tendency to abandonment which testifies the original vices and the failed promises of Neapolitan urban sprawl, spreading wastes in the form of roads and houses over wasted soils. Among the wastes, into the folds of abandonments and interruptions, new discarded materials, populations and uses find place, while new great works keep on attracting investments and expectations and, in-between the two, features, dynamics and peculiarity of the Neapolitan landscape re-emerge (Belli 1986; Capobianco 1991; Corsi, Franco 1991; Montesano, Trione 2007; Braucci, 2009).

The hypothesis is that this territory is devoted to discards, and that discards can be an interpreting key for its conditions and materials. Side effects of the project, put at the center of the territory's construction, discards produce an implicit landscape design; repressed unconscious elements of urban life, put at the center of the territory's investigation, they reveal dark sides of the city (Lynch 1990/a; Dematteis 1995; Scanlan 2004; Vidler 2006).

A lateral point of view tries and reconstruct the implicit project in Neapolitan sprawl town and the links between the visible city and the hidden one, retracing the clues of latent transformations, uncertain definitions, secret relations, which, here more than elsewhere, make by quantity the quality of the landscapes. This investigative look, which has been practiced in the last years by urban studies, and is all the more necessary in such an elusive place, while following clues of transformation, intercepts the issues and scales of city and landscape, is affected by the variations of both disciplinary debate and territorial reality, and reveals, behind the generic of urban sprawl, the anomalous nature of this extended town (Zardini 1996; Ingersoll 1993; Boeri Lanzani Marini 1996; Biraghi Ferlenga 2012). Throughout a collection of researches, recomposed in a portrait by samples of the territory, this look identifies landscape exemplars: the ordinary landscape of the places coming in succession along an highway, variations on a few types of spaces and buildings, which, along the Street of the Americans, in order to consent ambiguousness of uses, introduces ambiguousness in building types, spreading all around rough outlines of constructions available for any destinations; the individualist landscape of the city of houses produced by a street junction, which at the coastal junction of Varcaturò advances by individual tactics of appropriation, growth, adjustment, dissolving public space and landscape beneath the only element of the house; the compact landscape of the settlements of speculation, made of accumulation of residences and facilities, which, in Villaggio Coppola Pinetamare, shows advanced signs of decay while, with a new touristic port, adds another great work to a long story of sanctions and redemptions; the fenced-in landscape of military theme parks, product and origin of infrastructures, which from the NATO bases spreads along American imitation highways genetic mutations of the territory; the discarded landscape of the middle lands, locations of extraordinary works, which along the Asse Mediano state highway participates in the extension of the after-earthquake reconstruction through the endless construction of the street, and puts its redundancies and its mistakes to use as refuge and catalyst of discards; the linear landscape of the coastal city, shaped by a coastal road, which, along the Domiziana state highway, includes archeological and natural remains, cumulates old and new episodes of abandonment and absorbs traces of transits and temporary presences. In each of these cases the infrastructure is generator of landscape, in the sense of ordinary landscape, and absorbs conflicts and compromises between great interventions and everyday adjustments; in each case it is narrator of collective stories involving individual ones.

An account which moves between these two level of narration, wide-ranging visions and particular ones, raises design issues which find place in the intermediate space between the infrastructures and their landscapes, the generic structure of sprawl town and its specific situations. Within this account, infrastructures are the structure of the evanishing sprawl town and the potential framework for its progressive restoration; their remains are a warning to a new reflection on the development criterions and the visions which produce buildings and landscapes devoted to discards; their adjustments, reuses, manipulations, their compromising with site-specific inhabiting practices and land uses are indications for a project which finds in the reuse of the discards and in the cross-reference among different tools and scales of intervention strategies for repairing sprawl. While the urban debate looks at sprawl town with intents of restoration, while the policy of public works still bets on great work, and on the contrary landscape and environmental issues

advance, while the architectural and landscape design works on recycle, reuse and repair (Corner 1999; Mostafavi, Najile 2003; Berger 2007; Ciorra, Marini 2011), hereabout, where the discard seems to be a vocation, repairing sprawl town acquires a particular value. If, within the cacotopia of a cataclysm running over our urban world, among the residual forms of the city, the sprawl is the easiest one to be regenerated, thanks to its low density and to its extended connections, in such a territory, where the cataclysm seems to be already happened, and a rich frame of infrastructure remains among the scattered discards, maybe in-between this frame and fragments we can find the tools for repairing sprawl town.

Design the monument in the twentieth century. Innovation and tradition

Abstract

The use of reinforced concrete in the works of architecture in the twentieth century, has had to deal with the events that have come and gone during this period, and especially following the two world wars in Europe, it has become an interpreter the most extensive reconstruction of the history of the old continent has ever known. The emblematic story of the reconstruction of the units of the Cathedral of Reims, as a result of the bombing in 1914, then scored, officially the use of this material is considered useful only for the types of settlement of industrial works or civil use, even for places of worship, regarded for the history of mankind, monuments par excellence. In addition, at the initiative of Auguste Perret, were designed and built churches in which the material of modernity was truly exposed to view, and so, accepted, even in traditional environments suspicious, prone to encouraging the use of stylistic features of previous centuries. The Second World War has fully liberalized the use of concrete thus changing, even in sacred spaces, a number of aesthetic balance and developing a new conception of the forms and images of architecture that, in turn, have also been contributed by the changes introduced in the liturgy of the Second Vatican Council held in Rome between 1962 and 1968. In Italy traditional postwar similar experience was also a revolution in the conception of the idea of Monument.

Keywords: architecture sacred; concrete, modern types of churches.

Italian architectural culture of the twentieth century, sacred space dedicated to the project, has been greatly influenced by the events that have occurred during this period. The two world wars have introduced new ways of relating between people and, therefore, have also transformed the conceptions of the common life. The religious experience of man of the twentieth century showed novel ways to represent their spiritual attitude marked by characters of simplicity and essentiality. The same architectural culture of the Modern Movement has supported the transformation process of the creation of new spaces in which to live a social policy. The absence of decoration and the preference of the geometries has enabled modern man to transform radically the places where traditionally celebrate the relationship with the divine. The new technologies and mechanization of the construction site have favored the transformation process by helping to educate society to expectations of sacred spaces more sober and less flashy. In this way it is also brought back to its

Fig. 1-2: Roma Santa Sabina Church; Paris, Church of Le Raincy.

original meaning, the word "monument" that wants to mean mainly 'remember', 'memory'. In the historical culture of the architectural context of the Italian monumental quality of a building accomplished in the richness of the decoration, which also represented the true value of the building itself. For the same reason very complex is the reflection about the restoration on built.

This, by its nature, must refer to the 'values' of which the building is 'remember' and, in this way, the architecture transformed into 'monument'.

Fig. 3: Roma Santa Sabina Church

Fig. 4: Paris, Church of Le Raincy.

The introduction of electricity and the new machines in construction site brought great economic benefits and substantial reduction of costs in the execution of works.

The most obvious case is the Basilica Santa Sabina on the Aventine Hill, which Antonio Muñoz, during the first world war, back to its former glory.

The exemplary value of this experience, especially for the influence that the end result has had on the sacred projects of the twentieth century, lies in its expressive synthesis and ideological expression of cultural season after the war. During this period changes the very idea of setting up a monument, a time associated with the use of precious materials and a precise architectural design.

Fig. 5: Paris, Church of Le Raincy (by Art et décoration 1924)

Fig. 6-7: Paris, Church of Le Raincy; Church of Le Raincy (by Le Bulletin de la vie artistique 1924)

The church of Le Raincy has a plan with three naves divided by tall pillars that define the volume of five bays. Each module has a regular square plan which corresponds, in the aisle, a form divided by half. The sequence of spaces is repeated for the longitudinal bodies lower by half the width. Vaulted barrel lie on the individual areas between the pillars, while the aisles link up the pillars with a profile perpendicular to the axis of the central body. The entire perimeter of the sacred space is closed by a continuum of forms openwork design forming a barrier to that is repeated constantly.

The similarities with the upper part of the church of Santa Sabina are numerous because of the presence of windows hurdle released in arcades during the restoration of the arch. Muñoz. The entire space of the nave of the Roman church, the old church in this way provides an unprecedented condition of light that will be recognized as the novelty brought in by the substantial restoration work. The same restoration of the Roman architect, also documents that the columns of the church are all the same and, for this reason, must be treated as realized only the design of the church of the sixth century. Through the restoration, therefore, Muñoz documents that the church of Santa Sabina is the first project of basilica built exclusively for Christian worship. The Roman columns divide the whole environment of the classroom into three longitudinal bodies with different height between the higher and the lower side central space. The entire rectangle of plant of the nave, closed circular apse, becomes, as a result of the restoration, a strongly illuminated place giving, in this way, also highlight ancient paving clear and to the succession of the columns. The aisles are hiding in the shadows, in some parts, the successive chapels deeper. The apse is a very high end

Fig. 8: Roma Santa Sabina Church

very significant for the closure of the classroom acting as a crowning visual perspective to the whole environment.

For this reason the Roman Church will be treated in textbooks of art history as the prototype of the place of Christian worship. The similarity between the Romanesque basilica and the Paris church, the latter will make the reference model for the many classrooms of worship to be built in Europe at least until the celebration of the Second Vatican Council.

Fig. 9: Church of Le Raincy-Santa Sabina's hurdle (photomontage by G. Spera).

Fig. 10-13: Santa Sabina e Le Raincy- hurdle.

Even in 1935, one of the leading experts on sacred art of the twentieth century, the future cardinal Celso Costantini, argued: “«L’architettura ecclesiastica avrà sempre bisogno di colonne, di basi, di capitelli, di quel minimo di trabeazioni, che rappresentano esigenze inderogabili del razionalismo costruttivo e decorativo: sì, -come si è già detto- per le chiese, vi è un razionalismo anche decorativo, perché esse non sono delle sale d’aspetto di una stazione» (Costantini, 1935, 75)

It was still far from achieving thus the possibility of using new materials and technologies in sacred architecture. Only in 1947 papal encyclical recognized the potential use of new technologies in the liturgical: «Non si devono disprezzare e ripudiare genericamente e per partito preso le forme ed immagini recenti, più adatte ai nuovi materiali con i quali esse vengono oggi confezionate: ma evitando con saggio equilibrio l’eccessivo realismo da una parte e l’esagerato simbolismo dall’altra, e tenendo conto delle esigenze della comunità cristiana, piuttosto che del giudizio e del gusto personale degli artisti, è assolutamente necessario dar libero campo anche all’arte moderna, se serve con la dovuta riverenza e il dovuto onore, ai sacri edifici ed ai riti sacri; in modo che anch’essa possa unire la sua voce al mirabile cantico di gloria che geni hanno cantato nei secoli passati alla fede cattolica» (Pio XII, 1947).

Fig. 14: Santa Sabina, plan.

The restoration of Santa Sabina is in this context a prototype of high symbolic value for the historical circumstances (sixteenth centenary of Milan's Edict) and arrangements.

The invention of this architecture will be so convincing that there is no art history textbook that does not bear the heading "Early Christian basilica", the plant of the church built by Munoz. Remained as the only objection to the Roman model Perret and the use of exposed concrete: it was the main reason for the distrust of the modern language for the space of worship.

Fig. 15: Le Raincy, plan.

Fig. 16: Paris, Saint-Jean-de-Montmartre Church (by Emporium, 1906)

Fig. 17: Paris, Saint-Jean-de-Montmartre Church

Fig. 18: Paris, Notre Dame du Travail, Church

Remembered Costantini: «l'architettura novecentista cerca soprattutto la funzionalità, la praticità, la comodità. Ciò corrisponde mirabilmente all'indole di certe costruzioni, come magazzini, rimesse, uffici burocratici ecc. Ma ciò non basta per le chiese. Non basta neppure per una caserma. Semplicità sì, ma non sciatteria; praticità sì, ma non volgarità» (Costantini, 1935, 60).

As documented in the experience of historic buildings, the distrust of the clergy for the concrete limited to single exposure view of a matter, which, too, had allowed the recovery and expansion of important religious buildings.

Fig. 19: Beuron, St. Maurus Chapel.

Fig. 20-21: G. Vaccaro, project of the church in concrete; G. Ponti, Bonmoschetto, Carmelite convent church (by Domus 1958)

The rebuilding of the bell tower of San Marco in Venice (1912), the arrangement of the trusses of the cathedral of Reims, the expansion of the shrine of Pompeii document the wide use of new technologies with the general mechanization of the yard. From the cultural point of view to creating true "scenarios intellectuals": in the study of Perret in Rue Franklin was not unusual discuss literature as Valery's *Eupalino* and Claudel's *L'Annonce faite à Marie*. The same French architect remembered that "«cemento è pietra che fabbrichiamo noi stessi, ed è molto più bella e nobile della pietra naturale. Le va fatto l'onore di risvegliarla. La si può lavorare col martello, la si può bocciardare, tagliare, gradinare con tutti quegli arnesi che servono per rifinire la pietra naturale. Il cemento appena disarmato vibra tutto delle striature che gli vengono impresse dalle assi della cassaforma» (Gargiani, 1993, 82).

The sincerity of expression of Perret's works connects constructive outcome of the material used, about which the author also claims the aesthetic value that results for the architecture. The modernity of language is fully captured by one of the intellectuals are more favorable contemporary sacred art.

The Beuronese School and the Schwarz's essays in the architecture sacred of the XX century

Maria Carolina CAMPONE,¹

⁽¹⁾Department of Architecture and Industrial Design "Luigi Vanvitelli" Seconda Università di Napoli

E-mail: mariacarolina.campone@unina2.it

Abstract

"To restore the church inspiring at sacred theme": with this sentence Rudolph Schwarz, theorist of the architecture sacred contemporary, abridge, in his *Vom Bau der Kirche* of 1938, Desiderius Lenz's the responsibility (1832-1928), promoter of art School in Beuron, in the religious range.

Friar's consideration suggest content of faith in paradigms and shapes drawing at the iconographic repertory of the Near East and the classic Greek and rise to a summit, like is famous, with the publication of the *Kanon*. The title convey the author's attempt to latch on to the Phytagorean-platonic philosophy.

Lenz and his school abide by the works of greater commitment to the rules-harmonic proportional theorized in the work, were once again the idea of *nomos* and *rythmos* as a means of understanding the laws that govern the universe, and with it the arts and especially architecture, as in Maurus Kapelle, Montecassino's crypt and Beuron's Archabbey.

In a century marked by the discovery of the golden section in architecture and its practical applications, the treaty of Lenz is distinguished by direct reference to the Greek sources.

In connection with the work performed by Lenz, Steiner, Verkade and others in Montecassino, the centenary year, you must re-read the personality of monaco-architect and the value of his writings, in the light of the weight in the sacred place well before reforms introduced by the Second Council Vatican.

Keywords: architecture sacred contemporary; golden section; sacred geometry; metric relation; non-iconic art.

The minor role which ecclesiastical architecture in general occupies in the historiography of nineteenth century art is to be deplored.

Peter Lenz, whose monastic name was Desiderius, is not among those who have found a recognized place in the history of the nineteenth century German and European architecture and fine art.

There are two reasons for this: apart from some early works, he confined himself to the area of sacred art; and he lived a life separated from the artistic community, as a monk in the Benedictine monastery of Beuron. He was noticed beyond the circle of ecclesiastical art only in the few years round about 1905. At that time his *Aesthetic of Beuron* was published in a translation by the French *Nabi* painter Paul Sérusier, with an introduction by Maurice Denis and, through the intermediacy of Jan Verkade, the art of Beuron was shown in the Vienna Secession.

Contemporary architecture is based on that on Beuron and its geometric shapes. Rudolf Schwarz, father of contemporary sacred architecture, dedicated only to Lenz a chapter of his *Vom Bau der Kirche*. He attributes to the Benedictine the prototype of the "sacred way", a project template in which the sequence of the rooms of the building corresponds to the sequence of the episodes in the history of the *salveza*.

Not surprisingly, the architect in his essay only mentions Lenz and Mies van der Rohe, because in those years many artists have already left Germany and the Bauhaus has already been dissolved. Lenz in the *Kanon* leads sacred art to the standard classic geometric based on the golden section, theorized by Plato.

Fig. 1: Beuron, St. Maurus Chapel (by Kreitmaier , 1923).

The direct dependence of the German friar from Athenian philosopher is shown by the drawings which illustrate the treaty. They shall apply the reasoning Platonic which all plane figures can be split into triangles and each of them into two triangles rectangles, one isosceles, the other scalene, from which derive the four primordial elements, water, air, earth, fire[2]. Of these triangles «κάλλιστονέν» (*Tim.* 54a) is the equilateral form which the five Platonic polyhedra such.

By means of geometry and arithmetic, Plato was able to introduce into philosophical speculation the concepts of "infinity" and "proportion" of which all subsequent European culture was to be his debtor. Taking the concepts of the *Timaeus*, the most conceptually dense *Meno* has the problem dell'*antanairesis*, the doubling of a square built on the diagonal of a given square, determinant a rectangle whose height is three times the base[6].

It is the figure that symbolizes the infinite: through the solution of a geometry problem, Plato comes to express the irrational, announcing «la grande congiunzione dell'*esprit de géométrie* con l' *esprit fin puramente speculativo della grande metafisica*» (Toth, p.9).

If it is well known the long fortune of this Platonic reflection, through Vitruvius, in all artistic production to the present day, the Lenz's *Kanon* is, in the long fortune that Plato has enjoyed an episode of considerable thickness. The friar's Benedictine attempt is to go back directly to the Plato's theories, by skipping links in a long chain that the Athenian, through the centuries, had come up to him. In geometric figures he recovers the fundamental patterns of artistic representation in its aims specifically epistemological.

At the beginning of the essay states that the geometric proportion are an indispensable means of representation of the human figure in his dignity and that only in number allows us to understand the enigma of creation.

The first lines is a clear direct dependence on the *Timaeus*, since, as Plato, Lenz also inserts his discussion in a discourse cosmological.

Fig. 2: Montecassino, Crypt's decoration (by *Emporium*, 1911).

Fig. 3-4: A. Gresnicht in his atelier; Montecassino, S. Marco's altar (by *Emporium*, 1911).

Fig. 5: Beuron, St. Maurus Chapel (by *Emporium*, 1911).

In doing so, he connects the Jewish-Christian tradition to the classical, even resorting to the drawings which were to accompany the text. Made by Willibrord Verkade, Lenz's disciple and collaborator, they illustrate the steps that allow you to get a simple geometric shape (the circle) to the human body.

Lenz is, in the words of Schwarz, tried to restore the church building inspired by the sacred theme, combining classical roots to the Christian content. This is the end of the *Kanon* of which only recently has been published the first partial Italian version.

The series of sketches is the most modern and faithful of *teorema* explained by Socrates concludes his demonstration of innate ideas in the *Meno*.

Lenz's theories are a unique opportunity in St Maurus: come to Beuron in 1868, here he managed to get a commission from the Princess Katharina von Hohenzollern-Sigmaringen to erect a votive chapel not far from the monastery. By 1870, he had built the Chapel of St Maur, which is unique because of its unusual architecture and still more because of its painting, and deserves a prominent place in the sacred art of the nineteenth century. Jacob Wüger and his student Fridolin Steiner, as well as Lenz's sculptor friend Johannes Schwendfür, likewise contributed to the chapel. Lenz investigated the metric relations of Egyptians sculptures and Greek temples and was constantly searching for the ideal metric figure corresponding to the universally valid measure, according to that rule for the representation of human beings which he called "the canon". For he was ever more convinced that there must have been, analogous to the dogmas of the Church, a correspondingly dogmatic art.

Behind platonic philosophie, ancient sculptor Polyclitus, great Renaissance masters and other aesthetic doctrines stood the conviction that the ideal beauty of the human body rested

Fig. 6: Norcia, St. Benedict's Church, Crypt's decoration (by Carillo, *Spes*, 2007).

upon a geometric figuration or that it resulted from exact metric relationships of the parts to the whole. On the one hand, Lenz committed his ideas to two separate media: drawings - generally of male and female bodies frontally- and texts. On the other hand, neither of these media was suitable, except to a very limited degree, for carrying through his theories logically.

His drawings, however schematic they may be, also always show an artistic impulse: one almost gets the impression that Lenz wished to use the geometry as a justification after the event to reinforce a thrust towards symmetry and abstraction in his own creative will -while doing this, admittedly, only to the extent that geometric figures also held for him a symbolic significance.

It is only with difficulty that this side of his thinking can be gathered from his theoretical writings. Mathematical ideas are mixed in them with theological-mystical and artistic ideas, so that his thought takes on esoteric features. Throughout his life, Lenz time and again took up the project of formulating in words his studies of the canon and publishing them.

After short version, *The Canon*, appeared in 1921 in the *Benediktinische Monatsschrift*, in the following year, an extensive manuscript went astray in the post.

From all of these published utterances we can gather certain fundamental ideas of the Lenzian canon:

- the source of his conviction is the Biblical saying: hence, the creation, as well as in platonic *Timaeus*, has a sacred geometry as its basis; geometry and revelation were equated; Lenz himself speaks of a theological geometry;
- Lenz matches the basic geometrical figures, in particular the regular solids, to the triune being of God in the following way;
- Since God created man in His own image, it follows that underlying the original human image also there must be a measure, a -for Lenz- sacred geometry. With original Sin, this norm, however, was obscured; only in Jesus Christ is it once more revealed;
- This original human image exists in two figures, equal in value: male and female;

- Lenz believes that the normative image of the man can be traced back to root functions. In his regard, his deductions, which differ in particular details and are presented only with extreme brevity, remain in large part incomprehensible to the reader. He reaches the woman's normative image via a further root, which he calls the feminine, the diagonal of the double square «which as Golden Section can alone establish the contrast which is that of the second sex to the image of the man» (*Canon*, p. 64));

- the aesthetic principles derived from God's revelation are to be a basis for all future religious art: they should draw men towards the true, lead them towards the eternal, especially in places of worship and at the liturgical feasts.

If one asks, then, to what extent Lenz's geometry influenced his own artistic work, the evidence turns out to be meagre.

The value of the aesthetic geometry of Desiderius Lenz lies not in its utility for artistic practice, but in the fundamental position which Lenz adopted, namely that of a radical departure from the principle of the imitation of nature. For Lenz, the knowledge of the canonical figure made the nude model, superfluous.

Fig. 7: Norcia, St. Benedict's Church, Crypt's decoration (by Carillo, *Spes*, 2007).

Fig. 8-9: D. Lenz, Good Shepherd (by Kreitmaier, 1923).

Religious art has been led astray (in one place he goes so far as to use the word *entartet*, degenerate) by the imitation of nature, with its perfect reproduction of optical stimuli; only the rediscovery of the canon -through him- will lead it back to its original and true path.

Implicit here, though it is not expressed presumptuously, is a claim to leadership in the direction sacred art should take. In fact, no other artist followed Lenz on his course; even his own work follows his theories only to a qualified extent. He had all the more importance, however, for some of the artists of the early modern movement, who were on their own way to overcoming the obsession with history and realism, and who found in Lenz a like-minded forerunner. In terms of art and architecture history Lenz in fact anticipated significant moves towards the abstraction of the composed image.

The long quote of Lenz's theories in Schwarz is symptomatic of the complex position of the second: the intent of his deeds is in fact the technique to solve through spirituality.

In the Germany of the thirties, in which every energy was spent on the Great Berlin of Hitler and Speer, the technical problem was fundamental also from a theoretical point of view. The nation that had experienced the most rapid process of industrialization of the West, but has suffered defeat in a war essentially technological, the debate on the relationship between

technology and spirituality was on. In this debate, the position was that of shared Jünger, which seeks to connect the concept of “authenticity” with the technology or Dessauer, for whom the task of the technology is “serving the people”.

Schwarz invokes Lenz's ideas to indicate the urgency of bringing the technique to spirituality as evidenced already in the *Letters from Como's Lake*, published in “Schildgenossen” between 1923 and 1925.

No coincidence that the letters are addressed to a friend identified by Romano Guardini, philosopher and theologian who just Beuron had developed the arguments set out in *Vom Geist der Liturgie* (1919).

Lenz's speculation, his concern to bring together in one unit liturgical space artistically decorated, filtered through Schwarz's interpretation, anticipate many solutions proposed by the Second Vatican Council, playing in a trend semantically relevant contemporary sacred architecture, present in recent case. The design of a «liturgical church» -in the words with which Schwarz interprets Lenz's thought- will have no small influence on the choice of the Council (eg, survey and visibility of the main altar) unanimously shared.

Fig. 10: D. Lenz, *Canon* (by Kreitmaier, 1923).

Fig. 11: Montecassino, Torretta, A. Engel, Tabernacle (by Kreitmaier, 1923).

A striking example of this is *Christ The Light Cathedral* in Oakland, California, designed by Craig W. Hartman (2008), in which the architect solves the so-called “via sacra” the problems associated with liturgical requirements of a single nave, which is set according to the forms in this golden ratio. Derives directly from Beuron's symbology, mediated by Schwarz's reflection of spirit and technique, the project of a church that recovers in the plant the oldest Christian symbols with use of cutting-edge engineering solutions.

Oakland's project exemplifies the fundamental notion that emerged out of the Second Vatican Council, the “People of God”: Hartman's draft, as well as that of Lund and Slaatto in St. Hallvard in Oslo (1966) or *Our Lady of the Angels Cathedral* of Rafael Moneo (1998-2002), they propose, to varying degrees, this sense that we gather as one -a single people meant to worship together, gathered around the Eucharistic table to be fed and nourished and to celebrate culture and art and music. Recovering the oldest Christian symbols or formulas geometric Pythagorean ancestry, they reproduce the model of «processional church».

At the same time, some of these projects -such as the Holy Face of Mario Botta or Oakland's Cathedral- using historical quotes (the Shroud face, the Christ of Chartres) on the one hand emphasize the value of the symbol that was already in Lenz, from a other things, raise questions substantial contemporary art. The mention of the historic effigy makes it instantly recognizable, avoiding the problems still warned against non-iconic art.

The contribution of diagnostics in architectural survey; case study of combined thermography application.

Gerardo Maria CENNAME

Engineering Faculty, International Telematic University UNINETTUNO, Rome, Italy

E-mail g.cennamo@uninettunouniversity.net

Abstract

If up to fairly recent time, the relational system between perception, processing and representation during representation processes was perfected by concluding through natural "intuitus" (physical environment) and human intelligence (perception and processing capacity), the assumption of a dominant role, in terms of methodology and practice, of a third "virtual intelligence", deriving from contemporary developments in technologies such as electronics, information technology and telematics, has transformed the previous method of approach to the environment, natural or built, and to the project.

Applied to the study and investigation of architectural heritage, the contemporary evolution of these technologies of knowledge and simulation, evolve the discipline of representation in the direction of the broader interdisciplinary perspective, establishing a relational system of methods and information that precede and complement the process of knowledge.

The use of computer systems in the context of visual representation, while being purely a technical/operational aspect that does not conceptually introduce new modus or forms of representation, assumes an even epochal significance by creating a clear separation between pre-and post information.

Useful technologies for the material/formal control intervene in the field of diagnostics and in the behavior of materials by developing measurement, protection and monitoring systems of the performance characteristics.

Keywords: developments, technologies, survey, architectural heritage, diagnostics

1. Evolution of detection techniques

There is no doubt that such technologies supporting representative disciplines have strongly evolved the traditional method of investigation, detection and design, up unto determining an opportunity, if not a necessity, of broad insight in this regard by professionals and researchers.

As noted by Della Vecchia and Mura in the work "Technologies and techniques of graphic representation", in the history of visual representation there has never been such a radical transformation as that in the field of technical representation.

Currently with the development of technology, the acquisition of data is ensured in a more precise, quick and versatile manner. In fact even the same geometrical component of the detection does no longer appear as a simple dimensional measurement. Laser and photogrammetry are part of this innovation, and their integration is able to produce such a large volume of geometrical and material information that alone, already allow an in-depth knowledge of formal, constructional and technological values of the work.

The investigation and representation of degradation or damage can be carried out with tools that can simulate what happens inside the structure; these new opportunities are above all very useful in stratified and complex areas such as restoration work on historic heritage.

To know a building structure, in fact, signifies knowing its history, the natural and urban environment in which it is inserted, the distributional characters, the specific construction techniques, tools and materials used for its construction.

The knowledge of the events, also constructive, regarding the building allows the reconstruction of its evolution and the exact identification of architectural, formal and functional aspects.

2. Diagnostic analysis on architectural heritage

In the context diagnostics occupies a crucial role, or rather the set criteria, procedures and techniques for the identification, investigation and representation of the constituent elements, material and technological aspects and their evolution, which is essential for obtaining a deeper detection of architectural heritage.

The diagnostic action also analyses the changes in the structure and constituent materials of the object, produced by the most various causes, providing information on the composition of the materials used, on the technique of execution, on previous changes or maintenance interventions and on possible changes in the intended use.

The result of the diagnostic knowledge is also indispensable for implementing preventive measures.

The diagnosis for the conservation of artefacts is therefore based on the graphic documentation, which, starting from the autopsic examination includes a scale drawing and mapping of the deterioration. Along with the architectural detection and the mensorial activities, analysis and knowledge of the conservation status of broader area of archaeological and architectural heritage compared to the single artefact determines a regional level mapping that can delineate situations of greater or lesser uncertainty for the exposure to different risk factors.

Today the diagnostic phase tends to confirm its traditional skills, emphasizing the aspects of technical investigation due to the availability of efficient tools and recognized methods; in addition to the shape and architecture, it also investigates the structure with scientific rigor, objectivity and reliability, which is what is expected from a good diagnosis.

The possible progress in this sector today, however, often depends on the development of ever more advanced technologies, such as the use of innovative sensors based on optical fibres and on the miniaturisation of components in their energy autonomy.

The frontier of monitoring, therefore, moves towards the integration of skills and the development of integrated techniques of monitoring; the most frequently used non-destructive type diagnostic investigations are:

The sclerometry analysis, pachometric analysis, magnetometric analysis, sonic analysis, ultrasonic analysis, endoscopic analysis, analysis by X-ray and tomography and thermal and thermography analysis, the latter based on the visualization of thermal differences on the surface of architectural artefacts.

3. Thermography in the architectural survey

Among the non-destructive analysis techniques, thermography certainly represents an important tool of knowledge of architectural heritage and has found in recent years, after some initial setbacks, a wide application in the field of Cultural Heritage.

Thermography is definable as a true measurement procedure that is non-invasive and does not require direct action on the object and is applicable to the diagnosis of dysfunctions and constructive problems of the buildings. In most applications the absolute temperature of the buildings is not as important as the mutual difference that they have. Thermography can be active or passive; active if it detects the energy emitted from the wall, providing the distribution of surface temperature, active if it thermally stimulates the masonry. The thermography camera employed allows to investigate temperatures between - 40°C and 500°C, with a thermal sensitivity of 65mK and an error of $\pm 2\%$ on the reading or $\pm 2^\circ\text{C}$, operating on the wavelength band of the infrared radiation comprised between 8 and 14 μm , which is an interval of the broadest infrared spectrum of the infrared spectrum.

It can be therefore easily understood, which cognitive contribution this technique is able to give in a completely non-invasive manner, providing valuable information relating to the transformations undergone by the architectural system, thanks to shown discontinuity of thermal-physical characteristics of the materials constituting the first deep layer of the wall. The difference in "response" to the thermal stimulation of frequently used materials, such as wood, bricks, stone and mortar between blocks, can therefore be easily visualised by the impression that they project onto the layer of plaster that covers the view. The information obtained and translated into depictions allows us to detect critical situations such as the presence of hidden or detached structural elements, cracks, metal adhesions and everything necessary to determine the historical evolution of the building.

Through the thermography representation of an architectural structure as a whole, and even through the thermogram when the infrared image represents entities that are not otherwise viewable, you effectively obtain the complex of more hidden information regarding the detected object. In this manner it is possible to highlight the quality, the constructive adequacy, highlight architectural structures hidden in the masonry and then buffered, hidden structural defects, rising damp, stagnant water, points of water infiltration, thermal bridges or detect interventions carried out previously.

4. Case study: the bell tower of Sagittarius and the grange of Ventrile

The case study presented in this paper is based on a thesis developed in the degree course in Civil Environmental Engineering, and regards The Grange of Ventrile, a Cistercian complex located in the province of Potenza in the region of the municipality of Chiaromonte.

The complex consists of the remains of the Cistercian monastery of Sagittarius and the defensive grange, a fortified structure with a round tower to the south and a square tower to the north; they are two historical realities, among the most important, especially the Abbey of St. Mary of Sagittarius, that emerges among the ancient monastic one of the county of Chiaromonte and the whole Basilicata.

The case study concerns the detection and combined analysis through the thermography technique carried out on the bell tower of Sagittarius and part of the perimeter walls and the recovery of an area of a structure, the Grange of Ventrile, directed to a bigger recovery action and renovation of the site and nature trail along the valley of the Frido stream.

In the case under examination active thermography was used, where the masonry is thermally stimulated.

On the survey site the radiation was measured with the thermography camera, which had to have the ambient temperature, the emissivity of the material of the object being examined and the distance of the object, set adequately in the instrument as it is influenced by the external environment and also to avoid temperature assessment errors and take into account the parameter of the angle recording, also called angle of incidence, which increases the reflectance of the surface on increasing the angle and decreases the emissivity.

Two thermography recordings were carried out of the constructive wall element with different recording angles, the first with a high angle and the second frontally (angle of incidence close to zero), in order to highlight the different physical characteristics of the material that justify the distribution of temperatures, such as density, the state of inhibition, the surface porosity, alterations and the presence of organic residues.

Infrared analysis were carried out with the Flir, ThermaCam™ P65 model, therefore showing the acquired infrared images and, where needed, the corresponding visible images to better identify the examined area.

Fig. 1: The landscape

Fig. 2: Image of the site

Fig. 3: Ruins of the Grancia

Fig. 4: The village of Sagittario

The structure has been completely abandoned, built of stones and bricks; there are three openings on the west wall, while the openings to the north of the body of the building are narrow slits.

A cognitive thermography investigation was carried out, allowing the present structures such as the masonry work of different periods interfaced by different layers of bricks, contributing to reconstructing the history of the building; it was possible to recognize the bearing wall made from bricks with a regular structure with inclusions of stones and recycled material.

From the point of view of architectural assessment the recognition of the existing architectural structure, of the type of masonry present, its homogeneity and varieties, the regularity of the wall paths, and the size of the masonry unit were important. All this information input is important to correctly perform the structural study whether it is a numerical or analysis of the finished element. In the structural assessment it is important to know the alterations suffered by the building and thermography is a useful tool for investigation in this regard.

Defects of mechanical relevance were detected, such as cracks and crevices, with greater ease and completeness compared to structural and photographic detection. The appearance of the detection of cracks was enhanced in this historic building thanks to image rectification, in this case of thermograms, having a correct spatial restitution of crack distribution on each wall or macro-element. The structural value of this type of detection lies in being able to locally and globally evaluate the instabilities, deduce the causes and interpret the behaviour of the building: to that end, being an abandoned there are considerable cracks.

Fig. 5: Details of the Grancia

Fig. 6: Sectiones, village of Sagittario

Digital filter were also used to eliminate the influence of objects with temperatures higher or lower than a certain level in order to concentrate the temperature scale only on the masonry and overlooking the constructive element that do not regard the investigation. Advantages can be obtained if the filters are used accurately. You should decide from the moment of the shot what the object of the investigation is and restrict the temperature range used to investigate, in a manner to identify the details of the subject and decide where to shoot a photogram. When a thermogram is shot the element can be “burned” (or over-exposed) which does not apply, gaining on the ease of identifying the thermogram during the re-elaboration phase. In this phase a temperature scale is identified that mostly shows the details of interest of each thermogram, executing the mosaic and applying the filter, a detailed image is obtained in which only the masonry is visible.

With this procedure it is possible to identify even small details such as plug insertion used to support elements that are no longer present, but deducible by the regular distribution of their positioning.

In illustration 7 it can be noticed that the walls are subdivided in two main horizontal thermal layers. The dividing line is at approximately 1.5 metres from the floor and, considering the thermal gradient step which can be observed in passing from one area to another, it can be deduced that it is due to a different wall surface finish. In the high part a warmer area is present which could hide till preserved decorations.

Fig. 7: Thermographic survey on the Grangia

Fig. 8: Texture of the brickwork

Fig. 9: Survey points on the Grangia and on the north tower

Fig. 10: Survey points on the photographic image

From the analysis carried out, the following composition of materials was detected: the wall of the complex of Ventrile and the Abbey of Sagittarius were built with stone blocks of limestone, a material that tends to degrade rapidly, dissolving when attacked by acidic substances in the atmosphere. The masonry was built with stones of the river, partly mixed with flakes of clay and has in most cases, an absence of mortar in the joints. The roughness with the presence of cavities and the emerging on the surface of the concrete stone constitutes the element characterizing the stone surface. In general, the high porosity of the materials used in the two historical complexes, involves a strong sensitivity to the phenomena of frozenness which cause the disintegration of the wall surface. Furthermore, the micro fractures produced by roughing involve an accentuation of the disintegration of the materials, especially as in these cases, if they are in contact with water and exposed to winds, where the material undergoes thermal stress and investment from dust. The analysis of the instabilities and metric degradation, due to the investigation through thermography, led to the evidence of:

- Cracking in the wall and lack of continuity of it;
- Partial loss of bricks;
- Chromatic alteration for oxidation of ferrous substances present in the masonry;
- Efflorescence for crystallisation of salts detectable on blocks of stone due to the capillary rise of water from the soil;
- Progressive flaking of the stones associated to cracks;
- Cracks of mechanical breakage type;
- Patches, with flakes of clay;
- Marks at the edges as a result of the brick arches washing away arches arranged in joints, with an advanced state of internal fracture cracking;
- Internal corrosion phenomena for frozenness;
- Surface break-up and not brick.

Thermography is therefore an essential tool in order to plan with precision and accuracy the works of renewal interventions. Through the thermal image you can check the "health status" of the structure to be renewed. Being a non-destructive control, the thermal image cannot alter the state of the complex to be analysed. The thermography vision of an architectural structure as a whole, allows the quick and effective visualization of any structural defects. In this manner it is possible to highlight the quality and adequate or inadequate execution of work in construction works. Thermography applied to building allows you to highlight architectural structures hidden in the masonry and then tamponed, or go back to maintenance carried out prior to the thermography detection. It is therefore possible to reproduce the detailed account of the work itself, avoiding waste of time and invasive actions to identify areas of possible intervention.

The Ablution Room of the Hafsid dynasty in Tunis: architectural and artistic aspects

Lamia HADDA

Department of Architectural and Industrial Design "Luigi Vanvitelli", Second University of Naples, Aversa, Italy.

lamia.hadda@unina2.it

Abstract

Starting Ottoman era to the present day, the Hafsid monuments of the Medina of Tunis have undergone major transformations both from a structural and from stylistic-formal point of view. In many cases, the refurbishing have completely deleted the elevation of the original buildings, leaving only the fundamental trace of typological system. In other rare cases, however, it has preserved the original architectural structure, as the case of ablution room *Mid'at es-Soltāne*, built between 1448 and 1450.

The monument is located in the heart of the old town, down the road that leads to the *sūq al-'Attarin* (market Perfumers). This is an area adjacent to the mosque *al-Zaytūna* for the faithful who use the site for the ritual washing of the Muslim prayer. The room has a unique architectural style that draws much from the artistic traditions of Eastern from Syria and Egypt in particular.

The research is based on the study of the surviving parts of the planimetric and formal components by means of a systematic reading of the architecture of the second half of the fifteenth century in Tunisia and the Near East.

Keywords: Ablution Room, Hafsid architecture, *Mid'at es-Soltāne*, Medina of Tunis.

At the end of the Almohad dynasty (1147-1269), North Africa was ruled by three dynasties that were in constant conflict: the Marinid dynasty (1196-1465), that lived in Morocco; the western part of Algeria was under the control of the *Abd al-Wadids* (1235-1500); while the Hafsids (1235-1575) governed the eastern part of Algeria, modern day Tunisia and the west of Lybia. Under the constant threat of incursions by the surrounding Berbers, these dynasties fought for the hegemony of North Africa [1].

The founder of the Hafsid dynasty was Abū Zakariyā Yahya ibn Abī Hafs, known as Abū Zakariyā I (1228-1249). Whilst in Marrakesh, the capital of the Almohad kingdom, he declared his autonomy over the Ifriqiya territory. The hafsids princes governed Tunisia for almost three hundred years with its capital based in Tunis [2].

It was only towards the middle of the 14th century that the Hafsids were threatened from the west by the Marinids from Morocco, occupying the capital twice in 1349 and 1356. After the fall of Granada (1492), the Spanish – using naval power - threatened the coast of Maghreb up to Tunis. In the same period, the Barbary pirates, led by Redbeard, who had already occupied Algiers (1516), conquered Tunis in 1534, thus ending the reign of the Hafsid sultan Muhammad ibn al-Hasan (1573-1574). The rising power of the Spanish and the consequent fear of the Barbary pirates, led to the invitation for Turkish intervention which brought about the Ottoman conquest of Tunis under Sinan Pasha in 1574 [3]. From that time to the present period, the Hafsid monuments of the city have undergone significant transformations both from a structural and a formal-stylistic viewpoint. In many cases the change has completely modified the original buildings leaving only traces of the original foundations. Instead, in rare cases, the architectural structure has remained intact.

Fig. 1: Tunis, ablution room, floor plan.

In effect, Hafsid Tunisia went through a period of great economic and cultural prosperity under princes Abū Fāris 'Abd al-'Aziz (1394-1434) and Abū 'Amr 'Uthmān (1436-1488); many monuments were, in fact, built during this period. Among the most famous are: the Al Qasba with its mosque, the restoration of the *al-Zaytūna* mosque, with the annexion of the library, and the building of a prestigious ablution area called *Mid'at es-Soltāne* between 1448 and 1450 [4].

This monument is found in the heart of the historical centre, at the end of the road which leads to *sūq al-'Attarin* (market of the perfume makers). It is an area annexed to the great *al-Zaytūna* mosque, used by worshipers to wash according to the traditional rituals of the Muslim faith.

Written sources say that the monument was commissioned by the Hafsid sultan Abū 'Amr 'Uthmān (1436-1488). The building of the monument was presided over by the architect Ahmad al-Qusantini with work starting in 1448 and ending two years later [5]. The building has undergone some reconstruction especially of the wooden covering as can be seen from an inscription on a beam which dates back to the 18th century [6]. The rest of the building is in pure Hafsid style: the portal, the arches, the capitals, and the fountain.

The entrance still preserves an elegantly decorated portal in two-tone marble with columns adorned with Hispano-Moorish capitals. The architrave is enhanced by a large slab made of ashlar blocks of black and white marble arranged with horizontal courses at the sides and radiating from the centre. Towards the middle of the 13th century the French architect Villard de Honnecourt paid particular attention to this technical process for stone. In his notes, kept in the National Library in Paris (Ms. fr. 19093, tav. XL, fol. 20), the famous architect describes the technique used to cut blocks for an arch in such a way as to obtain blocks which are suitable to be placed radially [7].

The entrance door leads to two halls, separated by horseshoe shaped arches with two-tone ashlar blocks and surmounted by a rectangular panel decorated with strips of black marble which form three quadrants of black and white marble with a star enclosed in a square in the middle.

The inlaid panels used to decorate the walls are representative of two-tone geometrical decorations. They can be summarized according to various fundamental geometrical shapes: flat arches or medallions composed of thin strips with ashlar blocks in different shapes; stars, intertwined, cylindrical, polygonal. They have all been created through the use of inlaid black marble strips on white marble.

The ornate with stellar motifs uses the basic principles of geometry, repetition, subdivision and multiplication to create a multitude of designs. The source of inspiration is the polygonal composition which normally originates from a central circle divided by polygons from which the various polygonal weaves (called stellar) develop. They are formed by surfaces of perfect proportions. The star forms part of the originating motifs of the geometric decoration to such an extent as to be counted as the most symbolic of Islamic art [8].

This type of inlaid decoration is found in Hafsid architecture on both walls and floors as we can see, for example, in the internal courtyard of the mausoleum of Sidi Qāsim al-Zalījī (second half of the 15th century) [9].

Fig. 2: Tunis, ablution room, frontal view of the entrance.

Fig. 3: Tunis, ablution room, main hall, frontal view of a blind niche.

The fulcrum of *Mid'at es-Soltāne* is composed of a peristyle square room surrounded by four large horseshoe shaped arches with two-tone ashlar blocks which lie on Hispano-Moorish capitals. The arched lintels of the arches are covered with slabs of black and white marble and are decorated with geometrical motifs. In the middle of the room there is an octagonal fountain, whose facades have panels of marble that are almost a metre high and which are decorated with imaginative geometrical motifs.

At the base of the piers, on both sides, a snake like decoration carved in relief can be seen. It is often presented in the shape of one or two spirals whose surface is covered with scales and is very similar to the palmettes on the Hispano-Moorish capitals in Tunis of the same period. This motif is also present in other monuments of the Hafsid era: on the piers of the doors of the mausoleums of Sidi Ben Arus, Sidi al-Kala'i and Sidi Qāsim al-Zalījī and on the door of the library of Abū 'Amr 'Uthmān in the *al-Zaytūna mosque* in Tunis [10]. Therefore, it can be said that the snakelike ornamental motif subsequently developed, elaborately, and is used extensively in Ottoman buildings and religious monuments [11].

The beauty, and the particular style, of the room drew the attention of many scholars of the time. Among these the famous poem by ad-Damāmini can be recalled. It defined *mid'at* as a beautiful building built in a perfect architectural style which is so elegant and finely executed to the point that it can be considered a model in its genre [12]. The shapes, and the architectural and decorative techniques used in the Ablution room recall the Ayyubid and Mameluke buildings in Syria and Egypt built in the 14th and 15th centuries, where similar motifs are found in black and white inlaid marble which were used to exhalt the chromatic elements inside the monuments [13]. Among the most famous examples in Cairo are the masonry face of the funeral hall of Madrasah of Barkuk (14th century) and of the Ahmed al-Bardini mosque (15th century), the floor of the funeral mosque of the sultan *al-Malik al-Ashraf Barsabay* (1421-1438) and of the *Maqsura* of the Abū Bekr Mazal mosque (15th century) [14].

It is worth noting that these decorative motifs were probably brought to Tunisia through Egypt in the 15th century. This technique was widely used in the monuments during the following centuries, such as the *zāwiya* of Sidi Qāsim al-Zalījī (end of the 15th century), and even more so in the Ottoman era in the Medina of Tunis. Among the numerous examples of this last period, Dar Abū Zayane (15th – 16th century), The Palace of Dey 'Othman (16th-17th century), the Mausoleums of Sidi Yusef and Hammuda Pasha (17th century), *Dar al-Mrabet* (17th century) and *Dar al-Bey* (18th century) [15], should be mentioned.

Fig. 5: Tunis, ablution room, facade of the south side of the peristyle.

It is worth reiterating the Andalusian influence. This influence took root in *Ifriqiya* during the first influx of emigrants who took refuge in *Ifriqiya* starting from the 8th century. This is also confirmed by the famous historian of that time, Ibn Khaldūn: "The arts develop admirably albeit with less momentum than in Spain. In addition, the influence of Egypt is particularly fruitful. The two countries are not distant and Tunisian travellers visit Egypt every year. Sometimes they live there for some period of time making artistic objects and sharing technical knowledge. For this reason Tunis has become as educated as Cairo, and Spain itself, thanks to the Andalusian refugees of the 7th and 8th centuries [16]." Moreover, the good relations between the Hasid sultans and the Mamluk rulers of Egypt contributed to the spreading of this artistic style during the 15th century. All of this was possible thanks to the continuous exchange of artisans between the two countries as can be seen from inscriptions written, by Egyptian craftsmen, during particular public works [17].

In conclusion, it can be stated that the Hafsīd era was characterised by a simple but highly creative architectural output thanks to which diverse Mediterranean decorative features were brought together. On the one hand, the Hafsīd repertoire remained linked to the artistic and architectural elements which developed in *Ifriqiya* such as the ancient Punic, Roman and Byzantine ones as well as the Islamic Aghlabid, Fatimid and Zirid ones; on the other hand, it was influenced by diverse trends coming from Andalusia, Morocco and even Mamluk Egypt.

Abstract

In the last pages of *Architetture per i lavoratori tra Napoli e Caserta. Progetti e realizzazioni dal XVIII al XX secolo*, published last June, where I analyzed working houses, I wished for the chance to study the popular districts made in Caserta during the 18th century as it was evident they represented interesting urban architectural solutions. After a year studying archive and bibliographic data I realized the validity of such an hypothesis mainly during the years between the I and II World War when the Municipality approved the building of cheap dwellings in key areas to improve the future development of the City. In this period, in the area of the market built in 1890 and in piazza Venezia, the Southern part of the City, they made new residential buildings for lower classes. Through such a publication I am presenting the research by Patrizia Moschese PhD, architect Pasquale Vaiano and I, whose development will be published in a future detailed work.

Keywords: Cheap dwellings, lower-class dwellings.

Fig. 1: Caserta, aerial view of Via Battistessa and Piazzetta Commestibili.

Fig. 2: Caserta, aerial view of Piazza Venezia.

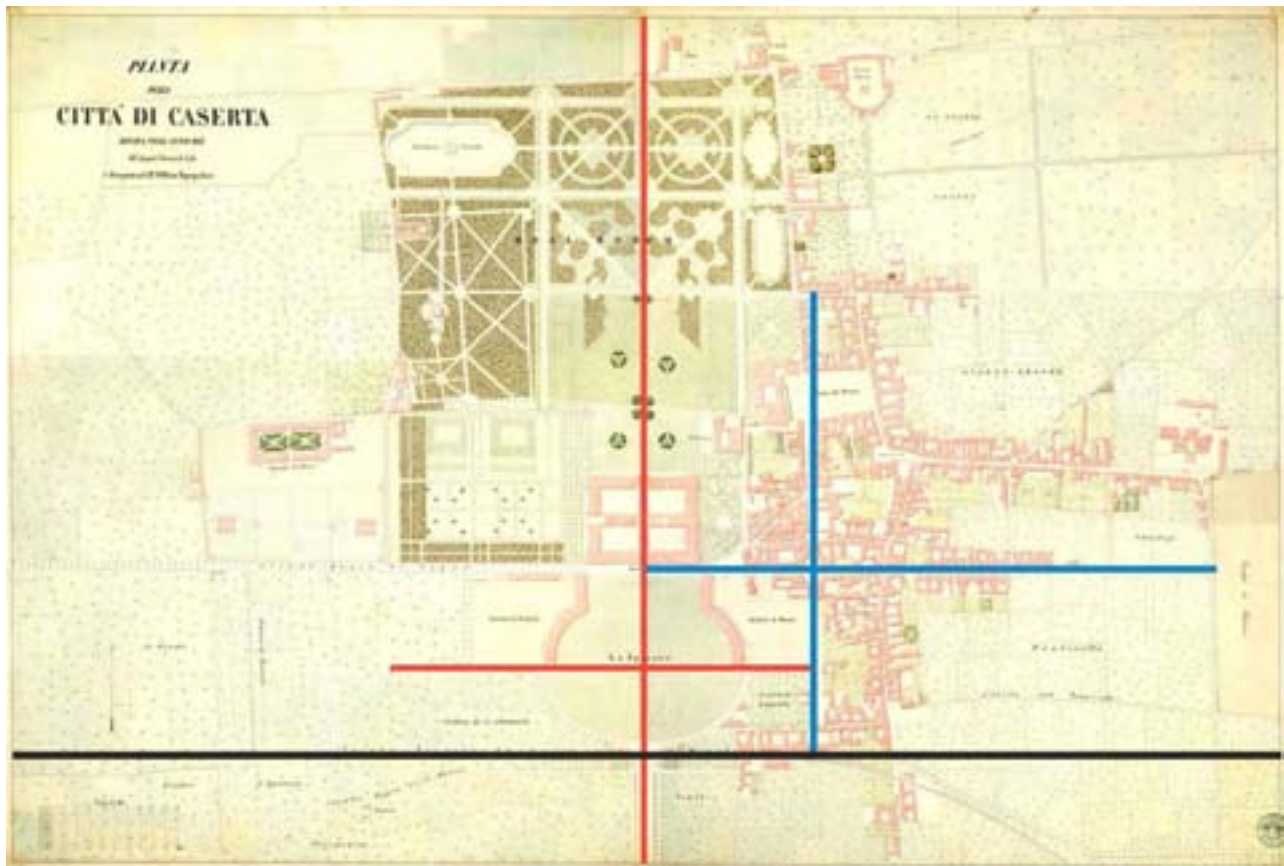

Fig. 3: Historical map (1857) with the axes of urban development in the eighteenth (red) and nineteenth (blue) century.

In 1920s, during a difficult building crisis, the ruling class of Caserta considered necessary the building of new low-cost dwellings. The coming back of world war survivors, the presence of a city military unit and employees, the idea of the Municipality «[...] to create the urban built-up in the city centre» calling to the city village people coming from the outskirts, shortly caused people increase and, consequently, «[...] an urgent need of small and medium sized houses and dwellings». This happened in a social context where building and agricultural activities were the main human income source, while the opening of new building sites would mean to revitalize local economy on one side, creating new jobs, and to provide the city with cheap dwellings they needed, on the other.

Moreover, from an optimistic point of view, they thought *Caserta* was capable of offering the best conditions to support the economic upturn: «it is necessary to underline that no city in Italy has such capabilities all together. The best and most perfect tufastone is nearby in the city-centre; the *pozzolana* is risen from the groundwork digging, the lime from the neighboring *Casagiove*, working men were little paid if compared to other cities, and we can easily get astonishing and dedicated masons».

The programmes of the Municipality were carried out in 1921 through «[...] the brilliant decision to create an Institution of “Case Popolari” (Housing Project) in order to build cheap and safe houses profiting governmental funds». At the beginning they used £. one million loan the Municipality got by “Cassa di Risparmio del Banco di Napoli”, thanks to their lands and buildings – some in Centurano area once to the former *padri Riformati di Santa Lucia* monastery, *padri Liguorini* garden in *Giannone* street, some buildings in Sant'Elena square, *Caprioli* building palace in *Ferrovia* square – the Institution of Case Popolari started the building of residential buildings in the north side of the city centre, in the area of the *Mercato dei Commestibili* built in 1890 according to the project of eng. Mr Arrigo Veccia who conceived it in a crossing of roads built to link the new building texture to the former one.

In 1922, they started to build four buildings in *Bologna* street and the elevated railroad of *Mercato dei Commestibili*, planned by eng. Mr Luigi Fabricat. However, as the Istituto was not cautious in managing economic resources in 1925 here were many interruptions and controversies, consequently Giovanni Tescione, the first podestà of Caserta from 1927 to 1931, wanted to manage the Istituto Case Popolari to restore the budget to balance in order to ultimate the buildings mentioned above: «[...] not easy commitment, but I considered it a duty for my engagement, despite the amount of economic interest of the Municipality».

Despite the managing difficulties of the Istituto Case Popolari, the podestà Tescione, decided to give to the

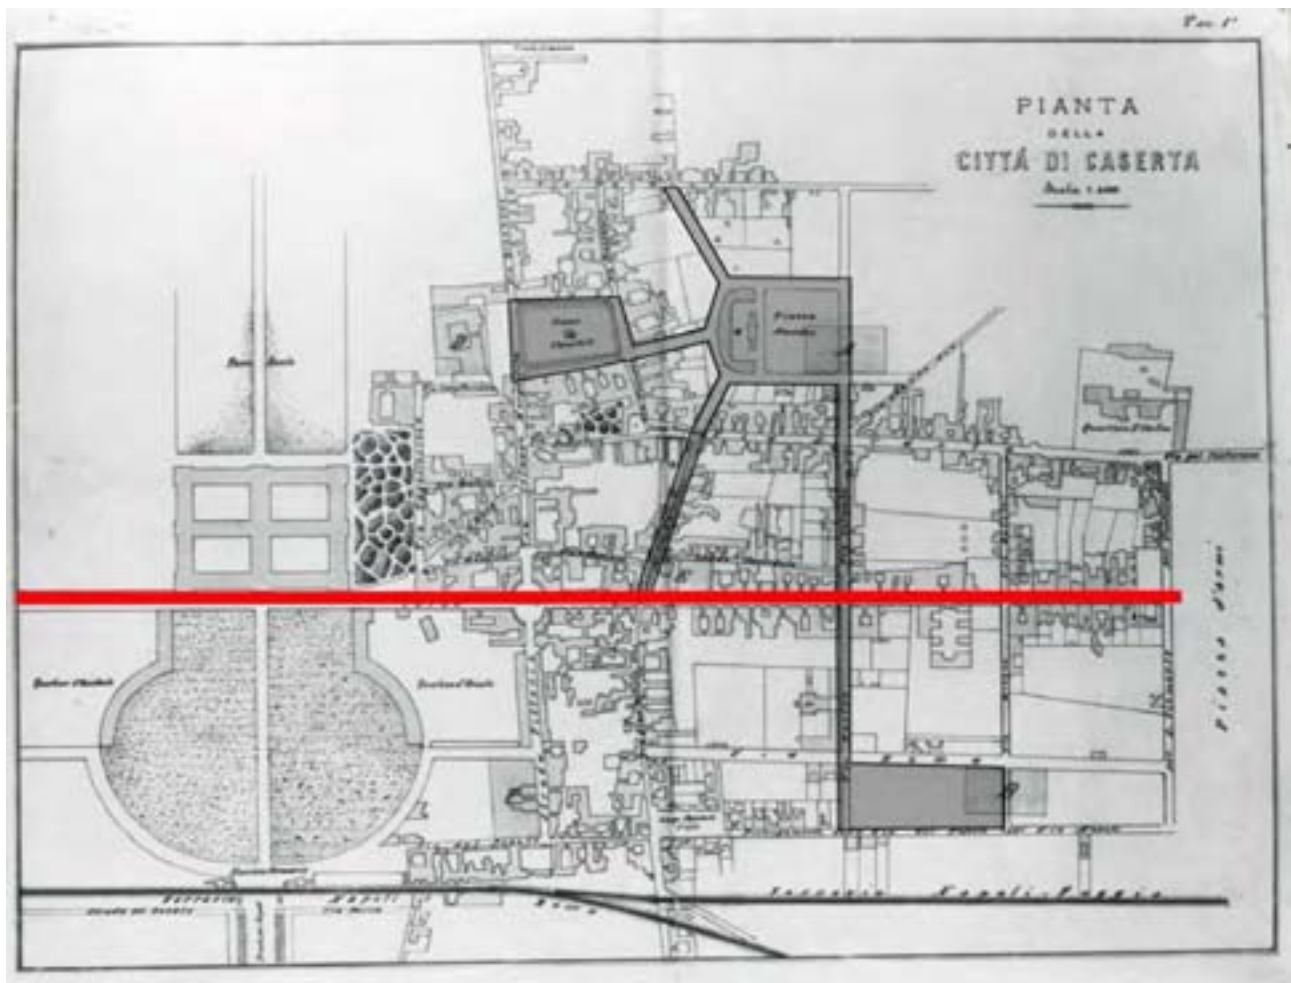

Fig. 4: Historical map (1902) with the central axis of the Corso Umberto I (red) and the new squares (gray).

Municipality Managing office the building of two residential buildings containing twelve flats, in the area of Venezia square, in the southern area of corso Umberto I, made up between 1927 and 1930 under the direction of eng. Mr Vincenzo Memma. In the same area and the same period five cheap dwelling- buildings were built: four small buildings belonging to *Cooperativa Ferrovieri*, built in Roma street in 1925-26 planned by Memma, and *Cooperativa Mutilati* and *Invalidi di guerra* building, built after 1929.

According to the press dating back to that time we know that they conceived cheap detached houses, not only the buildings mentioned above. In 1920 Memma's town plan called for small houses endowed with gardens, they were conceived for Soldiers in Giannone street, in an area they got by limiting the gardens of the Royal Palace of 30 metres, so reducing the wood which separated the public road by the Italian gardens planned by Vanvitelli, but luckily such a project has never been realised. On the contrary, in 1922 a report in *Fabricat* underlined the building of a "city garden" in Centurano, on a land probably belonging to a former monastery of *padri Riformati di Santa Lucia*, that the Municipality gave to *Istituto delle Case Popolari* in Bologna street and princess Maria del Belgio street and Amedeo square, and in Venezia square, so giving to the city about new 130 dwellings.

The first prerequisite of the new dwellings were cleanliness, comfortability and cheapness, as reported in *Fabricat* as regards the buildings in Bologna street: «[...] they correspond to their targets and blend modern cleanliness needs and comforts to cheap patterns in the available areas. Moreover they satisfy the City needs». They were the same needs they asked for the working class houses made in Naples soon after the State Union, making evident it was very important to take care of cheap and technical aspects instead of an architectural quality research. As a matter of the fact, the houses in Caserta were endowed with kitchens, bathrooms, limiting areas to separate the interiors, they were detailed as regards air and sun-light, private green areas and accessories (Shed, garages,...) everything was the expression of planning criteria aiming at optimizing and simplifying the well-known targets of residential low-cost buildings made up in many Italian cities in 20th century and codified by technical papers.

The most difficult planning aspect was to adapt to the irregular shape of the building lands, as in the case of "A" building in Bologna street, or in the case of previously existing buildings, as elevated structures in Com-

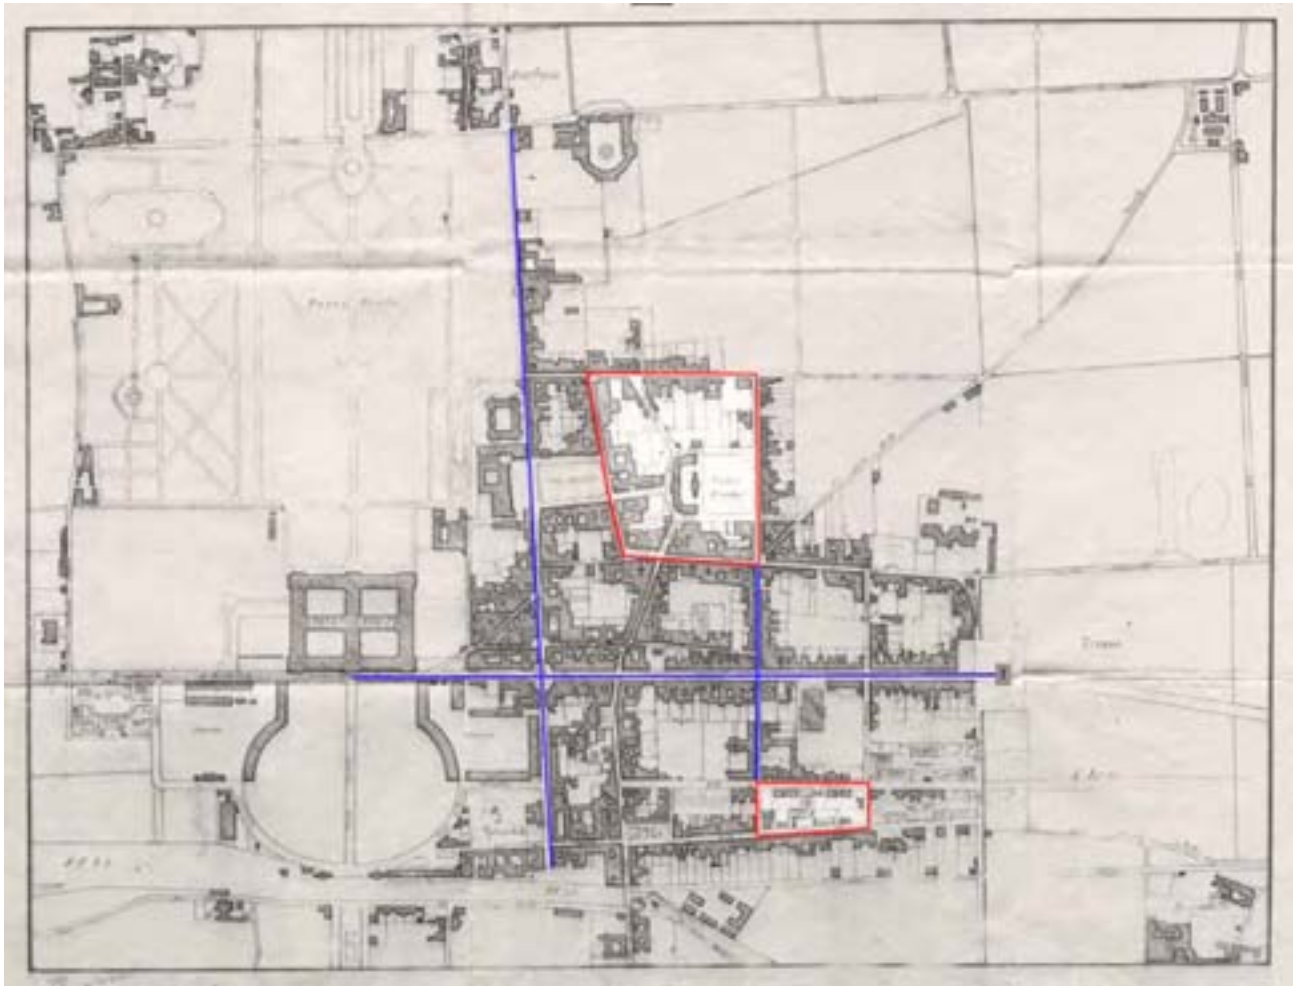

Fig. 5: Historical map (1935) with axes of urban development in the twentieth century (blue) and areas of Piazza Amedeo and Piazza Venezia (red).

mestibili place. However, even if they looked for cheapness and functionality they paid attention to building aesthetics through eclectic 19th century refinements and living to facades refinement and elegance instead of an excessive decoration, which was made by the same artists: «we have tried to give to the houses a simple, modest and not rich aspect but likely and decent, so to underline details and to make the tenant love his-own house in order to improve a moral aspect too linking personal cleanness to a spiritual one».

The building of the new lower-class dwellings was made necessary not only by the desire to build cheap houses or the chance to use governmental benefits but by a desire of up-to-dating the city. The managing class desire to empower and rationalize the urban system was clearly expressed in the town plan by eng. Mr Vincenzo Memma in 1920, only partly realized. In 1920s the city was made functional realizing new public buildings – Post office building in Redentore square, Chamber of Commerce in Roma street, the school building today titled “Edmondo De Amicis” in Giannone street, the local headquarter of the Fascist Party in Amedeo square etc. – and enriched by some valuable private dwellings (villa Vitrone in Napoli street, Tescione palace in Umberto I street etc.). Unluckily the continuity of urban renewing was sharply interrupted by Mussolini government restrictions that in 1927 established the abolition of Terra di Lavoro area. Since then the work in progress buildings were carried out despite many economic and administrative difficulties, while the developing plan of the city was re-started after the Second World War by defining new urban tools.

Borgo Appius - Borgo Domitius

Gianluca CIOFFI

Dipartimento di architettura e disegno industriale "L. Vanvitelli"
gianlucacioffi@hotmail.it

Abstract

Borgo Appius rural settlement in Grazzanise, and Borgo Domitius in Castel Volturno, both in the province of Caserta, were built since 1940 as part of a broader plan to colonize the country.

They are "sponsored" by the ONC (National Opera Fighters), the organization of war veterans, who takes various actions similar especially in central and southern. As well as residential settlements and productive for new inhabitants, had become a reference point for the neighboring agricultural landscape.

The project is written by Moses Tufaroli and Emanuele Filiberto Paolini, but the construction work, which should have been concluded in a short time, they were interrupted by the outbreak of the Second World War.

In fact, the Borgo Domitius are completed only the church and the home of the beam, while everything else remains unfinished. Borgo Appius, however, comes at a higher resolution, settlement, intended to house 500 residents, is designed as a small, self-contained rural community, consisting of houses, public buildings and a church. All buildings, following the guidelines of autarkic building practices of the time, they are designed using a simple architectural language inspired by the Mediterranean villages, using local materials and reducing the use of high-cost techniques. The urban layout is linear and balanced, concentrating all public buildings in the central square and the location of residential areas in direct connection with agricultural land. After the construction stopped in 1941 the settlement was damaged during the war and has undergone further changes in the following decades, leading up to its current state of disrepair.

Rural villages in southern Italy

1. ONC Lower Volturno in Campania

The action of the ONC in Campania is concentrated mainly in the area of the Volturno and the Sele. At the beginning of 1939, the Work of a colonization program of about 18,000 hectares, including sub-basins arranged in a more urgent need for environmental remediation and social development. The area in question, formed mostly by wetlands, had for centuries been used for the natural grazing cattle buffalo, which, however, has not been entirely lost, even if today happens in organized companies.

The first attempts to remedy the low use of these marsh areas date back to the early nineteenth century. While from 1917 to 1927, the consortia began plumbing and drainage work that subsequently led to the construction of a road network, which is essential to any attempt to change the land. "However, unlike other areas of remediation such as, for example, large parts of the Lowlands of Puglia, a suitable plan in this area of colonization could not be conceived, if not coordinated for a swift completion of reclamation public works" [1].

The ONC intervention allowed for the works to be carried out faster, delayed due to the low efficiency of consortia, and also allowed "to introduce in the intensive cropping systems - active and succeeded in what until then had been considered inevitable, and the permanent home, on the same spot of the cultivation of a stable agricultural community in comfortable farmhouses built on their farms" [2]. Through this experiment, there is the start of a real renewal culture, what would be impossible through the previous project to centralize human settlements in the city. The idea of setting up a widespread number of settlers in the area with their farms is made possible thanks to the construction of numerous roads, first through the consortia and then the ONC. "It is obvious that such a complex farm organization had to be sustained and built for the purpose of lasting permanence of families on farms, by the establishment of business centres where they also collected the civilian community services: schools, churches, barracks for the police, municipal

delegations, post offices, doctors' surgeries. This work was begun with the building of two boroughs: Appius, in the right Volturno, completely built and still efficient, and that of Domitius, which was under construction in Ponte a Mare and was interrupted by the war"[3].

1.1 Borgo Appius

Borgo Domitius and Borgo Appius were designed by Moses Tufaroli and Emanuele Filiberto Paolini. The two designers shared with Concezio Petrucci throughout the long history of the founding of the city, but in this case they were working alone just like Petrucci and Segezia. From Segezia onwards, the association is divided and is not reunited even if the Borgo Appio project is approved by the ONC, with note 325/79 of October 28, 1939, to the Ministry of Agriculture and Forestry in conjunction with its plan for the Tableland prepared by Petrucci. The works for the construction of centres (Appius and Domitius) were coordinated with the work of land division and began on January 30, 1940 with the company "Ing Antonio Caserta" from Naples.

The land division work of the Lower Volturno started on 1 April 1939 with a first phase involving the construction of about 15.60 km of farm roads (with a width that varies from five to three metres), 185 new farm houses (with about 13.50 hectares each), and the renovation of 28 existing houses [4]. In December 1939, work began on the second batch, comprising 50 km of farm roads and 607 newly built houses, for estates ranging from 7 to 12 Hectares, as well as the renovation of 42 existing homes to be used as farm houses, housing for employees, warehouses and various services. In the early months of 1940, work began on the construction of Borgo Domitius and Appius and the realisation of warehouses and silos. In the same year, work began on the water and electricity supply. All these works were, according to forecast, to be completed by 1941, but the difficulties caused by the war, leading to numerous slowdowns, with about 80 houses, 3.50 km of farm roads and two existing houses to be restored still missing in 1943. Borgo Appius was designed to give accommodation to 500 people and provide assistance to the settlers scattered throughout the territory. It fitted between two orthogonal connecting roads, one already present Cancellone - Brezza and a new one to be laid. The Plain was characterized, on the inside, by the intersection of the axes parallel to the first: these were generated by the intersection of the four quadrants placed where there were various buildings and services. The Hamlet resembled a fortified village, with several stylistic solutions for individual buildings, inspired by the local rural tradition. The difficulties arising from the war did not allow for the completion of the village, which in the post-war period was also partly demolished. In the first draft, the project for Borgo Appio is called a project for a "Civil Centre for Torre degli Scavi". The location is the one chosen by the ONC, at the intersection of the existing road Brezza - Cancellone and the road reclamation planned from the Volturno to the Regia Agnena Nuova [5].

The road system was set over two orthogonal directions that intersected at an angle of 27°. This approach was chosen to encourage the best sunshine in buildings throughout the year: in fact, along the north-south axis, which is the most beneficial, the buildings were predominantly residential. The complex had the following characteristics:

500 rooms, average size of room 25 square metres, Covered area about 6,250 square metres, the floor area ratio and the surface devoted to orchards and gardens 1:7 Total surface area of the blocks about 50.000mq. Calculating the surface of the lots corresponding to 60% of the total area of the town, including in the remaining 40% of the squares, streets, gardens, buffer zones, the total area of the town of is approximately 8.4 Hectares, leaving an area of expansion equal to that of a farm of 2 Hectares. The plan was developed on one side of the crossroads between the two roads, in such a way to avoid traffic through the centre, with it merely passing by. In the streets and the square, there are the most representative buildings. At right angles to the backbone, they intersect other roads leading to the residential project. The main access road Brezza - Cancellone had an initial 10-m section that tapers at the exit from the square, becoming of 8 m, 6 of which roadway and 2 docks, while buildings are set back from the line of 4 m road. The road was not very wide, imagining a low volume of domestic traffic, but within the parameters of hygiene and lighting needed, thanks to the limited height of buildings that do not exceed 8 metres in height and two floors above ground.

The central square was 36 x 30m with one side slightly flared to increase the effect of perspective, while at the side of the church there was a small wooded area. The roads and square were built on an embankment, as the campaign plan submitted to the street level of about one metre, and all the accessories of the project, (playing fields, vegetable gardens, a fair, square Agrarian company etc.), were expected to suffer for economic reasons. At the square, spatially enclosed by buildings, accessed via an archway, as well as in traditional fortified farms of the south and Lazio, defining an inner core compact. The square was dominated by the volume of the church, a circular plan, which echoes stylistically typical buildings bells, but was defined by all buildings representative that can envisage inside: Casa del Fascio, the company's management agrarian, pantry and porch with homes. The buildings, constructed according to the dictates of autarchy all had simple lines and features of Mediterranean architecture, the bases of the buildings and the pillars of the arcades were square blocks of limestone, plaster treated with a trowel, the crowning glory of the church in lava dome clad in grey and characteristic majolica glazed tiles, and while the covers were tiles channels. The walls were painted in tuffa plaster, the floors in brick-mixed concrete, the vaulted tuffa porch covered the roof

with big fir wood and plywood coverings, the floors were almost marble-chip. The buildings were all sized and calibrated to the space upon which there were well-placed in the context of rurality. The barracks of the RRCC was modest in size, designed to hold a few soldiers and a noncommissioned officer, consisting of an office, bedroom, dining room, security room and board for the commander of the station. The offices of the agrarian ONC were located in a space between the inner square and a street of land division flared near the entrance to the streets, so as to allow the smooth flow of cars. The square was bordered to the west, from the back of the building used for housing and office space, while on the opposite side of the road on the short sides, there was a canopy to shelter cars, a covered area of 250 square metres, and a stable for six horses with adjoining house. There were 7 company offices in total, three on the raised ground floor and four on the first floor. On either side of this building and connected to it, there are eight homes for managers, divided by number of rooms, from two to four more services. On the opposite side of the building, there were two houses for ONC officials without any family, consisting of four rooms each plus lunch room and conventions, kitchen and bathroom. The company director's house was rather isolated, consisting of five rooms plus accessories. In the square, there was also the building used as a pantry, on the first floor of the barber shop and the post office, while the upper floors, there were the home of the host of the pantry, the rented rooms and a studio for the nurse. Educational functions are contained in a single multipurpose building near the square that houses the kindergarten, elementary, and the home of the GIL; functions are communicating with each other and had a communal gym, while maintaining separate entrances. The school consists of three classrooms, more services, from kindergarten classroom largest single office, the home of the GIL had an office and the gym 7 x 14m, while in the back there was space for outdoor games; on the first floor, there was the caretaker's accommodation as well as for the teacher. The streets and plazas are raised, formed by limestone ballast of stones, gravel and crushed stone surfacing, in the square platforms shall have cord of stone and concrete floor detritus. The impending war and the inevitable repercussions on the market made materials significantly and continuously costly. The Ministry of Agriculture and Forestry, became aware of this situation, with note no. 4482 of 18 May 1940 and returned the projects Incoronata and Segezia so that the unit prices were updated to changing market conditions, the same was applied Borgo Appio [6]. The principal work of Borgo Appius was completed in October 1941 by Company Caserta already running price revisions as per law. The total cost of the work varied, therefore, as a result of the increases due to the war and rose from £ .1.966.090,95 as contained in the draft of 30 September 1939 to £. 3675800 29 May 1944. In 1942 air strikes in Borgo Appius began, causing the first damage which would be gradually increased until the maximum of destruction in conjunction with the Nazi retreat from Campania in September 1943. This was then followed further destruction due to military exercises, artillery fire, the use of structures such as storage, fire and other damage. Some houses were completely destroyed, others suffered damage to roofs and walls, many fixtures were severely damaged and many were completely removed. Even the farm roads suffered a lot of damage due to wear of the wagons and other means of war, as well as the explosions of bombs and artillery shells. Even the trenches suffered extensive damage primarily to ongoing flooding that held two-thirds of the company underwater October 1943 to June 1944, but even the damage will persist as the dewatering pump will start working only partially. In the month of October 1943, there was a collision between opposing factions: the fighting artillery left deep traces in the works of reclamation and of course on Borgo Appius, but also in the spirit of the people who lived in these places. At the outbreak of World War II, Borgo Appius was the centre and the reference point of the sparse population in the territory as well as the stable residing in the village, houses with understated simplicity, the "Management Company the right Volturno" ONC and the families of officers and employees. At the end of the conflict began the repair work: on 4 September 1945, the plan for the repair of damage caused by the war was drafted, which also covered the repairs of some farm houses.

1.2 Borgo Domitius

"The village was situated in the locality Domitius Ve na about 650 metres from the coastal road (Domitian Way), and laterally to the Villa Literno-Ponte a Mare" [7]. The building, as in the village of Appius began in September 1940, pending ministerial concession on the basis of the project dated 31-12-1939. The work was suspended in May 1942 for the pressure of war and until April of 1953 did not even receive any form of concession. The Opera tried in vain to recognize the consideration for the works partly completed by the Ministry of Agriculture for low Volturno and Capitanata, the underlying problem, however, was the lack of funds related to the allocation of Law 30.11.1939, n.2017 reported to the funds for the war then reused for new war initiatives. In December 1949, the General Directorate of Reclamation and the Colonization of the Ministry of Agriculture predisposed a plan financing the works already carried out and those to be (according to indication of the Opera), but as stated in the letter n.1373 of 10 August 1950 (dealing specifically with the township of Segezia on the plains, and by extension referred to all similar situations) the Ministry of Agriculture extinguished the hopes of competing the work, as the Treasury was unable to proceed with the funding provided and also added that the assets built up to an hour to become the property of the Opera. Thus, the Opera had specific buildings constructed that became its property and renewed, however, the request for input regarding the construction of churches and infrastructure (roads, sewers, aqueducts), letter

5084 of 19.2. 1951, subsequently letter 32758 of 11 .24.1951. Having noted the continuing inability, Opera waived any claims for the repayment formally declaring null and void the request made under the Law 11/30/1939, n.2017. Upon clarifying the issue of ownership remains from that of completion, which had become urgent for the many families settled in the area by Opera in Vena. In planning the completion of public works, Opera estimated about 60 million lira distributed as follows:

- 1 - completion of the building the Church and Rectory
- 2 - "" Elementary School and Kindergarten
- 3 - "" Carabinieri Barracks
- 4 - "" Post Office - Surgery
- 5 - "" of your teachers

The infrastructure and services (roads and streets, sewers, water supply, electrical works and fencing and gardening), were restricted to parts referred to above designed in accordance with the plan dated 12/31/1939. Project data 31/12/1939.

The project was set to an orthogonal system, rotated 28 degrees to the west. The rotation was suggested by the best solar radiation so as to facilitate, for housing, exposure to the east-south. The plan covered a portion of land at the side of the road Villa Literno -Mare so as not to have passing traffic into the centre. Close to the above-mentioned road, there was the Piazza (size 41 x 28 m) overlooked by the Church, Canonica, Post Office and the Doctor's Office, more than the building of the company and the restaurant-inn added to the original project. The square was accessed from the main road through the road Villa Literno - Mare 12 m in width, the road past the square was reduced by up to 8 m wide, there were also branches to reach the interior points to the establishment of equal width to 5 m, with 3.50 m of roadway. The streets were designed with the roadbed thickness of 20 cm, gravel of crushed limestone with a thickness of 15 cm, displacement and tarred. The sidewalks were in detritus of concrete and travertine.

The total area developed in relation to subsequent development was also calculated on the basis of an estimated population of 500 inhabitants:

Population 500

500 Rooms

Average surface area of each compartment 25 sqm

"" Blanket 25x500 m / 2 m = 6250

"" Public buildings 1300 sqm

Total about 7500 square metres.

The relationship between coverage and green (vegetable and flower gardens) was: 1:6-7.

Area 50,000 sq m private gardens and allotments

"" Total 7500 square metres of isolates +50,000 = 57,500 sq.m.

Surface lots 75% of the total built-up

Streets, squares, gardens etc. ... 25% of the total built-up area.

$57.500 \times 100 / 75 = 76680$ corresponding to 7.6 Hectares.

The buildings fronting the square were on two floors arranged along the road, while the buildings arranged along the streets were terraced houses with gardens at the front and rear. On the road to the junction with the main road, there were isolated houses with a garden as well as a vegetable garden.

The architectural features were borrowed from the characteristics of the local buildings of the countryside and the Mediterranean tradition. The outside parts of the buildings were designed with flower beds and ornamental plants, expanded metal fences on the tufa walls with iron gates and brick pillars. Two hundred pines were on the sides of the access road and around the square.

The plan of the church was classical with a single nave with an adjoining pastor's home and the sacristy which, if any, could be used as a catechism hall: the bell tower completed the composition giving upward thrust to the whole complex. The basement of the church and the rectory were in limestone blocks, square-face view, the plaisters were treated with a trowel. The crowns of the church and bell tower were covered with tiles from Vietri. The roof was vaulted brick with glazed tiles from Vietri.

The police station was designed for a few officers and a non-commissioned officer with the family. It consisted of a bedroom, dining room, two bedrooms, security and accommodation for the commander of the station.

The post office and clinic were located in the south east corner of the square, representing the buildings 5 and 6 of the Plan. The post office and the manager's house had three rooms on the ground floor, upstairs in four rooms, there were the surgery, the dispensary, the local doctor's lodges.

The school, kindergarten and gym were conceived together in one block accessible by two main roads, interrelated, but with separate entrances. The school had three classrooms with services, management and caretaker's house, while on the first floor, there was the teacher's accommodation. In the space behind, there was an area of 3250 square metres in which there was the playing field, a paved bottom covered by a layer of pozzolana of 26x24 m.

The teacher's accommodation could be accessed from the main road connecting residents and the teachers of the school. It was a modest dwelling on the ground floor and first floor.

The walls were in tufa blocks, the mixed floors in brick and reinforced concrete, the covering were Roman roofing tiles and a wooden square spruce framework of Trieste use. The window frames were made of cedar wood while the interior spruce and plywood. The floors were in terrazzo tiles, the internal plaster of a civil three-layer, the outer two layers were frattazzati. The interior steps were covered in white Carrara marble, the outer travertine marble. Encircling the buildings, there were concrete pietrini, travertine sidewalks.

As already described, the construction works were interrupted in May 1942, up to that date mainly the foundations and part of the walls in elevation had been built, totalling approximately 9.77 million lira in 1953, the year of the presentation of new completion project, which was estimated at 6,057,400 taking into account the decay due to the time that is with a reduction of 38%. In conclusion, in 1953, a project to complete the work for a total of 68,451,000 lira was presented and signed by Dr. Ing Giacomo Di Muro, and never realized.

Abstract

This PRIN research has been focused on the principles for the development of the Sarno plain structure, the urbanized countryside in the vesuvian area beyond Pompei. In order to take up an efficient strategy avoiding sprawl and soil cementing in the periurban areas, we propose to compact new buildings in a discontinuous system of small multifunction clusters, following the criterion "low rise – high density".

The concept is a green extended city, built up by urban parts with residential and productive structures and by public utilities separated by rural areas and parks. The discontinuity of urban parts alternating with agricultural plots allows that green and unbuilt areas avoid the building saturation of space among the detached cities.

The natural infrastructure of Sarno river should become an important element to order the next plans for the plain, increasing the multifold relationships among rural tradition and modern settlements. The urban projects follow different directions: the first one longitudinal direction will regenerate the riverbed, as the main "locus" plot of collective utilities (detached resorts, sporting utilities, vegetable-gardens with green houses etc.). These structures are integrated in parks and rural areas and connected by a continuous ribbon-road running along the river, recovering the landscape. The second ones are crossing projects adopted where the river cut the territory in the east-west direction: the solutions design new visual and functional connections between the Sarno utilities, the previous settlements and new residential clusters.

The Sarno plain, an area renowned for its specialist crops and manufacturing industry, has a twofold nature which helps explain the uneven concentrations of buildings. On the one hand, the area has been affected by strong pressures from the urban area of Naples which have led to high densities of building on the coast. On the other hand, the agrarian character of the fertile Sarno-Nocera valley accounts for the low density of building and scattered settlements moving upriver further inland.

As well as the coastal area around Castellamare di Stabia, the zones with high building density are related to the sprawl of urban centres, between Pompei and Scafati on the northern side towards Vesuvius and between Angri and Nocera in the foothills to the south. To the east two systems of urban settlement are situated in a position set back from the river (Striano, San Marzano, San Valentino, Poggioreale) separated by agricultural areas dotted with small-scale building and crossed by a dense network of canals.

Overall the Sarno plain appears as a set of urban complexes connected by thin strips of building along the roads, alternating with rows of greenhouses, small factories and warehouses. Although it is imperfect and of low architectural quality, this settlement system contains large tracts of rural

countryside which could be saved and reintegrated within a hypothetical extensive city. If the theory of the “city by parts” is transferred to a local scale, the Sarno plain can be viewed as the basis of a multi-polar settlement that extends into the countryside; existing urban settlements resemble multifunctional districts, cultivated areas correspond to parks and gardens, and the system of public buildings coincides with large structures (archaeological sites, the shrine of the Blessed Virgin, the Bourbon explosives factory, the new hypermarkets and infrastructure).

The river has long played an important part in defining the constituent features of the countryside and the localisation of settlements (beginning with the lakeside settlement of Longola found near Poggiomarino). The river Sarno now seems to be an extraneous feature and of little relevance to the layout of the land, the architecture and the countryside. Indeed, since the river distributes industrial waste, it can even be considered one of the multipliers of the ecological disaster that has devastated the area. With a few exceptions, there have been no significant examples of urban construction on the river or its canals, either as a waterfront or as a redesign of the banks of the urban area.

Due to its importance within the landscape, the Sarno can be considered a privileged vantage point from which to assess the settlement problems of the area. This is why this study has regarded the Sarno as an incubator of new relations and links between river sites and cities. Considering the environmental reclamation programmes (such as restoring the river’s traditional navigability) and activities related to horticulture and floriculture, the upgrading initiatives on the river Sarno could play a leading role in the reorganisation of the area and the development of urban, rural and manufacturing settlements. It would be possible to reintroduce the technical and formal logic that used to underpin the rural landscape and architecture.

Based on this analysis, our research unit has focused on several criteria on which the transformation and growth proposals are based.

-1 The decision to adopt a strategy designed to counter dispersal led to the use of a discontinuous system of accumulative forms of intervention, with mixed functions, based on the criterion of “low rise – high density”. The basic idea is to construct a ‘green city’ made up of “well-defined parts” of residences and productive structures, and of recognisable primary and infrastructural features, separated by cultivated green areas and parks. The “parts” consist of residential units integrated with greenhouses and workshops, or small industrial complexes, situated within the rural landscape, designed to emphasise the importance of integration between urban and rural features.

-2 The decision to experiment with solutions that follow the criteria of discontinuity and alternation between the residential-manufacturing parts and the agricultural zones and parks, helps to ensure the presence of inbuilt and/or cultivated areas, as “buffer” zones that prevent urban sprawl and the merging of urban centres.

-3 The Sarno river-canal network, a natural-artificial piece of infrastructure in the plain, is considered the backbone of the future local framework which needs to be redeveloped and reinforced both from the functional and landscape perspective. It is given the role of a regulating feature of the transformations of the urbanised countryside, restoring landscape continuity and linking functions between sites associated with rural traditions and new settlements.

-4 The proposed forms of intervention are arranged according to two directrices. Those along the longitudinal directrix are situated along the river Sarno which is redeveloped and reinforced with a series of facilities and collective places. The upgrading of the river-bed, the lateral canals and the buffer zones provides new margins and courses/layouts which provide useful reference points for the transformations of built-up areas and urban centres nearest to the river. Naturally, the upgrading system offers conditions of use that are compatible with its agricultural nature which should be reinforced as a resource. The new services on the river (with a low volumetric impact) are designed to be incubators of public and collective activities of public green areas rather than as accelerators of new building. The objective is to reconstruct relations and hierarchies between existing urban areas and give prominence to existing agricultural areas by preserving and enhancing them. The projects designed by Rejana Lucci offer a new way to cross the plain “at a leisurely pace” keeping parallel to the course of the river. A series of recognisable zones, collective places for existing urban settlements, have been identified along the Sarno where a series of activities linked to pre-existing features (archaeology, nature, agriculture and tourism) can be organised which need to be reinforced.

These centres, which will be systematically linked to previously existing infrastructure, will house the following: 1) tourism-hotel-spa facilities on the Castellammare coast; 2) info-points and fully equipped parks near Scafati (situated centrally between the river and the intersections between traditional local tracks and routes); 3) SouthEataly catering with locally sourced food at San Marzano; 4) teaching farms with fully equipped nature trails on the river, spaces for workshops, studios and residences linked to archaeology, specialist training centres and teaching farms at S. Valentino

In the parts where the river and other infrastructure such as motorways and railways have led to a rigid demarcation of the area in an east-west direction, work is required to re-establish relations

between the two sides. This will create new ways of crossing the two sides to ensure better functional and visual relations. The directrices that are transversal to the water course therefore provide new links between the river, existing urban centres, new residential and productive units and services, reinforcing the routes that run at right angles to the infrastructural corridors.

Small compact clusters of residential and productive units, together with new facilities, will be situated in the transversal zones. To provide practical support for this settlement pattern, town planning guidelines have been followed: both areas of “legalised” illegal accommodation which the PUC (town planning regulations) of Scafati describe as zones of redevelopment, and zones with potential for new facilities and services or the redevelopment of commercial areas. In general, the main criterion was to move the new building to the southern side of the Sarno to avoid increases in volume of the “red belt” at the foot of Vesuvius where there is a serious risk of a volcanic eruption.

The strategy of “transversal” initiatives also guides the design of several innovative pieces of infrastructure, such as the plan for a horizontal cableway between Pompei Sud and Pompei-Centro (Emanuele Carreri and Pasquale Zeppetella) which would pass over the Sarno river-canal system to link southern areas with the archaeological excavations and the Shrine, the two main tourist resources of the Vesuvius area.

Productive residences and “compact” horizontal units designed to create a “green” city.

As mentioned above, an effective anti-dispersal strategy is based on the concentration and densification of residential initiatives. This will involve the creation of compact horizontal units with functions integrated with agricultural activities which can become the main features of a controlled redesign of the landscape. In architectural terms, they are well-defined parts, small fenced-off sectors or clusters, according to the relationships of continuity, discontinuity or alternation that are sought with natural features and the characteristics of the different contexts.

The potential for residential expansion in these areas is extremely restricted for town planning and safety reasons. The new residential units with mixed functions, provided with services and facilities, are intended to discourage fragmentary residential accommodation, and can therefore “reabsorb” phenomena associated with dispersed building initiatives.

On the one hand, the integrated low rise - high density clusters are inspired by the idea of a small community equipped with infrastructure and collective services, while on the other hand, they safeguard the autonomy of the individual units, responding to the expectations of the single family or parental house. Designed as coordinated local plans, these initiatives are intended to encourage aggregation and cooperation, promoting rationalisation for the production, distribution and sale of horticultural and floricultural produce. In conclusion, these innovative solutions are believed to be valid alternatives to isolated small blocks of flats, terraced housing or a condominium with a linear layout.

Inhabitable houses with fences, houses on open plots of land linked to areas with a danger of overflow. –Each residential unit consists of a cluster of housing types that are suitable for the rural-urban nature of these areas. From the architectural perspective, this involves a reinterpretation of the suburban detached house or the courtyard house, closely linked to the design of free and cultivated areas. In functional terms, the design proposes an extended use of the productive house, with a close link between domestic spaces and work spaces (greenhouse and workshop) and with small “district” facilities.

Planning and compositional regulations have been experimented within a sample plot measuring 35 x 70 m. (a typical size for the local area and comparable to the dimensions of many insulae – blocks - in ancient Pompeii). The design can be extended to up to five or six residential units, a greenhouse or workshop or district facilities.

In order to allow a gradual reduction of land occupation, the study of the “extensive city” investigated equalisation mechanisms for local regeneration. An interesting field of application was identified in the areas to the south of the river Sarno, between Pompei and S.Marzano, where industrial plants buildings of low architectural quality and a substantial floricultural economy, based on greenhouse cultivation, exist side by side. Using equalisation models, it is possible to construct sections that will lead to the increase in cooperative coordination between floricultural entrepreneurs. On the one hand, the proposals (M. Borrelli) may involve the construction of residential units in dismantled industrial and commercial structures – “factory houses”, while on the other hand, they may include the creation of vegetable gardens or “productive gardens” (typical of local traditions of horticulture and nursery gardening) – in greenhouses or outdoors within the new residential systems. For the area to the south of the river Sarno, irrigated for many years by the polluted waters of the river, an experimental phytodepuration system is planned using medium-sized plants.

The theme of *urban regeneration* has played a strategic role during the last two decades in European and national urban building policies. Current addresses, also defined in *Leipzig Charter on Sustainable European Cities* in 2007, identify the necessity to invest in requalification of degraded residential assets and not in new developments, individuating in urban regeneration the main tool for development of contemporary city.

Public neighborhoods have developed, historically, a wide set of common problems. They are not only due to wrong planning but also to the concept of "housing for masses".

The original ambition of modern settlement, developed from German *Siedlung*, was to be an autonomous part, on the point of view of morphology, in urban expansion. Joined by new developments, a lot of neighborhoods became benchmarks for suburban areas and now we can define them as "new urban centralities". So their role in urban dynamics has changed and they can be individuate as precious reserves of public spaces and potential incubators for regeneration of larger areas.

Analyzing some Italian and European case studies, the most innovative relate to the densification of open spaces, inserting new services in a general redesign of green areas; concentration of built surfaces, in order to reduce land consumption and introduction of different residential types in order to improve *mischbebauung*.

Keywords: Regeneration, Neighborhoods, Develop

1. Fact-finding and design-related aspects for the Urban Regeneration (MAG)

The biggest problem with which our society must confront is the deep crisis of the concept of the distinction between city and country and the problem of redevelopment of public housing neighborhoods. The expansion of the built environment and urban fabric in farm and rural areas has led to a patchwork of hybrid spaces organized according to an alternation of full and empty spaces, cities and countryside, without any apparent connection. The complexity of the areas is formed by the overlapping of different layers sedimented in time according to a mysterious logic of cancellations and permanences that a cursory glance can not classify that as chaotic and incoherent. The gradual domination of the environmental characteristics of the area from the settlements built and networks, which began with the industrial city to another of the eighteenth century, in recent years has reached a high degree of irreversibility.

The address of the research project is measured by the substantial processing activities built that is taking place for several years in Europe, involving many parts of buildings, both old and new. Especially in the context of the progressive tradition has developed a sensitivity to the positive role that public spaces natural parks, gardens, green cities, agricultural areas, gardens metropolitan have in rebalancing the extreme artificiality of urban life by answering logical health benefits and recreation but also as places of practices and mobility alternatives and natural reserve. Similarly the processes of regeneration of the *housing* concern both the adaptation of existing buildings, both new functions and the redesign of open spaces and common areas. All work on the built becoming increasingly

expanded and diversified: additions, overlays, *infilling*, inserts, new coatings, *surefit*, remodeling of land.

In particular, the traditional affection of Italian culture to the conservation and protection has produced analysis on public housing and interesting contributions to recovery. The original idea of the modern district, which born from *Siedlung* German, is a morphologically independent part in the expansion of the city.

Fig. 1: Hufeisensiedlung, Berlino

Fig. 2: Bijlmermeer, Amsterdam

Achieved by the new expansions, many neighborhoods have become points of reference for decisive and peripheral areas that were once considered today as "new urban centers." The quality of the relationship between full and empty, evident within parties often saturated and congested, resulted in a gradual change of their role in the dynamics of urban identifying them as reserves of precious public spaces to redevelop larger areas.

It is necessary to change some of our assumptions, to make a shift of our look on the territories of the urban landscape to identify new ways in making and dealing.

1.2 Urban design in a "site-specific"

The analysis of the materials from which the city inevitably lead to recognize the uniqueness of each urban situation contingent and the specificity of each territory. The historical sequence of topography, river networks, infrastructure networks and agricultural land fragmentation, the morphology of the built and vegetation, has been a progressive sedimentation of materials that are stratified according to temporal logics very slow, unknown to the acceleration of the phenomena of the contemporary . Renew the look of the city means, then, refuse the apology to the city "generic" and get rid of that *habitus* of surface observations that the contemporary city is not understandable if you do not like chaos, homogenization, randomness. Urban problems that confront us today are, of course, essential to this situation. It is the responsibility of the project to recognize the specificity and adapt its operating modes to the complexity of contemporary space refusing to formulate formal models. This discussion suggests the possibility of reorganization as an alternative to exogenous control of traditional planning that is constructed from the conformations, needs and specificities of places. The design, techniques of representation and all the tools that allow the analysis of the sites have a key role to re-think the contemporary city, which otherwise escapes any meter of understanding. The project is common ground in many disciplines but it is precisely the disciplines of architecture to give it a result of spatial as well as linguistic.

So the disciplinary specificity of urban design is to be found in the relevance to run in the space of the city, in the "care of form." In particular we want to use here the term "urban design" in the sense of "*projet urbain*" French as a tool that is able to articulate the different scales and in different times both the spatial aspects, figurative and formal and the social intervention planning by means of a "morphological axis" and a "axis of the process", the first reported to the organization of the space, the second to the processing capacity along the time. In this sense, it is then possible to speak, especially in the French tradition of a "culture of urban design" in which some aspects are clear: attention to the context and history of the places the consideration of the temporal component in the process of building the city, the belief in the proposal of a *mixité* uses with particular attention to social complexity, typological and landscaping. It is interesting to note that in order to address an area suspended between town and country the best ideas come from their own disciplinary fields on the boundary between architecture and landscape, as if the morphological complexity should be reflected in a complex thought and analog.

1.3 The city in the landscape

Now seems inevitable reversal of perspective that is turning his attention to empty rather than full, open spaces and landscape rather than those built, to the relations between the parties rather than to objects.

The Ville Radieuse is perhaps the most accurate / fitting of this conception of urban design in the landscape. The project of Le Corbusier in 1933 for a million and a half people has the aim to solve the housing problem of mass. The residence of the "Ville verte" occupies buildings in line with eleven floors, bent into a series of right angles, the *redents*. The buildings are constructed on *pilotis* to keep out of the distance at ground level that is configured as a large public park open to the landscape in which departments are located at the residence.

Fig. 3: Plan Voisin, 1925, Le Corbusier

Fig. 4: La Ville Verte, 1935, Le Corbusier

The various research methodologies may have a number of basic assumptions and common lines:

- 1-The design as a tool capable of articulating the different scales and in different times both the spatial and the social aspects of the intervention on the landscape.
- 2- The territorial scale in relation to the concept of landscape and its implications in the field of design in its various forms (architectural, urban, ecological, artistic).
- 3- The discourse on the form and, in particular, on the morphology of the territory.
- 4- The emptiness, the open space as the beginning of the project reflection operand fact a reversal on the usual relationship between design and object.

2. The city expands (AG)

Starting from the last century we are observing, in Italy and in the world, a degenerative process caused by the sprawl of the city, the major cause of loss of identity and social space of places. The explosion of the city, due to factors of an economic, social, political, technological discontinuity creating fragmented urban form of the built and functional segregation. The enlargement of the urban fabric has led to a progressive increase of the cemented surfaces, driven by a strong desire to build, sometimes with no correspondences to the real demographic and market needs, and by the multiplication of places that the French anthropologist Marc Augé called "non-places". In big peripheral areas, near major thoroughfares are born giant malls, multiplex cinemas, nightclubs, train, industrial areas and functional centers which, being inserted by force, often results in irreparable fractures with the surrounding area, going to upset dynamics and balances between the natural and artificial components of the landscape. Residential neighborhoods, public or private in the suburbs, often occur as areas without commingling functional and social, dormitories or even simply ghettos. While the expansion has occurred without intervention lines and then through a process of random and spontaneous addition that responded exclusively to individual needs, the other is the result of precise planning strategies to certain goals. In both cases, the spread of cities has caused and continues to cause a relentless consumption of land with big consequences, devastating for the environment, in order to reduction of the agricultural areas, in a worsening of the quality of the landscape, impoverishment of biodiversity, hydrological and physical problems due to deforestation and soil waterproofing. All the data concerning the expansion of urban agglomerations are worrying. ISPRA, Institute for the Protection and Environmental Research, conducted a study on the use of land in Italy from 1956 to 2010, which shows that in recent years it has come to lose more than 8 square meters of soil per second. The settlement pattern characterized by urban dispersion is an inefficient system, in particular for what concerns the power consumption, the connections, the possibility of social interaction. The widespread location of residences, equipment, services, forces people to travel

greater distances, resulting in an increased need for means of public or private transport, an increase in energy consumption, more pollution, more and longer travel times.

Fig. 1: Public housing in Afragola, near Naples.

2.1 Intervention Strategies

The concept of "ecosystem" of the city sees itself as the environment in which man lives and interacts with the various components of a complex and open system in which many factors contribute to the establishment and characterization of every single part of it through interactions in dynamic equilibrium. This dynamism is expressed in the urban structure through urban planning and construction work which often irreversibly affect the quality of life and use of space. Urbanized areas, in this relentless advance, have become more extensive, covering the surrounding territories, making the invisible boundary between a city and another, between the city and the countryside, unrecognizable identities and vocations of the individual sites. In this continuously evolves and expands comes the need to rethink the ways of making city, through the adoption of new strategic development aimed at curbing urban sprawl, conserve, regenerate and innovate the existing, reversing the processes of decay and neglect, working on urban spaces, structures and infrastructures already implemented, improving the quality of living and more generally of the city, creating new connections, more effective services and social and functional mix. In order to govern and limit the land use you for first must know the existing city. Through detailed analysis, elaborating a multidimensional representation of the urban fabric is possible to identify the potential and manage resources such as games of a profit and loss account to be used for the sustainable development of natural and built. On the one hand, through the knowledge and optimizing the use of available resources, we can protect and enhance local identity, the historical sites and monuments of existing cities, on the other we can build new projects in the areas of more recent formation, define lines of action innovative and sustainable that limit or even cancel the land consumption. Precise strategies for urban equalization, associated with the use of certain building types and the introduction of special purpose, make it possible to rationalize and optimize the use of space within the city area. These opportunities management and control systems could certainly be the responsibility of local authorities, called directly manage some important actions of transformation of the city as well as in the Federal Republic of Germany, where the Länder contribute to the achievement of the reduction of land consumption fixed by so-called "law Merkel" in force since 1998.

Fig. 2: Housing expansion in Giugliano, Napoli, Campania

A further line of action is the ability to act on the urban fabric already built. The overbuilding, driven by speculative logic first, but the city did not create clusters of buildings with no identity. The expansions, even those that are planned, often occur through building works of poor quality. Should intervene on the existing, giving it value and meaning, creating connections and new solutions. It would therefore be appropriate, before occupying new territories, check out what you can do using all the opportunities available within the city. By conducting a survey of the use of existing building elements, identifying underutilized facilities and those not used, you might plan the recovery and regeneration of individual buildings or building complexes on brownfield sites, paths of disused railway lines or roads never completed. These offer great opportunities for development of recycling architectural and urban interventions, through which it would be possible to restore and enhance large parts of the city. The cognitive processes, systems, information management, enable us to design new urban structures and develop new solutions and territorial quality. And it is the quality of the fundamental prerogative of the city of the future, the distinguishing feature of the architecture to make it feasible to realize the sustainable development of the environment. Quality as the result of democratic participation in decision making and therefore the expression of specific needs and collective, as an effective balance between economy, efficiency and operation, as a result of a wise warping of relations between the artifact and its surroundings, as a response to the need to lower consumption of soil, as an expression of the awareness that the territory, seen as a common good, should be preserved so that it can be enjoyed by future generations.

3. Urban regeneration in Europe, the example of Robin Hood Garden in London (GO)

This contribution is about public initiative developments realized in Europe from second post-war period to Eighties. The recent proposal for urban regeneration of Robin Hood Gardens (RHG) complex in London, advanced by Sarah Wigglesworth Architects (SWA), can be taken as a best practice in the field of urban regeneration policies for degraded situations in planned developments.

3.1 Principles for urban regeneration in planned developments

French grand ensembles, German siedlungen and many works by IACP (Autonomous Institute for Public Housing) in Italy (INA casa e 167 plans) are characterized by big extension and their value is more evident in urban structure than in individual buildings. Hypotheses of discontinuity and big dimension of the buildings, taken as urban principles, involve the concentration of built surfaces in few volumes and the presence of big open spaces that stand as green stocks in deregulated and extensive development of contemporary European city. Concentration, as typical character of modern development, can be pursued, considered actual problems connected with land consumption, as sustainable and desirable hypothesis for new urban policies.

We have to overcome the prejudice about big dimension of modern developments, because this feature is not a cause of the decay of this areas. Big dimension must be considered not only as a condition for a sustainable urban project, but also as the representation of a collective idea about housing, that for the second part of Twentieth Century had inspired social housing experiences in the whole Europe.

Intervention in modern neighborhoods should be respectful of developments' specific features and should propose adjustments and improvements adding new contents to existing elements we consider as values, first of all the presence of big open spaces.

Possible interventions, we can take from a wide range of contemporary examples and realizations, can be organized in three big categories:

- Provision of equipments or improvement of existing equipments
- Change in distribution and typological features
- Technological adjustments

Collective buildings are often missing in modern development or their realization is incomplete. First category is about interventions that introduce collective uses and improve conditions of existing services. This kind of buildings, as interaction elements with open spaces, produce new ways of using open spaces, improving safety and social dynamics. About intervention techniques, we can work in different ways. Ground modeling allows to integrate new architectures with open spaces. The conversion of ground floors, if they host accommodations, and their occupation, if they are empty, allow to insert new uses without new volumes.

If we talk about buildings realized between 1920 and 1950, distribution features are often connected with existenz-minimum culture, that, in response to a large demand of houses, used to propose houses with very small rooms. These small and spartan spaces are nowadays insufficient for actual housing needs. Urban regeneration of Kiefhoek development in Rotterdam (designed in Twenties by Oud) demonstrate that is possible to adapt modern houses respecting the base-idea and character of original buildings. This project provided the union of original terrace houses two by two to obtain bigger accommodations.

Many modern developments were characterized by a single house type and so the social composition of these urban areas were not various. Contemporary regeneration interventions should realize conditions for coexistence, in a common urban context, of different kind of inhabitants. In this way, social dynamics and phenomena connected with control and appropriation of collective places could develop. Coexistence of different house types (simplex and duplexes houses in multifamily buildings, single-family houses, terrace houses and patio houses, ...), that modern architects called *mischbebauung*, represents the condition for the presence of different typologies of inhabitants.

We can talk about some urban project realized in Italy between 1940 and 1960, built on the hypothesis of typological mix. Between them the most interesting are Tuscolano development in Rome by Adalberto Libera and Via Dessiè development in Milan by Piero Bottoni, Gio Ponti, Luigi Figini and Gino Pollini. In the first example we can find the minute fabric formed by patio houses and a three storey multi-family building; in the second example there are big slab blocks with decks organized following a centrifugal logic, creating a half open central space, and there are some aggregations of one level single-family houses. These experiences represent successful attempts of spatial integration between different types through the definition of high quality external spaces.

Technological adjustment interventions represent the precondition for regeneration of modern developments.

3.2 Robin Hood Garden (RHG) project by Alison and Peter Smithson

For this development, commissioned by Greater London City Council in 1966 on a two hectare site in Tower Hamlets in the East End of London, Alison and Peter Smithson, as designers, proposed a scheme recuperating distributive solutions developed in competition project for residential buildings in Golden Lane in 1952. Site was surrounded on three sides by streets and the main goal, on the urban point view, was the definition of a huge and protected green space. Accommodations, organized in two slab blocks with mixtilinear shapes and different lengths, face on this central open space that architects called "soft landscape". The two small hills situated in central area are artificial and they were realized recovering the rubble from excavation of the site. Smithsons realized an operation similar to Piero Bottoni's solution for QT8 development in Milan, where the big artificial hill were built using rubble from bombed buildings of that area.

On the typological point of view, the two buildings are characterized by presence of galleries as distribution systems and they consist of repetition of just one duplex house-type. Designers decided to place galleries (decks), intended as *streets-in-the-air* with a social vocation, on the sides facing perimeter streets while dining rooms and bedrooms overlook peaceful landscape of internal park through tall windows and small loggias. On the ground floor there are small houses for elderly and in correspondence of buildings' southern sides there are special accommodations with turned views.

Fig. 1: The park of RHC in a photo of 1978

Fig. 2: External view of RHC

The interest of the project, on the architectural point of view, is the definition of an interesting distributional device. Studying the transversal section of the building we can observe that duplex houses have dining and living rooms at deck level while bedrooms are situated on the upper or the lower level. This solution was proposed by Smithsons in Golden Lane project some years before. This competition project was more radical than RHG, in fact decks used to have the same width of the building and they used to host small stairs to reach accommodations below and above. Scheme's complexity was enriched also by a big number of different house-types and by the presence of a series of half-open courtyards between buildings.

The will to transform connective spaces, decks, in places of social interaction is for sure the most interesting aspect of RHG and Golden Lane buildings.

A small excerpt taken from the text titled "Urban Re-Identification" presented by Alison and Peter Smithson during CIAM IX in Aix-En-Provence in 1953 with drawings about Golden Lane, allows us to deeply understand what designers thought about social attitudes of the project:

"...we proposed three levels of streets-in-the-air; each level we called a deck. Each deck was to be occupied by a sufficient number of people – 90 families – in such a way that it would constitute a social entity. The streets-in-the-air would thus become places with their own identity [...] The total penetration of deck dissolves the dead-wall effect of the conventional slab block, and produces ever-changing vignettes of life and sky; the individual dwelling clearly being the measure and reason of the whole. People are its predestined ornament".

Fig. 3: - Plan and axonometric view of Robin Hood Garden

3.3 Urban regeneration for Robin Hood Garden (RHC)

The demolition of this residential development seems almost certain. It is supported by predisposition of design proposals that are about the realization of 1700 accommodations in substitution of 214 existing duplexes. They have generated a big discussion about second post-war period architecture in UK.

Many urban transformations, changing completely urban fabric of Tower Hamlets, have produced new high density areas (Canary Wharf, Docklands,...) and RHG looks like out of scale. For public and private actors is better to demolish existing buildings to realize new development quintupling inhabitants, than do complicated and expensive regeneration interventions.

In these context Sarah Wigglesworth Architects (SWA) has proposed a regeneration project for RHC and it provides different levels of intervention oriented towards improvement of technological performances of the building and increasing of number of inhabitants:

- Re-configuration of existing accommodations

- Introduction of new accommodations

- Improvement of energy performance

Existing duplexes should be changed into simplex houses with different sizes rather than insert new stairs and reducing at minimum new windows to limit alteration of Smithson's buildings character.

The proposal individuates in coverings and perimeter areas the most suitable sites for new accommodations. In this way there are no problems for nucleus of original design, the big central park, that represents a strongly characterized common place. Perimeter blocks host garages and they should be converted into houses obtaining brand-new 33 duplexes. Existing stairs reach cover level and so it could be possible to realize duplex houses with wooden structure at last level of the building, obtaining other 38 houses. Overall RHG would have 71 brand-new houses.

On the technological performance point of view, SWA says that substitution of actual windows with new ones characterized by high thermal performance and inserting of suitable panels for external walls could induce a halving of current costs for air conditioning and heating.

4. The construction of Public Works. Criteria and tools for finding resources (FO)

The dramatic financial crisis of recent years has been a decline in the construction of public works.

To avoid suspend the implementation of Public Works, it is necessary for the public administration of complex systems of access to financial resources, with the participation of public-private partnership, such as sponsorship, leasing of public property, contract of availability, project financing, all alternative forms to finance public works.

Two important elements are: the fundamental role of banks and the ability to unlock the financial resources to ensure that the Public Administration debtor is no longer with the business.

The introduction of sponsorship contracts, as provided by art. 43 of Law 449/1997 and then implemented by the "Code Contracts" under Legislative Decree n. 163/2006, art. 26 and 27 introduces a system of private funding for the construction of works of public interest that is difficult to apply because the private entity intends to finance a work must necessarily have an economic return and image.

Examples of use of this tool are represented by financing the restoration of the Flavian Amphitheatre, Rome (Colosseum) operated by the group Tod's Spa and the renovation of the Police Station in Square San Lorenzo in Lucina in Rome. These interventions have a strategic character and give private parties a significant economic return and image.

Fig. 1: Colosseo, Square San Lorenzo in Lucina, Rome

Fig. 2: Colosseo, Rome

Fig. 3: Front of the Police Station in Square San Lorenzo in Lucina, Rome

The sponsorship contract provide two forms of sponsorship: the pure sponsorship and technique sponsorship. The first is aimed at financing by the sponsor, while the second is a form of partnership extended to the design and realization of the work to care and expense of the sponsor. In this case, the Public administration has the obligation to ensure the exact and proper completion of the work.

The introduction of the leasing of public property, with the art. 160 bis of Legislative Decree 163/2006, poses in the availability of public administration a 'financial instrument' innovative, in most cases, does not affect the "Stability Pact" and enables the construction of public works by the same Administration that engaging the private funds made available by leasing institutions. For the correct use of the instrument of leasing of public property in the public sphere, it would be appropriate to hope for a greater share information and knowledge of the content and potential of the instrument itself, that also aims to highlight the ways in which the public administration should act. The choice in favor of the leasing of public property must be appropriately weighted according to the feasibility and practicability of the operation through the use of forms of borrowing for capital expenditures. From an economic point remains essential for the Public Administration the need to draw up accurate feasibility studies, from which would emerge the comparison between several alternative solutions, designed to capture the most suitable methods of construction of the infrastructure and to allow the choice founded and motivated of the solution that will produce the best result in terms of benefits, social and economic costs. The potential benefits to the adoption of the leasing of public property are subject to a careful division of risks between the Administration, the leasing companies and the manufacturer, which is achieved through a careful and clear definition of the contract, as to exert both in the notice that in the contract and related contracts for the entire duration of the relationship. As said before, although there was an increase in the use of leasing of public property, this instrument is not yet seen as a solution to public-private partnership for the construction of public works.

The introduction of the contract of availability required by art. 160 ter of Legislative Decree 163/2006, it was an incentive contained in the DL 1/2012, "development decree", converted into Law 27/2012. Through this contract are entrusted, construction and the provision of a work of private property intended for the exercise for a public service, in the face of a price. The Administration gives the caregiver a user fee, as consideration for the construction and provision of the work. However, not having the legislature intended a definite pattern, the correct classification of each transaction for accounting purposes can only result from careful consideration on a case-by-case basis, of an individual case. In particular, the exclusion of the budgeting of the expenditure as an investment, is based on the actual allocation of the risks of construction and availability of the ends of the private contractor, not affecting the Stability Pact.

Other form of public-private partnership is given by the project financing governed by art. 152 of Legislative Decree 163/2006 that you can define as a tool for the realization of Public Works without financial burden of the public administration by transferring risk and financial coverage to the promoter.

For example, always with the spirit of promoting the project financing is guaranteed to the promoter, if it were to be the successful bidder, the possibility of pre-emption, or the instrument of project financing can be added later, and only after that the Administration has approved, in the three-year program of Public Works under art.128 of Legislative Decree 163/2006, and not least the possibility of tax relief sanctioned by the CIPE recently. This circumstance, however, will be the subject of the next government for final approval. This circumstance, however, will be the subject of the next government for final approval. For the use of project financing have been issued guidelines for the process of financing for construction UNI / TS 11453 which are not binding, but may be useful to develop and encourage the use of such an instrument.

All possible forms of alternative finance highlighted above still need to be used depending on the type of work to be carried out that are basically divided into three categories: works cold, warm and hot.

For cold works are the works that during the course of use do not generate substantial economic returns, so you will need to have, as part of the public, of economic hedges for the payment of the rental payments.

To warm works, however, are those works which, during the course of use, generate economic returns not quite enough to pay back the initial investment and need a partial level of contribution from the budget of the Public. (example : thermo-hydraulic or electric systems for energy saving, public lighting with flow control).

For hot works, finally, are the works whose management generates its own financial resources in excess or at least sufficient to pay off, with the revenues, fees and costs of routine maintenance and repairs, as well as the "Redemption Price" during a certain period of time.

The rural homestead of Casignano: taken from documents regarding the monument

Rossella BICCO

Departments of Architecture and Industrial design "Luigi Vanvitelli", Aversa, Italy
rossellabicco@live.it

Abstract

The analysis conducted traces a journey in "Terra di Lavoro". Casignano in Aversa was already mapped in the XV century as an independent rural hamlet. In 1793 it was attributed as having 29 fires, however by the end of the 18th century the name had disappeared from the maps, having been absorbed within the folds of Carinara. What remains today is an vast "garden" abandoned along with the ruins of the antique farmhouse of Lieto and the annexed shrine dedicated to the Holy Virgin. Examination of the soil has highlighted that to this day the bottom ground has an elevated capacity and aptitude for different uses in particular the cultivation of tree crops, vegetables, and flowers. In reference to the latter, a restoration project has been developed for evocative contiguity, inspired by the closed garden that is the backdrop for the Annunciazioni del Beato Angelico. A particular and original prompt is the reinterpretation of the enclosure and of the plants in the garden. The former made up of the rose hedges, and the latter modeled for the production of wild roses, one of the few with pentagonal symmetry, an intense and expressive symbol of the medieval theme of pure love and the giving of oneself, that is ingrained in the catholic-Christian nature, as it is in Hellenic mythology, traditional Rosicrucian order themes and in alchemy.

Keywords: Landesign, hortus conclusus, Casignano, agricultural park.

1. Taken from documents regarding the monument

The purpose of this analysis is to individuate a possible area of interaction between the fields of urbanization and landscaping.

Focusing particularly on the panorama of the periphery territory which runs a greater risk because of its lack of identity and its absence of a specific role in the territorial structure, however, at the same time it could be rediscovered as an environmental and social resource within the city area, we must keep in mind that the quality indicator that determines the level of attractiveness of an area is the natural environment.

The settlement system in the Aversa area was formed along the ancient roads of via Appia, Campania and Atellana during the transformation of the plains owing to the abatement of land recuperated from the flooding of the River Clanio. The historical structure of the area was clearly characterized by an obvious hierarchy of centers which gravitated around Aversa.

The structure of the historical center of Carinara is made up of a dense network of courtyard house that mark its characteristic personality.

The courtyard house which descended directly from the style of Pompeian homes typical of the Aversa area, has among them some examples of noteworthy craftsmanship and environmental value.

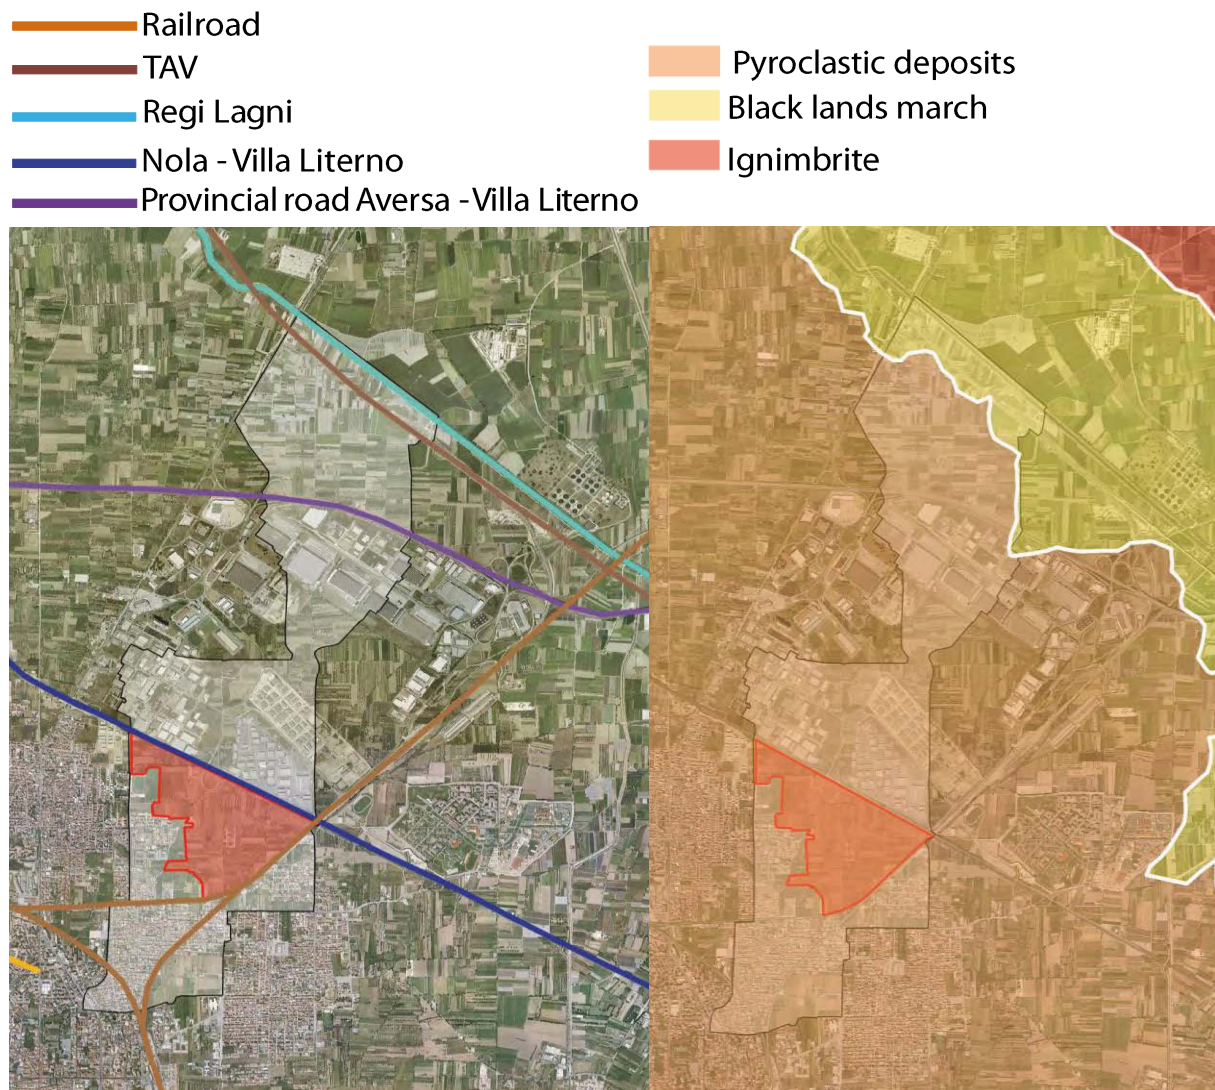

Fig. 1: Infrastructure network and geology

Among the many examples of single family patriarchal homes there are also many courtyard homes with condominium structures or small agricultural villages with annexed chapels, mills etc. as in the case of Casignano and other sites in the area of Aversa. Construction in the post war period occurred around the historical nucleus within the barriers formed by the railway system.

Historically the territory of the town of Carinara is divided into two original pre Norman constituencies: Casale di Casignano dating 1104 and Carinara 1158. The two constituencies were united in the 18th century, designating the inhabitants of Casignano to the parish of Carinara. The unit developed as a farming village with dwellings and other annexes that gravitated around the small church named for San Martino until it was suppressed for lack of inhabitants in 1847 by the Papal brief; L. Giustiniani in the *Dictionario Geografico Ragionato del Regno di Napoli* of the year 1757 states: «There was an antique parish named for San Martino placed by the Bishop, as seen during a visit made by P. Ursini on 28 October 1597. As time went on and the diminishing number of souls in the desert of Casignano it was suppressed with a Papal Brief dated 1 February of 1847 “executed” the 30 June that same year; and the care of those same souls given over to the nearby parish of Carinara by a decree of Bishop De Luca in February 1848, “the annuities to it associated go to the seminary convent, to the seminary were also given organ, parameters, wardrobes and to the above mentioned parish pyx, and I don’t know what else.; to the other parish of S. Spirito in Aversa goes the baptismal fountain [...]».^[1] Since that time, the site, which was completely abandoned has gone to ruins, which was further aggravated by the seismic activity in 1980, afterwards a fire provoked further damages such as the collapse of the roofing.

The Casale of Casignano, has been over the centuries fief to many noble families, such as the Brancaccio, Capece, Crispano, Del Tufo, Di Sangro, De Lieto;^[2] a symbol of importance and wealth that land holdings represented which to this day is surrounded by vast agricultural areas characterized

Fig. 2: Office Topographic military, Map of the Kingdom of Naples, I series, sheet 18, 1839. Particular of “agro aversano”.

Fig. 3: Military Geographical Institute, Italian paper, sheet 184, 1905. Particular of “agro aversano”.

Fig. 4: Military Geographical Institute, Italian paper, sheet 184, 1957. Particular of “agro aversano”.

by their tradition of quality cultivation and by high levels of environmental integrity, characteristics which we intend to safeguard with the formation of an agricultural park. In reference to the most traditional and profound cultivation and production processes of the area as highlighted by L. Giustiniani in the dictionary Geografico Ragionato del Regno di Napoli “the territory is inseminated by its inhabitants [...] with grain, hemp; they produce light asprigni vines, and gathering suggestions made by observing the very area of which we speak, I have based the form of the project on the outline of a wine leaf using its principal arteries as pre existing communication axis.

Fig. 5: Historical evolution

Fig. 6: Natural trace

As an incentive and to facilitate movement we have designed three thematic entrance ways, the north entrance called “Ubi Facit” comes from the adjoining production area ASI that aims to reunite the idea of finished product and raw material, towards the west is the entrance called “Mens sana in corpora sana” where we will create areas equipped with sports equipment and the possibility to be close to nature, nature walks, bike paths, horse riding, the east entrance instead is named “Mediatio” which dedicates a part of the open space to activities like meditation and contemplation of the divine due to the shrine which was situated in this area, the only remains of the small church dedicated to San Martino present in that space. As a finale project for this type of intervention the positioning of a Hortus Conclusus, that in mystic medieval symbolism becomes a metaphor of the bride and the virgin Mary and of the church; in a Christian translation, the proposal of a “bosco sacro” sacred glen.

Referring to the Virgin whose image is the subject of an afresco which is still visible in the shrine, we have based the form for the Hortus Conclusus. The wild rose, the most symbolic image for the Mother of Christ, because this type of rose does not need to be pollinated (thanks to this characteristic it has been chosen as an example that symbolizes virginity and the splendid face of the Madonna, absolute perfection and conception, without defect).^[3] A through choice was made in the selection of the trees and flowers that design in their own way a chromatic journey, careful consideration was given to their individual reproductive cycles determining an optimal result throughout the year.

Characteristic elements of this Landesign project are the paving in irregular stones, the stone benches; the lawn, Juniperus horizontalis Glauca; wild rose hedges arranged along the way called “Way of the Rosary”; the Peonia Sinensis also called “Thorn less Rose” and the violets that bud in the spring which symbolize the humility and modesty of the Holy Virgin Mary; the red rose hedges that

symbolize the maternity of the Madonna and white that represents her virginity; Carnations (*Dianthus Allwoodii*) that with their shape and color remind us of the nails in the cross and in reference to the iris which is a symbol of Mary's broken heart; *Galanthus Nivalis* (snowdrop) the first flowers to bloom after a harsh winter.

Saint Lawrence outside the walls. Notes on the nineteenth-century restoration by Virginio Vespignani

Cesare CUNDARI¹, Gian Carlo CUNDARI², Maria Rosaria CUNDARI³

Abstract

After the original Church of St. Lawrence was restored in the first half of the thirteenth century, two events were particularly important in the history of the Basilica of St. Lawrence outside the walls: the restoration by Virginio Vespignani in the second half of the nineteenth century, between 1857 and 1865, and a later restoration after it was bombed in 1943. Both events affected the configuration of the building as we see it today, but the first restoration is certainly the one which – as we have already mentioned – not only changed the appearance of the basilica, but also the area around it. In fact, during that restoration the first basilica, commissioned by Pope Pelagius between 579 and 590, was almost entirely brought to light. The Lanciani Holding, housed in the Institute of Archaeology and History of Art, has an extensive selection of drawings about the restoration. Based on these drawings it is possible to reconstruct almost the pre-restoration state of the building as well as Vespignani's project. In this paper we will analyse the most important drawings in the Holding in order to reconstruct the pre-restoration state of the building and the main guidelines of the project.

Keywords: survey, design of the architecture; architectural design of the project

Premise¹

After the original Church of St. Lawrence was restored in the first half of the thirteenth century, two events were particularly important in the history of the Basilica of St. Lawrence outside the walls: the restoration by Virginio Vespignani in the second half of the nineteenth century, between 1857 and 1865, and a later restoration after it was bombed in 1943. Both events affected its current configuration, but the first restoration is certainly the one which – as we have already mentioned – not only changed the appearance of the basilica, but also modified the area around it. In fact, during that restoration brought to light almost the entire first basilica commissioned by Pope Pelagius between 579 and 590.

The Lanciani Holding, housed in the Institute of Archaeology and History of Art, has an extensive selection of drawings regarding the restoration. Based on these drawings it is possible to reconstruct not only the almost entire state of the building before Vespignani's restoration, but the project itself. Indeed, Vespignani's project was monumental; the portfolio in the Lanciani holding has drawings of a multi-coloured façade with the coat of arms of Pope Pius IX and an inscription with the words: *Engraving and chromolithograph of the Basilica of St. Lawrence outside the Walls after the general restoration commissioned by the magnificent and Supreme Pope Pius IX under the supervision and with the drawings by the architect Count Commendatore Virginio Vespignani.*¹ These drawings, which provide very useful iconographic and graphic information about Vespignani's project, prompted us to elaborate the considerations set out in this article, considerations which are in line with the conclusions of previous scholars. While in this article we will focus only on some of the main aspects

of the restoration, a more extensive and comprehensive review will be provided in another article; it is important to point out that an accurate reconstruction of the building of the basilica complex has already been carried out by Krautheimer.²

The reader may also find useful the book written by the Capuchin friar Giuseppe Da Bra and published in 1952; the book summarises the main steps in the construction of the complex.³

The basilica complex of St. Lawrence was restored during the construction of the Verano cemetery. Early work on the cemetery (begun in 1837) had damaged the catacombs of St. Cyriaca (the Basilica was part of this complex); this prompted the Holy Archaeology Commission to raise the problem of the restoration of the basilica. Due to its importance, Pope Pius IX was asked to personally make a decision on this matter and he entrusted the project to the architect Virginio Vespignani. Vespignani's project included its restoration, consolidation, and detachment from the Verano Hill. One of Vespignani's most industrious and diligent collaborators was the archaeologist Giambattista De Rossi, an authoritative member of the above-mentioned Commission.⁴

1.1 The state of the surroundings and building before restoration ²

The state of the building and immediate surroundings is clearly illustrated in some of the tables in the Lanciani Holding; the first (fig. 1) is a drawing of the project with all the elements of the subsequent redevelopment of the area around the basilica. The table shows the layout of the site and indicates the areas which had to be excavated to the north and east of the complex in order to detach it from the Verano Hill. The former redevelopment is visible in the area in front of the basilica, with the perimeter of the Verano Hill threatening the left side of the square.

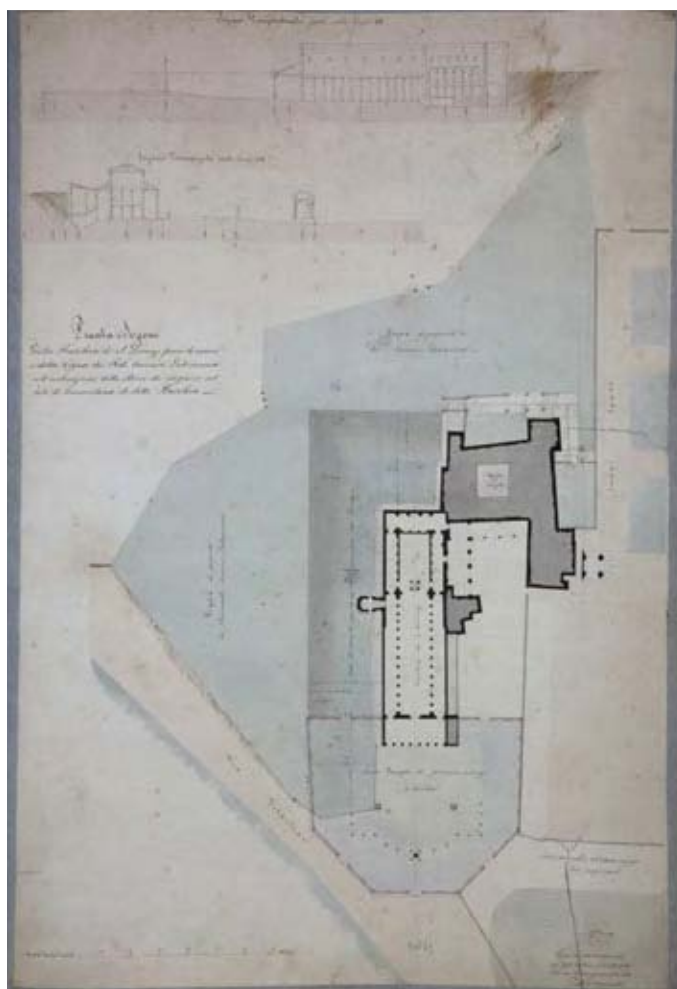

Fig. 1: The plan of the complex included the layout of the basilica and adjacent convent; it also shows the path leading to the side entrance of the façade, continuing on to the buildings next to the belfry alongside the south wall of the basilica, and protected to the south by a wall; the plan also shows that following on from these buildings the basilica had a side portico (later turned into a sacristy) and another portico in front of the convent; there is also a double entrance from the portico to the side nave of the basilica, the first is located in the middle of the southern nave of the east church, while the second leads to the former narthex area near the portico in front of the convent (dis. V. Vespignani – Lanciani Holding).

The table also includes two sections showing the site before Vespignani's restoration project: a longitudinal section (in axis to the basilica) and a transversal section (near the Chapel of St. Cyriaca). The longitudinal section shows that since the basilica was below the level of the nearby road (via Tiburtina), the area in front of it was very steep so that it could be accessed from this important road. The transversal section also shows the outline of the Verano Hill with a slope to the north of the church; this slope was perhaps created to try and stop water from filtering into the church. The slope can also be made out thanks to the different colours used in the plan showing the planimetric image of the Verano Hill. The transversal section also shows that there was another building above the Chapel of St. Cyriaca; this building was eliminated during the restoration by Vespignani.

This situation is described in more detail in another drawing in the same holding which has four survey drawings of just the basilica: apart from a longitudinal section there is also a façade and two transversal sections. In all three sections the floor of the area around the apse – the two side naves and the old narthex – is on a slightly different level compared to the floor of the other naves; this was due to the fact that the area underneath had been filled in many centuries earlier. However, more importantly, in all three sections in this drawing (fig. 3) the base of the giant columns we see today on three side of the apse were all free standing. It is even possible to see a parapet in the transversal sections which reduces the width of the ambulatories and allows the latter to be seen. We should point out that several decades before Vespignani's project (in 1921, 1822) the lower level of the columns had already been ascertained.⁵

1095

Fig. 3: The transversal section – of the apse area – showing how the columns were already completely visible when Vespignani surveyed the area (dis. V. Vespignani – Lanciani Holding).

Fig. 4: The engraving by Rossini shows the interior before restoration by Vespignani; note the small dome over the ciborium and, in the background, the arches of the blocked transept.

The transversal section of the apse also shows the blocked arches of the women's gallery visible in the longitudinal section and in several engravings (cfr. Fig. 4). The extensive iconographic material on this issue is housed in the Institute of Archaeology and History of Art; the documents illustrate the basilica before and after Vespignani's restoration project.

The careful and systematic study of the drawings in the Lanciani Holding reveals how Vespignani tackled and solved the major restoration issues regarding the complex of St. Lawrence.

First and foremost, the afore-mentioned general plan shows that a decision had been taken to isolate the monument from the Verano Hill; the drawing indicates the distances envisaged for the new containment walls.

Fig. 5: .Plan of the lower level of the Basilica with the area of the old narthex which had been freed from debris (red perimeter) and the crypt of the Saint (dis. V. Vespignani – Lanciani Holding).

Apart from this decision to isolate the monument from the hill, Vespignani focused primarily on freeing the old buried basilica from all debris. A drawing (fig. 5) of the lower level of the east church shows that it has been freed; the drawing also shows: the crypt of the Saint surrounded on three sides by a wall without any openings (cfr. Fig. 6), the old narthex to the east (and the results of the excavations of the floor), and several remains of the paving discovered in the side naves. The perimeter of the old narthex is particularly interesting; apart from its irregular shape, there's a circular niche in the centre of the east wall and a rectangular niche towards the south end; both niches are embedded in the Verano Hill. Steps appear to be represented towards the south end; it's possible that they used to either lead outside or to the next portico of the Convent nearby (?).

We should point out that the basilica was surrounded by catacombs; in fact, from the basilica it was possible to access the five levels of the catacomb of St. Cyriaca underneath the Verano Hill.⁶

Furthermore, bibliographical material reports that when the Verano Hill was excavated to isolate the basilica, part of the catacomb corridors on several levels had to be demolished in order to cut into the hillside.⁷

During the restoration, Vespignani worked closely with the archaeologist G. B. De Rossi and together they discovered (and re-interpreted) many elements of the original basilica. However it wasn't until almost a hundred years later that the elements needed to reconstruct the development of the original building, in particular the apsidal area, were brought to light during the excavations carried out as part of the restoration project implemented after the basilica was bombed in 1943. The results of the excavations are illustrated and critically commented by Krautheimer in his afore-mentioned book.

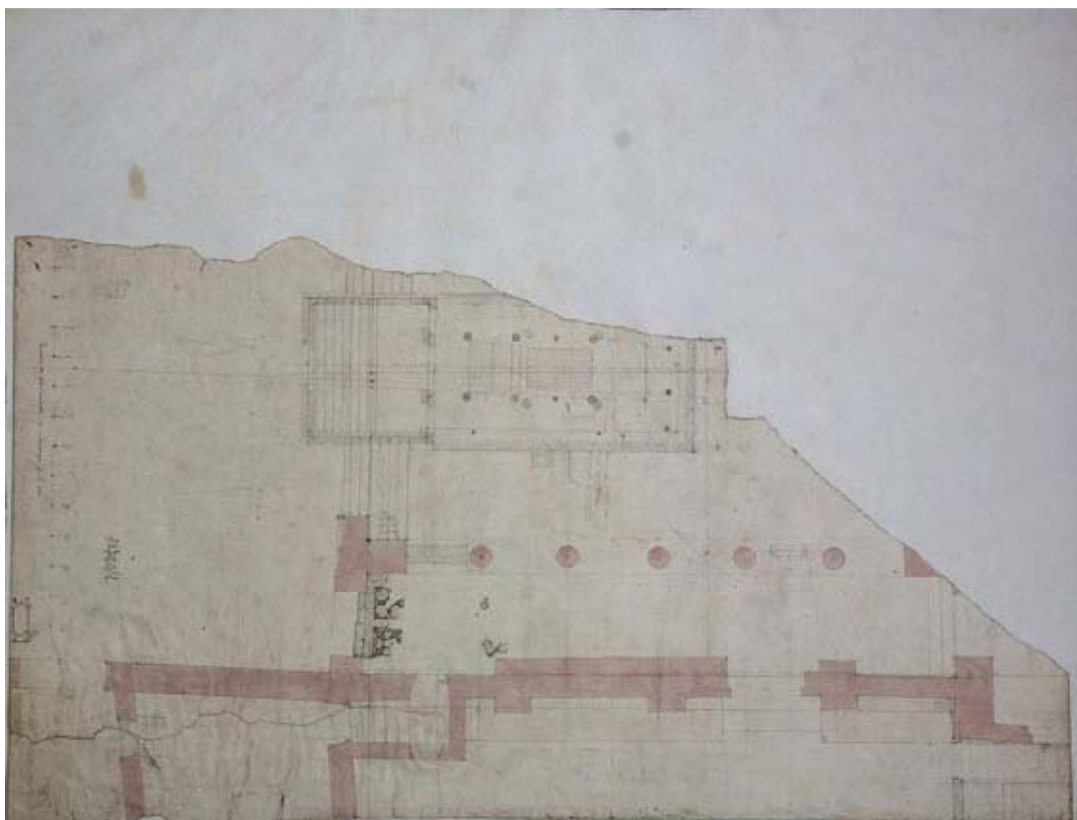

Fig. 6: Although incomplete, the drawing shows the plan of the lower level of the basilica freed from all debris and earthwork (dis. V. Vespignani – Lanciani Holding).

When the old church had been completely cleared of debris and could be accessed, the areas which had previously been decorated but had remained hidden were finally brought to light.

1.2 The restoration project²

After the basilica had been freed from all debris and many of its elements had been brought to light, Vespignani worked on his restoration project. Apart from detaching the basilica from the hillside, the project for the basilica also included a new layout (which is in essence the one we see today) and the merger of the two buildings into a single organism.

The main goals of Vespignani's project were: a) removal of debris from the lower level of the east church and joining it to the naves of the east church; b) redevelopment of the old narthex of the early Christian church; c) restoration of the envelope of the crypt of the Saint and redevelopment of the surrounding area under the presbytery; d) transformation of the southern portico into a sacristy; e) connection with the convent. The architect also built a staircase near the belfry to access the women's gallery where new floors had been laid.

In this article we will focus on the first two parts of the restoration project and will discuss the others in another longer paper. We will also propose several considerations about the redevelopment of the floors which was a particularly important part of the overall reorganisation of the monument.

1.3 The construction of the new presbytery³

Regarding point a), the architect created two sets of steps between the lower level of the east church and the two side naves of the west church (fig. 7). Freeing the area from debris also required the construction of structures to support the large upper presbytery.

Another drawing, also in the Lanciani Holding (fig. 8), shows the overall structural solution used to support the large presbytery which, apart from the new perimetral structure of the crypt (more on this further on), also had fewer slender columns and marble pilasters holding up a grid of beams (now visible in the intrados of the ceiling). The first columns (only four) are positioned in the centre area, the others (mixtilinear: column + pilaster) are located against the columns of the giant order along the perimeter of the presbytery area (five on each of the long sides, west and east, two behind the Bishop's throne towards the old narthex, and two in the corners at the intersection of the walls). In short, a very ingenious solution completely independent from the other pre-existent structures in the church.⁸

Fig. 7: The drawing shows the overall plan of the Basilica with the new redevelopment of the lower level (dis. V. Vespignani – Lanciani Holding).

Fig. 8: The drawing shows the restoration project of the lower level of the Basilica. In red the load-bearing structural elements of the new floor of the apse and the new elements closing off the crypt of the Saint. The drawing also shows the increase in width of some of the walls envisaged by Vespignani, and the new counter walls (most probably to protect from moisture). Finally, the drawing shows the design of the new floor envisaged by Vespignani which corresponds to the one which exists below the apse. For information about the Chapel of Pius, see figs. 10, 11 (dis. Vespignani – Lanciani Holding).

Vespignani also modified the top of the canopy over the main altar clearly inspired by several famous models in old Roman churches, and even by the canopy over Cardinal Fieschi's funerary monument located against the counter-façade of the church; this project is also illustrated in several drawings in the Lanciani Holding (fig. 9), as well as in several contemporary views.

Fig. 9: The engraving shows the new canopy top designed by Vespignani.

1.4 Transformation of the old narthex and the lower level³

With regard to the narthex of the old east church, the drawing of fig. DSC 0026A probably reflects Vespignani's initial intention to maintain an opening in the centre of the wall towards the hillside (in turn connected by several ramps to the cemetery area above); in fact the design includes two symmetrical flights of steps to access the lower floor level. The drawing also reveals that he had envisaged a staircase to the ambulatory of the cloister (access was through the grated opening which still exists at the southern end of the east exterior wall of the chapel of Pius IX). We have cited this drawing because it shows Vespignani's intention (unimplemented) to build a ramp between the area on the northern side of the basilica (freed by the work to isolate the basilica) and the Verano cemetery above.

Redevelopment of the lower level inevitably required work on the presbytery area and the women's gallery. Several drawings in the Lanciani Holding refer to the splendid mosaic of the presbytery pavement (fig. 10); we believe that these works were necessary because freeing the lower level from all debris had somehow required the demolition and reconstruction of the floor of the presbytery area.⁹ Although Vespignani's project already had very important solutions to recover and make the areas of the old narthex functional again, a competition for the construction of the new chapel within the old narthex was launched just after the death of the Pope who had devoted so much attention to Roman basilicas. The competition was won by the architect Raffaele Cattaneo: his solution was very respectful of the previous spatial arrangement of the area and yet was also very innovative with regard to the coating (mostly figurative mosaics) of the walls and floor. Several of the plans by the architect are also housed in the Lanciani Holding.

1.5 The floors³

The floors were naturally part of Vespignani's overall project for the basilica; the work almost certainly involved not only partial recovery and restoration (for example, the areas under the altars of the side naves), but also maintenance because the figurative works are similar to others in traditional Roman buildings. Most of the work was to be done on the lower floor (the crypt of the Saint) where the entire area, discovered after earthwork, had to be paved. Figure 8 illustrates Vespignani's solution.

This floor was only built in the area under the apse; instead a much more elaborate and chromatically brighter floor, with an alternate pattern of geometric figures, was built in the chapel of Pius IX during the work designed by Cattaneo (figs. 11, 12).

Fig. 10: The drawing shows the floor of the apse area rebuilt by Vespignani (dis. V. Vespignani – Lanciani Holding).

Fig. 11-12: The floor of the Chapel of Pius IX. A) partial image, B) graphic restitution showing how the geometric pattern was developed.

Notes

1. Cfr. Munoz (La Basilica di S. Lorenzo fuori le mura, Rome, Fratelli Palombi, 1944, p. 101, 102). The intervention designed by Vespignani was never published; some of the tables are very rare, others were displayed at the Exhibition of the city of Rome at the Expo in Turin in 1884. The following words were published in the catalogue: *"These tables are part of a design which, supervised by Commendatore De Rossi and the cooperation of the late lamented Count Virginio Vespignani, should have been published about the grandiose restoration work of the basilica of St. Lawrence commissioned by Pius IX, but which instead remained unpublished. We took advantage of this exhibition to present several tables elaborated for the restoration; these tables represent the monuments and frescoes of the old basilica"*. Even Munoz remarked on the fact that this important material had been lost.
2. Richard Krautheimer retraced the history of the basilica complex of St. Lawrence outside the Walls also thanks to the archaeological excavations which had been carried out in the previous two hundred years and, above all, the surveys conducted during restoration after the basilica was bombed in 1943. His studies were published in the important and remarkable book (edited with Wolfgang Frankl and Spencer Corbett) *CORPUS BASILICARUM CHRISTIANARUM ROMAE - LE BASILICHE PALEOCRISTIANE DI ROMA*, vol. II, 1962, Vatican City; the book has an extensive selection of important photographs and drawings.
3. P. Giuseppe Da Bra, *SAN LORENZO FUORI LE MURA*, Rome, 1952. The book was reprinted in 2005 and curated by the Order of the Capuchin Friars Minor (to celebrate the 150th anniversary of their arrival in the Basilica of St. Lawrence outside the Walls). We should point out, however, that the studies by Friar Da Bra were carried out before the excavations which, years afterwards, led to the discovery and identification of the Constantinian basilica, as reported by Krautheimer in the afore-mentioned book.
4. Cfr. Munoz A., op. cit., Rome, 1944, p. 93.
5. Cfr. Krautheimer, op. cit., p. 16.
6. Cfr. Krautheimer, op. cit., p. 23
7. Cfr. Krautheimer, op. cit., p. 24
8. With regard to the visit by Pope Pius IX on 20 October 1864, Munoz (op. cit., p. 100) writes: *"Having entered (the Pope) in the sacred temple he saw, with manifest satisfaction, that work had been completed on all parts of the Basilica of Hadrian and Sixtus III, and then, after praying for some time in front of the tombs of the Saints and Martyrs Lawrence and Steven, he descended the new stairs, on the left, decorated with a balustrade made of various kinds of coloured marbles, and saw the Constantinian Basilica, where with great artistic expertise the floor, Confessional, papal throne, and marble seats and seatbacks rested on a robust support after being dug out of the earth which Pelagius II had commissioned to be deposited....."*. We were not able to verify using other documentary or bibliographical sources whether after freeing the area from the debris which had been deposited Vespignani found the pre-existing structures under the presbytery area. Nor were we able to find any further information, except for the information extrapolated from the afore-mentioned drawings.
9. Confirmation of this theory comes from Munoz (op. cit., p. 94): *".... the tomb of the martyrs was unearthed and protected with golden grates, and fourteen pilasters made of Carrara marble were installed to support the aynali vaults on which the presbytery floor rests; the strange small dome of the ciborium was removed, and a cusped crown on slender columns installed."*

Kusadasi, the Ancient 'Scalanova'.

Prof. Dr. Ahmet Vefik ALP TMMOB, AIA, RIBA, IAA

Architect, Urbanist, Regional President of International Academy of Architects, Istanbul, Turkey
ahmetvefikalp@alparchitects.com.tr

Abstract

Past few years, Turkey's western and south-western coastal zones have experienced a significantly rewarding tourism-oriented growth throughout. Certain centers, however, specifically Kusadasi, have recently been subject to a reverse trend and decline in touristic demand.

A splendid town of very comfortable climate amidst world-renown antiquities, religious centers and natural beauties, Kusadasi, the ancient 'Scalanova', has been increasingly condemned to haphazard urban planning and cheap architectural design activity, primarily as a result of inappropriate and biased actions of authorities. A significant majority of the developers and architects active in the region have also remained insensitive to the loss of historical and natural heritage in trade of a characterless built-environment, and, occasionally, misused the weaknesses of local and central decision-makers and planners in favour of individual interest and profits.

Consequent to a sensible decrease in the tourism market primarily caused by the overbuilt, messageless environment and dull architecture, the people of Kusadasi have, at last, realized the mistakes committed. Yet, attitudes have remained similar while, now, remedial measures are being worked on.

Keywords: Urban planning, urban heritage, natural heritage, tourism

1. Degrading the Cultural Heritage and Touristic Attraction Via Poor Planning, Design and Implementation

Kusadasi was born as a new port village as a result of receding waters of Ephesus and Miletus in the Menderes Valley. The name 'Scalanova', meaning new port, was attributed by the Genoese and Venetians who have been governing the trade in the region. 'Scalanova' has then been a colony of traders, comprising consulates and warehouses, the Muslim Turks living primarily on the hinterland in a settlement called 'Ardiz' on the skirts of 'Pilavtepe'.

Fig. 1: Scalanova (New Port) in old times.

Fig. 2: Aegean coast of Turkey.

The present city structure of Kusadasi originated from the early XVIIth century. The Prime Minister Okuz Mehmet Pasha, 'Sadrazam' of the Ottoman Empire during the reign of Sultan Ahmet I and Sultan Osman II, built the city walls together with a caravanserai, public baths and a mosque in 1618. The two-level caravanserai, 19x22 m large, surrounds a courtyard entered from north. The structure originally conceived for sea trade was restored in 1966 towards touristic use.

Kusadasi's nuclei were two neighbourhoods: The 'Camiikebir' was built on the flat zone with narrow, grid-iron street fabric. The distance between two parallel streets allowed two back-two-back lots with houses on the street side and courtyards on the rear. The 'Dag' neighbourhood on the hillside was structured in terms of houses and courts terraced in accordance with the topography, depicting an Ottoman architectural accent primarily expressed in the form of deep projecting roofs, horizontal eaves and classical roof tiles. Today, most of the genuine fabric is gone forever. Few remaining fragments of the city wall stand unattended, yet witness the origins of the settlement. Many new neighbourhoods have been born, bringing the population to 30.000, and an unprecedented touristic potential came to surface in 1960's.

Fig. 3: Kusadasi and environs.

Fig. 4: Kusadasi city plan.

2. The Historical Development

The origins of Kusadasi are not fully known. It is strongly believed that at the point called today 'Yilanci Burnu' a satellite of Ephesus called 'Neopolis' was founded by Ionians.

Famous traders and sailors, the Ionians reigned from the beginning of the IXth century BC in the zone between the Menderes and Gediz Rivers called Ionia of the antique era. Very rapidly, they enjoyed political superiority and established 12 cities named Ionian Colonies. In the VIIth century BC the Lydians, two centuries later the Persians, then in BC 334 the Great Alexander, and subsequently a synthesis of Greek and Local Anatolian Cultures have shaped the surroundings of Kusadasi giving birth to the antique cities of Ephesus, Miletus, Priene, Didyma, amongst others. In the IInd century AC, Romans gained dominance in the area which then became a religious focus. Kusadasi, a pirate port for many years, became Scalanova in the XVth century.

The Turkish Seljuk State won sovereignty over the area in 1186 under Kilic Aslan II, rendering Kusadasi an opening of caravan routes to the Aegean Sea. The Ottomans embodied Kusadasi in 1413 with Mehmet I, or Okuz Mehmet Pasha. Since then, Kusadasi remained under Turkish rule.

The island 'Guvercinada' (Pigeon Island) has been functioning as a cost-guard station during Byzantine and Ottoman rule. The fort, built in 1834, enjoys a tower for observation now called 'Pirate Fort' due to its defensive role against such attacks. The fort is today linked to the shore by a promenade jetty.

3. Antique Sites Around Kusadasi

Panionion is reported to be located south of Kusadasi, between the villages of Davutlar and Guzelcamli. It was the capital of the 12 Ionian Cities Confederation. All rituals, ceremonies and similar gatherings used to be performed here. Phygela has been built by Agamemnon at a point 3 km north of Kusadasi. It is believed he had the settlement built for his ill soldiers during the Trojan War. Ephesus, one of the most important antique settlements in the world, was founded by Androcles, yet the area has been already inhabited by Lelegians and Carrians earlier.

Ephesus was colonized by the Ionians by the end of Xth century BC. During its climax, Ephesus had a population of 300.000 and was a center of culture, art and wealth. The Temple of Artemis, a sector of Ephesus complex, has once been numbered among the seven wonders of the ancient world. The Basilica of St. John is a Byzantine citadel built by the Emperor Justinian in the VIth century AD. It is adjacent to Isa Bey Mosque, a typical Seljuk structure. Priene on the south was the most vibrant port of the Ionian Federation. Its grid-iron geometric city fabric is the work of Hippodamus of Miletus in the IVth century BC. Miletus, once a port again; and Didyma with its Temple of Apollo further south; Aphrodisias, Heraklia are other antiquities of international popularity around Kusadasi.

Fig. 5: Okuz Mehmet Pasha caravanserai with marina in the rear.

Fig. 6: Vernacular houses of Kusadasi.

4. Kusadasi's Touristic Powers

The antique sites in the vicinity of Kusadasi, all half or one-day round trip distances, make the town a major tourist center. In addition to those, The Church of Holy Virgin in Ephesus is a pilgrimage point for Christianity.

Furthermore, a 625-yacht international marina, a port for touristic vessels with custom facilities, an international airport 60 km away, a national park of extreme natural beauty, exceptional beaches, a wonderful climate render Kusadasi a focus of touristic activity. The presence of a major city, Izmir at 1 hour car distance further enhances the touristic potential of Kusadasi.

5. The Unhealthy Developments

Numerous facts, already mentioned, make Kusadasi a point of prime touristic potential. Indeed, the town has experienced an unprecedented growth in tourism industry since 1960's. The Ministry of Tourism has declared Kusadasi a pilot area, and a master project GAC "South and West Anatolian Environmental Project", receiving funds from international sources, has chosen Kusadasi the target point for action.

In spite of all these positive aspects, now Kusadasi is now industry and recreational popularity. Although the downwards trends may partially be attributed to global forces such as the Gulf War and some other negative developments in and around Turkey, Kusadasi's gradual loss in touristic interest is believed to be result of the following actions.

5.1 Overbuilding

The sudden touristic breakthrough in Kusadasi has resulted in an immense and dense building activity mostly in the form of hotels, motels, resorts villages, pension houses, summer houses and the like without any attention to the insufficient infrastructure.

5.2 Poor Architectural Quality

Almost invariably, the architectural quality of the new building stock is poor, ugly and repulsive.

The following points may be cited as significant architectural setbacks:

- a. Poor design quality in general, devoid of aesthetic and visual character and insensitivity to environment.
- b. Poor material and workmanship even in highly luxury establishments.
- c. Unfinished, roofless buildings with rebars left exposed on the roof terrace for possible future floor addition.
- d. Visually disturbing solar energy packs installed on the roofs.
- e. Additions such as pergolas, venetians blinds, aluminium framing in balconies executed haphazardly after the completion of the construction.
- f. Absence of any reference to the traditional and vernacular building tradition.

- g. Absence of sensibility to the historic and natural context.
- h. Drawbacks resulting from poor urban planning.
- i. Invariable urge to maximize the built up area, even beyond the permissible limits.
- j. Construction which is not in line with building permits documents.
- k. Poor site supervision and maintenance.

5.3 Poor Urban Planning

The city plans of Kusadasi have been initially undertaken by Iller Bankasi, a governmental agency responsible for producing city and town plans across Turkey. Subsequently, the local authorities, entrusted with planning powers through legal action, have commissioned a private city planning office which has been changed in every political takeover. Upon the sight of the catastrophic building trend in Kusadasi, the Central Government has warned the Municipality in many occasions.

Almost invariably, the plans prepared for the town, both by the Iller Bankasi and by private firms commissioned by the Mayor, resulted in poor and inappropriate plans, and the architectural character of the town has gradually worsened. Among numerous points, the following ones may be cited as the weaknesses of the plans and planning process for Kusadasi:

- a. Lack of an underlying philosophy.
- b. Absence of references to the historical and natural entities and landmarks.
- c. Absence of a strategy which would enhance and reinforce the old town's fabric and elements such as the caravanserai, the mosque, the city walls, the gates and the like.
- d. Insensibility towards the topographical morphology, with impossible streets, improper slopes and indifference towards the plant cover.
- e. Insensibility to the property lines and ownership structures, rendering either impossible or ugly architectural execution of the city plan.
- f. Higher land coverage ratios.
- g. Improper circulation network design and traffic studies.
- h. Weaknesses in face of pressures from investors.
- i. Absence of academically qualified critics and approval bodies, plans produced by the planning office circulating between councils and approval bodies without structured and coordinated criticism and expert critics.
- j. Method of compensation of the planning office which is occasionally asked to establish direct financial contacts with investors, developers and the people in general.
- k. Biased influences and pressures from local and central authorities.

In addition to all these chaotic, biased, improper processes resulting in a characterless, messageless building environment in Kusadasi, the garbage collection and storage problem, the pollution of the sea, the shortage of water, and other drawbacks resulting of the lack of proper substructure and incapability of the Mayoral office which is short of funds, have negatively affected the tourist attraction power of Kusadasi from inside and outside.

6. What Can Be Done for Kusadasi?

The statistical data demonstrate the downwards trend in the tourism activity in Kusadasi in spite of the very significant incentives for tourist attraction in and around the town.

The officials express that the touristic activity would have been 300 % higher if the town has not been subject to the destructive and degrading effect of the cheap architecture and urban planning. Tourists would favour Kusadasi more if the cultural heritage and the natural wealth have not been vandalised in favour of concrete monsters, however there is still much which could be done for Kusadasi:

- a. The present private planning office for Kusadasi commissioned by the Mayor seems in principle appropriate and mature to the preparation of plans. Yet a body formed primarily by academicians and experts with at least one foreign member should govern the policy making, the criticism and approval processes of the city plans.
- b. The preparation of the city plan should be totally closed to political pressures and other influences directed to work for the profit of individuals rather than the welfare of Kusadasi in general.
- c. The city office responsible for approval of building permits shall be supplemented by expert architects.
- d. The Mayor shall use academic advisors in all matters related to building and construction.
- e. Aesthetic standards shall be developed and required for all building to be built within Kusadasi.
- f. Close coordination and cooperation with the Council for the Preservation of Cultural and Natural Entities shall be initiated.
- g. Close cooperation with surrounding municipalities, primarily Davutlar and Selcuk shall be initiated.
- h. Planning works shall be conducted in close cooperation with related Ministry and Directorates.
- i. A comprehensive landscape project shall be developed to mask the present architectural terror.

- j. National and international symposia on the planning of Kusadasi shall be organised and competitions be launched.
- k. The skyline and the sea cornice shall be given priority in planning and design.
- l. The public awareness on architectural issues shall be enhanced and matured.
- m. More efforts shall be devoted to obtain sources from governmental and international establishments and agencies.
- n. Developers, investors, landlords which do not properly follow the guidelines shall be severely punished.
- o. Architects active in the area shall be educated through seminars.

7. Conclusion

The intention of this paper is not to establish definitive remedies to the problems of Kusadasi or to criticize certain offices or agencies. The points listed above consist only of a sampling of measures to be considered in the process of restoring Kusadasi's genuine character. The goal of this contribution is to diffuse S.O.S. messages in all directions to stimulate concerned bodies and officials to act at once. If proper action is further delayed, the trend to catastrophe will then be irreversible and Kusadasi whose nature and culture have been favoured so much will be lost forever.

Abstract

The project has been developed, with a group of architects: Anna Mandia, Giuseppe Mandia, Alexandros Karim Alevas, Barbara Blondi, in order to participate in the International concept and design competition for the new contemporary art museum in Buenos Aires. The proposal is to create architecture which refers directly to contemporary art. An amorphous objects of unnatural size, presented to the public on a geometrically simple base. Its morphology reminds of a diverse quantity of forms in nature: from bubbles to clouds to various marine mammals or more abstract shapes. But as a matter of fact this project is not designed to be referable to something really existing. It tries to be a work of art itself rather than only a container for it – an object capable of surprising and moving, intriguing and inviting anyone who looks at it. Like contemporary art which refuses to be interpreted in a rational way but still achieves to evoke an emotion in the observers mind. Located in the Puerto Madero District - which currently represents the largest urban renewal project in the city of Buenos Aires - the museum is situated on the intersection of two important pedestrian axes: the north-south promenade (Juana Manuela Gorriti) and the east-west axis connecting the city with the new urban barrio with the impressive Puente de la Mujer by the Spanish Architect Santiago Calatrava.

Keywords: design competition, contemporary art museum,

1. The project

The initial idea of this proposal is to create architecture which refers directly to contemporary art; An amorphous objects of unnatural size, presented to the public on a geometrically simple base. Its morphology reminds of a diverse quantity of forms in nature: from bubbles to clouds to various marine mammals or more abstract shapes. But as a matter of fact this project is not designed to be referable to something really existing.

It tries to be a work of art itself rather than only a container for it – an object capable of surprising and moving, intriguing and inviting anyone who looks at it. Like contemporary art which refuses to be interpreted in a rational way but still achieves to evoke an emotion in the observers mind.

Located in the Puerto Madero District - which currently represents the largest urban renewal project in the city of Buenos Aires - the museum is situated on the intersection of two important pedestrian axes: the north-south promenade (Juana Manuela Gorriti) and the east-west axis connecting the city with the new urban barrio with the impressive Puente de la Mujer by the Spanish Architect Santiago Calatrava. On this exact point of intersection our proposal opens itself inviting the public offering an urban square, which – being connected to the multi-purpose space on the ground level – becomes a point of urban art, performance, installation, exhibition, open air theatre, concert, etc... Continuing along the promenade the ground level remains open to the pedestrian public providing one entrance, a café and the souvenir shop while it hosts the technical and administrative areas in the west part of the building easily reached by car through Av. Alicia Moreau de Justo.

2. Description of the museum - interior -

Entering the ground level the visitor finds oneself inside a wide and luminous foyer defined by a sculptural ramp and the functional core hosting elevators, emergency stairs and rest-rooms. These vertical elements are also of structural importance being the main pillars of the building, sustaining its three levels together with minor pilasters. Walking up the ramp and entering private space inside the "object", four open-space galleries of different height are to be found on these three floors. Through a rational channel system their ceilings make it easy to hang different types of module-panels and lights in order to change room situations and routes according to the ongoing exhibition. On the last level the museum hosts an auditorium with space for up to 250 persons and its foyer with a small bar.

2.1 The structure

The structure of the "blob" itself is self-supporting and lies on the ground level base. Its surface material is ethylene tetrafluoroethylene, a fluorine based plastic, designed to have high corrosion resistance and strength over a wide temperature range combined with excellent chemical and electrical resistance properties. It is a lightweight material (1% the weight of glass), and its self-cleaning and 100% recyclable characteristics make it an ideal material for the eco-aware society of the 21st century. Pneumatic panels of ETFE furthermore provide optimal acoustic and thermal isolation thanks to the layer of air lying between two membranes. According to specific requirements, opaque or transparent facade-cushions can be used to provide perfect diffuse lighting conditions for an exhibition interior.

"Architecture is a art when one consciously or unconsciously creates aesthetic emotion in the atmosphere and when this environment produces well being."

Luis Barragan

Confronting Contemporary Sustainability Norms with the Durability of Historical Buildings

Carmela CUCUZZELLA

Abstract

Environmental norms and certifications are increasingly used today to measure the level of environmental sustainability of buildings, often reducing the definition of sustainability to these norms or certifications. Our previous research has demonstrated, through an analysis of contemporary architectural competitions, some of the paradoxes resulting in design projects from the use of environmental norms and certifications, particularly in the Canadian context. This paper seeks to highlight a new series of contradictions related to the use of environmental norms or certifications for addressing the sustainability of buildings, through the analysis of a selection of historical buildings from the early 20th century. Research has already shown that some historical buildings are closer to addressing the challenges we face in the unsustainability crisis today, than some of today's projects built using rigid prescriptive processes, such as the LEED green building rating system. The highly publicized energy efficiency results of the building in New York city, the 7 World Trade Center, showed that even a LEED Gold certified building can be less energy efficient than the historical Empire State Building in New York city, albeit after upgrades to the insulation and mechanical systems of the building.

Keywords: sustainability, environmental certifications, judgment, contradictions, architectural competitions

1. Introduction

When it comes to addressing the sustainability of architectural projects, the questions of energy efficiency and the performance of buildings are considered prevalent concerns by most stakeholders. The objective of this paper is to question the idea that says, contemporary buildings would be more sustainable than traditional buildings. Amongst the traditional buildings, what happens when we consider those that are worth preserving as heritage buildings? Can we say that historical buildings are more or less sustainable than contemporary buildings? In other words, how would historical buildings fair today within the discourse of sustainability?

In this paper, rather than presenting the results of a variety of case studies, we use a few illustrative examples in order that we may deconstruct contemporary environmental management tools to present a new theoretical framework based on their ontological, epistemological and operational definitions. A first example can help illustrate some of these contradictions that our present condition addresses, specifically related to the strict use of environmental certifications in competitions today. Then we will present a second example outside the competition process showing that some historical buildings are closer to addressing the challenges we face in the unsustainability crisis when compared to some contemporary projects built using rigid prescriptive tools.

To study this complex phenomenon, the architectural competition format is a perfect empirical situation to analyze some of the paradoxes of contemporary approaches to sustainability. Indeed, the debate on quality during the competition jury process highlights the variety of value systems represented by the members of the jury, which are themselves representative of a variety of stakeholders. The increasing importance of arguments related to environmental certifications in competitions is showing indications of a shift of the ideal of quality in competitions and by extension in most situations where architectural quality goes through a judgment process.

2. Competitions as Empirical Situations

A first example can help highlight how sustainability as a new value system can be somehow counter-productive regarding the way in which we judge quality and sustainability altogether. This competition was rigidly driven by the measurable requirements of low carbon performance: the Concours EDF Architecture Bas Carbone 2011. This was the 4th edition of this competition, organized by EDF (Electricite de France) on the premise that “the low carbon performance requirement stimulates architectural innovation on all the planes and drives design towards a global quality that privileges comfort and harmony with the habitat.” [2, p.15]. In spite of the fact that the jury consisted of mostly architects, the jury’s comments regarding the winning project were very divided since there was much concern about the lack of overall architectural quality, while all competitors very rigidly addressed the question of carbon emissions. It is clear that technical solutions won this competition. In fact, the state architect/urbanist, a member of the minister of ecology of sustainable development and a member of the jury, voiced profound concern about the project saying that, “I have some fears with regards to the image, as part of a larger whole, and with the omissions it may encourage. I think that we must one day give ourselves the means to analyse the existent correlation between the technical solutions and the urban form and to measure these on the architecture.” [2, p.29] (Figure 1).

This competition is indicative that a serious problem is emerging in architectural competitions when the winning project of an architectural competition is lacking architectural qualities. The rigid environmental requirements can be considered as the invisible ‘member of the jury’, driving the entire deliberation process by focusing heavily on the questions of carbon emission, while essentially ignoring the overall qualitative architectural debate. Our research on competitions conducted with scholars at the *Laboratoire d'étude de l'architecture potentielle* (www.leap.umontreal.ca) in recent years have shown that environmental experts and certifications are not only problematic for the jury process, but they also seem to impact the design phase, shifting the designer’s focus to technological solutions.

Figure 1: Winning project of the « EDF Architecture Bas Carbone » 2011, les Docks de Saint-Ouen, Saint-Ouen (Seine-Saint-Denis). X-TU Architectes, avec Berim et le Sommer (source: d'a hors série, 2011).

What is interesting with this example is that it is a competition for young architects dedicated to sustainability. Rather than finding innovative ways to address the very complex questions, it seems that the low carbon achievements became the competition prize.

There seems to be an increasing occurrence, where the least controversial project wins rather than the best overall project whenever it comes to questions of energy performance. It follows that a building could be at once, an exceptionally performing building and considered high quality on this question, and yet on other qualitative architectural aspects, such as symbolism, identity, space, fluidity, etc., it is judged extremely poor.

Let us highlight here that the competition process is a format that allows comparisons among a variety of proposals each addressing the same given problematic. In the domain of architecture, it is mostly through comparison and debate that we can create new knowledge. This is noteworthy because usually the preservation of historical buildings is precisely supported by a strong qualitative appraisal of their value. What happens then when we consider the complex issue of the qualitative assessment of historical buildings in the growing demand for sustainability?

3. Can Historical Buildings Compete with Contemporary Buildings?

A recent survey in New York showed some astounding paradoxes regarding our current impetus towards the use of environmental certifications for many new commercial or public buildings. The city of New York ran a citywide survey of more than 2500 commercial high-rise buildings in Manhattan in 2012. The buildings surveyed were the largest in New York and account for just 2% of the approximately one million buildings in the city, yet they also account for about 45% of the energy used by the whole set of New York buildings. The buildings were compared with regards to their energy efficiency. The Environmental Protection Agency's *Energy Star* rating was used to score the energy efficiency of these commercial buildings considering that a minimum energy score of 75 is needed to pass the Energy Star rating.

The Chrysler building, constructed between 1928-1930, and designed by architect William Van Alen is an example of an Art Deco style masterpiece. In 1976, this building was declared a national historic landmark. It is 77 stories high. At the time it was built, in 1930, it was considered the tallest building in the world, at 319 metres. But it only retained this claim until the Empire State Building was completed the year after, in 1931, designed by architect William F. Lamb from the architectural firm Shreve, Lamb and Harmon. The Empire State Building was 381 metres (102 stories) and kept this claim until 1972. Both these buildings were part of this energy efficiency survey. Some of the results of this survey were unexpected.

The Chrysler building (Figure 2, left) received a score of 85, a very respectable score, as it was 10 points beyond an acceptable minimum. The Empire State building (Figure 2, middle) received a score of 80, also quite respectable. Both buildings were built during a time where the questions of sustainability were far off into the very distant horizon and the debate on architectural quality was not substantiated through questions of energy efficiency. When we compare the results of these two buildings with that of the 7 World Trade Center building, built in 2006, 52 stories, LEED Gold certified, and the first LEED certified commercial building in New York, the results are somewhat surprising. The 7 World Trade Center building (Figure 2, right) received a score of 74, below the optimal threshold.

The less than optimal performance of the 7 World Trade Center Building is not surprising since LEED New Construction, which is the certification received for this building, evaluates buildings before the occupancy phase without a follow-up after tenants move in. Yet this building is highly appreciated because of its LEED Gold label. Older buildings have their own intrinsic values of appreciation, which have nothing to do with the LEED label. The Chrysler building is one of the most identifiable icons of New York City's skyline. And they fair rather well when faced with today's energy survey, to some extent because older buildings have superior thermal envelopes as a result of their thick walls, less glass, and less ventilation.

Figure 2: (left) Chrysler Building, New York, built 1930, 77 stories, energy score 85; (middle) Empire State Building, New York, built 1931, 102 stories, energy score 80; (right) 7 World Trade Center, New York, built 2006, 52 stories, energy score 74.

Consequently, the Empire state and Chrysler buildings were both recently retrofitted with upgrades to their energy and water systems and from these renovations, both received LEED Gold certifications for existing buildings, in 2011 and 2012 respectively. The Chrysler building had however already won the Energy Star credibility in 2008, three years before these retrofits.

The unexpected results of this survey as well as the results of many architectural competitions that must meet very rigid certification requirements even before any other requirements, highlights the very crucial question of what is the value added by these certifications today. Can we say that our present unsustainability condition represents a 'crisis within a crisis'? In order to address such a complex issue, it appears necessary to revise both our epistemological and operational frameworks.

4. Sustainability: A Crisis Within a Crisis

We have seen how environmental norms can be counter-productive in competitions. We have also seen that some historical buildings can compete with contemporary buildings if we reduce our understanding of sustainability to that of the certification or rating tools. In addition, our previous researches on evaluation practices and qualitative judgment suggest that the sudden introduction of environmental certifications in the architectural competition can be at the expense of a more qualitative assessment of the design project [1].

Let us highlight here that research on tools, certifications and methods for assessing concerns related to sustainability, particularly the environmental pillar, has been conducted since the early 70's. This reflective, at times critical, activity is growing exponentially, as these instruments are continually being improved and as new ones are constantly being introduced to address newly uncovered concerns or impacts. Whether this increasing precision in today's tools for assessing environmental or social impacts is actually getting us closer to a more sustainable development is unclear and is the subject of another research. But what is evident is that there is a huge disciplinary gap between the enormous body of research on evaluation tools for environmental, economic or social sustainability, many of which are oriented towards performance efficiency and optimization, and the shallow body of research

on how these are used in design projects, particularly on architectural and urban design, and how they impact the outcomes of these designs. There is little regard to how these tools are ultimately adopted by professionals, including architects, urban designers, or even public planners – in a context of design for sustainability.

In this light, we cannot avoid a deep reflection and criticism of these tools, not only at the epistemological or operational levels, but also at the ontological level. So doing our current research program endeavours a deconstruction of environmental management tools from this perspective.

4.1 Ontological Definition: Plethora of Tools, Lack of Integration

The environmental management tools and methods that are increasingly being used in design projects are as diverse around the globe as they have been in time. The tools have been in constant fluctuation, as they are constantly being modified to better handle the on-going limitations. And as we can see through the variety of environmental building certifications systems around the world, there is an attempt to accommodate these concerns with regards to the varying cultures and climates (Figure 3).

Figure 3: Environmental building certifications around the world (source: <http://www.usgbc.org/International>)

The paradox at the international level is that there is a demand to find development solutions that integrate concerns related to the four pillars of a sustainable development (culture, social, economic, and environment), yet the tools that are being developed do the exact opposite. The current environmental management tools reduce the concerns in any one pillar to a series of fragments of concerns. These reductionist tools are being heavily advocated for development projects around the world, whether they are urban, architectural or landscape projects. They have become increasingly prevalent for many reasons, two of which are that: (1) They simplify a very complex problem into a manageable set of criteria; and (2) we are embedded in a risk society obsessed with the quantification and prediction of risks. The question that comes up at this time is: what kind of unintended consequences will emerge from actions based on such reductionist tools for addressing the very complex problems of architectural projects in the contemporary context of sustainability?

4.2 Operational Concerns: Contradictions from their Use

Even if the intentions of any green building certification system are to seek to reduce environmental impact of the building, unintended consequences often arise from their use. If we take the example of the LEED (Leadership in Energy and Environmental Design) certification, which is consequently the basis of many other certifications, it is based on a point system. It is very standardized, usually for a national context. In fact, there is actually very little adjustment from country to country, even if the climate, the geography, the cultures and the societal habits are very different. Here, we can see that such a universal system has trouble addressing the specificities of projects. This standardization, in many cases, will encourage the game of 'finding the most points', rather than the searching for the most appropriate and efficient technologies for the given site, or more generally, exploring innovative or creative approaches towards environmental, social and cultural responsibility. So the project is set against the point system rather than using the criteria of the certification as a set of universally accepted general guidelines that may or may not be appropriate for any specific project. Often, creative and unique approaches, which may offer transformational sustainable improvements, are just not considered in the LEED point system because they cannot be *proven* to be an improvement, as they are not 'tried and tested' technical solutions.

In addition, we are seeing an increasing number of buildings being certified, where the notion of green certification is contradictory to the purpose of the building itself. For example, the spaceport project won by Foster and Partners in New Mexico, USA, located in the middle of a desert. The enormous amount of toxins emitted from the use of this spaceport allows us to question: what is LEED certifying? This project is designed to be LEED Platinum, the strictest of the LEED certifications. Will the performance improvements obtained from a LEED Platinum certification outweigh the emissions resulting from the building's operations? Unlikely.

In fact there have been several studies regarding the performance outcome of LEED certified buildings. A first research has shown that there is no correlation between the level of LEED certification and energy performance of post-occupancy buildings [9]. A second research has shown that LEED-certified buildings do not collectively use less energy than their non-LEED counterparts [10].

4.3 Epistemological Reflections: Risk Society, Technology, and Expertise

What we are increasingly observing, particularly through the growing imposition of the use of environmental certifications for public buildings, is an evaluation of quality emerging from risk society. Proving that a building is environmentally sustainable through the acquisition of some green building certification has become a goal in itself. How are these certifications shifting the ideal of quality in today's buildings? A more rhetorical question would be: are buildings allowed to be beautiful today? This question actually introduces a contemporary paradox where risk society and its plethora of environmental analysis or prescriptive tools are redefining quality in general. This has become an epistemological problem since quantifiable empirical data is increasingly needed to design and judge a quality building.

"Risk may be defined as a systematic way of dealing with hazards and insecurities induced and introduced by modernization itself" [3, p.21]. By modernization we mean the way humans increasingly seek technological mastery over nature. Risk society is "a society increasingly preoccupied with the future (and also with safety), which generates the notion of risk" [4, p.3]. It describes the way that modern society responds to risk. Risk society emerged with the growing concerns of environmental risk - as these had come to be the predominant product of industrial society – and development of probabilistic risk assessment. The prevention of these 'manufactured' risks through measurable, predictable means became inadequate in a society where risks were being introduced faster than they could be understood, let alone quantified. So even if this modern understanding of risk was supposed to help humans control their future or to normalize it, attempts to control the future through these measurable methods have led to the realization that humans need different approaches for relating with uncertainty.

With the increasing need to quantify environmental risk, there is a parallel imposition of environmental experts embedded within architectural projects. Should the question of expertise be reconsidered and evaluated within the general theory of qualitative judgment?

We have observed in various European and North American competitions today, that when environmental experts are “part of the jury”, the deliberation may result in a series of discursive deadlocks directly related to the gap between the specific and varying lexicons of the many members of the jury. Qualitative debate is needed to collectively construct and agree on the best overall project. When a deadlock is reached, then this implies that we cannot arrive at a best project since the debate is circumvented by the quantitative rigidity of the experts. It is difficult then to circumvent the general theory of judgment in dealing with this discursive gap. According to Dewey reflective thinking is judgment suspended during further inquiry, where a state of doubt is maintained until some conclusion can be finally reached [5]. In order to reach a judgment, a series of inquiries where elements such as evidential facts, principles, and tacit knowledge, may all be necessary. Evidential facts are a result of the evaluation of empirical data – an objective perspective. Principles provide the worldview – a normative perspective. Tacit knowledge is the knowledge acquired through experience and is considered subjective, where experience is the natural stimuli for reflective inquiry. These three can be related to what Habermas terms the cognitive-instrumental (objective), the moral-practical (normative), and the aesthetic-expressive (subjective); all three dimensions of modern culture that have become increasingly detached as they have become increasingly expert driven [6]. From this point of view, the declared experts can be easily observed to provide quick conclusions in their evaluations, since they assume to have enough evidence – however on their very fragmented vision of the project. Architects in the jury, on the other hand, are observed to be in a continual state of suspended conclusion and reflective thinking, grounding the information from declared experts within their overall project experience.

As far back as 1954 (original French publication), according to Ellul, the paradox with technology is that it drives intention and so individuals have become the slaves of the technologic society, where *“the multiplicity of means is reduced to one: the most efficient”* [8, p.21]. And yet,

“(...) the individual participates only to the degree that he is subordinate to the search for efficiency, to the degree that he resists all the currents today considered secondary, such as aesthetics, ethics, fantasy. Insofar as the individual represents this abstract tendency, he is permitted to participate in the technical creation, which is increasingly independent of him and increasingly linked to its own mathematical law.” [8, p.74]

For this author, the search for efficiency has overwhelmed the individual’s ability to consider other ways of thinking, such as aesthetics, ethics, etc. impoverishing humanity’s ability for creativity and reflection. The rigid use of environmental certifications for architectural projects has become a main protagonist of this impoverishment.

5. Conclusion

As the recent New York survey showed, older commercial high-rise buildings tend to be more energy efficient because of their larger mass and are therefore naturally insulated through this very characteristic. It may be that whether the architecture is a result of a competition or a call for tender, it seems that the expertise on heritage preservation and the understanding of the historical value of buildings would be more *sustainable* than the ‘mechanical’ imposition of norms and certifications of performance which can be at times put into question. There is still much work to do on the method for evaluation. This question of evaluation becomes crucial when trying to judge overall architectural quality. Although in North America competitions are rarely addressing historical preservation issues, most European contexts witness a real clash between the problematic of qualitative judgment, heritage preservation and sustainability.

Finally, the dichotomy between performance measurements and the complexity of projects is a disciplinary problematic. This becomes quite evident when we confront today’s performance measurements with historical buildings. This increasing need to *quantify quality* represents a point of fragility since architectural projects are judged nowadays by measuring quality, rather than through debate. But can we speak of heritage conservation outside a collective construction?

THE INFLUENCE OF NEW TECHNOLOGIES ON SUSTAINABLE PARKS: DUISBURG NORTH PARK AND CENTRAL PARK VALENCIA.

M^a Carmen VESES JIMENEZ¹; Dr. Ignacio BOSCH REIG²

⁽¹⁾ Department of Architectural Design, ETSAV, UPV, Valencia, Spain.

maveji@upv.es

⁽²⁾ ibosch@pra.upv.es

Abstract

The case studies considered are Duisburg North Park, 1999, and the winner of the Valencian Central Park project competition, 2011. Duisburg was one of the first sustainable parks created and the Valencian case study is a recent sustainable park.

In Duisburg North Park sustainable actions are delivered by passive measures: maintenance of pre-existing constructions as ruins, implying a low cost intervention and historical preservation, analysis of the water cycle, closing some contaminated areas to public and allowing spontaneous growth of vegetation, among others.

In Central Park Valencia, sustainability is manifested through technological advances in the field combined with passive design: catalogued protection of the industrial heritage, the bowl design of park structures for collecting rainwater, the choice of plant species of low water consumption, among others. Highlighted active measures include: the use of low-carbon technologies, and drip irrigation with recycled water, sustainable urban drainage systems, LED lighting with daylight sensors and implementation of geothermal collectors.

After comparative analysis of both cases, the presentation raises the debate about the need to combine passive and active mechanisms in the design of sustainable parks, establishing relationships and differences between the two.

Keywords: sustainable, passive, active, park, Duisburg, Valencia.

1. Features of sustainable park

Firstly it is necessary to define what we mean when describing a sustainable park. According to the definition of CRANZ and BOLAND ^[1], the sustainable park is the latest model in the evolution of park design, which appearing in 1990, characterized by the following features:

- Self-sufficiency with regards to natural resources and maintenance.
- Resolve larger urban problems, such as fragmentation and conurbation.
- Create a new standard for aesthetics standards, innovating landscape management both in parks and urban spaces.

SUSTAINABLE PARK 1990 - PRESENT	
Social Goal	Health, ecology.
Activities	Walking, excursions, cycling, recreation, enjoyment of nature, culture.
Size	Diverse, generally in form of corridors
Relation to the city	Linked to a larger urban system.
Order	Shape and area are adapted to solve an urban problem.
Elements	Native plants, ecological restoration, green infrastructure, resource self-sufficiency.
Promoters	Environmentalists, local communities, landscape architects, volunteer groups.
Beneficiaries	Residents, wildfire, city spaces.

Fig. 1: Features of sustainable park. Chart adapted from CRANZ and BOLAND^[2]

Further demonstrate that, Duisburg North Park (DNP) and Central Park Valencia (PCV) satisfy the requirements indicated in the chart. Both are partially self-sufficient with regards to material resources and maintenance, do not have a heavy energy consumption, do not waste resources (such as water) and have established mechanisms for the treatment of residues.

Both parks solve large urban problems, DNP forms a green belt within a conurbation zone of fragmented infrastructure. PCV will eventually successfully link six different areas physically separated by train lines. The park and boulevard will also improve social permeability and will give the city a central focus.

1.1 Passive and active measures in the design of sustainable parks.

In the definition of a sustainable park one differentiates between passive and active measures.

Passive measures are based on the rational use of different shapes and materials related to design. An example of these could be: the choice of plants with low water consumption, investigation into lowering maintenance costs, consideration and treatment of the water cycle, low cost interventions involving existing material, among others.

Active systems are related to the use of new technologies, such as renewable energy (solar, wind and photovoltaic energy), also systems which need an initial input of energy to function (domotics, daylight sensors...)

2. Features of Duisburg North Park

The decline of industrial activity in the Ruhr left large areas contaminated by the coal, iron and steel industry, with a strange landscape, environmental damage and contaminated soils.

The Emscher Park International Exhibition Building (IBA) was created to repair the area (environmentally, economically and culturally) on the former site of the steelmaker Thyssen, including the park inside a large urban green system, as part of a green corridor of about 300 km².

One of the main projects of the IBA Emscher Park is Duisburg North Park. The area has a dimension of 230 hectares, located between several urban centres and is crossed by huge traffic arteries.

The project, designed by Peter Latz, produced a metamorphosis of the industrial buildings, considering them as a ruin to be conquered by vegetation. The main interventions are in the area where constructions accumulate, the remaining land, 200 hectares, are areas where leaves grow spontaneously vegetation, there are some areas, like where was the lake of coal tar covered today, which are closed to the public due to the high pollution.

Multiple sports and leisure activities have been developed in the park, such as the exploitation of the scars and cracks in the walls of the ore deposits for use as a climbing wall, a dive centre in the gas works and the ability to go cycling in the entire area.

The park is divided in four different sections ^[3]:

-AREA A- The industrial buildings are concentrated forming the cultural center of the park. Activities held in this area include summer film screenings, theatre, operas and concerts at the Old Hall, large-scale events in the Power Plant and various cultural activities in the Storeroom.

-AREA B- The northwest area composed of the bunkers, the old Emscher, and the wind power plant. Diverse sport and leisure activities: the huge detritus walls are used for climbing, there is a diving center in the old gasometer, cycling throughout the whole area...

-AREA C- Educational farm; maintains a record of the agricultural past of the place.

-AREA D- Areas with high contamination are closed to the public. One of the most polluted areas, where the coke plant was situated is now converted to a tertiary center.

The park has achieved social and economic regeneration of an area marked by the economic crisis after the closing of industry whilst preserving the industrial heritage of the area.

3. Duisburg North Park: Sustainable measures and considerations applied

All the main sustainable measures in DNP are passive, thus alluding to the design, but each assume a different character: environmental, social and economic. Sustainable measures considered in the project can be summarized in the themes developed below.

3.1 Conservation of industrial heritage. Historical memory.

Despite the apparent low heritage value of the remains, they have been maintained in the park, reconfigured as their symbol of identity; helped the zonification of the park and form the basis for many recreational and sporting activities.

In addition to the conservation of the industrial ruins, their recycling has two objectives:

- Low operational cost: In comparison to dismantling, conservation is a low-cost intervention, as the former was estimated at 50 million euros, while the current project cost about 15 million euros, not including new building, demolition and decontamination.

- Generation of a tourist attraction: The park is integrated within the Emscher industrial route, and designed so as to generate a green, industrial themed corridor.

3.2 Analysis and study of the water cycle

The "Old Emscher" was a channel which used to transport the waste material from the steelmaking process to the river Emscher. The intervention has achieved that the channel now carries clean water gathered from the roofs of buildings and other horizontal surfaces to the ponds and gardens. Sewage waste is transported away via sealed underground tubes 3.5 metres in diameter. This facility was one of the biggest investments of the park^[4].

A wind-powered water wheel installed in a factory tower has been used to improve the oxygenation of the water.

3.3 Consideration of waste

Soil at the site was contaminated with arsenic, cyanide^[5] and polyaromatic hydrocarbons among others. The following measures were carried out according to the German federal soil protection *Bundes-Bodenschutzgesetz* (BBodSchG) law of 1998 which refers to former industrial facilities, *Altstandorten*^[6].

- Decontamination measures: cleaning the contaminated site

500 tonnes of arsenic mud was removed from settling tanks, which were drained and the slime moved to other old mines.

The old sinter plant was demolished almost entirely due to serious pollution. Contaminated materials were stored in sealed containers in sinter deposits and covered with roof gardens. The stones which were not contaminated were grounded and used to form new land surfaces and aggregates for concrete.

-Safety measures include a long term reduction of the spread of the polluting agent.

The dams that crossed the park carried high pH slag and therefore were able to bind heavy metals. The external surfaces are covered by dolomitic limestone chips, also with a high pH ^[7].

-Protection and limitation measures: When it is not possible to apply the aforementioned measures for technical and economic reasons, the area is closed and access restricted.

The soils of the coking plant, which was demolished, are contaminated with polyaromatic hydrocarbons. In the project it was decided that the place was to remain a part of the park and to accept a slow release of gas during several generations to allow a reduction in contamination, limiting the use of the area to bicycle riding and walking only. Currently these lands are not part of the park a tertiary centre has been built on them.

It was decided during the project to close some highly contaminated areas, such as the coal and tar lake, and take no action on them. At present the coal and tar lake has been covered.

The model therefore seeks to isolate the toxic substances from the natural cycle through: cleaning highly polluted areas, moving the waste to another place or to maintain it in place if it is completely isolated. Finally, to counteract heavily polluted land whose removal or isolation is uneconomical and technically unfeasible the area may be closed to the public.

3.4 Recycling of materials

The industrial structures themselves were recycled because, as discussed, they serve as a basis for sporting activities, such as the use of a former gas tank as a dive center, mining deposits as climbing walls ... also some of the local materials were reused. In the central square, *piazza metallica*, the floor is made from sheet metal from the melting tanks. Demolition debris has also been used as a substrate for new plantations, recycled concrete or pavements. Some overpasses and stairs have been made with existing steel, for example with the steel from dismantled maintenance corridors.

3.5 Low maintenance cost

The park has a total of 230 hectares, and 200 of them are composed of land where vegetation is allowed to grow spontaneously without special care. Areas that were closed due to pollution do not require maintenance. Also the system collecting rainwater from roofs managed to reduce maintenance costs.

In 1999, the maintenance cost for the entire park was 1,789,521€ (3.5 DM). In comparison, in the same year the budget for labour and maintenance of Regent Park in London, half the surface area of DNP, was 3.125.980 € (£2.2 million) ^[8].

Despite the low cost of maintenance the park maintains a high diversity of plant species through the action of gardeners trained to maintain the variety of vegetation found there.

Also exist in the park other measures about diminution of energy consume, as the wind-power plant, the photovoltaic system and the solar panels ^[9].

3.6 Social and economic issues

Because of the industrial crisis many miners and steelmakers lost their jobs. The unemployment rate in the Ruhr, which was 0.6% in 1970, reached 12.2% in 2000. One objective of the IBA was to regenerate socially the zone and to generate employment.

Although the tourism industry only generated a fraction of the employment in the region, in 1999 DNP employed between 250 and 300 people, therefore, the environmental revitalization of the area attracted investment. The technology sector accounted for the bulk of job creation. Specialization in the technology sector directed towards the environment and waste treatment, and therefore against the environmental consequences of the old industries. According to HOSPERS ^[10] in 2004 this environmental technology cluster created more than 100,000 jobs, a number that keeps growing.

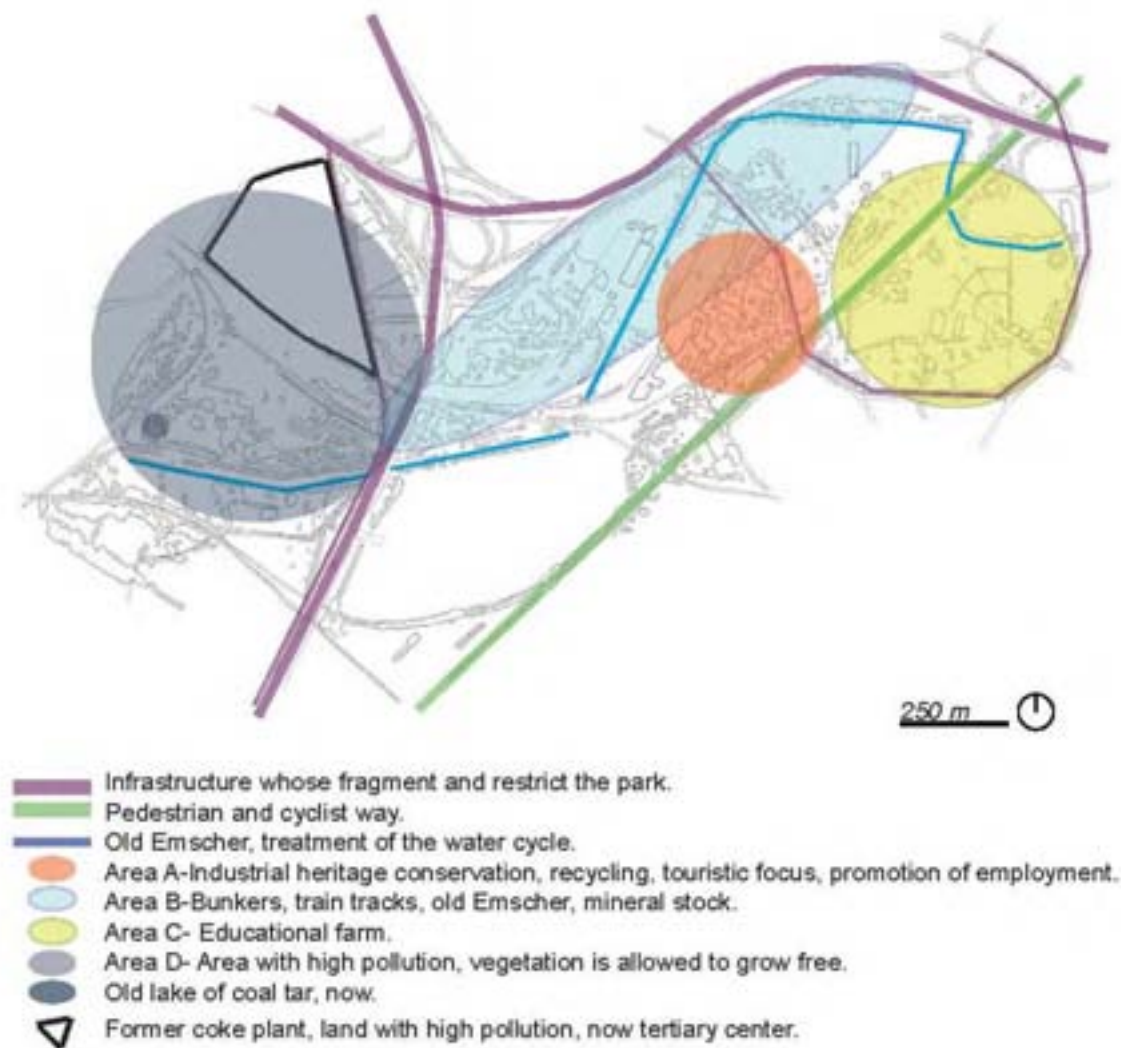

Fig.2: Duisburg North Park project, plan based on TATE ^[11]

4. Features of Central Park Valencia

The grounds of the central station, located in the centre of Valencia will provide 80 hectares of land to the city once the train tracks are buried underground. The train tracks divide the city of Valencia in two parts, creating a physical barrier between six neighborhoods.

The Central Park and a new boulevard, both designed by Gustafson Porter team, have been designed to occupy the empty urban space, aiming to promote permeability between different neighborhoods. The park's mission is to connect the disjointed parts of the city, it is also the opportunity to provide the city with a large park, as it is devoid of green spaces.

The proposed uses of the park are varied and are related to culture and leisure, such as a library, a restaurant, or a space for children, among others.

5. Central Park Valencia: Consideration of the sustainable measures applied

The measures under consideration are passive and active. The park has used BREEAM certification as a design tool, which assesses the sustainability level of the proposal, it is a voluntary certificate with international recognition. The following fields have been developed to achieve future certification: climate and energy issues (studying the topography of the park to allow maximum storage rain water), community, workplace design (residential streets as safe spaces for recommendations urban insurance), ecology and biodiversity (mostly native trees and shrubs), transportation (bicycle network planning), resources (low impact material) and economy and buildings (although these actions have

been determined by preliminary planning and are more difficult to justify.)^[12] They can be summarized as detailed in the following points.

5.1 Conservation of industrial heritage. Historical memory.

Regarding to industrial heritage, the park's design seeks to preserve the historical memory of the zone via the existing industrial structure. The warehouse workshops of Renfe, most likely designed by Demetrio Ribes, will be preserved and restored in their original location, but the covered springs which are on the route of the new undercover rail tunnel, will be moved to the perimeter of the park allowing their preservation. The covered springs were also catalogued by the General Urban Development Plan of Valencia in the areas of Sant Marcel·li y Camí Reial, although they suggested their transfer to a different location.

5.2 Analysis and study of the water cycle

On the surface of the park will be arranged sustainable drainage systems (SUDS) that collect rainwater. In addition, one of the main strategies is divide the area in different bowls. The park is divided into six bowls sloping inwards. The rain water in SUDS will be collected in the soakage pits (polypropylene compounds modules) located in these low points. Subsequently a pump lifts the water and gray water will be recycled. Specifically in the park is collected 35.6% of the consumption needs of the park (irrigation and fountains) and the boulevard 62% of the same amount.

The central lake ecosystem is proposed as cleaning (grey water) and also proposed drip irrigation and low water consumption plants.

5.3 Consideration of waste

In this case there is no highly contaminated soil due to industrial activity. Other measures have been taken in consideration of future park waste.

- Organic waste: It is proposed to have a composter to process and reuse materials from pruning and cleaning.
- Light pollution: Uplighting will be minimized, thereby reducing light pollution and energy consumption.

5.4 Recycling of materials

Stone blocks currently existing on site will be recycled for new flooring and the steel rails will be used in the construction of retaining walls and pergolas.

5.5 Low maintenance cost

- It is proposed to enforce a closing time and therefore the allow the possibility of regulating the daily energy consumption.
- The proposal includes efficient external lighting systems controlled by daylight sensors, LED lighting and photovoltaic technology will also be used and applied to the luminaires.
- Regarding energy capture, restored buildings will be provided with solar collection panels. Also a high efficiency photovoltaic installation in the four warehouse workshop will be developed, which will provide 60% of the energy consumed by the park^[13].
- It intends to implement in buildings of the park sensors geothermal and biomass, for heating, air conditioning and hot water production.

5.6 Social and economic issues

The development of the Central Park project will be a social improvement for the environment, on one hand there will be the union of the six districts and on the other is the regeneration of a degraded and abandoned area. The design of the park is conditioned by the user.

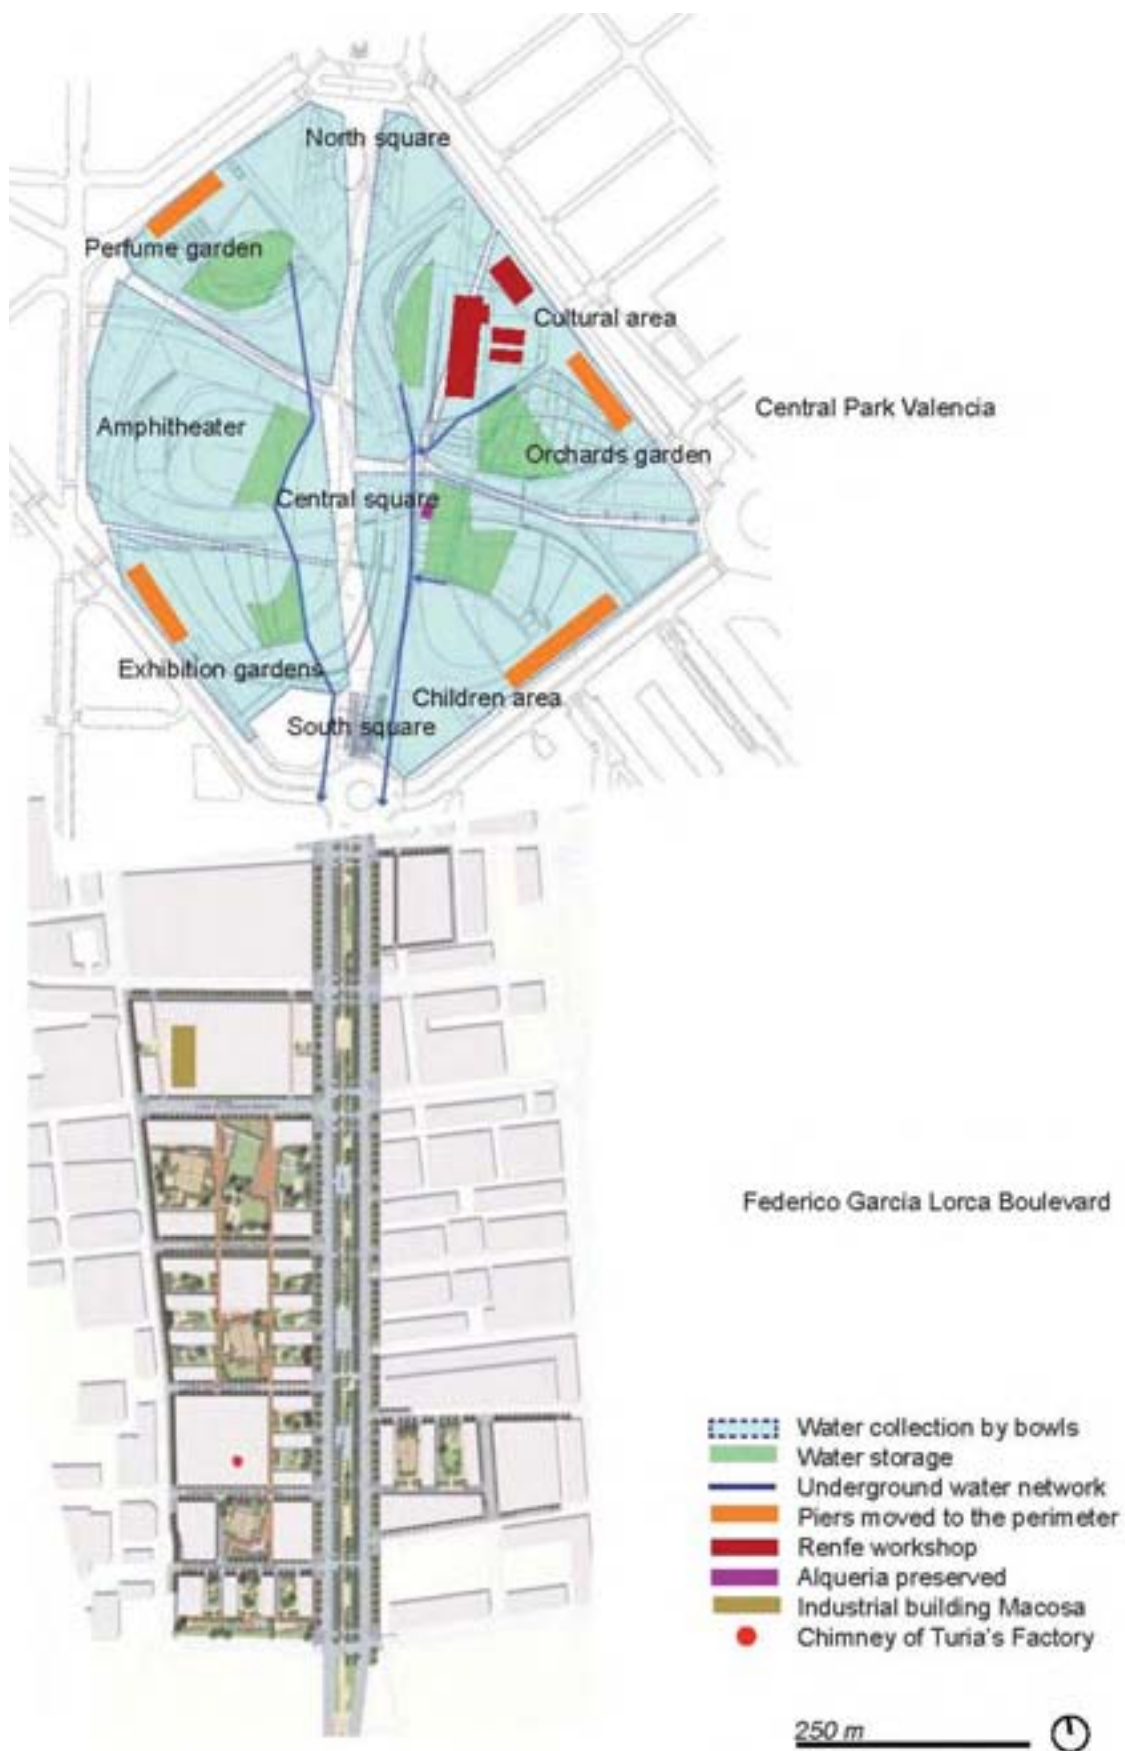

Fig. 3: Park Central Valencia project. Based on GUSTAFSON ^{[14][15]}.

6. Comparison and conclusions

Both parks are made by renowned landscape architects, being the temporal distance between them of 12 years. In DNP sustainable measures taken, which made it, accordingly to numerous authors, one of the first sustainable parks, are passive, as they allude to the low cost of maintenance and execution, preserving the historical memory of the place, such as study of the cycle water, among others. This is regardless of whether nowadays it has installed new mechanisms to control energy consumption, since these were not considered to qualify as a sustainable park.

PCV has been certified by BREEAM as sustainable, by integrating new technologies and therefore active measures. A whole study of energy strategies that can be applied in the park has been carried out. Implementation of solar thermal, photovoltaic, biomass and geothermal energy technologies has been proposed. With the implementation of the photovoltaic technology the park will generate sixty percent of the energy which it consumes^[16].

The highlighted sustainable interventions include the geothermal wells, LED lighting, solar and photovoltaic panels, and the composting facility. These are accompanied by other measures relating to the design (passive) such as sustainable urban drainage systems, reduction of paved areas and the choice of plant species with low water consumption.

	Duisburg North Park		Valencia Central Park	
	Active	Passive	Active	Passive
Social		Conservation of industrial heritage. Maintenance of the ruins.		Conservation of the industrial constructions by moving them to the perimeter.
		Partially solve the conurbation problem.		Improve the link between neighborhoods, and social mobility.
Environmental	Natural oxygenation of water by the wind plant.	Water evacuation separate system.	Gray water pumping	Sustainable urban drainage systems. The park is designed in bowls which facilitated the storage and recycling of water. The use of a lake as a water cleaning system. Selection of plants with low water consumption
		Treatment of contaminated soil with respect to technical and economic considerations.	Composter for future organic waste.	Cleanup of contaminated sites if it is necessary.
	Low maintenance cost: Solar and photovoltaic panels.	Low maintenance cost -In most of the park vegetation grows spontaneously. -Reusing rainwater	Low maintenance cost -LED technology and solar panels. -Using photovoltaic lighting. -Solar panels in buildings. -Photovoltaic panels on the roof of warehouse four. -Geotherm wells in buildings. - Use biomass in restored buildings	
		Recycling steel plates as new pavement. Use products of demolition for concrete.		Recycling of railways for retaining walls. Recycling stones of the place for new pavements.
		Development of industrial tourism. Recovering environmentally the area for new investments.		Promotion of tourism. Investments in marginal neighborhoods.

Fig. 4: Table of sustainable measures applied in projects. Created by the authors.

In Figure 4 we can compare the different measures applied to achieve sustainability in both parks. In the case of DNP the measures are passive and are included in the design, in the case of PCV the interventions are varied.

In the case of DNP, the IBA, a territorial institution, lead the intervention for the conservation of the heritage and industrial ruins. In PCV, industrial buildings with heritage value, have been preserved more traditionally, creating a testimony to the railroad history of the area. The town planning and protection of the industrial heritage was determined by the Special Plan for Internal Reform. It also decided to move the former industrial warehouses away from the trajectory of the the new rail tunnel, allowing their preservation.

Sustainable urban park projects should be a perfect integration between the design of passive and active measures for energy saving, so that the latter do not become liabilities. The active measures need to be integrated into the design and serve to strengthen the passive measures. An example of these are the environmental measures considered in PCV. Specifically the rainwater storage and recycling systemis designed simultaneously to the park itself allowing its installation to coincide with the construction of the bowls used to define park zones.

Linear limbic spaces between land and sea: Landscape designing in river Evros' delta.

Eleni OUREILIDOU

Faculty of Engineering, School of Architecture, Aristotle University of Thessaloniki, Thessaloniki, Greece
elourel@gmail.com

Abstract

Delta of river Evros, located in the frontier between Greece and Turkey at the crossroad of east and west culture, consists of a physical form in the borderline between land and sea. Landscape designing in a river's delta environment requires the analysis of physical, geological, geographical and building reserve parameters. Taking these factors into consideration, a strong conceptual background is formed, which examines the significance of the borderline as a matter of structure both in the existing environment and in the proposing one. In order to create a limbic space from the scratch and to implement it in the landscape of Evros' delta, my research focuses on the formation of a linear structure. As a result, every particular physical procedure, which can generate a linear form, is thoroughly examined. The requested linear structure is found in the pre-existing microstructures of metals, which is transferred in the 3d space under the certain conditions of lineation and cleavage. As far as the design process has been developing, the final curves create a route with several forks interacting with the characteristics of the given environment and resulting in the creation of dry ecosystems inside the flooding areas of the river's delta. In the end the possibility of creating new ecosystems with different characteristics inside existing ones through the creation of limbic spaces is of great importance and could create a future approach in landscape design.

Keywords: landscape designing, landscape analysis, microstructures, borderline, limbic space

1. Introduction

Delta of river Evros, as a physical phenomenon, triggers of human curiosity since ancient times. According to Plutarch, delta was known as "Rhombus", an expression to describe the constant penetration of the water in the land and the formation of the river's branches. Nowadays, Evros is considered to be the longest river flowing in the Balkans. It stems from Bulgaria and just before emptying into the Aegean Sea, it bifurcates forming a biotope of great value, defined by two territories. During the winter time period the land of the northern part of the delta stays dry, creating proper conditions for cultivation, while the land of the southern part is flooded, preserving the growth of rare plant communities and animal species.

Geographically, river Evros' delta is a tabular ground occupying the intermediate space that separates Greece from Turkey, Europe from Asia and the West from the East. As the river flows, it creates the natural linear border between the two countries. Although both of them are claiming its ownership, the only temporary residents of the site are the illegal immigrants and the birds. Furthermore, during the past years, the construction of dams, dikes and artificial canals undermined its existence, resulting in the gradual degradation of its ecosystem.

Being a vast territory, almost completely abandoned, river Evros' delta provokes feelings of insecurity and disorientation. The reasons are the innumerable natural and artificial water canals and the fact that the environment of the delta is constantly changing, since the traces of previous conditions are vanished due to the eternal water movement. Another fact is that the birds overpower the presence of the humans, enhancing the natural sublime but also undermining the possible aesthetic dynamics of the landscape.

People have to look to nature and if they learn to look, it will become landscape [1]. Thus, the initial purpose of the intervention is to recall the human presence on the site and to enrich their overall experience of this rare natural formation. The necessary frames should be proposed in order to manage the spatial quantities of the territory and subsequently to transform it into landscape. Possible way of framing is the construction of paths and arrivals that guide the visitors' movement, highlighting interesting places and providing a way to look at the nature.

At first, are defined the structural characteristics of the context according to the physical and geological parameters of the landscape. From the structural point of view, river Evros' delta landscape consists of a patchwork of surfaces along with the fishermen's huts spread locally and unorganized over the entire area. Thus, surfaces and points undermine the existence of the linear form. The already existing network of the dikes is inadequate and therefore, it requires the implementation of a new route, which can interact with some of them, by reshaping them, or diverting them.

This new route extends mainly along the flooding area of the river Evros' delta, intersecting vertically with its branches. Its position derives from the topography of the site and especially from the visible and invisible borders of the landscape. The visible borders concern the areas of the alternative plant communities, and the invisible borders underline the areas of different water salinity, including also particular areas of birds' activities as they are denoted in Fig.1.

After detecting where the new route extends, the strong conceptual background generates also the possible designing methods. The design process focuses on the creation of a linear form that derives from the borders of the landscape and occupies the limbic space between heterogeneous surfaces such as the ground and the water. The intervention conceptually intends to create a megaform. In the past, megaforms were distinguished thanks to their capacity to act as a catalytic agent in the context. They were able to create new states of equilibrium, but still were perceived as consistent objects, providing a sense of continuity [2]. The proposed linear form interacts constantly with the context of river Evros' delta and positively transforms it at a larger scale, acquiring a conceptual correlation with the former megaforms.

Since the design process triggers of linear forms, the requested procedures that are able to generate them, are found in the geological forms of the landscape and especially in the transitional spaces of the local microstructures. The geologic turn reveals the vitality of the earth itself and proves that matter is not passive; it awakens the ability to discern the force of things [3]. The examination of the typical geological microstructures proves that the emerging linear structures bifurcate and reunite. The initial designing purpose is to revise the geometry of these lines according to the established compositional rules and then to apply them in the context by preserving their proportions and their flowing characteristics [4].

Nowadays, there is an increasing interest on the way we are living on the planet earth, and the way we interact with the geological phenomena. It can be claimed that we are like walking rocks, as part of our aliveness is composed of geologic materials such as calcium, iron and phosphorous [5]. The ground is no longer perceived as a thin, folded surface to build upon but something deeper and meaningful. Additionally, the geological form devises new regimes of perception of the nonhuman [6]. Therefore, by analysing the existing landscape to its geological attributes and by transforming the results of the analysis to the design procedure, it is possible to enable the visitors of the river Evros' delta landscape to see and sense the slow and vast geologic dynamics as visible flows, delivering at the same time the knowledge of the emergence of the geological space. In the end, the purpose of designing the limbic space between the land and the sea is the perception of the natural landscape along with the experience of the geological landscape.

1.1 Exploring the physical and geological context

Landscape designing in such a fragile ecosystem, requires the comprehension of both visible characteristics and invisible procedures, which contribute to its topographic formation. All the physical and geological parameters are taken into consideration so that the specific territorial relationships of the site can be explored and for the definition of the conceptual background of the project.

As a functional apparatus, a river's delta enables the gradual expansion of land over sea, through the creation of alluvial depositions. Earth material is extracted from high speed river's flow areas and is later on reposed in the estuary of the river. This procedure of subtraction and reposition indicates the gradual preponderance of land over sea. Before the river debouches into the sea, it widens and creates a branching system, which extends like the Greek letter Delta (Δ). Structurally, there are four main delta types: the radial type of delta, the birds' treads type of delta, the lobed type and the sagittal type as they appear in Fig.2. Evros' delta belongs to the lobed type, because the sediments caused by the flowing water of its branches create irregular protrusions around lobes [7].

Fig. 1: The borders of the plant and birds communities.

The network of the river's branches and the water canals monitors the mixing process of the sweet water of the river with the salty water of the sea. Along with the movement of the underground water, salty sea water penetrates the land and causes a constant change of the substantial equilibrium, which is crucial for the vitality of the ecosystem. On the one hand, the discharging areas of the underground water form layers of organic material, which is essential for the growth of the rare vegetation, and on the other hand, superficial waters classified according to their salinity, creates salty and sweet water lakes. The most important lakes of delta's ecosystem are: Lake Drana, Lake Nymfon and Lake Paloukia, and sustain the accumulation of genetic material and nutritional substances.

This constant change of the salinity of the water is also responsible for the growth of the plant communities. The most important components of the ecosystem's plant diversity are: the halophytic vegetation, which grows because of the high water's salinity, the aquatic vegetation, the riparian forests and the cultivated fields. Apart from the movement of the water, another crucial physical parameter that configures the landscape is the depositional power of the wind, which results in the creation of sand dunes and contributes as well to the growth of different types of vegetation [8]. All these plant communities appear in zones and in combination with the water lakes define the landscape as an extensive horizontal field of interconnected surfaces.

The internal sustainable relationship between the growth of plant communities and the movement of the water establishes a perfectly regulated mechanism that supports the ecosystem, and determines the existence of avifauna. Rare species of birds can find a shelter during their long migratory trip, establishing their own boundaries in the landscape. There are areas where they rest, move and reproduce, determined by the consistency of the ground and the vital ingredients of the vegetation.

Additionally, as far as the geological background is concerned, linear formations, tectonic fabrics and transitional forms are the visual results of the hidden geological procedures that take place both in micro and macro scale. The starting point of this research derives from the alluvial depositions of the river Evros, which under certain conditions of pressure and temperature can create sedimentary rocks, appearing in the landscape at most of spatial and temporal scales. By definition, deposition proceeds when sediments, soil and rocks are added to a landform by building up layers. In some occasions, flows imprinted on the microstructure's surface of the sediments, create interesting linear shapes and reveal natural procedures and physical forces that formed the sedimentary rock through the ages. Thus, the microstructures of the landscape can be perceived as an icon of the infinite geological processes.

In macro-scale, two layers of different sediments and rocks can never be in abutting engagement with one another. There is always an additional layer, which exists between them and is always positioned in vertical direction, known as the phyllitic layer [9]. These vertical layers along with the cracks that are identified on the rock mass are the most obvious linear forms of the underground geologic formations.

Fig. 2: The structural types of delta. From left to right: the radial type, the birds treads type, the lobed type and the sagittal type.

In micro-scale, there is a variety of structures produced by procedures, believed to be chaotic. Two of these procedures are responsible for the unexplored spatial geometries: foliation or cleavage and lineation. The foliation causes the division of the microstructure's surface into layers, while the lineation defines the elements of the microstructure that display a standard linear orientation. Both contribute to the emergence of the tectonic fabric [10].

Furthermore, geological parameters form the folds of the ground, which structure the matrix of the river's water flow. River's route is defined by three main stages: the stage of youth, the stage of maturity and the stage of anility. These stages are classified according to the section of the riverbed. During the age of youth, riverbed section is shaped like "V", which means that the ground is pretty sharp resulting in the creation of waterfalls. Subsequently, the riverbed is shaped like "U", and the river follows a curved route, which locally forms meanders. Although during the first stage, the river erodes, during the next stage the river deposits. In the end, when the river starts to bifurcate, the banks become plain, leaning towards the sea. The water volume is very low implying that the deposition of the extracted material reaches the highest point as the final stage of anility [11].

1.2 Introducing the concept of the "borderline"

The borderline identifies the context as the limbic space between controversial physical phenomena. Delta's environment appears to be the hinge between the physical transactions, supporting the bipolar territorial relationships. While Evros provides the ground with sweet water, forming the surfaces of the corresponding vegetation and the water lakes, its delta accommodates the slow penetration of the sea streams inside the territory. The water surfaces become mixed and configure areas of different water salinity and areas of controversial plant communities. The tide constantly changes the pre-established orders and enables the coevolution of the dipoles: land and sea, areas of sweet and salty water and the relative plant communities.

According to the geological phenomena, the borderline concerns the phyllitic layer, which is positioned between the rock masses made of different materials: the lava or the sedimentation. The phyllitic layer exists also between the layers of the masses created in different time periods. In the micro scale, the concept of the borderline appears also in the tectonic fabric, which consists of two main structures: the cleavage domains and the cleavage lamellae or the microlithons. The relation between the cleavage domains can be parallel, anastomosing or conjugate as it is denoted in Fig.3. Since the microlithon is located inside the cleavage domains, the borderline appears as the transitional space that separates the one from the other and it can be either gradational or discrete [12], as it is shown in Fig.4. The tectonic flow takes part along the transitional space between the cleavage domains and the microlithons, or else in the limbic space between them.

Fig. 3: The relation between the cleavage domains. From left to right: the parallel, the anastomosing and the conjugate.

Fig. 4: The transition between the cleavage domains and the microlithons. From left to right: the gradational and the discreet.

2. Transforming the design process from the physical and geological principals

Primary design purpose is to explore the possible physical and geological parameters, so that they can be transformed as the main conceptual tools for the design process. Actually, during the design process, there are two distinct stages: the stage of research based mainly on observation and the stage of proposal based mainly on composition. The concept of the borderline is introduced in order to define the structures that emerge from the osmotic procedures of the physical and geological phenomena.

In order to compose a linear structure, the design process focusses on the main procedures that are able to generate it. The first procedure derives from the physical background of the river and the way the folds of the riverbed are formed. The second focuses on the geological background and especially on the characteristics of the rocks' microstructures. There is a wide range of patterns to be explored, which display lines and surfaces and are able to provide the design process with the essential structural instructions.

The examination of a variety of such microstructures including the local rocks leads to the detection of a particular rock called "rhyolite". The root of the word comes from the Greek verb "reo", which means flow. Through the observation of the rhyolite's microstructure, it is noticed, that the tectonic fabric is an imprint of the flows that were created when the original material formed the rock.

At first sight, the flows of the rhyolite seem to be irregular. After observing the sequence of its patterns formed through the ages, under specific environmental conditions, it is observed that the initial linear forms gradually acquire additional curvature points and start to bifurcate and relink. As they extend on the microstructure's surface, the linear forms occupy lenticular transforming spaces framing the cleavage domains as it is shown in Fig. 5. The microlithons appear inside these lenticular shapes. The linear structures extending along the transitional field between the microlithons and the cleavage domains are chosen to be used in the design process. Thus, in order to reproduce them, the design process triggers of the geological procedures that are able to generate them: the foliation and the cleavage.

2.1 Designing the limbic space

The design process establishes possible ways for the application of the foliation and lineation on the plain board surface, in order to form the limbic space between the surfaces of the cleavage domains and the microlithons. At first, the surface is divided into tandem stripes according to the division of the rock's microstructure into layers, imitating the way foliation is performed on the rock. The stripes are not completely detached from the surface, because otherwise it would result in the creation of singular useless stripes. Then, a curved linear system is imprinted on the cleaved surface, in an attempt to operate the procedure of lineation on it. Different creased surfaces are produced with imprints of alternative linear systems on them. After the particular linear system is established on the surface, the model is put under pressure and as a result it creates folds, which could resemble to the shape of the riverbed's ground.

Afterwards, the wrinkled surface is additionally modified embedding some physical orders. As it is already mentioned, certain folds of the riverbed direct the water flow and determine its stages. Numerous folds that mark the beginning of the route on the surface create a rough background, just like the stage of youth. Subsequently the folds of the surface become gentler and the linear system forms meanders. The end of the route is marked by a completely osmotic field resembling to the final stage of the river, when the folds of the surface become almost plain. Based on these physical principals, the initial random folds are adjusted according to this physical conceptual background.

Fig. 5: Typical microstructures. From left to right: the gradational transition between cleavage domains and microlithons, the discrete transition and the lenticular shape appearing inside the cleavage domains.

Apart from the regulation of the pleated surface, some additional orders are applied to determine the geometry of the linear structure that is inscribed on it. The analysis of the applied curving system includes the definition of the distance between the curvature points, the regarding angles and the proportions.

The process that leads to the regulation of the curves is described here. Firstly, a single line is selected to be slightly deformed through a constant change of its curvature angle, just like the sequence of the rhyolite's microstructure. The results of these deformations are drawn one after the other and create a regulated two-dimensional linear system. A single line is again pointed out of it and is placed in mirror position in order to create the lenticular shape according to the cleavage domains appearing in the microstructure. This along with the slightly deformed lines consists of the core of the infinite system of the curves (Fig. 6). The additional rules concerning the distances and the angles stem from that core and are repeated along the rest of the system and regulate it. Thereafter, the spatial articulations of the deformed multiple curves along with the lenticular shapes are inscribed on the divided surface and create a model of artificial contour lines (Fig. 7).

In the end the divided surface with the vertical contours, is put under pressure. The stripes move because of the pressure and the linear imprints create folds on the surface. The angles and the proportions of the distances that define the points of curvature are repeated except for the existence of a particular angle that provokes a point of instability in the linear structure. All the lines have a standard orientation and along with the folds generate the route, which forms an osmotic field like a regulated artificial riverbed (Fig. 8).

3. Forming the requested syntactical background of a curved line synthesis

In order to explore the syntactical background of the curved line synthesis, the distances, the angles and the proportions of the conceptual linear structure should be applied on a route that derives from the context. The linear structure is reshaped as it adopts the contextual characteristics. The application causes the relocation of its curvature points, while its angles and its proportions stay the same.

Fig. 6: The core of the infinite linear system. From left to right: the form of the lenticular shape, the distorted curves of the system and the final outcome of the codification.

Fig. 7: The linear system according to the rules of the core and the alternative regulated linear systems.

Fig. 8: The model of the pleated surface. From left to right: the folds that define the beginning of the route, the bifurcating and relinking curves and the multiple folds that define the end of the route

As it passes through the interesting areas, the deriving route is deflected locally and in particular occasions enters in to the water. In this point it starts to extend in a different way, acquiring multiple curves according to the geometry of the artificial contour lines that were established before. The single line is replaced by the pattern of the curves, which form the transitional osmotic field between the route and the water surface. Its spatial formation associates two contradictory elements and derives as an expansion of the coastline that marks lenticular grounds within the larger water surfaces.

Initially, the structure of the limbic space consists of two agglomerated parts: the torn surface and the folds generated by the lines, resembling to the rock mass. Both of them enable the variable curvature of the surface. On one hand, the divided surface illustrates the procedure of foliation where the parallel stripes represent the traces of the divided layers of the rocks' micro-surface. On the other hand the linear imprints that generate the folds indicate the procedure of lineation and provide with the horizontal continuity. In order to be incorporated in Evros' delta landscape, these elements interact with the spatial characteristics of the context. The surface where the geological procedures were performed is replaced by the water surface of the context. Furthermore, the discontinuities caused by the movable, almost detached, stripes are now inscribed in the landscape through the intermediate voids that have been created as it is denoted in the second model of Fig. 9. These parallel vertical surfaces consist in the backbone of the new and flexible structure and are reformed in order to support structurally the bifurcating dikes. As a result, they display the undoing procedure of the interaction between the conceptual pleated surface and the existing surface of the context.

The structural backbone provides a system of parallel buttresses endowing it with a sense of repetition and rhythm. In addition, some of them are subtracted, while others are added in another place along the linear intervention, in order to create spatial dilutions and densifications. These buttresses scan the entire curved line composition and like blades slice the bifurcating paths into several parts just as foliation subdivides the surface of the sediment's microstructure. The backbone is made of steel and arises in Evros' delta landscape as a piece of land art.

The composition is enriched by additional linear elements made of steel according to the procedure of lineation as it is shown in the first model of Fig. 9. These elements extend along the site like choreography, following the direction of the established dikes. They appear and disappear due to the linear pattern of the initial structure and they unveil traces of its preexistence. Most of these linear components are canopies, railings, ramps and bridges that are necessary for the composition's interaction with the water. Ramps made of steel intervene between the branches of the paths and the water. In Lake Drana where the curved line composition starts to expand, tide and ebb occur every six hours. As a result, the parts of the construction that are made of steel are gradually corroded, imprinting the movement of the water on their surface.

The limbic space reveals structural continuities and discontinuities and appears in this landscape as the transitional space between the land and the sea. Its materiality refers to the route that is formed as a dike made of soil and the rest of the structural elements that are made of steel. The use of casting and malleable materials tends to feed the confusion between artificial and natural. In the end, the artificial landform interacts with the existing one through its materiality.

From functional point of view, the entire route extends to a distance of 25km, connecting the Lake Drana, which is mainly constituted of salty water, with the Lake Nymphon, which is on the contrary constituted of sweet water. When the route passes through the Lake Drana, it is formed according to the rules of the initial patterns. It is deflected and enters the water, acquiring the characteristics of the curved line synthesis. The metallic backbone appears in the landscape, fastening the system of the bifurcating dikes horizontally and disconnecting them vertically by separating them into several parallel parts. The flowing characteristics of the new dikes are enhanced by the extra metallic elements. The leading dike is designed for the cars and the bicycles and as it locally bifurcates, it enables the movement of the pedestrians. In a central point is also located a parking lot. The branches that are designed for the pedestrians are developed like extended steps following the vertical direction of the metallic backbone. There are four arrivals attached to them. Two of them are covered and are designed appropriately for bird observation. Therefore, they are placed on the highest level of the dikes. The rest are formed amphitheatrically, placed on the lowest level of the dikes and completely exposed to the water.

4. Conclusions

The use of the geological procedures in the design process results in the creation of a mutant landscape. The new hybrid landscape transforms locally the existing ecology of the landscape, exceeding the boundaries between natural and anthropogenic environment, between nature and culture. It refers no more to a simple plan of a garden; instead it creates a landform reconstructing the site itself.

The geometrical discipline of the entire architectural composition avoids approaching the complexity and the smoothness of the natural form. The blades made of steel underline the remnants of the folded initial surface and provide the razed plane of delta's landscape with a sense of sharpness. Thus, the existence of these parallel articulations that support the curved line system endows it with a sense of accuracy, revealing at the same time the possible ways of its morphogenesis.

Additionally, the act of revealing the visible and the invisible borders of the context through the implementation of the transformed geological space deliver to humans a versatile experience of the entire landscape. The final outcome of the design process resembles to the act of scenography. The metal surfaces are gradually distorted because of the water chemical reaction with some of the metal substances.

Fig. 9: The syntactical elements of the curved line synthesis. From left to right: the spatial transformation of the lineation and the foliation.

As a result, natural forces, like the movement of the water, are exposed to human perception through the materiality of the construction. Furthermore, the lenticular dry precincts accommodate exotic vegetation and inform the visitors about the growing procedure of the vegetation. In the end, the project constructs a new topography through the constant interaction with the context of the Evros' delta. The lenticular voids appear as holes in the water and create new forms of inhabitation, smaller landscapes that can be expansive according to the length and curvature of their artificial shore-lines. Eventually, exploring the matter of the borderline and composing the limbic spaces between land and sea in vast territories like deltaic environments establishes new boundaries for the existing surfaces and new ecologies.

Fig. 10: Top view of the linear structure that displays the way the route expands as it enters the lake Drana.

Fig. 11: Renders displaying the dry lenticular precincts and the relation between the natural and the artificial.

This paper is based on the diploma project with the title: A hole in the water, supervisor: Vana Tentokali, September 2012 , Faculty of Engineering, School of Architecture, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Abstract

Architectural heritage is inseparable part of the city as whole and represents source for manifestation of identity as well as the place for representing the identity. In that context, space is considerable element of these relations and produces physical and psychical frame for perception of heritage. Thus, investigating spaces of heritage, is search for the aspects of contemporary state of site, presentation and visibility of monuments.

This paper represents a theoretical framework for design of spaces of heritage within living urban ensembles in terms of landscape principals and landscape architecture approaches (socio economic, ecological and perceptual) for overall treatment of landscape and sustainable management.

Through examination and critical investigation of landscape design practice for spaces of heritage in Europe, it is presented contemporary state in landscape design of these sites as well the level of integration in urban landscape.

Thinking about spaces of heritage as public open spaces from discourse of landscape and within the frame of landscape architecture where landscape is seen as a space for living and social interaction, together with the trend for the enjoyment of space could contribute to understanding of these sites and creating their future what is presented as a concept for affirmation, integration and creative preservation of architectural heritage in urban landscapes and urban structure of historic matrix of the city.

Keywords: architectural heritage, urban landscape, historic landscape, identity, landscape architecture.

* We would like to express our gratitude to Prof. Dr. E. Dimitriadis and Prof. Dr D. Drakoulis for their support and assistance.

1. Introduction

The question of affirmation and integration of architectural heritage in urban landscape, opens up the question of landscape designing and respectively planning of landscapes and open spaces surrounding architectural heritage.

In the last two or three decades great attention has been given to the conservation and rehabilitation of such historical urban and rural sites, as expressed in recommendations given by UNESCO and resolutions of ICOMOS. From this engagements the concept of historical urban landscape is also created, that implies combination of natural characteristics and built spaces.

In Article 14 of The Venice Charter 1964: "*The sites of monuments must be the object of special care in order to safeguard their integrity and ensure that they are cleared and presented in a seemly manner*". The Charter further writes that "the conservation of a monument implies preserving a setting which is not out of scale" (Article 6). It is worth to mention and UNESCO's *Recommendation concerning the safeguarding and contemporary role of historic areas* (1976), that puts emphasis on

the entire historical frame and the need to consider all valid elements "*including human interventions, no matter how modest they are*", that are significant in relation to the whole.

International conventions and charters about architectural heritage have common basic postulate that the future of architectural heritage greatly depends on its integration in context of social life.

Therefore, Investigating spaces of heritage is, above all, search for the mechanisms of collecting, preserving, researching and presenting testimonies of past within continuously changing urban landscape, in structure of space. In that context, landscape is considerable element of these relations and produces a frame for perception of heritage.

Today in many cases, archaeological sites and monuments within their natural environment and landscape's setting are still far away from being integrated into their present day setting. Therefore, the landscape design of a heritage site is still one of the most controversial and unsolved aesthetic and functional design tasks.

In that context, Landscape architecture is here introduced as science and art dedicated to study and design of landscape.

Two questions are set in this study: What are landscapes in the study of landscape architecture and how are landscape approaches relevant for protection, enhancement and integration of architectural heritage.

2. Theoretical background: landscape and study of landscape architecture

For need of this study it is necessary to limit and explain the terms of landscape used in the study of landscape architecture, that can provide adequate frame for forming the specific landscape architecture approach for improvement of heritage sites.

Landscape is a very complicated and ambitious word which has been used in different connotations for the purposes depending on the profession which it deals with, including geography, cultural anthropology, archaeology.

First connotation that should be repeated is the one given by Michel Laure that the land becomes landscape when it is described or seen in terms of its physiographic and environmental characteristics [8]. As defined in European Landscape Convention, Florence 2000.: *Landscape represents an area, seen by human eye, which characteristics are result of activity and interrelation of natural and/or human factors.* In its broad definition landscape is the place where humans and nature interact.

Within landscape architecture, a number of scholars (Hayden, 1981, 1997; Jojola, 1990; Rainey, 1997; Stilgoe, 1982, 1998; Swentzell, 1990a; Zube 1994) view landscape not as a single uniform construct but as a multiplicity of coexisting texts that either provide unity for a community or serve as an arena of cultural tension and social conflict (Groth, 1997) [16].

For Jackson a landscape is "a collection of spaces made by a group of people who modify the natural environment to survive, to create order, and to produce ... society" (Jackson, 1995, p. 43; see also Jackson, 1984, 1994). In viewing varied landscape elements as products of human values and aspirations, Jackson maintains that a landscape "is never simply a natural space, a feature of the natural environment" (1984, p. 156.) [3].

The landscape is both medium for and outcome of action and previous histories of action. Landscapes are experienced in practice, in life activities [12]

The two major directions dominating landscape terminology are firstly the specific one, considering landscape as a three dimensional environment, where man lives, works and spends his time; and secondly an abstract one, where landscape is nothing other than what human senses can record. That means the landscape is perceived as visual sensual and perceptual space according to the later definition, and as an ecological space according to the former [1].

Contemporary trends following the spatial image of the landscape are observed as follows: landscape, as an experience space, a space of social interaction. It is an approach recognizing its social dimension. Landscape as a live recording that is an expression of social relationship and history, it is an effort to comprehend it, to read it [1].

Therefore, we cannot derive that landscapes without users and activities that fulfill the essence of its existence. It gets the attribute of quality ambient only through contribution to everyday life of users, and therefore contributes and involves into cultural value.

Conclusion is that landscape cannot be seen inseparable from human activity in space over time.

Recent trend toward the "creative landscape", as seen as an attempt to restore the lost meaning of creation and creativity in landscape architecture and looks landscapes as works of art [1]. For John Davey, ecological and community values derive directly from an understanding of human-nature relationship and, indeed, that the formulation and understanding of this relationships is expressed in and through art [3].

According to recent theoretical framework, landscape architecture is determined as science and art dedicated to study and design of landscape.

Study of landscape architecture is the evaluation or exploring the potential suitability of the landscape for social use, in the context of the conditions that created and form landscape [2].

Landscape analysis is based on a socio-ecological and perceptual approach in order to specify the potential, suitability, capacity and the capabilities for development (Ananiadou 1984).

During the landscape study of specific ecological, social, historical and cultural information about the landscape are collected, revealing specific particularities and character of given landscape, its genius loci, what represent backdrop for guiding principles necessary for decision making in design proposal.

3. Conceptual framework: urban landscape – historic landscape

Urban landscape is seen as a result and synthesis of unity of human activities in space, and processes of community life in motion and constant change - with one word the expression of total culture of one environment and timeline, is alive, changeable living environment, in constantly changeable time of always new meanings and brand new values [10]. On the other hand architectural objects are the basis of physical structure of the city, they are according to their shape and character the most static part of urban structure. Controversy is found in confrontation of past values contained in terms identity, tradition, authenticity, uniqueness combined with architectural heritage on one hand, and on the other, urban landscape presenting contemporary values and changing identity.

In historical centers open spaces are above all those at locations of archeological excavations. Areas that are typical public spaces, have timeless landscape in collective subconscious. Cities that possess rich architectural heritage express explicit historicity.

Historic landscape is therefore seen as a special case of landscape.

In our conscience, that designing of structures and free spaces gives places certain specific character that we remember. Monuments and landscapes are therefore embedded in the social and individual times of memory. Their pasts as much as their spaces are crucially constitutive of their presents. Neither space nor time can be understood apart from social practices which serve to bind them together [12].

Exactly such places have those qualities that are assumed as tradition and terms: authentic, indigenous, autonomic, unique, unrepeatable and such. When talking about those places, it is considered their specific, recognizable character, their spirit of place or genius loci. The fact that historical cities and settlements today lose their identity more and more, due to the negative influence of globalization processes, influences the disappearance of specific meanings of the place, their spirit [9]. This process is seen in isolation of historic setting which is detached from its surrounding environment.

A landscape has ontological import because it is lived in and through, mediated, worked on and altered, replete with cultural meaning and symbolism – and not just something looked at or thought about, an object merely for contemplation, depiction, representation and anesthetization [12].

Kevin Lynch stated that the images of environment are result of two processes within which the surrounding points to differences and relations, within which the observers choose, organize and connect with meaning that what they see. According to him, image is made through physical qualities that refer to identity and structure [7]. And other researchers made similar differences between "identity", the real appearance of the place, and "image", the combination of that identity with perception of place by individual, with their own feelings and impressions of it [7].

Mental maps and images of the place and surroundings, especially common images, represent backbone for research of perception of environment and landscape design [7].

in order to define potentials for future design, knowledge about specific particularities and features that influence the character and identity of historic landscapes with prevailing historic value, explicit historicity and sense of continuity, seem necessary.

4. The role of landscape architecture approach for integration and affirmation of heritage sites in urban landscape

"Attitude towards the past becomes creative if the architect is able to understand its inner meaning"

S. Gideon, in: Space, Time and Architecture

Given that historic landscapes are site specific because they contain notable historic information of past activities and tradition attached with values as authenticity, and they contain a certain meaning for social use and the inhabitants, it seems of crucial important, before approaching design to be done landscape architecture study according to mentioned approaches fully with specific emphasis on the symbolic resources that reveal historicity and genius loci.

Landscape architecture approaches toward analytical studying of different aspect and meaning of landscape, and its essence as product of human values and aspirations, establishes framework for integration, affirmation and preservation of architectural heritage. This framework is seen in direct relations that occurs between monuments as heritage historical values and urban landscape that is a space for social activity and daily life, with its natural and cultural qualities.

Integration and affirmation of architectural heritage in urban landscape is determined by reading of the particularities of the landscape's setting of architectural heritage, historic landscape and its surrounding urban environment, urban landscape.

In order to accomplish successful design, two specific analysis should be applied on two previously mentioned specific cases of landscapes (historic and urban) that are adjacent and simultaneously intertwine.

First, the analysis of the architectural heritage and its historical setting: historic landscape; socio-economic, historic context of the monument and its spatial-physical characteristics, ecological, environmental characteristics, and perceptual approach, combining visual-aesthetic qualities with the image of the place, its genius loci and its semiotic content which posses and express explicit historicity and sense of continuity, as elaborated previously.

Second, to analyze live boundary urban environment-contemporary urban landscape according to landscape analysis based on the socio-economic, ecological and perceptual principles leads in defining landscape identity and character, what will give information for possibilities of altering social activities and functions in sense of sustainable development.

These approaches are presented as part of the analysis that is involved in reading of the particular landscape identity, what is a first step in design making decision.

Until now contemporary design approaches range from the absolute respect of the historic site / memorial with a kind of allegiance to the new configuration historicity of the first, accompanied by a marked tendency mimicry, especially in morphology and material selection, to the search for a more free and creative approach design, without excluding original, innovative forms, structures, materials and plantings for the new surgery, often alien to the character and the character of the landscape. Displayed intermediate course views, which converge to the dominant current methods of rehabilitation and enhancement of archaeological sites, which try to balance work as the previous two and suggest mild (Astrinidis 1997: 16), and "invisible" (Lava 1998) interventions so as not to compete with the site [5].

This is possible to achieve with design practice based on landscape architecture approaches for treating of the historic places integrated to the urban landscape and public spaces, where historical places are combined with public usage and enriched with the visual and cultural quality of open urban spaces respecting ecological conditions.

Investigating spaces of heritage, is search for the aspects of contemporary state of site, presentation and visibility of monuments.

According to data collected and presented before, we can conclude that the goal of the landscape design and planning on archaeological site in order to provide integration of architectural heritage in urban landscape, are argued in terms of:

1. perception, visibility and aesthetic qualities (design materials used, also planting as design tool) and presentation of site for the public.
2. social and economic dimensions of sites involved through new functions and usages in terms of tourism, education, information, leisure.
3. conservation of natural resources. (for spaces with special natural beauties)

Design practice of places of heritage should be oriented to create the link between the historical value of the monument and social, cultural and natural value of the landscape. Possibility of integration the sense of past within the visual character of the place, respecting the past values in its public life and natural conditions avoiding on the same time mimicry of the past landscapes, greatly depends on the creativity of the author.

Therefore, there is no doubt that such landscape architecture projects are seen as works of art, which may project the enjoyment of space, not as an expression of nostalgia for the past, but as cultural projects for a contemporary society [1].

Within the theoretical approach presented before, in order to enable integration of architectural heritage in social context for purpose of their preservation, conversion of heritage sites into public parks, squares and green spaces, based on appropriate design that includes landscape analysis which respect the conditions of protection of historic monument, historic values and genius loci of historic landscape will ensure creative preservation, resulting in improving conditions and quality of life of residents and users within urban ensembles.

5. Landscape design practice. Current state

Given that the particular design issue is site-specific and time-dependent it is considered necessary that the new design proposal is adjusted to the individuality of the urban space in total [5]. In this chapter are presented examples of designed heritage sites to demonstrate current state of the sites where integration is examined through level of altering surrounding urban space whit emphasis on land uses, without giving notice to specific particularities of design proposal.

Selection of heritage sites is based on next criteria:

1. sites within living urban ensembles, where a contemporary population is active.
2. presentation of heritage sites in its current state
3. sites where architectural concept of the heritage is possible to be perceived.

5.1 The remains of Roman bath in Frankfurt's 'Domhügel' (Cathedral hill)/ German

Archeological finding is situated between the Cathedral, Schirn, Art Gallery and the Technical City Hall. It was set up in 1972/73, during construction of the underground car park and the Technical City Hall, as an open-air archaeological installation [18]. The site of Roman bath remains in Frankfurt lies within active urban landscape. This example represent a case study of integrating heritage to the physical setting of the urban fabric as using it as a component of the open public space. The remains are displayed in a park-like space, between buildings of the modern urban fabric [16].

In this case public access is altered through involving new social use in model of park for the heritage site, making possible perception and visibility for the site with altering plantings what will improve conditions and quality of life within contemporary urban landscape.

Fig. 1: The remains of Roman bath in Frankfurt's 'Domhügel' (Cathedral hill)/ German, [18]

5.2 Archeological findings on Michaelerplatz | Vienna | Austria

In the historical centre of Vienna, World Heritage City since 2001, the archaeological findings from roman and medieval periods excavated in 1990-1991, are now integrated to the historical square, Michaelerplatz, of the historic city. The contemporary design concept with modern materials enables the historical structures to display in the historic urban landscape and enhance the quality of the square (Wehdorn 2004: 67) [16].

Considering the high level of social use and visitation intensity within dominate structured space which appears at the Michel square, the quality of the square has been increased with historical monument as its main component. Square like solution is involved to alter new public use.

Fig. 2: Archeological findings on Michaelerplatz | Vienna | Austria,

6. The example of Thessaloniki, Greece

Greek cities have unique distinctiveness. In historical centers open spaces are above all those at locations of archeological excavations. Areas that are typical public spaces, have timeless landscape in collective subconscious [11]. Cities with rich cultural heritage, continuous history and strong cultural identity show explicit need for successful integration of historic monument within their urban landscape, and should be presented as specific case of study. City of Thessaloniki is therefore a case in point to be presented.

Few cities can claim continuous history lasting over two millennia: fewer yet can claim that their primary places of daily business – their streets, their market spaces occupy the same locations as they did two thousand years ago. Thessaloniki is one of them [13].

Archeologists date the foundation of the Thessaloniki from 315 BC. The city plan of Roman Thessaloniki was based on the network of roads parallel with and at right angles to the shoreline with *Cardo* and *Decumanus*, as most important of these roads. From the second half of the second century AD, the closed urban complex of the Roman Forum is constructed at the intersection and to the northwest of the intersection of *Cardo* and *Decumanus*, the later -*Via Regia*- representing the extension of *Via Egnatia* eastward into the city. In about AD 300 the city becomes a “walled city”, a form which Thessaloniki remained up to the end of the 19th century [4]. The emperor Galerius (293-311) selects the city as his seat and extends the fortification. Around the fourth century AD Thessaloniki's functions are dominated by two centres (Fig 1, left):

- the economic and cultural center (forum, odeion, baths)
- Galerius', administrative and religious center. [4].

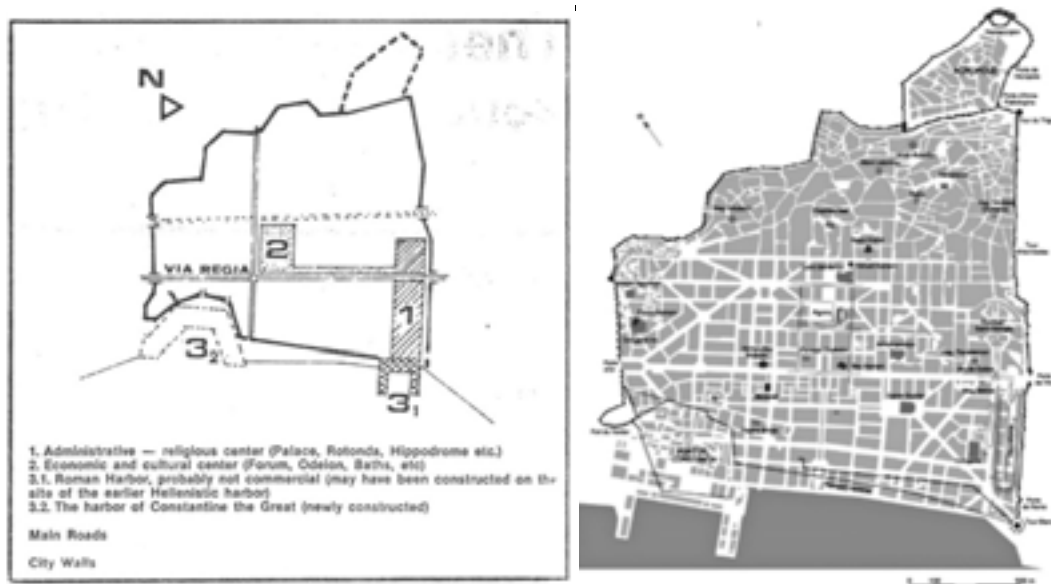

Fig. 3: Left: Schematic plan of Thessaloniki from the period of Galerius to the 4th century AD, [4].

Right: Contemporary look of Historic center of Thessaloniki with marked main historical monuments, [14].

Its urban fabric was given its initial form by its Hellenistic origins during the late 4th century BC. Enlarged and developed during the Roman era, its city plan was continuously modified ever since, yet in its core it retains certain key elements which have eluded change in the course of history. [13]. (Fig 1, right). The first substantive attempt to enhance the physiognomy of the city was manifested in the Thessaloniki Master Plan, approved in 1985. Its aims included highlighting the city's historical profile and enhancing the historic centre [14]. In 1997 Thessaloniki was designated as the Cultural Capital of Europe. Within this context numerous urban and architectural projects were advanced: pedestrian areas of east, west and central archeological paths renovations, and archaeological excavations and restorations [14].

For purpose of this study therefore, it will be presented current state at archeological site of Ancient Agora. The Ancient Agora (Roman Forum) is surrounded from Filippou, Agnostou Stratiotou, Olympou and Makedonikis Amynis streets. Historic place of Ancient Agora has its own calm atmosphere surrounded with everyday life of the residents of surrounding buildings with small café shops. People today find this place appropriate for day visiting small café shops and magazines because of the grandiose open view on the ancient agora which in today appearance with aromatic plants and only one tree in the middle represents one theater scene where past time is seen to be captured.

Fig. 4: Thessaloniki, the Ancient Agora, view from north east side, (photo: M.Dimanic)

Archeological findings today are presented as open air museum, within museum successfully integrated in space of the archeological finding not disturbing the image of the place. Open space of agora are redesigned and adapted for cultural manifestation which occur occasionally. Therefore a potential for use of historic place of Ancient agora as green space and free open space for social gatherings and open air activities has been recognized and would contribute in higher level of integration within urban landscape.

7. Conclusion

The need of integration of architectural heritage in its urban landscape and context of social life has been recognized by International Conventions and Charters.

Art and science of landscape architecture, dedicated to design and study of landscapes in terms of evaluation and exploration of potentials and suitability of the landscape for social use, is introduced in this paper as conceptual approach for affirmation and integration of architectural heritage.

Two questions have been set: What are landscapes in the study of landscape architecture and how are landscape approaches relevant for protection, enhancement and integration of architectural heritage.

Landscape, in its essential meaning is a place for interaction between human and nature, respecting its qualities and inherited values, reading its specific genius loci, what is especially drawn to the attention at historic sites where monuments as past testimonies with strong symbolic support contribute to the character which has to be taken into account in order to preserve the monument and integrate it in urban context.

Thinking about spaces of heritage as public open spaces from discourse of landscape and within the frame of landscape architecture where landscape is seen as a space for living and social interaction, ecological space together with the trend for the enjoyment of space could contribute to understanding of these sites and creating their future what is presented as a concept for affirmation, integration, presentation and creative preservation of architectural heritage in urban landscapes and urban structure of historic matrix of the city.

It is therefore carried out the conclusion that successful design of spaces of heritage in urban landscapes, should include two group of analysis:

First, carried out for heritage site and its historic landscape, in order to read and record all landscape particularities and qualities, the image of the place, its genius loci and its semiotic content which posses and express explicit historicity and sense of continuity.

Second, carried out for urban landscape, which will lead in defining landscape identity and character, what will give information for possibilities of altering social activities and functions in sense of sustainable development.

Given examples show that each instance of altering of a system of open spaces from surrounding urban landscape, with altering land uses and functions (as long as the protection of the monument is fully secured) will contribute its integration in urban landscape with involving users in active preservation.

Proper analysis based on: socio-ecological, perceptual and ecological approach (Ananiadou 1984), can provide design guidelines, determine the activities that may be altered, respecting authenticity of historic sites, its genius loci and involving the user to get in touch with historic monument through understanding of its inner meaning, resulting in affirmation and integration of architectural heritage in urban landscape.

Making Belief: Tastemaking, the Public Imagination, and the Spaces of Everyday Life

Tim WATERMAN

Department of Landscape Architecture and Garden Design, Writtle School of Design, Writtle College, Chelmsford, Essex, United Kingdom
tim.waterman@writtle.ac.uk

Abstract

Popular taste-makers have long exerted a profound influence on the practice of everyday life and on the built environment, and many landscapes we now see as particularly vernacular or local are actually the result of recent or contemporary media influence. Tastemaking events, home shows, for example, have had a powerful impact which lingered on in the public memory much longer than the products featured in them might have survived in people's homes. The influence of such personalities and events is usually concerned primarily in a strictly domestic sphere, proscribed by the limits of the kitchen, home, and garden.

Cumulatively and collectively considered, however, the manipulation of popular tastes that may have been intended to sell products or improve domestic life has just as effectively determined the built form of neighbourhoods and cities. Further, urban form is shaped by the actions, tactics, and associations of everyday life as modified by shifts in taste and public belief. Collectively held ideals - in part beliefs constructed by tastemaking - facilitated by technological innovations can, in a contemporary environment, redefine how designers and communities work together to create built form. This paper will evaluate the place of make-believe and future landscape imaginaries in the creation and adaptation of suburbia.

Keywords: Taste, tastemaking, landscape, urban design, everyday life

"Here, in the new town, boredom is pregnant with desires, frustrated frenzies, unrealized possibilities. A magnificent life is waiting just around the corner, and far, far away." -Henri Lefebvre

The land of make-believe

Once upon a time has become frozen in timeless time, a world of immediacy and simultaneity that is seemingly ecstatic but is merely frenetically banal. Reduced to a image, cypher, the land of make-believe has folded itself into a glossy, multi-sided brochure advertising the idea of 'away'. Make-believe, properly, belongs in the here and now, for it is the *away* that acts on the *here* reflexively, remembering, prophesying, and creating.

To practice 'make-believe' is to *fabricate* an imaginary situation and to populate it with stories, actions, activities. These stories, no matter how incredible, are believed in the course of the imagining, and vestiges of new beliefs may still cling after the reverie has ceased. Make-believe begins in childhood, a process of imagining the world, of inhabiting scenarios, a way of beginning to comprehend the machinations and associations of the adult world. This can often be seen in the activity of making dens or forts, and then of inventing elaborate rules of admittance to and

occupation and practice within. Childhood games often rehearse adult situations, preparing the child for adulthood, but these processes are also critical, with children using make-believe to figure solutions for problems they see in the adult world. Play can be solitary or it can involve multiple children; make-believe can be a collaborative as well as an individual act.

As the child ages, the act of make-believe accommodates different possibilities and fantasies, complicated by sexuality, adolescent alienation, and high emotion. Make-believe can be benign, malign, or more often somewhere in between as the situation warrants, and this range continues on into adulthood. A daydream might spirit one away to a land of rainbows and unicorns, or allow one to envision strangling one's boss.* There is both an element of escape and of experimentation with roles and environments that allows possibilities for actual improvements to follow. By the time adulthood has been attained, within western culture it is commonly assumed that we have left the land of make-believe behind, which is reinforced in our educational methods that fail to reward imaginative thinking. Many believe that adult creativity is compromised by this process.

Teaching design, I often see my role as to enable students to regain the powers of creative imagination that are lost in the welter of rote learning and examination preparation that is secondary education. In particular design for landscape requires the envisioning of scenarios, using drawings and models to aid the imagination to test whether a design will work. Designers in the architectures do not have the luxury of making full-scale prototypes, and thus the modes of representation they employ for creation and communication are primarily aids to the imagination. Designers are also engaged in the act of manufacturing belief. First, their own belief that a design will work, and then second that of the clients, who must be convinced that a design will work to accommodate their needs, and further the belief that the design is beautiful and appropriate in a variety of other ways. Further, the designer is often seeking to 'educate' a client, to introduce them to new ideas that may even run counter to their expectations, installing a belief in new possibilities. In this way the designer works as a tastemaker. The designer takes his ability for child-like play and combines it with the ability to make and construct. The designer for the built environment is both *Homo ludens* and *Homo faber*.

Here we have introduced the tastemaker. Note that the term, like make-believe, combines the notion of construction or fabrication with a concept that is decidedly less substantial than bricks and mortar, but that is not without its own power. And if make-believe is an act of prefiguration, then so is what might otherwise be called 'make-taste'; in each desirable scenarios are envisioned that allow us to advance a progressive notion of living. Tastes are influenced and manipulated for a variety of reasons. The imagining of future modes of inhabitation or everyday practice is of paramount importance to those who would seek to influence people to act in a certain way. Perhaps the most obvious role of the tastemaker today is as salesperson. It is certainly an oversimplification to say that tastemaking is the act of creating a market for a new product or service, but this is the realm in which the average person encounters tastemakers regularly.

This is a one-sided view, however, of the process of tastemaking, which, when combined with design is actually a dialogic process, within which new practices, products, or services are necessitated by or invented for the technological improvement of evolving environments. Thus creativity is framed within and grows from existing (traditional) conditions, but those conditions are augmented or transformed by the original creative act. The process of tastemaking and design, further, recodifies and reclassifies everyday practice, refashioning and reframing rituals and beliefs. Imaginative processes allow the introduction of new metaphors and metonyms. These distinctly reframe experience, and can be used to suggest new possibilities that cannot yet be framed in words; as Paul Ricoeur notes,

...poetic discourse brings to language aspects, qualities, and values of reality that lack access to language that is directly descriptive and that can be spoken only by means of the complex interplay between the metaphorical utterance and the rule-governed transgression of the usual meanings of our words. I risked speaking not just of a metaphorical sense but

* Don't worry, Ruth.

also of a metaphorical reference in talking about this power of the metaphorical utterance to redescribe a reality inaccessible to direct description. I even suggested that 'seeing-as,' which sums up the power of metaphor, could be the revealer of 'being-as' on the deepest ontological level. (1984, p. xi)

The process of reaching into the past and tradition while simultaneously casting into the future recalls what Colin Rowe and Fred Koetter in their seminal *Collage City* might call 'theatres of dreams', in which the city is envisioned as a collage of enacted spaces. Rowe and Koetter distinguish between, but stress the interdependence of 'theatres of memory' and 'theatres of prophecy'; in which prophecy signifies hope and memory enables communication. (1978, p. 49) Ultimately, the city is a theatre of civilization, where scripts and rituals of memory and prophecy are acted out continually.

Edward Said cautions that these processes of envisioning can be manipulated positively or negatively, and that the spectre of nationalism and bigotry can be raised within them; "Memory and its representations touch very significantly upon questions of identity, of nationalism, of power and authority." (2002, p. 242) This in turn is true of projections into the future. The imagination of the world-yet-to-come is every bit as fraught. Have we been overly occupied with memory? Constructing place is a balancing act of creating both pasts and futures. It is the act of creating the story of the place where one lives happily ever after. Said talks about constructed, imaginary, often literary worlds as "imaginative geography", which he describes as "the invention and construction of a geographical place called the Orient, for instance, with scant attention paid to the actuality of the geography or its inhabitants," (2002, p. 243) but then he goes on to explain there is great power in the imaginaries of narrative history to "mobilize people around a common goal." (2002, p. 249) These imaginaries involve the creation of political and social metaphors that can shift real processes of place-making, dwelling, and community.

Is make-believe a place or an image?

Tastemaking events and publications with a focus on marketing tend to treat landscape scenographically, presenting a consumable image; a 'happily ever after' that is as fixed and frozen a nowhen as the 'once upon a time' with which I opened this essay. There are, however, other approaches to tastemaking that have had considerable impact upon the built environment, and understanding the underlying motives helps to chart some of the motivations for tastemaking, how these approaches are presented and consumed, and what the ultimate effect is upon the landscape, particularly the suburban landscape.

This imageability of land begins with the picturesque and is implicated not just in capitalistic landscape and property practices, but also in the mechanisms of nationalism. The idea of the land began to be fixed and delimited in the Renaissance, at which time the land as polity is "reified as the material scenic groundwork upon which the edifice of the state as an absolutist national unity is built, and the parliament is marginalized, if not abolished. Land becomes one with the physical property of the state, and with those who serve its political estate and hold a share in that land as a national territorial unity, its boundaries (rather than its parliament) defining its state." (Olwig, p. 27)

Here we see that the idea of place and of politics has shifted from one which is negotiated (in *parliament*) to one that is distributed across parcels of land; framed in discrete spaces, the aggregate of which compose the polity, and hence the state. It is important to nationalism that the obsessive, unresponsive imprinting of landscape as image is employed repeatedly in order to structure beliefs that are impervious to being influenced by context. Here we see tastemaking as a function of state and of control, its dark side.

Kenneth Olwig goes on to explain that, in the time that John Clare was writing so evocatively about the death of the commons, that

the land was not merely transformed into private property, to be exploited for agricultural

'improvement,'; it was also transformed into vast pastoral pleasure parks, ideologically shaped to resemble an idealized commons, while, at the same time obliterating 'real' (in law) working commons. In this way the representation of ideas of the ideal nature of the land in landscape art and gardening, in the Renaissance Italian tradition, creates an ideological landscape which is doubly alienating to those, like Clare, whose lives are attached to the working pastoral landscape. The social reality defined by shared rights in land is here transformed into private realty and its accompanying scenic landscape backdrop. 'Land' and 'place' became equated with 'propriety' - meaning in seventeenth-century English both property and knowing one's place. Whereas the term estate had once referred to one's place in the polity, landed property itself now became known as an estate, the seat of one's status in the countryside and nation; one's place in the country was thus effectively defined in terms of the possession of a country place. (2005, pp. 28-9)

Here nationalism is compounded by privatization; or is one a condition of the other?

These associations are difficult to unpick, and modern times have shown us that 'blood and soil' in the working landscape can equally be employed as a driver for nationalism. The idea of land and belonging is still tainted by this phenomenon, casting suspicion, for example, upon the slow food movement and new urbanism as containing both the memory and the prophecy of right wing extremism (I will return to slow food below). Perhaps the point to highlight is that where tastemaking and the manipulation or influencing of the popular imagination is concerned, there is a continuum between totalizing approaches and *bricolage*. There is no clear boundary, and this spectrum may not reliably be used to parse what is 'good' propaganda or 'bad'.

To further complicate understanding the phenomena, propagandizing tastemaking engines have evolved through the late twentieth and early twenty-first centuries from expressing ideals of private property in the service of nationalism into instruments of neoliberalism that transcend the waning power of the state. Take, for example, the British magazine and bastion of the conservative middle class *Country Life*, which is, according to the splash page of its website, "the essential weekly read for those who are passionate about the British countryside, fine art, gardening and property." The magazine not only champions private property and a picturesque notion of the countryside, as it has for many decades, but it now champions the 'heroics' of land trading as pure profit-making enterprise. A recent article, for example, seeks to make celebrities out of real estate agents. The piece, entitled "Property's Dream Team", elects a pantheon of "pillars in status" amongst estate agents, modelled as a rugby team with all the language of professional warfare ("Blind-side flanker: Tim Garbett (Knight Frank): 'A big fellow who'd be jolly polite once he'd flattened you, and won't let opponents blindside him'"). (Easdale, 2012) Only neoliberalism could promote the contemporary FIRE sector (Finance, Insurance, Real Estate), devoid as it is of moral motivations, as a clash of the titans appropriate for the myths of our present and future.

Contrast this with the tastemaking apparatuses of the last century, particularly in France, where Curnonsky helped to popularize regional cuisines and encourage tourism (Mennell, p. 243) and interest in traditional culture; Britain, where Elizabeth David helped to rebuild culinary, domestic, and community practices after the war, and likewise MFK Fisher and Julia Child in America. These authors wrote with genuine warmth and love about place, culture, and food. They certainly hoped to enrich themselves financially with their endeavours - no one may be faulted for wishing to earn a living - but were first and foremost dedicated to sharing their *joie de vivre* with their readers in order to enrich their lives. What is important about the influence of these culinary tastemakers is that they consistently associated the pleasures of the table and the kitchen with ways of life - foodways - that extended far beyond the walls of the home, and these modes of thinking and associated had a wider influence on urban form (the amazing arrival of the sidewalk cafe in London is one such example). Witness some of these place relationships and their romanticization at play in this evocative text by Elizabeth David:

Provence is now a great market garden centre, and from Cavaillon and Pertuis come melons, asparagus, artichokes, lettuces, courgettes, aubergines, peaches and cherries to enrich our own English markets. The little town of Le Thor supplies France with great

quantities of table grapes; Carpentras is the centre of a lively trade in the local black truffles. The natural caves round about the astonishing red and ochre village of Roussillon are used for a large-scale cultivation of mushrooms; Apt provides peach jam and bitter cherry jam and most of the crystallized apricots we ourselves buy at Christmas time. It is also one of the few places hereabouts where you can still find the old traditional earthenware *gratin* dishes, saucepans and cooking pots of Provence. (2006, p. 7)

English readers were both encouraged to rediscover their own regional food heritage, which had been so seriously compromised by the effect of rationing in the war and long after, and to look to surviving traditions in mainland Europe for inspiration and motivation. Literature allows for a much more effective transmission of ideas of movement and interaction in space than does an image, and begins to set up the associations necessary for tastemaking to create real spaces through aspirations spurred by text.

Interestingly, it is impossible to uncouple these noble efforts from twentieth-century developments that were much less savoury, such as the tremendous impact of the car and the concomitant effect of sprawl (facilitated by Curnonsky and Michelin in France as people drove around like mad in their search for authenticity) and the increasing atomization of public and community life as greater wealth allowed people to retreat to their private kitchens and living rooms. This proliferation of separations provided opportunities for tastemakers, as marketers, to fill these isolated, ringfenced homes with millions of duplicate items that might once have been, like farm tools and land, shared amongst many. Representations of the landed country life became fused with suburban imagery throughout the twentieth century, and thus the process of alienation from the commons was completed.

The suburbs

As I've mentioned above, rather than thinking of tastemaking as a determinant of urban form, it should rather be thought of as dialogic. As innovation occurs, new images and myths accommodate them, or they are worked into the fabric of existing patterns. Imagining suburbia as a fixed concept both denies it an evolutionary past and militates against reclaiming or adapting it for the future. As *tabula rasa*, neoliberal processes of total erasure and regrowth can be recruited, and these inhuman processes prevent the creation or furtherance of communities and the success of families, which require environments that grow and change incrementally over time, not in the 'timeless time' of contemporary development.

Thus I don't intend to abandon suburbia as unreal. Peter Rowe, in *Making a Middle Landscape* states: "It is only by recognizing the middle landscape as a real locus of growth and innovation in our society, rather than trying to make it in the manner of somewhere else, that progress will be made." (1991, p.291) and Rosalyn Deutsche both echoes and deepens this by warning, "Idealizing traditional cities as real ignores the politics of their constitution and transformation. Dismissing new kinds of spaces as unreal abandons them as spaces of political action." (2001, p. 78)

And in fact, the opposite might be coming to be true, particularly in global cities, as their centres are increasingly hollowed out by processes of real estate acquisition which leave giant luxury apartments standing empty in the ownership of the international wealthy (Mayfair and Belgravia, Lower Manhattan, Ipanema, downtown Hong Kong) while the streets outside are filled with tourists and businesspeople rather than communities or families. It is certainly the suburbs in these cities where most 'real life' is lived. Families, indeed, are foundational to civil society and are the cornerstones of communities. Janet Flammang explains,

"Most communitarians see the family as foundational to civil society. For example, Jean Bethke Elshtain defines civil society as 'the many forms of community and association that dot the landscape of democratic culture, from families to churches to neighborhood groups to trade unions to self-help movements to voluntary assistance to the needy.' Alan Wolfe

contends that the contemporary Left and Right rely on the state and the market to 'organize their codes of moral obligation, but what they really need is civil society - families, communities, friendship networks, solidaristic workplace ties, voluntarism, spontaneous groups and movements - not to reject, but to complete the project of modernity.'"(2009, p. 7)

The industrial age, though not the root, but a symptom of modernity, shifted everything. It redefined domestic roles in the west as well as creating new types of urban and rural landscapes through a great variety of spatial uses and typologies ranging from tourism, theme parks, open air museums, fast food outlets, and the strip, to name a few. With the decline of the nation-state, we need to look for solutions to the construction of space and culture even further, perhaps, in the past (a very old theatre of memory). In the middle ages, the concept of 'society' was utterly different. "The fundamental conceptions about 'social groups' were centripetal and hierarchical, rather than boundary-oriented and horizontal." (Anderson, p. 15) When the concepts of private property was introduced the social order and the construction of both urban and rural life shifted. "But in the older imagining, where states were defined by centres, borders were porous and indistinct, and sovereignties faded imperceptibly into one another." (Anderson, p.19)

A new and very contemporary imagining of the landscape of the future could very well be based upon the logic of the Occupy movement. The communitarian ideals, based in direct and local action, could well be compared to medieval constructions of space and society, but without the uncomfortable oversight of overweening structures of church and state.

Occupy the land of make-believe!

In an interview last year, David Graeber, the anthropologist who is one of the principal voices behind the Occupy movement, stresses that prefigurative processes of make-believe are at the core of the movements lack of concrete demands, and that the protestors "act as though they are already living in a free society," refusing to "accept the legitimacy of existing political institutions and legal order." This imaginary leap challenges the dominant metaphors and narratives and opens a space for creativity in public life and public space. We need to occupy the space of our future landscape imaginaries to prevent them being hijacked by forces that are counter to the city for families and communities. Occupying the imaginary can give ownership of the theatre of dreams back to the citizen, reclaiming it from the paralyzing forces of neoliberal media and development.

Suburbia is commonly seen as a la-la land of desperate housewives and kooks, but it is another sort of fantasy land entirely. It is the convergence of myriad tastemaking engines acting upon space. This fantasy land is the real space of many people's lives and it deserves tastemaking that is not just mercantile but moral. It needs a dialogic process of tastemaking that engages with both environmental and social ecologies to create future imaginaries that are both beautiful and sustainable.

PLANNING FORM THE AWARENESS OF A PLACE.

Miguel A. MEDINA

CEO; Medina Architects, Mexico City, Mexico
miguel@medinaarquitectos.com

Abstract

This paper deals with the presentation of a Municipal Sustainable Land Management Program in central region of Mexico.

For the development of the Program we were invited by the local government. We won the contest because the proposed work presented, however it was the most expensive of the competition.

The local government of Cuernavaca (that is the name of the place) raised the need to do this program because there was great insistence of some groups of investors to develop the West Township. To which our program said no because the most important ecological infrastructure with which has precisely this territory is located in the West.

For the preparation of the program we build the corresponding topographic map scale 1:2000 for which a specific flight was conducted to obtain an aerial photograph that once restored as a basis for the construction of the map. Should clarify that in Mexico there are official maps produced at scales 1:50000 and 1:100000

Then, we develop all maps of physical-environmental analysis and strategies for land use planning. But beyond that, we offered people a new perspective on where they live and invite the government and the people to transform the place where they live in an urban ecological region of environmental services shared with neighboring municipality. In a water supplier for the entire region viewing to the future and a city of outsourced services that benefit the poorest municipalities in their environment.

Keywords: Planning, awareness, sustainable development, methodology, knowledge

1. METHODOLOGY.

The municipality we have studied is located in the center of the country at 85.0 km. from the city of Mexico. It has an area of 15120 hectares and a population of 340000.

Our way of working in this type of study requires us to primarily know the place and meet the people. We carry out the required charts of geographical information, issues of our interest were: Geology, Geomorphology, Topography, Pedology, Climatology, Hidrology, Land use, Open space, Conflict and Ecological evaluation (Fig 2 and 3).

Fig. 2: Geology Geomorphology Topography Pedology Climatology

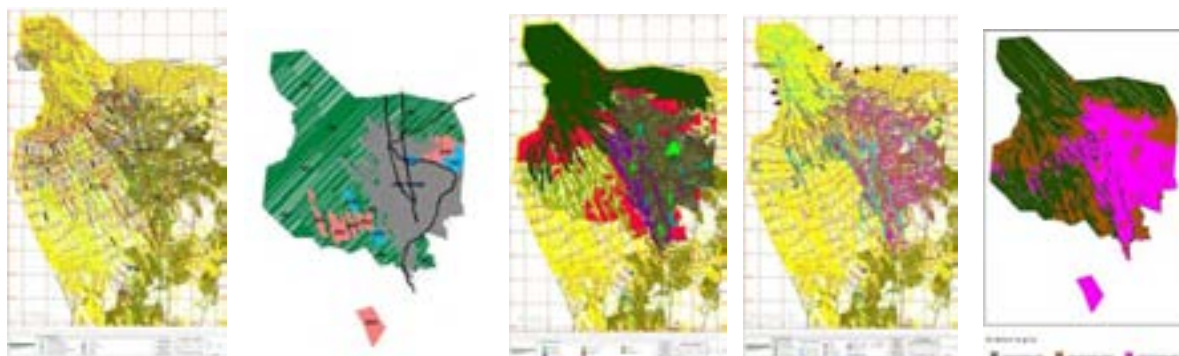

Fig. 3: Hidrology Land use Open space Conflict Ecological evaluation

Parallel to the study of the physical and environmental characteristics we did a study of environmental psychology based questionnaires and systematic assessment to meet the expectations of the population in relation to what might be the sustainable development of the municipality, and the perception that the population had of their environment.

Unfortunately we found that people did not have sufficient knowledge of planning, environmental problems or sustainable development and concerned only generalized data on air pollution but most showed a particular interest in Apatlaco river pollution associating to urban growth. This finding fundamentally guided our research.

As a result of our analysis we decided to do a combination of the four qualities that characterize the territory uniquely: its physiography, topography, hydrology and climatology (the city of Cuernavaca is known as the city of eternal spring) to better understand their nature and discover its Genius Locci.

The study of the physiography of the territory led us to understand that this is composed of four main regions we call Mountain, Upper slope, Lower slope and Plain.

In the Mountain and Slopes there is deposited as natural wealth of the municipality: its pine forests, oak forests and riparian forests growing on deep canyons that descend throughout the western portion of the territory.

In the Plain there sits the city that has a history as a human settlement since the fourteenth century and are large tracts of land used for agriculture but are getting pressure from urban growth and becoming peripheral semi-rural settlements or sub-urban poor development.

Moreover, the analysis of the hydrology of the site led us to consider that the restoration and conservation of water resources planning is the key issue for future development. Not only by the amount of biomass, natural resources and environmental services that contribute runoff to the streams and place, but also because the Municipality is seated on one of the largest aquifers in the Midwest.

(Fig 4 to 15).

Fig 4: Aerial photography of Municipality of Cuernavaca

The municipal territory is located in the Rio Grande Amacuzac Basin and is crossed by the watersheds of three rivers: Tambembe, Apatlaco and Yautepec. This unique quality of the Municipality is due to its geographic location: the territory is part of the foothills of one of the highest mountains in the center of the country and its altitude gradient goes from 3000 to 800 meters above sea level.

Fig 5: View of highway descending from the high mountains to the valley of Cuernavaca.

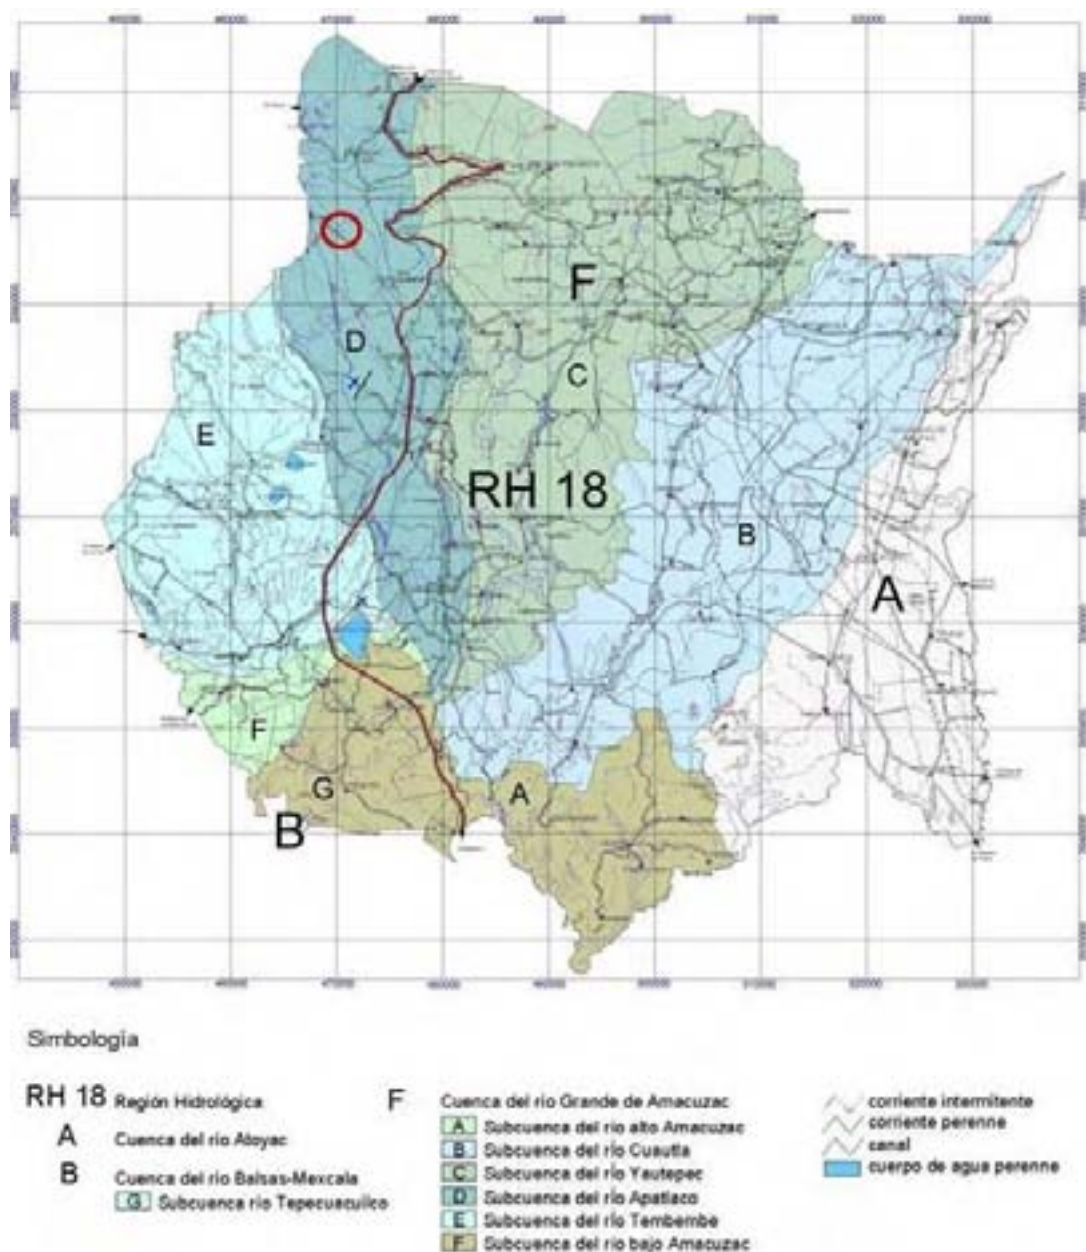

Fig 6: Cuernavaca Valley location in the context of the watersheds of Morelos State

Our analysis of the place made us realize that the site has a privileged location in relation to neighboring municipalities: Northbound Huitzilac Township is nestled in the mountains and its economic activity is very limited due to topographic conditions and legal protection of forests. Southbound Municipalities of Temixco, Jiutepec, Emiliano Zapata and Xochitepec hold basically agricultural activity in their economy but significantly influences the location of popular Tívolis and Spas dependent on water coming from the mountains across the valley of Cuernavaca. Also, the city of Cuernavaca is the capital of the state of Morelos and therefore has a diverse economy and a great political importance. Moreover, the city occupies only 30% of the municipal territory. It has important water resources, climate (mild climate is ideal for the development of human life and in the extreme south of the municipality is located one of the largest place basking in the country with a Solar Research Center), along with its plant and animal biodiversity.

2. CONCEPTUAL PLANNING FROM DE AWARENESS OF SITE AND PEOPLE.

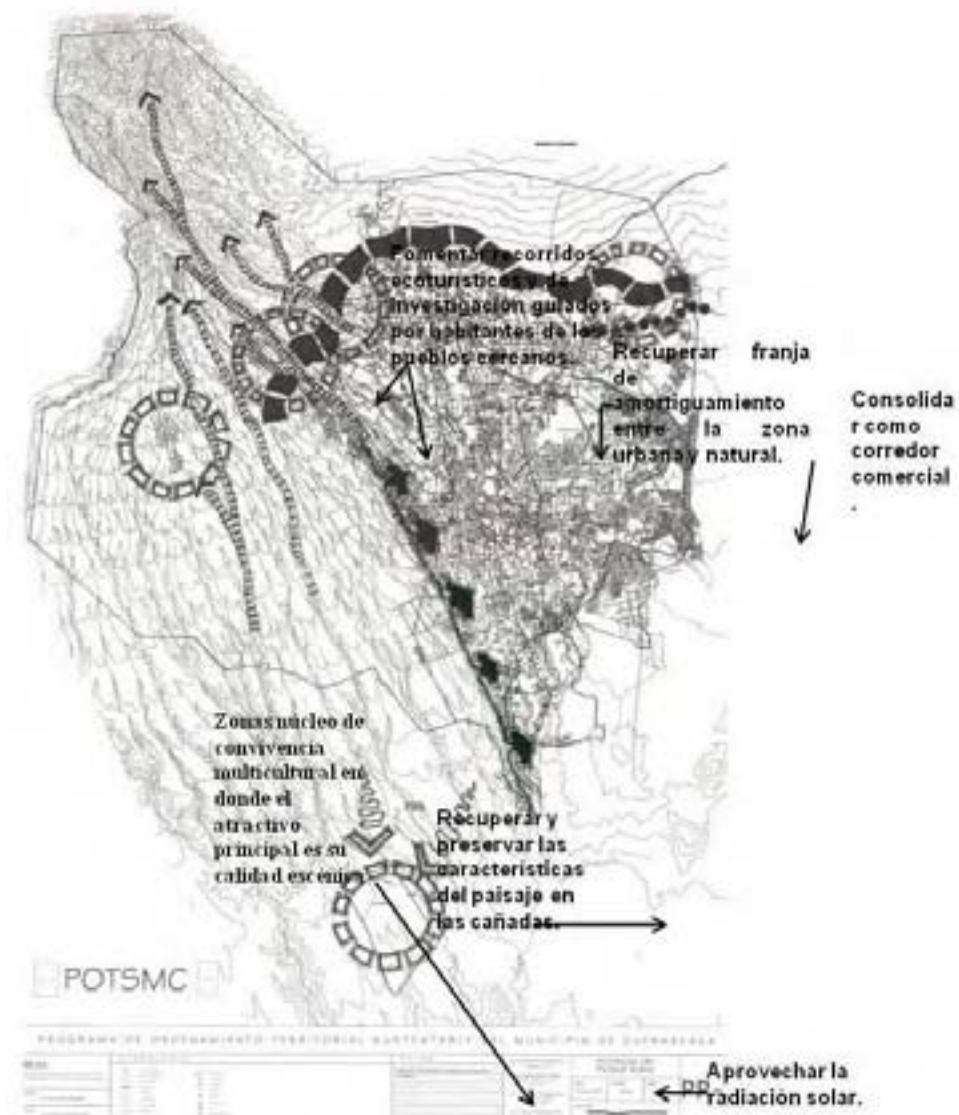

Fig 16: Conceptual Plan for sustainable development of Cuernavaca Municipality.

In Medina Architects we think that what we call sustainable development is not a goal or the result of a project, but the promotion of socio-environmental, economic-environmental and political-environmental processes that in time determine the establish and sustainability of different bio-geographic regions.

Therefore, to promote sustainable development of the municipality produced a document which set out the following aspects:

We define a physical division of the territory based on the four physiographic areas: Mountain, Upper slope, Lower slope and Plain. And the three hydrological basins mentioned above. Within this division proposed a zoning legally called Local Environmental Management Units (ULGA'S).

Determined in each ULGA conflicts concerning: natural hazards by seismicity, volcanism, weathering and erosion, and anthropogenic threats. Conflicts over political and administrative division, with the structure of land use, housing, commerce, industry, the classification of the territory, with the road structure, urban transport. Conflicts over mountain system, with the water system, defragmentation of forests, deforestation, urban growth and the expansion of the agricultural area, with fire, introduction of exotic species and the opening of roads.

We made a strategic plan whose main objective was to design a possible future project, able to face the risks of local environmental decline in its full extent, and to combine integrated actions aimed at preserving the natural heritage, modernize tourism, economy, and improve the quality of life of the population of the municipality (Fig 17).

Fig 17: ULGA's examples

Strategic Plan for the Cuernavaca Municipality Sustainable Development

In our strategic plan include guidelines for what we call a preventive planning to avoid late solutions to environmental problems. We established conditions to access a local Agenda 21 based on strategic potential advantage of the Municipality in terms of ecological infrastructure, regional central city, multimodal

communications, multimodal tourism, targeted on management and conservation of natural resources, social and economic dimensions and strengthening the role social groups.

To achieve these objectives we established 10 lines of action including 40 strategic projects:

Line1. Contain human pressure, limit growth and promote rehabilitation of the Territory.

1. New municipal urban development plan
2. New urban development in areas of immediate growth
3. Norms of urban eco-responsibility

Line 2 Encourage integration, coexistence and quality of life of the resident population.

Living in Cuernavaca, new urban and rural

4. Social integration, training and employment in Cuernavaca
5. Volunteers Cuernavaca
6. Coexistence, cultural integration and quality of life in Cuernavaca
7. Cuernavaca, sustainable city
8. Cuernavaca, Clean Water Town

Line3. Preserving the natural heritage and promoting the creation of a regional tourist ecotax environmental fate.

9. Preserving the natural water in Cuernavaca
10. Protect soil and forest systems in Cuernavaca
11. Recovering mesoclimatic quality of Cuernavaca
12. Restore the main environmental impacts and landscape in Cuernavaca

Line 4. Rescue the historical, cultural and natural heritage of Municipality.

13. Knowing and caring heritage of Cuernavaca
14. Historic downtown of Cuernavaca
15. The Parks and Gardens of Cuernavaca
16. Chichinautzin Range biological corridor
17. The Canyons of Cuernavaca
18. Constitution of a public natural history in Cuernavaca

Line 5. Promote the rehabilitation of population towns and middle-income residential and popular.

19. Rehabilitate and strengthen cores Cuernavaca
20. Development of a plan to expand urban eco-
21. Pilot programs "Environmental Rehabilitation Areas"

Line 6. Improve Cuernavaca as a tourist destination: replace sustainable quality growth, seeking the lifting of spending per visitor and tend to balance the season.

22. Cuernavaca, multimodal tourist destination
23. Cuernavaca, American Spring
24. Modernize the existing tourist park
25. Development of new ecotourism products
26. Promoting the ecological quality in Cuernavaca

Line 7. Improve public transport and encourage pedestrian and bicycle travel within population towns.

27. Improve existing public transport in Cuernavaca
28. Promotion multimodal forms of transportation
29. Plan for ecological conversion of mobility in Cuernavaca

Line 8. Introduction of sustainable management in key environmental sectors: water, energy and waste

30. Water Year Plan
31. Local program management to stabilize energy demand, reduce consumption
32. Promotion of renewable energy production
33. Year plan of waste in Cuernavaca

Line 9. Investing in human resources and knowledge, stimulate and diversify the economic system

34. Creating a sustainable development agency in Cuernavaca
35. Investment in human resources in Cuernavaca
36. Development of new business projects in Cuernavaca
37. Stimulation of "rural" in Cuernavaca

Line 10. Innovating into the Municipal Government and expanding the capacity of concerted public-private investment.

38. Modernization of Municipal organization in Cuernavaca
39. Expanding the investment capacity of the Municipality of Cuernavaca
40. Knowing and caring environmental heritage of Cuernavaca

Fig 18: *Bombax ellipticum* the representative tree of Cuernavaca

Our plan is fully explained about the meaning behind the lines of action we propose and how strategic projects should be agreed and implemented with the population as the basis of the acquisition of sustainable practices in the municipality.

I think the most significant contribution of our plan to the municipality is to offer its inhabitants a new vision of the territory in which we consider the Municipality of Cuernavaca as the heart of an eco-region and the precursor of the establishment of a virtuous circle of Municipal interaction in which the villages located in the upper conserve ecosystem services which benefit the peoples of the lower basin by remuneration which covers not only a green tax but also the exchange of goods and services.

We propose, among other things, that the City of Cuernavaca stop urban growth expansion offering investors in real estate facilities for reinvestment in decaying or abandoned areas of the city re-densifying built space and upgrading the services and infrastructure.

We also propose that the City of Cuernavaca specializes in tertiary activities so it can offer a menu of advanced technology in communications, financial operations and management to its neighboring municipalities

Similarly, we propose to create a multimodal and inter-municipal transportation network that serves to facilitate the flow of people and goods in the region.

Finally, we propose that the City preserved itself as a water reservoir that in future times could offer the use of this resource to other parts of the country, considering that 60% of the country is semi-arid areas that definitely will have great needs to solve.

A Discussion On The Micro-Scale Urban Preservation Projects In Turkey

Dr. Şeyda Güngör Açıkgoz, Dr. Burcu CEYLAN

Abstract

Even though Turkey puts considerable effort in complying with the international regulations concerning the preservation historic sites, due to various local realities, desired outcome has not been achieved. As a result, the loss of historic fabric in urban sites is a common issue of Turkish towns. Recently a new practice, which is restoring a small portion of the site -generally the most preserved street- has become a trend in urban preservation. Advised and financially supported by the central government, “street renovation” promises a rather feasible solution to the problems of urban preservation practices in Turkey. Moreover, it presents an intermediate stage between the urban preservation and restoration of individual buildings. On the other hand, this practice contradicts the idea of total preservation of historic sites by reducing the cities to fragments.

The presentation aims to discuss these types of micro-scale urban preservation projects, in relation with the social and economic realities of Turkey. The legal background, fiscal possibilities, application processes will also be mentioned. The outcome of such projects will be evaluated in reference to case studies.

1. The Idea of Urban Preservation and International Charters

The idea of safeguarding the urban areas entered the universal notion of preservation as early as 1931. Article 3 of Athens Charter, “AESTHETIC ENHANCEMENT OF ANCIENT MONUMENTS”, states that the surroundings of a monument should be given special consideration. However, the urban environment, referred as “surroundings” here, was taken as a background of the monuments to be preserved. In Venice Charter, while the monuments still take the centre stage, their preservation also incorporates the preservation of its traditional setting (Article 6,14). On the other hand, article 1 regards urban or rural settlements monuments, as they evidence of a particular civilization, a significant development or an historic event. With these articles, the historic areas became another subject of conservation. It is mainly the Amsterdam Charter that accentuates the importance of urban preservation as a subject of its own right. Article B states that architectural heritage includes not only individual buildings of exceptional quality and their surroundings, but also all areas of towns or villages of historic or cultural interest. A year later Nairobi Charter, makes a meticulous definition of historic

sites as “any groups of buildings, structures and open spaces including archaeological and paleontological sites, constituting human settlements in an urban or rural environment, the cohesion and value of which, from the archaeological, architectural, prehistoric, historic, aesthetic or socio-cultural point of view are recognized.” Urban preservation had a comprehensive definition with the Washington Charter, which “concerns historic urban areas, large and small, including cities, towns and historic centres or quarters, together with their natural and man-made environments”. Historic sites given importance since they embody the values of traditional urban cultures, and they have a role as historical documents. Washington Charter aims to complement the International Charter for the Conservation and Restoration of Monuments and Sites (Venice Charter) in that it defines the principles, objectives, and methods necessary for the conservation of historic towns and urban areas.

2. Urban Preservation in Turkey

In Turkey, the legal frame of the urban conservation developed simultaneously with the European practices. After the enactment of “the Law for Safeguarding the Natural and Cultural Assets” in 1973, historic urban areas of almost every city have been listed as ‘historic sites’[1]. Unfortunately, as it is well known, the legislation alone is never enough in preserving the historic environments. Even though the legal frame work was formed; it is difficult to state that Turkey has put up respectable preservation practices. In fact very few cases of integrated urban preservation can be mentioned with confidence like Amasya and Safranbolu (Fig. 1, Fig. 2) Though it presents a major topic of discussion which has several social and economic factors, here we would like to sum the conditions of urban preservation in Turkey.

- Actions of preservation and its continuity require a social awareness. In Europe the consciousness for preserving the historic monuments and settlements evolved by the actions of civil initiatives during 19th and 20th centuries. Turkey, which didnot go through a similar historical phase, imported the idea of preservation by the weak efforts of scholars but majorly by the international agreements. Therefore the preservation has not been supported by the internal dynamics of the society. In fact, almost all of the practices of preservation in Turkey, whether it is about a single building or for a historic site, have been achieved by the governmental bodies and through state finance. The fact that historic sites in Turkey are in a poor state of preservation is due to the lack of civic consciousness rather than legal irregularities.

- Preservation of historic sites always includes the problems arisen from the private ownership. The persuasion, encouragement and support of owners, together with the before mentioned social problem, becomes even a bigger issue in the preservation of historic sites.

- Preservation in urban scale requires considerable economic resources. Turkey, as a developing country, has difficulties in providing the necessary funds.

- Legislation leaves the safeguarding of historic sites to the local preservation councils. Unfortunately, the effective formulation and structuring of these councils took some time. Even today, the formation of the councils, the regions which each council is responsible of still being altered, causing a lack of consistency and continuity in urban preservation practices.

- Since the concept of preservation had been limited only to the monumental buildings, the vernacular architecture, which forms the greater parts of the historic sites, was neglected. Except palaces and large mansions, very few examples of domestic architecture were listed until the 1980's.

- Within the protected area of historic sites, buildings which are not individually listed have been ignored. However, these buildings have indispensable role in the formation of the urban pattern with their dimensions, ratios and relations with the neighbouring buildings and urban spaces; even though their stylistic characteristics are not qualified for being listed. Since they are not protected by the law, they are either in dilapidated condition or replaced by modern constructions. In either case, they create visual gaps in the historic pattern.

Therefore, the situation of the historic sites in Turkey entering the second decade of the millennium is as follows: Several cities had already lost large parts of their historic areas when the law was promulgated in 1973. The loss continued even after that date, such that in some cities historic sites were needed to be redefined with reduced areas. In some of the cities only small fragments of historic pattern survived. In several cities, the listed buildings are still in dilapidated condition, due to the lack of the will and resources for proper restoration. The historic areas are torn by recent constructions, most of which lacks decent architectural quality and almost all of which alien to the character of the area. In addition to the buildings, other

urban amenities like pavements, garden walls, street furniture or greenery which defines the urban character, are also not preserved and changed with modern counterparts.

In these circumstances a seminal project was initiated in 1977 in İstanbul. The project area was the vicinity of Sultan Ahmet Square, the most important touristic centre of the old city, which also encompasses monuments like Blue Mosque and St. Sophia and Topkapı Palace. Here the area was planned to be transformed into an 'open museum' which would house exhibitions, cultural activities and tourist accommodation. [2] The initial project had particularly refrained from reserving the area only for touristic activities by including culture and accommodation. The first phase of the project involved a detailed survey of buildings, archaeological ruins, traffic and other usages, and function analysis. The design offered a contemporary architectural approach, but complied with the existing historic pattern with appropriate dimensions, material and facade characteristics.

Despite all its good intentions, the project was not realized as expected. Soğukçeşme Street, runs between the walls of Topkapı Palace and St. Sophia, was "renovated". The method was highly criticized for being against the universally accepted rules of architectural restoration: the buildings on the street were rebuilt, as similitude of 18th century houses by modern materials and techniques. The historic integrity of the area was compromised. What achieved is a stage set for touristic purposes where the original was lost among the fake. The ideal of authenticity was completely sacrificed. (Fig. 3)

3. 'Street Renovation' as Minor Scale Urban preservation Project

By a queer twist of fate, Soğukçeşme project became an inspiration for urban renovation projects. It was initiated by the Ministry of Tourism and realised by an association promoting the development of tourism in Turkey. Even though it was only a fragment of the original project, it created the expected tourism income as intended. Therefore it opened a new path in urban preservation practices. It demonstrated that when an integrated urban renovation project is not possible, minor scale projects, limited to a portion large enough to create the desired atmosphere would be more than enough for tourist attraction.

The last two decades, "street renovation" projects are being prepared in growing numbers. According to the Ministry of Culture 12 projects from different cities are presented to the local preservation councils for the year 2010. (Fig.4,5,6)

The related specification issued by the Ministry of Culture defines 'street renovation' as a project for preservation, rehabilitation and revitalisation of a street by restoring the street facing facades of buildings, listed or unlisted, courtyard/garden walls, outbuildings/annexes together with other architectural elements like gateways, fountains. It also requires the restoration of original street pavement and other street furniture.

The guidelines for 'street renovation' projects are specified as follows:

- The motive should be preserving the natural, cultural, architectural, historical aesthetical, visual values and original identity of the city.
- The accordance with the environment should be aimed. The project should be sustainable and consider ecological preservation. The project should provide optimum climatic conditions
- The project should be in accordance with the user profile, the needs of disadvantaged users, i.e. children, elderly or handicapped should also be considered.
- The project should protect the functional integrity of open spaces, while promoting the development of traditional architecture
- The project should provide an integrated pedestrian and vehicle traffic between the area and its surrounding
- The visual pollution of alien features like energy and communication lines, billboards and like should be prevented.
- All infrastructures like water, sewage, garbage, fire prevention should be updated
- The improvement of housing should be considered.

The specification clearly shows that the legal basis of the street renovation is derived from the Washington Charter, especially its principles section. In close examination, the similarity of the language is obvious, as in the definition of the urban preservation (Articles 9, 12, 13, 14).

The street renovation projects are bound by the Law for Safeguarding the Natural and Cultural Assets. They should also comply with the local urban development plans and urban preservation plans. The street in question should be in a listed historic site. The approval and

control of the project is left to the local preservation council. It must be noted that the specification does not have any regulation or references to financing of the project.

4. Discussion

Behind the wide acceptance of street renovation projects, lies the fact that, it offers several of the profits of an urban preservation project (a rise in the land value, touristic income, improvement of the physical quality etc.) yet it is relatively easier and quicker to achieve and apply. On the other hand, a smaller scale would be much more effective in creating the image of a perceivable environment [3].

However, street renovation projects come together with problems of restoration ideals, finance, and application. The legislation places projects under the guidance of development plans, which mostly have minor concerns for preservation. In the occasion of a conflict, preservation would automatically be rendered as secondary.

The street to be renovated is chosen by the numbers of the existing historic buildings. Even though this has a merit, when the quantity becomes the dominant parameter, another area, more valuable in terms of artistic or historic value but fewer buildings would be ignored.

The local preservation councils may have different interpretation of legal framework. Therefore there are differences in the extent and context of the project depending on the demands of the council. Some councils approach the project as facade renovation, -only the facades facing the street- while some regard it as a complete restoration project, with more detailed designs.

Another problem comes with the application. Since the specification does not force immediate application, some of the projects are prepared as small scale urban preservation projects. The application is left to private initiative to be completed with time. In this case, for every single building detailed restoration projects would be prepared based on the preservation decisions. In several cases, restoration project was not designed by the authors of street renovation projects since there is no specification for that. Different teams of applicators may cause inconsistency of the quality of restoration and damage the integrity of the project. Moreover, for the continuously decaying historic building sites, projects may require updating, causing the waste of time and effort.

The projects with provided finances are in fact not in the context of preservation. They should be considered as large scale restoration projects. In this case the phrase "facades facing the street" of the specification becomes irrelevant since there cannot be such a thing as "half restoration". As a result there is a tremendous inconsistency between the projects presented to different councils.

Consistency of the street renovation projects to the universal ideas of preservation is another topic for discussion. As mentioned earlier, the conservation of historic towns and other historic urban areas are not necessarily an integral part of urban and regional planning. Even this fact alone raises serious problems.

One of the aims of urban preservation is to renovate the traditional character or the city within the possible boundaries. The 'renovation' should include the revitalisation of the urban life of the area as well as restoring the architectural character. Boundaries on the other hand should be carefully designated, depending not only on the structural remains but also on the other visual and physical factors like topography or landscape.[4] The preservation should cover the chosen area as whole and should ensuring a harmonious relationship between the historic urban areas and the town as a whole (Washington Charter Article 5). Here street renovation projects are totally contradicts the holistic, integrated idea of urban conservation. Street renovations due to its limited character, compartmentalises and isolates the area visually from the rest of the town as well as the rest of the historic area. In addition to that, it creates the illusion of total preservation and results in ignoring the other parts of the historic area, which might well have more values than the renovated street.

It is a fact that historic areas, when they are well presented, provide a considerable income as tourist attraction. This is the main motivating factor for the local governments in pursuing street renovation projects. With this goal in mind, the historic character of the area is limited to a face value, and converted into 'Disneylands'. Another negative outcome would be the loss of original function of the area. In several projects, the buildings of the street, i.e. the houses of the local population, are designed to provide luxury lodgings for tourists, with the addition of non-original features like swimming pools. Inaccurate practices are not only confined to historic buildings themselves but also to the new constructions on the site, that are designed as copies of the traditional architecture. These practices would compromise the authenticity of the historic town

or urban area (Washington Charter Article 2). On the other hand, the change of function, from residential to touristic, most often results in the casting out of the local population. However, the conservation of historic towns and urban areas should concern their residents first of all (Washington Charter Article 3). The process may also fail in promoting “the harmony of both private and community life in these areas and to encourage the preservation of those cultural properties, however modest in scale, that constitute the memory of mankind”.

5. Conclusion

Some of the above mentioned problems are the result of wrong practices and approaches. However, in Turkey, the historic sites are decaying in such a velocity that it becomes a luxury to pursue comprehensive urban preservation projects that complies with all the universal principles of conservation. In these circumstances “rigidity should be avoided since individual cases may present specific problems” as the article 4 of Washington Charter states. Street renovation projects are constructive attempts in protecting the bond between past and present. Moreover, their inspiring effect on the promotion of preserving historic areas, by creating visual as well as economic values, cannot be denied.

Two recent mainstream scholarly debates in Turkey on preserving the historic towns also supports the potentiality of street renovation projects. Both present a cynical approach to the subject: to achieve the ideal urban conservation is merely impossible. Kuban states that the orthodox methods of conservation are the reason behind the loss of historic sites in Turkey.[5] Tanyeli proposes a new concept which he calls “preservation of visual values” on urban scale. Here the conservation of buildings only as a facade or as a body would be enough to preserve the appearance of an area. Tanyeli carefully refrains using the term historic conservation, since what is achieved by the method would not be conservation. However, he claims that even though this creates an illusion of historic site, towns require that illusion.[6]

Within the light of these theories, new approaches to urban conservation, like street renovation should be taken seriously. However, in order to achieve healthier projects, the above mentioned problems should be solved. Here the Ministry of Culture should take the initiative to instruct the local governments and also the local preservation councils about the ideals of conservation.

Abstract

In line with the architecture of lightness, the transparent "skin" of the building is playing an increasing important role by ensuring the comfort of the building system. It is becoming a type of extremely sensitive component in order to design choices.

About control of material fluxes and especially of energy, incoming and outgoing the building system, the glazed surfaces constitute the weakest point of the envelope. A correct exposure, a suitable distribution and a proportionate sizing on the opaque surfaces significantly affect the comfort conditions of users, not only in terms of natural light, but also in terms of sensible heat, so as to become a real source of passive income in the winter season.

Solar heat gained in the summer is an unsolved (but not unsolvable) issue, especially in the climate zones belonging to the Mediterranean area; they are a negative entry in the energy balance, a discomfort factor, an amount of energy to be dissipated.

This study, developed in the second phase of the "Solar Eco-efficient Envelope Model" Project, financed by the Environmental Ministry in a wide range of research projects, is aimed at both energy efficiency measures and use of renewable energy sources in urban areas. This is in the middle between a market survey and a magnifying glass on the progress of the last technologies offered by glass components producers, so it is aimed at monitoring the range of opportunities launched on the marketplace and making it available to a technician/engineer in order to support his/her intervention choices.

Keywords: transparent skin, glass components, passive solar system, energy efficiency

1. Analysis Methodology¹

"We need to learn how technologies work, not trying to reproduce them, because they became obsolete just one year later" (Mario Bellini).

The leading companies in designing and processing transparent components for the construction industry daily confront each other on the field of innovation. This is increasingly oriented to strengthen the variety of the market supply, trying to elaborate solutions in order to respond each time to specific needs, closely connected with both the use of the building and energy performances that are more and more restrictive according to the last standards.

The advance of the technological research in the construction industry, engaged in manufacturing transparent components for the envelope, is essentially based on the study of glass performance.

It is finalized to improve the relationship of the components with solar radiation at different wavelengths that they intend either to capture or to screen: the radiation component of light (falling into the visible range) and the thermal component (falling into the infrared range).

We analyzed different types of products, more or less widely available on the market. They respond to either different applications in the field of ex-novo projects or rehabilitation of the existing ones, or in the field of rehabilitation of historic buildings, ranging from insulation glass unit to the hyper-thin surface coating, to the avant-garde of the vacuum system and the chromogenic glasses.

2. The insulation glass unit²

Heat exchange through a single glass happens only by conduction: a single 4 mm clear glass reaches 5.8 W/m²K of transmittance, the same 8 mm glass reaches 5.7 W/m²K.

So it's almost irrelevant to increase the thickness because the material shows low intrinsic thermal capacities. In order to obtain high quality performances, it is necessary to adopt the IGU (insulation glass unit) system, also to respect the limits of transmittance imposed by the standards.

The IGU uses the transmission of the thermal wave combining conduction in the glass and convection in the gap, filled with air or other low-density gases such as argon or krypton, which decrease the heat transmission of about 0.2-0.3 W/m²K.

It's possible to change the convective/radiation glass behaviour coating their surfaces inside or outside the gap, without considering more specific features.

There are two major types in the industrial production of the sector: low-emission glasses, allowing the light and thermal radiation to go through them and prevent them from exiting, and selective solar control glasses, able to select and reject the thermal component that arises from a direct solar radiation. The surface treatment called "coating" could be either of a pyrolytic type (a physical deposition of vapours of metal: for example silver or tin), or of a magnetron type (vacuum chemical vapours deposition).

This last technology, in comparison with the previous one, is more laborious and obviously more expensive, but it provides higher benefits in terms of durability and workability of the surfaces. The deposited film directly influences the emissivity of the glass surface and, for the coating positioning it's possible to obtain different results in terms of selection of the transmitted or reflected wavelengths and returned chromatic aspect.

The designer has to select the component with the best performances according to specific needs. He/she can be helped by the evaluation of some important parameters:

- light transmitted through the glass (in percentage in comparison with the incident light);
- heat transmitted through the glass (in percentage in comparison with the incident radiation);
- Transmittance value (in KWh/m²K);
- Solar Factor *g* (a percentage value that ranges between 0 and 1): it indicates the ratio between the thermal energy globally transmitted through the glass and the incident one.

It's important that the designer makes his/her own choice considering the heat component is not the only variable: conditions of light comfort and fruition of the confined space need a different quantity of natural light in relationship with both the intended use, and exposition and characteristics of the environmental surroundings (presence of obstructions close to the glass front and their shadows).

The recent standard developments about the calculation and certification of the energy performances of the building-plant system give great importance to the transparent envelope design.

A very important requirement is the glazing percentage, between the transparent surface of the building and its overall useful surface.

F	2.3	1.7	1.3

Fig. 2: D.Lgs 311/06 – All. C - Limit values of U Thermal conductivity of transparent closures - glass (W/m²K)

If it is below 0.18, it is possible directly to attribute the value $EPI = EPI = \text{limit}$ to the building, where they occur simultaneously other requirements on the plants and on the envelope: useful thermal efficiency and transmittance. In other cases, it is very important valuating the effective performances of the transparent envelope (see DPR 59/09, article 4 paragraph 4: transmittance of transparent closings below the tabulated limits).

The D.Lgs no. 311/06 has introduced some interesting innovations: the designer has to use better external environmental conditions and distribution features of the spaces to encourage natural ventilation of the building and introduces, with the enclosure I, the obligation of sun protection systems to control solar gain in summer conditions.

The companies chosen for the comparison have been identified among the most widely diffused and publicized in Italy and abroad by architecture and design magazines, according to some criteria:

- Wide distribution on home market
- Large productive supply
- Clarity of information about technical performances
- Availability of contacts with local branches
- Possibility of performance verification using business software.

For the comparison some energy parameters are considered, within the technical files provided by the companies, as well as the type of glass (single, double or triple glass):

- Transmittance U-value ($\text{W/m}^2\text{K}$)
- overall thickness of the glazed component
- gap filling (Air, Argon, Krypton).

Among the light parameters Solar Factor g , external aspect, that is color response, and type of surface coating are considered. The selected products are able to offer a good thermal resistance, without substantially reducing their Solar Factor g and maintaining their transparent appearance almost unchanged. The maximization of the Solar Factor is desired in order to ensure passive solar gain in the wintertime, especially if it is complied with the law obligation of sunscreens selectively protecting windows in the summertime.

Fig. 3: An example of technical characteristics of glasses with solar control coatings

Fig. 4: An example of technical characteristics of glass with high selectivity, high transparency and very good thermal insulation: an ideal design solution for school building and hospital

Fig. 5: An example of technical characteristics of glass with very low transparency and excellent thermal insulation

Fig. 6: An example of technical characteristics of glass with very high transparency and poor thermal insulation

The survey shows that of course big businesses offer a very wide supply for any type of use, not only for the number of finished products placed on the market, but also for the possibility of different glass combinations, while small businesses tend to be oriented to a specific segment of the market, obtaining very highly performing products that meet less very specific uses.

Finally the three parameters that characterize a solution of glazing visible light, Solar Factor g and transmittance are directly compared, identifying four levels of performance: insufficient, sufficient, good or Best Practices, attributing consequently, a score from one to three on the elaborated rating scale. (Fig7)

Fig. 7: Assessment of the significant parameters for glass.

The IGU totally responds to the need of the installation of a glazing system (glass-frame), suitable to meet the requirements of standard comfort and performance for each type of environment.

The rehabilitation of the buildings, especially for a tertiary use, characterized by large glass surfaces, usually without screens, involves the necessary adjustment of the glazing systems. Very often, however, the installation of a double glass system with an ex-novo selective or solar control film is prohibitively expensive, both for the finished product cost (considering the involved areas), and the subsequent replacement of the whole frame system. The application of a superficial adhesive film is a very practical technological solution; it is quicker in installation and has a minimal influence on the regular use of the building.

3. Coating for the energy building retrofit³

The polyester self-adhesive films are installed directly on the glass by highly transparent adhesives, UV rays inhibitors, in a "sandwich" structure, in the middle of which there is a layer of metallization, acting as a reflector of solar radiation; the surface finish is made up of one or more layers of scratch-resistant coating.

There are different types of films suitable to meet different requirements of comfort for confined spaces and areas immediately surrounding the building, but that guarantee a reflection of the sunlight equal at least to 70% of the incident one.

The installation can be done both outside and inside the glass, getting different results, especially for the discomfort glare and the raising of the surface temperatures, but that creates also different conditions of duration and maintenance.

There are different types of films on the market, suitable to meet security needs or specific for the protection from UV rays. We can distinguish two main categories of films based on the deposition of metals and the external chromatic response among those studied in order to save energy.

The first type of product is defined reflective, its processing is done by the vaporization of metals (usually aluminum) with a controlled density on the glass; the final effect is a high chromatic response, and a mirror effect. This solution is excellent for breaking down the thermal summer gains and the problems caused by insulation on the transparent walls.

The sputtered type instead presents a more complex process called sputtering and is done through the disintegration of the atoms of the metals by ion bombardments. The use of this type of process ensures a low mirror effect, making it suitable for applications in the historic centre, while maintaining excellent performances in terms of reduction of discomfort glare.

For both types there are different versions according to the need to shield the solar radiation more or less densely, the distinction is made through the combination of different surface layers, lightly colored (defined: "*fumè*") improving the conditions of glare, avoiding the reflections inside the rooms, but of course reducing transparency and visibility outwards.

The real drawback in these films installation, in the past, was the poor resistance to atmospheric agents, which compromised their functionality (reductions experienced by 90% of the performance), and their transparence becoming opaque layers applied to windows, causing greater energy expenditure for artificial lighting.

The current market trend is oriented towards hyper-thin films, a few microns thick, highly transparent and at the same time with a better solar control, that are able to guarantee their performances in extreme conditions for periods ranging from five to ten years.

4. The forefront of the glass vacuum system⁴

The research on transparent surfaces, especially in Italy (where they intervene heavily on the existing heritage), doesn't become the research of highly performing double and triple coating components of a reinforced thermal insulation (ITR), but it is oriented to identify high benefits in reduced thickness.

Heat flows through the glass surface by conduction and convection by means of air and gas inside the gap, which serve as the carrier fluid. Imposing vacuum condition means to block the passage of energy by convection and only allow the radiation transfer. The vacuum system allows reaching, in low thicknesses of glasses, insulation performance equal to 0.30 W/m²K: it is necessary a minimum thickness of "empty" to be complied with the standard requirements in comparison with the traditional glass unit with gas.

There are many studies about it and the uncertainties due to its limited uses. The hardest study is the research of clear technical specifications, available on the network, but surely the perspectives let the margins of reducing energy consumption understand, with transmittance values conformed with the *passivhaus*.

The glazing evacuated or vacuum is made up of two glass layers of 3 mm spaced of just 0.2 mm (for a 6.5 mm total component thickness), the surfaces composition depends on the producer but a low-emissivity glass and a clear float glass are used from inside towards outside.

The vacuum condition alters the pressure between the transparent panels, where metal-made spacers of 0.5 mm diameter placed every 20 mm along the whole area of the layer are inserted in order to prevent the implosion.

Most producers analyzed for the IGU system propose their own version of the vacuum system, but only some of them have their own patented product; it's still lower the number of products actually available on the market.

It is interesting to notice, however, the tendency of some Italian companies, which have focused heavily on the vacuum sector, launching their preview products in the most famous exhibitions of products for the construction industry, creating a market segment as an immediate response to the supply for the rehabilitation of the historical heritage.

5. The smart changing glasses⁵

If the research and testing company reserve an infinitely large range of chances and combinations of the glazed surfaces performances, as we have seen, the real avant-garde for the transparent skin of the building is the ability to change, adapting itself to different external conditions.

The chromogenic glasses react to the changing conditions of light, heat, charge or electric field, passing from a state of total transparency to a gradual and more or less quick opaqueness.

The variation acts on the light spectrum of the glass component that passes from the transmitter to the reflector or absorber of the light.

There are two types of chromogenic windows: those activated by external conditions such as temperature and light (photo-chromic and thermo-chromic), and those activated by electrical systems (electro-chromic and liquid crystal).

The photo-chromic glasses pass from a state of high transparency (about 80%, 90% of the visible range) to an opaque state (about 10%, 15% of the visible range) with changing of the solar radiation incident on them. The transition takes place in a natural and rather slow way, and these glasses have good chances for durability.

The thermo-chromic glasses are composed of polymers that change their transparency when the surface temperature varies by passing from a condition of good transparency (80 -90% of visible light) to an opacity condition (20% -30%), they set themselves independently, but they might also benefit from the activation of thin resistors within them.

The electro-chromic glasses are composed of five layers within the glasses; the layers serving as conductors and accumulators act on a layer of tungsten oxide or nickel that is activated when the electric field changes. The variation decreases of about a third the percentage of light transmission (from 50-70% to 10-20%). This type of glasses has a specular appearance both in the active phase and in the passive one; it is necessary to charge the electric field only to start the process.

The liquid crystal glasses are the only ones among the chromogenic glasses to be diffusely available on the market, even in large amounts; its working is due to the constant administration of electricity. The system is made up of molecules encapsulated in a polymer, randomly arranged, therefore the effect of the light radiation is the diffusion of a white-opaque glass, the application of the electric charge puts in order the molecules according to the electric field making the surface transparent (the oscillation is between 60-40% and 40-60%).

There are applications of all these types of glasses in different fields of industry, including aviation, but they are still testing their adaptability to applications in architecture, that have not been established yet, both for the uncertainty of their duration and for their prohibitive costs.

Abstract

Impact of physical pollutions (electromagnetic fields, noise, vibration, ionization etc.) may cause significant discomfort and health damage of inhabitants of urban territories and of workers of industrial enterprises as well as of ecological state of territory. Peculiarities of negative influence of different physical pollutions to the man's health and to environment are considered. During design and construction of industrial objects it is necessary to estimate and forecast expected levels of physical pollutions. Approaches to environmental impact assessment of physical pollutions of territories during design and construction of industrial objects are discussed. It is pointed out that during environmental impact assessment it is necessary to undertake a complex of steps: identification of the most intensive sources of physical pollutions, calculations and measurements of physical pollutions propagation to the nearest living territories and of its impact to the workers of industrial enterprises, estimation of results of calculations and measurements, mapping of physical pollutions, development and implementation of measures to reduce negative impact of physical pollutions. Experience of realization of suggested approaches to environmental impact assessment of physical pollutions of territories are discussed on the example of Samara Region of Russia.

Keywords: Physical pollution, assessment, design, construction

1. Introduction

Modern city may be considered as a sophisticated system with increased impact of negative factors to environment. Some of such factors are physical pollutions, especially noise, vibration, infrasound, electromagnetic fields, ionization etc. [2, 4].

Noise level is increasing together with the cities growth. Noise pollution adversely affects the lives of millions of people. Studies have shown that there are direct links between noise and health. More than 60% of population of large cities is living in exceeding noise conditions [1, 3]. Damaging influence of intensive noise to the human's health is not restricted only by impact to ears. It is known, that noise is affecting to the human's central and vegetative nervous systems, influencing to the human's psychological condition etc. Problems related to noise include stress related illnesses, high blood pressure, speech interference, hearing loss, sleep disruption, and lost productivity. Noise Induced Hearing Loss (NIHL) is the most common and often discussed health effect, but research has shown that exposure to constant or high levels of noise can cause countless adverse health affects. The most serious problems are caused by low frequency acoustic impact.

Recently vibration impact to the urban areas (environmental, industrial, domestic) is rapidly growing. It is difficult to find in modern town the place where vibration is completely absent. Vibration in urban areas may cause serious negative problems up to the buildings and construction breakdown and inhabitants decrease. Vibration and structural noise may cause decrease the operational characteristic, durability, reliability of different kind of power plant and industrial equipment. Among of the negative sequences are destruction of parts and units of machines and equipment, pipelines, junctions of

aggregates etc. Industrial vibration leads to workers disease, fatigue breakdown of pipeline and apparatus junction, disturbance of sealing airproof, decreasing of machine operating characteristics, etc. It should be noted that the accidents connected with pipelines destruction by vibration are rapidly growing and may cause other negative sequences like fires.

It is possible to subdivide two main types of vibration: free and forced vibration. Free vibration occurs when a mechanical system is set off with an initial input and then allowed to vibrate freely. Examples of this type of vibration are pulling a child back on a swing and then letting go or hitting a tuning fork and letting it ring. The mechanical system will then vibrate at one or more of its "natural frequency" and damp down to zero. Forced vibration is when an alternating force or motion is applied to a mechanical system. Examples of this type of vibration include a shaking washing machine due to an imbalance, transportation vibration (caused by truck engine, springs, road, etc), or the vibration of a building during an earthquake. In forced vibration the frequency of the vibration is the frequency of the force or motion applied, with order of magnitude being dependent on the actual mechanical system.

Noise and vibration sources of environment may be divided on two main groups: separate sources and complex sources. Separate noise and vibration sources are: separate vehicles, electric transformers, holes of ventilation systems, plants of industrial or energetic enterprises etc. Complex noise and vibration sources are transport flows at highways and street roads, train flows at railway, industrial enterprises with complex noise sources, stadiums, sports grounds etc.

Electromagnetic radiation (non-ionizing) is the term generally applied to all forms of electromagnetic radiation whose primary mode of interaction with matter is other than by producing ionization. Therefore non-ionizing radiation (NIR) refers to electromagnetic radiation with wavelengths exceeding 100 nm, equivalent to quantum energies below 12 eV, i.e., encompassing the spectrum which includes all radiation sources whose frequencies are equal to or less than those of the near ultraviolet. Scientific, medical, industrial and domestic uses of devices producing non-ionizing radiation are rapidly expanding in type and number, leading to a steady increase in the amount of NIR in man's environment and causing concern about potential health hazards to workers and to the general public from uncontrolled or excessive radiation exposure.

Ionizing radiation is either partical radiation or electromagnetic radiation in which an individual particle/photon carries enough energy to ionize an atom or molecule by completely removing an electron from its orbit. If the individual particles do not carry this amount of energy, it is essentially impossible for even a large flood of particles to cause ionization. Examples of ionizing particles are energetic alpha particles, beta particles, and neutrons.

The ability of electromagnetic waves (photons) to ionize an atom or molecule depends on its frequency. Electromagnetic radiation can cause ionization if the energy per photon, or frequency, is high enough, and thus the wavelength is short enough.

The most dangerous illness caused by the impact of ionizing radiation is cancer: a class of diseases in which a group of cells display *uncontrolled growth* (division beyond the normal limits), *invasion* (intrusion on and destruction of adjacent tissues), and sometimes metastasis (spread to other locations in the body via lymph or blood). These three malignant properties of cancers differentiate them from benign tumors, which are self-limited, and do not invade or metastasize. Most cancers form a tumor but some, like leukemia, do not. The branch of medicine concerned with the study, diagnosis, treatment, and prevention of cancer is oncology. Mutations are changes in the deoxyribonucleic acid sequence of a cell's genome.

Radon is a colorless, odorless gas that can be found in the soil and rocks beneath homes, in well water, and in building materials. Radon is in the soil because the soil contains naturally occurring uranium that eventually decays to radon gas. Radon can get into our homes from the soil through any cracks or holes in the foundation and from the water supply. The radon concentration allowed in water supplies is highly regulated; therefore, it is the radon in air coming in to your home from the ground that can pose a danger.

Radon is estimated to cause many thousands of deaths each year. That's because when you breathe air containing radon, you can get lung cancer. In fact, the Surgeon General has warned that radon is the second leading cause of lung cancer in the United States today. Only smoking causes more lung cancer deaths.

Thus, the impact of physical pollutions (electromagnetic fields, noise, vibration, ionization etc.) may cause significant discomfort and health damage of inhabitants of urban territories and of workers of industrial enterprises as well as of ecological state of territory.

During design and construction of industrial objects it is necessary to estimate and forecast expected levels of physical pollutions. This paper is devoted to discussion of approaches to environmental impact assessment of physical pollutions of territories during design and construction of industrial objects.

2. Environmental impact assessment as a tool of estimation of pollutions

Environmental Impact Assessment (EIA), is now regarded as one of the principal tools in the estimation of pollutions of environment, including physical pollutions. Overall, EIA should be seen as a practical, anticipatory, decision making tool that allows the likely effects of a project upon the environment to be determined, and indicates the need for appropriate mitigating measures to reduce adverse effects and maximise positive effects.

Typical policy requirements for EIA:

- compliance with regional/national/international planning objectives and priorities;
- the assessment of alternative options that provide the same benefits;
- compliance with the requirements of emerging regulatory authorities;
- the increasingly pronounced definition of environmental protection purposes;
- awareness of the public's growing concern for environmental issues and the associated political and economical implications.

EIA began to emerge as a separate and distinct planning tool, allowing the decision makers to weigh up the potential cost and benefits of particular schemes. The basic principle is that prevention is better than cure.

EIA it is required to be undertaken prior to the project receiving authorisation (from planning authorities) to proceed. The term "project" means the execution of construction works or other interventions in natural surroundings and landscape.

Some types of public and private projects (e.g. large thermal power stations or reactors; installations for the reprocessing of irradiated nuclear fuel; iron and steel works; oil refineries, integrated chemical installations; construction of motorways, railway lines, airports etc.) may cause a significant environmental effect and, therefore, prior to the development of these projects, the developers must submit information about the project and, where appropriate, consult all interested parties for their views on the proposal (including members of the public).

Some projects are exempt from EIA. For example, projects serving national defence purposes are not covered.

For the developers of a project it is necessary to undertake an EIA that will identify, describe and assess the direct and indirect effects of a project on the following factors:

- human beings, fauna and flora;
- soil, water, air, climate and the landscape;
- the interaction between these two groups of factors;
- material assets and cultural heritage.

Developers are also asked to provide any appropriate alternatives and justify the options that have been selected. Consultation must take place with all relevant authorities and members of the public who have an interest in the project proposal. These parties are to be given access to the information outlined above and must be given an opportunity to express an opinion before the proposal is taken beyond the planning stage. Likewise, authorities with relevant information are to make this available to the developers on request.

Protection of the natural resources is also part of the protection of human life. However, there are other socio-cultural aspects which require consideration during a planning process and which are part of a comprehensive environmental impact assessment.

Key steps of the EIA process may be determining as following.

1. Screening – determining whether an EIA is necessary for the particular project.
2. Scoping – determining.
3. Gathering information/data.
4. Predicting and assessing the impact.
5. Preparing the "Environmental Statement".
6. Consultations with some parties throughout the EIA.
7. Synthesising the findings and reaching a decision.
8. Monitoring the impacts of the project.

General EIA principles may be described as following:

1. Timing – the EIA should begin at the earliest possible stage in the planning process, integrating with engineers and economic phases of the project planning.
2. Multi-disciplinary – the EIA will require inputs from a number of experts. These should be identified and briefed at the earliest possible stage.
3. Organization – the EIA must be well managed as it will require the assimilation of inputs from various sources.
4. All findings should be based on documented evidence and supported where possible by hard data open to verification.

The EIA process will often not end with the submission of a report or environmental statement. It is necessary to provide continuous monitoring and reconsideration of issues as the project develops.

3. Environmental impact assessment of physical pollutions of territories during design and construction of industrial objects

Industrial enterprises operational activity leads to the negative impact both to environment and to the health of staff. EIA estimation of physical pollutions not only allows to make a conclusion about industrial object construction/reconstruction, but also may be used for taking the required measures for physical pollutions reduction. During environmental impact assessment of physical pollutions it is necessary to undertake a complex of steps: identification of the most intensive sources of physical pollutions, calculations and measurements of physical pollutions propagation to the nearest living territories and of its impact to the workers of industrial enterprises, estimation of results of calculations and measurements, mapping of physical pollutions, development and implementation of measures to reduce negative impact of physical pollutions.

Let us consider some experiences of realization of suggested approaches to environmental impact assessment of physical pollutions of territories are discussed on the example of Samara Region of Russia.

3.1 EIA of noise at industrial site of construction of carbon dioxide production of "Khimteco" Company

The characteristic of noise and vibration differs for the different branches of industry (e.g. machinery, civil engineering, energetic etc.). During operation of chemical plants it is possible to point out as specific industrial equipment (compressors, chemical aggregates, pumps etc.) as chemical processes (oxidation, ammonia production etc.) as the sources of high level noise and vibration. In order to forecast in time possible negative sequences from noise and vibration impact and to develop the measures for efficient noise and vibration reduction it is necessary to carry out the monitoring.

In order to illustrate the examples of noise and vibration EIA at industrial sites of chemical production of Russia let us describe noise EIA at industrial site of construction of carbon dioxide production of "Khimteco" Company.

Carbon dioxide production of "Khimteco" Company it was decided to construct in 2-store building in the Central district of Togliatti city. The nearest living areas are situated at the distance of 2,5 kilometers from the site. Using SLM "Octave 101AM" more than 15 noise level measurements were provided. Example of presentation of measurements data is shown at the figure 1.

Fig. 1: Diagram of spectral characteristics of sound levels for point 1 of measurements (octave and 1/3 octave bands)

Also control measurements of noise levels at nearest living areas were provided. The results of measurements were estimated according to hygiene requirements, stated by valid Sanitary Norms (Sanitary Norms 2.2.4/2.1.8.562-96, Russian State Standards etc.) and Building Norms and Rules [6]. Analysis of measurements results is showing that the most significant equivalent level of sound power is 73 dBA. Calculations of sound levels of industrial site to the nearest living houses of the Central district of Togliatti city have been provided. Methodic of calculations have been described in [9].

Sound pressure level (dB) of the point source on the distance r (m) in homogeneous medium without the absorption is equal to:

$$L(r) = L_p + 10 \lg \Phi - 20 \lg r - 10 \lg \Omega, \quad (1)$$

where L_p - source sound power level (or sound level), dB (dBA);

Φ - factor of source directivity for the point of observation;

$\Omega = 4\pi$ - full space angle, in which the sound is radiated, $10 \lg 4\pi = 11$.

Results of calculations are showing that normative requirements are not exceeded.

3.2 EIA of vibration at industrial cite of construction of energy-efficient production of cycloheksanon of "Kuibyshevazot" Company

It was decided to construct energy-efficient production of cycloheksanon of "Kuibyshevazot" Company situated in the Central district of Togliatti city. The nearest living areas are situated at the distance of 2 kilometers from the site. Using SLM "Octave 101AM" more that 20 noise level measurements were provided. The scheme of measurements is shown at the figure 2. Example of presentation of vibration measurements data for the point 9 (direction z) is shown at the figure 3.

Fig. 2: The scheme of points of vibration measurements at industrial cite of construction of energy-efficient production of "Kuibyshevazot" Company

Analysis of results of measurement of vibration of energy-efficient production of cycloheksanon of "Kuibyshevazot" Company shows that maximal value of vibration according to equivalent correcting level of vibration acceleration is in point 9 and equal to 92 dB. Analysis of potential sources of vibration generated in the industrial site of construction of energy-efficient production of cycloheksanon of

"Kuibyshevazot" Company after beginning of exploitation have been carried out by using of technical documentation, studying of used industrial equipment and of kinds of technological processes. Results of analysis are showing that maximal values of vibration according to equivalent correcting level of vibration acceleration will not exceed 95 dB. It means that vibration levels are fitting to Russian sanitary norms rules.

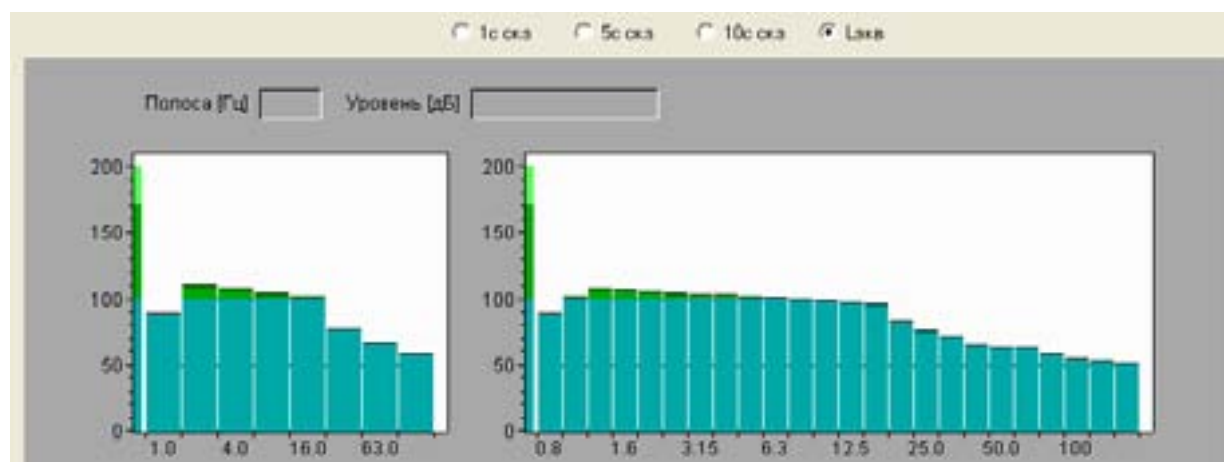

Fig. 3: Diagram of vibration measurement results for point 9 (direction z) at industrial cite of construction of energy-efficient production of "Kuibyshevazot" Company

Fig. 4: The scheme of points of vibration measurements at industrial cite of construction of polyamid-6 production of "Kuibyshevazot" Company

3.3 EIA of electromagnetic fields and ionizing radiation at industrial cite of construction of polyamid-6 production of "Kuibyshevazot" Company

It was decided to construct energy-efficient production of polyamid-6 of "Kuibyshevazot" Company situated in the Central district of Togliatti city. The nearest living areas are situated at the distance of 2 kilometers from the site. Using SLM "Octave 101AM" more that 20 noise level measurements were provided. The scheme of measurements is shown at the figure 4.

For estimation of ionizing radiation dosimeter of gamma-radiation DKG-07 D "DROZD" was used. In total 45 measurements of power of ambient equivalent of doze of gamma-radiation and of ambient equivalent of doze of gamma-radiation have been carried out in 15 points. Requirements of radiation safety in Russia are determined by Norms of radiation safety in form of main doze limits, admissible levels of impact of ionized radiation and according to the other requirements for restriction of man's radiation exposure. Efficient doze for population for the all period of life must not exceed 70 mZv, for one year – 1 mZv. Natural ionizing radiation background must not exceed 0,2 mkZv per hour.

Analysis of measurements results of ionizing radiation levels at the site of construction of energy-efficient production of polyamid-6 of "Kuibyshevazot" Company have showed that exceeding of normative values is absent. Maximal level of power of ambient equivalent of doze of gamma-radiation was in points 5 and 14 and not exceeding of usual background values. Potential sources of ionizing radiation generation after starting of production exploitation are also absent.

For estimation of electromagnetic field of industrial frequency range meter of intensity of field of industrial frequency PZ-50 was used. For estimation of electromagnetic field of radio frequency range small-size microprocessor meter of intensity of field IPM-101 was used. In total over 100 measurements of electromagnetic fields of different frequency ranges have been provided. All measurements results are correspond to sanitary requirements.

Example of mapping of electric part of radio frequency range electromagnetic fields measurements at industrial cite of construction of polyamid-6 production of "Kuibyshevazot" Company is shown at the figure 5.

Fig. 5: Mapping of electric part of radio frequency range electromagnetic fields measurements at industrial cite of construction of polyamid-6 production of "Kuibyshevazot" Company

4. Conclusions

It was shown that physical pollutions influence during exploitation of industrial enterprises may cause significant negative impact to the health of population and to environment, therefore it is necessary to carry out environmental impact assessment (EIA).

Methods and results of EIA of physical pollutions at industrial sites of enterprises of Samara region of Russia have been described. Main physical pollutions sources of the industrial enterprises have been considered. Methods and values of some physical pollutions of industrial enterprises estimation are described in the hygiene requirements, stated by valid Sanitary Norms and Russian State Standards. EIA estimation of physical pollutions not only allows to make a conclusion about industrial object construction/reconstruction, but also may be used for taking the required measures for its efficient reduction.

Abstract

Lubricating cooling liquids are widely used as in industry as for domestic purposes. The problem of its negative influence to the human's health and to environment have become especially important for the last years due to the significant volumes of it and the high toxicity. Results of analysis of negative influence of lubricating cooling liquids to the human's health and to environment are described. Methods of classification of negative impact of lubricating cooling liquids are suggested including its biological, chemical and physical features. Approaches to lubricating cooling liquids negative impact reduction are suggested. The main directions of lubricating cooling liquids reduction are including:

- Using of ecologically safe materials instead of lubricating cooling liquids;
- Treatment without using of lubricating cooling liquids;
- Treatment with minimal using of lubricating cooling liquids.

It is pointed out that only design and implementation of complex of methods may give efficient results and significant reduction of negative influence of lubricating cooling liquids and to reduce the damage to the environment and to the man's health.

Keywords: Lubricating cooling liquids, classification, reduction

1. Introduction

Lubricating cooling liquids are widely used not only in industry, but also for domestic purposes. The problem of its negative influence to the human's health both in industry and in domestic conditions have become urgent for the last years as due to the significant volumes of it as or the high toxicity.

Mainly lubricating cooling liquids are the mineral oils or the oils with wear-protective additives or its water emulsions consisting of water, mineral oils, emulsifiers, inhibitors of corrosion, bactericides or other dangerous components.

Due to its chemical nature lubricating cooling liquids may cause different negative impact to the humans leading to the damage of cardiovascular and respiratory systems, skin damage, toxicity poisoning and other negative sequences.

According to the results of many researches, all existing marks of lubricating cooling liquids are toxic and having the different degrees of toxicity (from hyper toxicity to middle toxicity). It contains components polluting the environment: oil products, ether extracting particles, fatty acids etc.

That is why it is important to make an analysis of lubricating cooling liquids negative influence to the human's health and to suggest the ways of its reduction.

This paper is devoted to development of approaches to classification and to reduction of negative impact of lubricating cooling liquids.

2. Analysis of negative influence of lubricating cooling liquids to the human's health and to environment

Lubricating cooling liquids (LCL) may cause negative influence to the man as in result of direct contact with skin of man or due to the contact through the special protective clothing and also in result of

penetration of gases, aerosols, condensate of LCL to the human organism through the respiratory system.

Analysis of special features of negative influence of lubricating cooling liquids to the human's health shows that it tends to the growth of professional illnesses of workers of different branches of industry. E.g. in Public Joint Stock Company "AVTOVAZ" it tends to increase the growth of such professional illnesses as bronchitis and eczemas.

Statistics of distribution of illnesses caused by lubricating cooling liquids impact in conditions of Public Joint Stock Company "AVTOVAZ" for men and women (years 2002-2012) is shown in figure 1.

Influence of used lubricating cooling liquids is especially dangerous both for man and for environment. It is well known influence of lubricating cooling liquids to the man's health in industrial conditions. One of the main sequences of lubricating cooling liquids impact are professional illnesses. Analysis of scientific papers in this field is proving the that aerosols of lubricating cooling liquids may cause pneumonia, cause skin illnesses, damage heart muscles, liver and kidney [1, 5, 7, 9]. Moreover, it is determined that products of thermal destruction of harmless components of lubricating cooling liquids as well as possible chemical formations in zone of treatment are also may cause negative impact to the man's health.

Due to the chemical nature lubricating cooling liquids are causing negative impact to the workers in industrial conditions in result of direct contact with skin and as result of lubricating cooling liquids evaporation. Degree of negative impact is depending to the chemical composition of lubricating cooling liquids; conditions of treatment of metals; conditions of surrounding microclimate.

Influence of lubricating cooling liquids may cause significant negative impact to environment mainly due to the toxic impact. For example, atmosphere pollution by lubricating cooling liquids impact may occur not only in the process of it exploitation, but also due to evaporation and combustion of lubricating oils. Used lubricating cooling liquids may be considered as dangerous toxic wastes, utilization of which is very difficult [3].

It should be noted that even feebly toxic medium may cause significant negative influence on water reservoir biota. Waste waters of industrial enterprises are containing LCL causing toxic impact to water resources. For example, waste water of Public Joint Stock Company "AVTOVAZ" is causing low toxic impact to Kuibyshevsky water reservoir. Therefore it is very necessary to develop efficient methods and means of further minimization of negative impact of toxicity of LCL.

Fig. 1: Illnesses caused by lubricating cooling liquids impact in conditions of Public Joint Stock Company "AVTOVAZ" for men and women (years 2002-2012)

3. Classification of negative influence of lubricating cooling liquids to the human's health and to environment

Environmental control of toxicity is a complex procedure including estimation of sources of toxicity, determination of the most potentially dangerous zones of toxicity of urban territories, selection of

methods for estimation of toxicity, analysis of results of estimation of toxicity, conclusions about the degree of toxicity, and, finally, development and implementation of methods concerning reduction of negative impact of toxicants.

New method for estimation of toxicity has been suggested by the authors of this paper. Characteristic feature of the developed method in comparison with existing methods is complex consideration of the main toxicological values of toxicants (e.g. lubricating cooling liquids) on the basis of its point-rating ranging.

The following toxicological characteristics have been taken into consideration:

- irritating effect on eyes;
- skin-resorptive effect;
- sensitizing effect;
- toxic particles assignable under exploitation of lubricating cooling liquids (number of singled out toxicants and its class of danger);
- toxicity during inside-stomach injection.

In table 1 the scheme of distribution of points during estimation of degree of toxic effect of lubricating cooling liquids on the man and environment is presented.

TABLE I

DISTRIBUTION OF POINTS FOR ESTIMATION OF DEGREE OF EFFECT OF TOXICANTS ON THE MAN AND ENVIRONMENT

Name of indicator of estimation	Parameter of estimation	Points
Irritating effect on eyes	No effect	0 points
	Weak effect	1 point
	Irritating effect	2 points
Skin-resorptive effect	No effect	0 points
	Weak effect	1 point
	Irritating effect	2 points
Sensitizing effect	No effect	0 points
	Weak effect	1 point
	Irritating effect	2 points
Toxic substances assignable under exploitation of lubricating cooling liquids (for estimation the substance corresponding to the most high class of danger is selected)	I class of danger	4 points
	II class of danger	3 points
	III class of danger	2 points
	IV class of danger	1 point
Toxicity during inside-stomach injection (medium mortal dose (LD ₅₀) under injection into the stomach)	LD ₅₀ ≤ 5000 mg/kg	2 points
	LD ₅₀ > 5000 mg/kg	1 point
	Toxic impact is not determined	0 points

4. Classification of negative influence of lubricating cooling liquids to the human's health and to environment

The general ways of lubricating cooling liquids negative impact reduction are shown in fig. 2. It is suggested to subdivide the ways of lubricating cooling liquids reduction into three main directions:

- Using of ecologically safe materials instead of LCL;
- Treatment without of using of LCL;
- Treatment with minimal using of LCL.

Traditional approach to reduction of negative influence of by lubricating cooling liquids to environment is its utilization. But utilization of used LCL it is not safe and rather expensive.

As an alternative to the expensive and ecologically dangerous process of LCL utilization is investigation and implementation of methods of reduction of using of LCL or the full avoiding of LCL using during technological operations. According to the data of Swiss company «Micron SA Agno», the average cost of lubricating cooling liquids used for one lathe daily is equal to the sum of 50-250 of US dollars. It means that annually company «Micron SA Agno» spends the money for application of

one lathe approximately 12 750 - 63 730 of US dollars. For machines building enterprises the average cost of lubricating cooling liquids used for one lathe is equal to 8000 US dollars annually.

Avoiding of using of lubricating cooling liquids allows to increase also the quality of manufactures parts, for example in work [2] is shown that chemically-active elements of LCL are causing the reduction of endurance and corrosion protection of surfaces of details. It should be noted that the absence of lubricating cooling liquids in zone of treatment allows to use more widely an active control in process of treatment and to eliminate the effect of heat shock on the surface of the instrument.

Avoiding of using of lubricating cooling liquids in the process of treatment force to decide the following main problems:

- Withdrawal of heat from the zone of cutting;
- Reduction of coefficient of friction in the process of treatment;
- Moving off shaving from the zone of treatment.

Analysis of authors is showing that presently technologies of ecologically sound treatment without of lubricating cooling liquids only for 10% of all existing lathe equipment in Russian Federation and in West countries.

The more carefully the questions of treatment without of using of lubricating cooling liquids are investigated in West European countries, and also in USA and in Japan. In these countries different kinds of blade and abrasive processing without of lubricating cooling liquids are investigated: drilling, turning, grinding, glazing.

Review of Russian and foreign literature allows to point out the basis of investigations of dry treatment by using of methods of surface plastic warping and allows to determine the ways of decision of problems arising during the treatment without of lubricating cooling liquids. Such process of treatment is mostly convenient for the primary stage of investigations of processes occurring during the dry treatment because it has no such intensive heat emission and chip forming as cutting or grinding. Thus, the main task is reduction of coefficient of friction between the instrument and procurement.

Implementation of new technology allows to decide the following problems: —

1. Reduction of expenses, because of the most of lubricating cooling liquids on the basis of oils are having comparatively small flash temperature.
2. Improvement of labor conditions, because of lubricating cooling liquids components may cause different illnesses.
3. To increase ecological safety of industrial production because of losses during the leakages and of carry-over, emission, flushing water and utilization of waste LCL are polluting soil, water and air.
4. To reduce the expenses for purchase, storage, transportation and utilization of lubricating cooling liquids.
5. To increase the quality of treatment due to expansion of possibilities of using of the means of active control.

It should be noted that monitoring of the state of environment is also efficient way of estimation and of forecasting of changes of the state and of pollution of biosphere or of it separate components under the impact of lubricating cooling liquids. Presently many scientists are carrying out researches for using of different biological indicators as test-objects. In a meantime, estimation of degree of toxicity of lubricating cooling liquids is having certain specific and needs in detailed examination.

Analysis of literature sources shows that during the estimation of toxicity of several objects of biological testing (including also lubricating cooling liquids) the mostly generally studied. It is reasonable to use as a test-objects of green algae *Chlorella* (*Chlorella vulgaris* Beijer), ПНД Ф 14.1:2:4.10-04, 16.1:2:3:3.7-04, and of crawfishes *Daphnia magna* Straus, ПНД Ф Т 14.1:2:4.12-06, 16.1:2:3:3.9-06.

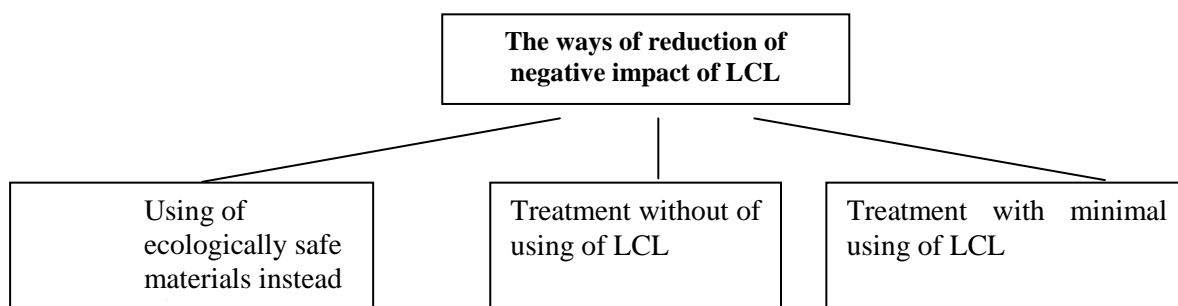

Fig. 2: The main ways of reduction of negative impact of lubricating cooling liquids (LCL)

Above mentioned methods are accredited in Russia. It allows to obtain rather high precision of results

during it using for researches.

Generally, only using of complex of methods may give efficient results of significant reduction of negative influence of lubricating cooling liquids.

5. Conclusions

Lubricating cooling liquids are used in industry in large volumes. Due to the high toxicity and other negative characteristics lubricating cooling liquids may cause significant negative impact both to the man's health and to environment. Analysis of special features of negative influence of lubricating cooling liquids to the human's health shows that it tends to the growth of professional illnesses of workers of different branches of industry. Statistics of lubricating cooling liquids impact in conditions of Public Joint Stock Company "AVTOVAZ" is described and analyzed.

New method for estimation of toxicity has been suggested. Characteristic feature of the developed method in comparison with existing methods is complex consideration of the main toxicological values of toxicants (e.g. lubricating cooling liquids) on the basis of its point-rating ranging.

The scheme of distribution of points during estimation of degree of toxic effect of lubricating cooling liquids on the man and environment is presented.

The general ways of lubricating cooling liquids negative impact reduction are described. It is suggested to subdivide the ways of lubricating cooling liquids reduction into three main directions: using of ecologically safe materials instead of LCL; treatment without of using of LCL; treatment with minimal using of LCL. It is pointed out that as an alternative to the expensive and ecologically dangerous process of LCL utilization it is reasonable to investigate and implement the methods of reduction of using of LCL or the full avoiding of LCL using during technological operations.

Monitoring of the state of environment is also efficient way of estimation and of forecasting of changes of the state and of pollution of biosphere or of its separate components under the impact of lubricating cooling liquids. Different methods of LCL impact monitoring are discussed.

Generally, only using of complex of methods may give efficient results of significant reduction of negative influence of lubricating cooling liquids.

The iso 50001: a tool of energetic management of architectural public heritage

Monica Cannaviello,¹

⁽¹⁾ Department of Architecture and Industrial Design "L. Vanvitelli"- Second University of Naples
Aversa (CE), Italy
monica.cannaviello@virgilio.it

Abstract

The energy efficiency of the architectural public heritage is a strategic goal of Europe. This type of buildings should be, in fact, an example for the entire construction industry. In fact, the actions taken by the government about its heritage in order to improve the energy performance is twofold: on the one hand they bring direct benefits in terms of reduced fuel consumption, on the other hand they are demonstrative projects that act as incentives for the construction private sector.

To achieve the expected levels of energy efficiency, it is not sufficient to impose minimum requirements to be met. It is important to act with the support of voluntary instruments. From this approach, the international standard ISO 50001 - Energy Management System, originates.

Particularly, the ISO 50001 was created with the objective of promoting the development and implementation of policies aimed at improving energy efficiency, and it's applicable to any organization wishes to communicate to the outside world the conformity of its energy policy.

The ISO 50001 is a very useful tool for the public administration that wants to improve its energy performance in a systematic way. The Energy Management System can be considered an effective tool for continuous improvement to manage the energy efficiency of public building, because the buildings are usually the most significant portion of the energy consumption of a public administration.

Keywords: energy efficiency, public heritage, Energy Management System

1. European targets for energy efficiency for public heritage

The energy efficiency of public heritage is a strategic objective at European level. The legislature has clearly spelled out in the Directive 2010/31/EC known as the Energy Performance of Building Directive (EPBD) recast, which replaces the 2002/91/EC, stating that for the buildings occupied by a public authority or at least open to the public, the obligation to be "nearly zero energy" will start with two years ahead of all the other buildings.

This is motivated by the exemplary nature of this type of building, which should take a leading role in the path towards the energy efficiency of the entire construction sector. In fact, the actions taken by government on its assets in order to improve the energy performance are twofold: on the one hand make direct benefits in terms of reduced fuel consumption from fossil fuels and consequently emissions, on the other hand should be aimed at illustrating that act as a stimulus for the private sector.

This intention of the EU to focus on public buildings is also confirmed in the Directive on energy efficiency 2012/27/UE [5] which entered into force December 5, 2012 and must be transposed by 5 June 2014. It amending Directives 2009/125/EC and 2010/30/EU and repealing Directives 2004/8/EC and 2006/32/EC.

Chapter II is for efficiency in energy use and, in particular art. 5 deepen the "Exemplary role of the public bodies' buildings".

For heated and/or cooled buildings owned and occupied by its central government, with functional areas greater than 500 square meters, the Directive introduces the requirement to renovated each year at least 3% of the total useful floor area, to meet at least the minimum energy performance

requirements that it has set in application of Article 4 of Directive 2010/31/EU. Since July 2015, the renewal will also cover public buildings that have functional areas greater than 250 square meters.

This requirement is very significant and is related to the fact that in Europe the setting of minimum standards, even if severe, only for new buildings and those undergoing substantial restructuring, it is not a sufficient measure to drastically reduce energy consumption. The new building represents a marginal part (just over 1%) compared to the entire building stock. The public heritage, in particular, is mainly composed of old buildings and highly energy-intensive. And the public bodies hardly decide "spontaneously" to renovate its buildings, to improve energy performance requirements.

In this sense, the article 5 of the Directive 2012/27/UE is certainly an interesting addition to improving the energy efficiency of public housing.

The energy efficiency measures should be primarily aimed:

- buildings with "the poorest energy performance "
- where is " cost-effective and technically feasible "

In order to make these assessments it is necessary that the central government has, for each building, an updated energy audit or energy performance certificate within which is located a scale of priorities for redevelopment energy as a function of ' cost-benefit analysis.

Always article 5 provides that, no later than 31 December 2013, Member States shall establish and make publicly available an inventory of heated and/or cooled central government buildings with a total useful floor area over 500 m², which must include , for each building, as well as the covered area also its energy performance or relevant energy data.

Member States should also be encouraged among other public bodies, including at regional and local level, to

- adopt an energy efficiency plan, containing specific energy saving and efficiency objectives and actions,
- put in place an energy management system, including energy audits, as part of the implementation of their plan.

2. The tools: the role of ISO 50001

To achieve the levels of efficiency expected by the European Union to impose minimum requirements to be met, as well as resulted from Directive 2002/91/EC, now replaced by 2010/31/EU, is a necessary, but not sufficient. It is essential to act through voluntary instruments, the application of which is expressly determined by the organization that decides to use them and not from external impositions.

From this assumption flows the international standard ISO 50001 (International Standard for Energy Management) related to Management Systems for Energy.

The ISO 50001, which represents the development of the European standard UNI CEI EN 16001 "Energy Management Systems - Requirements and Guidelines for Use", is part of the voluntary instruments for environmental management, together with ISO 9001 therefore for the management of quality in the processes, and the ISO 14001 certification for the improvement of environmental performance. These types of rules, created initially in the industry, you are then spread to other types of private and especially public.

In particular, the ISO 50001 was created with the aim of promoting the development and implementation of policies aimed at improving energy efficiency, and is applicable to any organization wishes to communicate to the outside world the conformity of its energy policy.

The voluntary approach of the standard involves an active attitude in the definition of the objectives in the implementation of the measures needed to achieve them, and also offers the advantage of each organization to establish from time to time objectives, both in terms of quality and quantity and the relative timing of implementation, depending also on the financial resources available.

The ISO 50001 appears therefore as a very useful tool in the hands of a public administration that wants to improve their energy efficiency systematically. And because the buildings are generally the most significant slice of the energy consumption of an Entity, then, the Energy Management System can be considered an effective means for continuous improvement (in line with the provisions of the Deming cycle: Plan, do, check, act) the energy efficiency of public housing.

First the body which decides to implement an Energy Management System must define its own "energy policy."

It is important to highlight that the ISO 50001, like the other tools of a voluntary, does not define minimum criteria for energy performance, but give how to organize systems and processes aimed at continuous improvement of energy efficiency. The main objectives are to bring economic benefits to organizations resulting from lower energy consumption and benefits to the community, especially in terms of reducing greenhouse gas emissions.

One of the key points of the energy policy is the commitment made by the Organization to comply with applicable laws and regulations. This aspect may seem trivial, but often it is not.

Suffice it to say that the law 192 of 2005 requiring all public buildings to adopt energy performance certificate (ACE), which was to be displayed in a prominent place clearly visible to the public. Well, at a distance of about eight years, many public buildings are in fact accompanied by ACE?

The next step is what is called the Energy Planning. This schedule, which of course must be consistent with the energy policy previously defined, takes its cue from the identification and analysis of energy aspects considered significant. This means understanding what are the processes that use energy and is the basis to identify opportunities to improve energy performance and prioritize interventions to reduce consumption.

Fig. 1: Scheme of Energy Management Systems

It is considered significant when an energy aspect, in addition to affecting a high proportion of energy consumption can impact on one of the following aspects:

- a more efficient use of energy
- increase the use of renewable energy on site
- a greater exchange of energy with the rest of society

The building heritage is certainly one of the most significant energy aspects of a public body.

The process of energy planning must start from the analysis of energy use and energy consumption of the building, past and present. This allows you to identify areas of significant energy use and consumption within the building. Through the evaluation of fuel consumption and performance you can get help to put in place plans to improve energy efficiency and to define the scale of priorities.

The best tool in this regard is represented by Energy audit.

The D. Lgs. 115/08 defines 'energy audit' a systematic procedure to:

- Provide adequate knowledge of the energy consumption profile of a building or group of buildings, of an asset or industrial facility or public or private services;
- identify and quantify energy saving opportunities in terms of costs and benefits;
- report on the results.

It just arise from the audit will require energy and energy objectives, which shall be consistent with the energy policy, both targets, which must be consistent with the objectives.

The audit will arise also the action plan through which the organization intends to achieve its objectives and targets.

3. The professional in charge of the implementation of an Energy Management System

Once identified the Energy Management System as the most appropriate tool to improve the energy efficiency of public housing, it is also necessary to identify the most suitable professional to use this tool.

Start by saying that if a public administration in one year consumes more than 1,000 tons of oil equivalent (TOE), are obliged by law 10/91 the appointment of a consultant for the rational use of energy, called "Energy Manager".

The functions and the profile of this professional are defined inside a circular MICA N219 / F.

The E. M. must be a "professional with functions that support the decision-maker about the best use of energy in the structure of its competence, however, having no responsibility for the effective implementation of actions and interventions proposed, but only in relation to the technical and economic viability opportunities that have been identified "

The ISO 50001 specifies that the top management shall appoint a representative who shall have defined roles, responsibility and authority to ensure that the energy management system is established, implemented and maintained in accordance with the standard. This representative must possess appropriate skills and competencies. The Energy manager represented, until a few years ago, the only figure in a government that had the tasks of management and rationalization of energy use and that it was therefore unable to perform the tasks previously identified.

The liberalization of energy markets and the continuous updating of the energy and environmental measures and financial instruments, have necessitated a new professional, modern and interdisciplinary expert in energy management (EGE). This figure, which associates, technical skills in the field of energy, solid foundation in environmental matters, economic-financial, business management and communication, lends itself very well to the role of head of the Energy Management System under the ISO 50001.

4. Conclusions

As was made clear in the preceding paragraphs, Europe assigns public building energy efficiency a strategic role as early as 2002 with the first EBBD directive. The Directive 2012/27/UE strengthens the exemplary role of such buildings and invites public administrations to adopt Energy Management Systems. The consideration is that which arises from the application of a SGE of a public building can result in considerable benefits in terms of energy efficiency.

The centrality of the role of public buildings in energy efficiency targets has also been reaffirmed in the assembly of the States General of the Green Economy, which was held in Rimini in November 2012. The States-General, promoted by an organizing committee which includes the Italian Minister of the Environment and the main associations of undertakings "green", are intended to steer the Italian economy towards a more sustainable approach. The final acts of the assembly have shown that, by acting with energy efficiency measures on 11,000 offices, 30,000 school buildings and buildings of 70,000 social housing, you can achieve energy savings of 1 to 2020 Mtep, equivalent to 33% reduction in consumption in the buildings considered.

Among the objectives identified by the working group for "energy efficiency and savings" are highlighted those "facilitate energy efficiency in Public Administration" and "to promote energy management systems and training of energy managers and experts in management of energy ".

This confirms the idea that these objectives are strongly correlated, and that ISO 50001 represents a new and powerful tool in the hands of a public administration to improve continuously and systematically, the energy efficiency of their housing stock.

DESIGN AND HANDCRAFT FOR NEW CREATIVE DIMENSIONS OF INDUSTRY

Marco BORRELLI

Department of Architecture and Industrial Design, Second University of Naples, Aversa, Italy
marco.borrelli@unina2.it

Abstract

The famous definition “*farewell to growth*” by **Serge Latouche** develops new considerations in the scientific debate concentrating on the economic and social issues as well as relating to the purpose of design in standardized production which is concerning the global economic crisis identifying the new millennium in a negative direction. Research focused on the furniture product's theme tries to recover the creative value, expressed more effectively through the productive dimension of the prototype, and encourages the development of **new methods** of production standing between **handcraft and industrial** production.

The actual economic crisis is weakening the great standardized industrial production and the growth of small and medium enterprises is considered as the “*innovative company*” which is getting its strength from the peculiarities of the local areas such as more material resources, human and identity, as well as a greater appreciation of the local handcraft traditions.

Therefore, supposing a process and technique's review proposed by the industrial production model, in order to recover the local identity for the processes and products regeneration, it will be better to use an alternative model of technological and industrial development through the promotion and rediscovery of sustainable handcrafted processes and eco-friendly products strictly linked to the cultural and territorial values.

Finally, the aim is the revaluation of a creative figure expressed through traditional handcraft methods (makers) capable of enhancing the size of the test through the prototype of a designed project idea.

Keywords: Handcraft Design, Slow Factory, Innovative Company, Soft Technology, Self-production

1. From the artisans' knowledge to the knowledge of the project designer: contamination of the creative process to improve production competitiveness.

The opportunity to participate in the convention entitled “Design, technology and craftsmanship: prospect and trends” promoted as the Report of the outcomes of the Furniture Fair of Milano 2013, held during the event Campania Design week, has prompted me to collect part of the scientific research work around the theme of the virtuous relationships that exist between design, productive technology and creative process, framed in the current time of economic social and ethical crisis. The scientific research, in the schools where it deepens the **culture** of the project design, to keep pace with the times, has to deal with a situation of uncertain productivity since the models of economic and industrial development are slowing down and primarily for the delivery of a new philosophy of

consumption focusing on a more fuel efficient lifestyle, that is more careful and therefore more sustainable.

Starting from the famous definition of “**peaceful decrease**”¹ of Serge Latouche numerous considerations and guidelines have been developed, in the social and economic field, that in my opinion, discusses the role of **design** in **standardized production**.

1.1 Social-economic scenery

The social-economic development of these recent years continues to be based on an economic weakness that has slowed the markets by reducing employment and production capacity of enterprises to such an extent so as to create a process of **recession** that is no longer manageable. The production slowdown that results can be considered a consequence of a series of “**excesses**”, accumulated during the last decades of the last century, the result of a capitalist system inherited and imposed, and also considered as the results of the model that today is now promoted and adopted from the **knowledge** of economy and that result too formalized, too encompassing and too global. Leveraging on a form of economy linked to knowledge, replicability of the knowledge and the use of the product, in the field of the **design**, it has favoured an excessive of generative capacity that cannot find more grip and acceptance in the market, and the new life philosophy suggested by those currents of thought emerging that are based on the concept of **peaceful decrease**.

Fig.1 Presentation picture of the evolution of man that favours natural evolution

According to this “thinking”, the world is full of objects and design, aware of this new trend devoted to the control of resources and the consequential reduction of waste, has to be prepared to **respond** to new lifestyles, and consequential new styles of **consuming**, no longer through the *invasion* of the market with **unnecessary** products, how has been done and continues to be done, but mainly proposing **solutions** that are designed to spread a culture richer in the content of a promoted and responsible production, paying attention to sustainability and recovery, that moves away from the devastating ideology of **disposable**².

1.2 The soft factory

What follows, analyzing the emerging theories of this *new vision*, is the possibility of adopting **alternative** types of economic-productive, even more closer and closer to the **slow model** (and an initial reference of this thought can be certainly be considered the *Slow movement*³ in particular with *Slow Food*, long been a well established on the market, in the specific field of agro-industrial , born as an alternative to the illness of frenetic consumerism of the poorly health of the fast generation.) This

new state of *conscious of economic slowdown* is progressively leading to a new trend in which the size of the deal with the **slowness** is an **advantage** rather than a defect to contain and suppress, contrasting sharply with the standards imposed by the speed and progress induced by the Second Industrial Revolution and the processing in steps promoted by the taylorist assembly line. Even current economic models consider fundamental paradigms between them the value of slowness that coincides with the profound quality, with attention to the details, in contravention of the customary law in contrast to the scheme of the "cage imposed by the scientific management"⁴ around which, for decades the success of the market has been established.

In such a ferment, slowness takes the lead new proposal and *new needs*, to which only a **manufacturing process** that follows new and different dynamics more sensitive, slower, more attentive to the creative dimension, typical of the culture of the current design, can be significantly characterized new habits of consumption.

The anticipated growth planned for the first quarter of the 2014⁵-showed desire for new needs, to **dare**, as a response of the economic downfall, through the increase of the activism in the seeking employment, even more to create it. This **trend** is due, in part, to the positive results derived from the enterprises that have adopted different strategic guidelines and, in a sense, in a new **trustworthy** man crafting that has revived to an interest to production and to do business through the rediscovery of the value of the **talent** of craftsmanship.

1.3 The Innovation through "Future Craftsman"

The Desire to Dare, feature phase youth of the life of every human being, seems to be the right road **inventing** a job and an employment in fact, we might say, inventing the *project company*. If the business and production appear too static to the point of not hiring and promoting the contribution of young minds active and creative able to promote the new, but considering expected but strangely still a success productive current economic model, in fact it happens that always more of the young creative are rejected by this productive system, they strive to self-style "do it yourself" *Anglo-Saxon* manner, through new forms of Entrepreneurial Development known as the term **start-up**⁶. Perhaps, in coincidence with the view expressed by Stefano Micelli in the Future Craftsman⁷, "... the work is not to be sought, instead it's created..."⁸ many young people get activated in various parts of Italy (in this case there is no distinction between north and south, we are all united under the ideology of "roll up our sleeves"), driven by a new spirit loaded of life energy and, encouraged by the possibility of access to a series of differentiating announcements and funding, they are organized to share and spread orient the future Working towards new opportunities that reward **creativity**. A classical example of post visible in the web come to witness a race of ideas organized by Ninja Marketing Napoli¹⁰ where are activated new forms of viral communication focused on the promotion **innovation and technology** among youth and between young people spreaded through a new model and a little 'provocative *guerrilla marketing*¹¹.

So its born a new way of thinking at work, a new idea of doing enterprise. This spirit adventurer characterized the passion of "doing" is also the road which should tend more towards the world of entrepreneurship and industrial too still and anchored in the habit of their partner, that manipulate to its liking, instead favouring a greater specialization and a greater **new figures** qualification of operators (designer), talented of very good ideas, good capacity management and great practical sense. The traditional relationship between industry and distribution (including Also the GDO) has lost value because through new tools for communication and dissemination of the web, it has introduced new logics, new tools and new approaches that open up completely new markets overturning the old rules.

1.4 The rebirth through new forms of contamination

The main objective consists in relying on **talent** and **creativity** that feeds of the effervescence of the youth, in order to improve the integration between phase ideational and realization phase, that result more able to make a more efficient production system because it improves the competitiveness of its products in the current market through the provision of Shared Values (Sharing the Retailers that shared distribution tied to concepts economy hybrid¹²) and widely supported by new systems appreciation widespread In the culture of the Web and in the dynamics of distribution linked to the short chain¹³. The **rebirth of productive companies** and diversified industrial sectors from different scales can occur, however, only through a greater focus to offer these new dynamics of sharing of the project and

product **laboratories experiencing new production free, alternative and creative (Fabrication Laboratories)** that the world and the market seems to be ready to welcome today more favourably, so perhaps new tools Intangible promotes the internationalization because global joins the size that a local (glo-cal¹⁴) by way of information and the sharing expressed through virtual communities that creates a new trading system that in the past struggled to institutionalize small Creative Workshop. Greater propensity for research and investment for the development and adoption of new technologies experimental places produced in places where some of the young people and creativity, in the places of the knowledge of diffusion, culture of the university is a new form of dialogue capable of build connecting bridge between reality industrial inclined only at the cost-benefit ratio and the creative world that have gotten back in a solitary dimension in a domestic artesian laboratory and in the threading of small reality chain of small business continuously enriched the knowledge in gated community in creative territories.

The current disconnect between production and creation must mend the breach that has been created in the last years of the twentieth century favouring a synthesis between the two worlds that for too long have opposed statically and that today the market wants to encourage a convergent contamination of knowledge and skills not disjoint more's techniques and processes product processing. Perhaps the recognition of the dominance of large retail of manufacturing industry has authorized the subversion of old relations of production and economic rules that for almost a century had powered a system that then has degenerated into a mechanism that has diminished the creative contribution of 'man and that advantages too automated production and everything suffocates. The economic and social crisis has place more clearly the limits of this system making it necessary to revise the Taylorist model, intercepting, through the help of new process technology also accessible to those who are not a part of this system, a new attitude simultaneous complicity, and an instinctive traits, of doing, thinking and producing.

1.5 Emerging figures and new protagonists

There are many signs of this new trend as there are numerous occasions where the **new protagonists** of doing business make progress: the *Crafters*, namely the category of highly skilled craftsmen who, starting from their own vocation, expand it, *contaminating it* with new digital technologies thus characterizing the emergence of a new category of creative talent, the *Makers*.

These digital cousins, while being capable of producing artefacts, even if only in some specific sectors, integrate operational expertise to current technologies and digital tools through the new 3D printers, with the result of combining the immaterial stage of the creative process to the immediate implementation of a prototype, also starting from a simple mock-up¹⁵, until completion of the construction phase of the production process. It is therefore evident that the *makers*, compared to the *crafters*, represent the *advanced stage of doing craftsmanship*, with the doing not only taking advantage of *technique* but also on the basis of the *designer's own creative process*.

Fig.2 The thinking hands of a craftsman who designs and produces as if a self-producing designer

It is difficult to count the number of events, fairs and exhibitions of objects, furniture and garments that fall into the category of self-production, due to the trend of the design, now more than ever, using new forms of promotion and communication that have been altered by modifying the relationships in the supply chain of manufacturing and distribution.

The *originality* which launches the makers' product onto the market in a more competitive form is the digital control of the production process (**Digital Fab Lab**) carried out with self-production using **3D printers**¹⁶. This novelty should encourage the creation of many small personal factories with by "digital artisans" replacing mass production. Innovation is the ability to self-promote themselves using the new tools of the trade as well as new virtual sales platforms, thus reversing the rules of distribution of industrial mass product. Even **eBay** has been surpassed, with new types of networks such as **Etsy** or **Blooming**¹⁷ becoming more and more popular as well as more effective and efficient in the sharing of values and content consistent with commercial products.

What has been lost in the field of design research and product design, even in schools of architecture, is the intrinsic value expressed in the drafting process of the project, where the material culture plays a central role along with the higher dimension of **creative doing**. For too long, the industry has orchestrated at will the culture of product design, deceiving the market through the promotion of miraculous outcomes and innovators, mixing the primary stakeholders and actors, without obtaining any high value results in terms of originality, authenticity and expression of individuality. At present, the reasons that have led to a different production culture through creative doing by exploiting the ability of the individual operator who produces the product is triggered by the market availability of new tools with numerical control and new technologies that allow for prototyping experimentation in the field of three-dimensional project moving from a virtual dimension (three-dimensional modeling and photo-rendering) to the actual size.

This particular **stage of the production phase** should not be neglected or stifled by the industry that is used to suppressing the creative dimension of industrial product design subject to its liking, thus attributing to an object that belongs to the disposable sphere very little character, memory, personality considered as the relationship between man, the territory and his roots. The limits of the industrial world are in the distribution of **strong** objects, durable and resistant, but **weak** as they are unable to preserve memories of being objects of memory and therefore leave only the value that is now considered negative that is the increase in waste. The cultural shift is indicated in the self-production as a stage of doing that is capable of restoring the right time and right values to the product that physically materializes in the making. Finally, arriving at the season of self-production, where the brightest innovators will be those who will combine new "products" to new "visions" without being affected by the conditioning of the manufacturing industry.

1.6 Self-production in the production process

Self-production, therefore, becomes one of the most current forms of innovation and **renewal** of both the production and socio-economic systems, resulting in a possible creative alternative to the situation of production stagnation and involution that is characterizing this period of crisis.

It is the **revolt of doing**, the revolt of "*thinking hands*"¹⁸, the sincere and genuine collaboration between who has ideas and who creates without any intermediary. The craftsman who governs the processes of digital automation completes his personal profile and frees himself in the world of production and distribution.

It is in this **renewal**, in this socio-economic revival of "*Renaissance style*"¹⁹, in which the innovation of the new society of the future is played, i.e. the reality that is increasingly being called by many the **2.0 society**. In addition to the talented creative dimension, a new concept of **design** plays an extraordinarily important role, intended as a system of government of the project that creates a more balanced form of synthesis between the idea and the product both as a product as well as an artefact, i.e., with the ability to activate extemporaneous processes, almost *maieutic* in close connection with the subject and the object-product without abandoning the expectations of man.

However, is it really true that the industry, by far, does not accept a possible compromise? In the culture of production, there is no will **to risk**, thus favouring some creative and experimental spontaneous initiatives, also probably because the culture that precedes us, and perhaps still be with us for a long time, is based on an ideology of profit, of mere commercial success of the single market product of taste and trend, without, however, listening to the real needs of the market, without

understanding the value of resources and without understanding the involutions which are bending the production system.

It is worth recalling that, in the culture of the project, a major role was played by the educational dimension and popularization of the project in order to educate the thinking, feeling, and the user's taste and allow for a better understanding of the conceptual effort that results in, in concrete form, in the product.

Self-production must be interpreted in the right way, without falling into easy mode, without luring the user into hasty decisions, due to this moment of the production phase without question, helps in the verification after the implementation phase of the project because, through the control of the material and the feasibility of the combination of material-production system, it brings additional value to the product as it allows for the expression of personality and feel of the self-producing designer, a feature now almost completely lost in what is the serial and automation of processes.

1.7 Conclusions

The **new season** should, therefore, be based on a new “awareness”, centred on an evolution of the relationship between man and object, where *doing* provides new visions and perspectives. The craft dimension yesterday, as well as the self-production today, may be the verification phase of the project fostering improved cooperation with the industry as it must be considered as its next bet in enhancing the act of creation meant by “giving shape to things”.

Fig.4 Concept Map realized in the Thesis in Fashion Design by Maria Antonia Salomè (student of Department of Architecture and Industrial design “Luigi Vanvitelli” SUN)

The figure of the self-producing designer has tremendous benefits when placed in the context of the industry, especially through forms of mutual support in creative workshops that test solutions and proposals enabling a principle of research and innovation, as an essential requirement of the product of “design of the technological artefact” that promotes an innovative technology (*calm*) as a “non-hyper presentational and not ostentatious”²⁰.

Creative man, which at the same time designing and producing, assumes a central position in the man-object process allowing for a renewal process through a different use of technology due to the **integration** of *knowledge* and *skills*, those *values* that the industrial production system has, for too long, set aside. These values result in a *new figure* who through his own experiences brings with him the *artisan skill* and *design knowledge*, mixing them with current production processes giving the hybrid figure of artidesigner or “third kind with its own characteristics and purpose”²¹.

The artidesigner actives, through his knowledge and skills, personal relationships with the material, with the project-object, which becomes part of himself, of his being and his work and that, through his hands, turns into a part of the world, taking on its own identity. To paraphrase the message of the tale of Pinocchio by Collodi, the artisan can be symbolically identified in the person of Mastro Geppetto, persuaded by his manual dexterity, he decides to transform the material of wood into the figure of an

icon that in the inner imagination of a man that completes his path of life enriching it with emotions and values.

At the same time, however, the object does not have its own identity, except for that of the wood, in this case the wood, with the intervention of the creativity of the designer being necessary, who with his “magic” contribution of technical knowledge of materials, “gives new life” to the material allowing the just finished artefact to join a “community”, as the guardian of “memories” as well as virtuous model loaded with emotions.

In our socio-economic-productive context, the designer craftsman (artidesigner) becomes the **interpreter** of the change, the only person able to develop *new visions* in which design is a *mediator* to integrate the knowledge as well as trace out new routes of innovation that can follow social change and become productive as well as a promoter capable of directing society towards more sustainable and balanced new heights.

This consideration, based on the right balance between new digital technologies and crafts, introduces us to the combined use of new technologies, combined with skilful craftsmanship, allowing for new **testing** of the product-project that can be realized through the integration of craft figures in the production processes, changing the traditional rule of the production-creative process of technological culture of the industrial project. In many cases, they currently have invaded the world of design, with the experimentation being only ideological and stops the recovery and reuse of parts or small pieces of discarded objects into neglected disuse. However, the real contribution that innovative technology of energy saving, and not only, could be implemented to promote the right balance between best craftsmanship and design.

During this time of stagnation and **slowness**, the time and manner, always “slow” of the craftsman allows entrepreneurship, especially in the part that is careful and **sensitive** to the problems and, above all, interested in resolving them in the best ways to acquire **new potentials**, represented by the rediscovery of knowledge that has always meant, in the material culture, the symbol of a production process as well as a series of processes and techniques of quality but also, and above all, values that are related to both the territory and cultural heritage of that particular local context. Promoting the potential of being able to make their own crafts products leads to recovering and preserving the historical memory of a place and its community, protecting what represents the **cultural heritage** of that place, enhancing the territory thus allowing for the creation of new opportunities enabling the gradual advancement of innovation.

Applying this thinking to business practices, implies placing on the market products that are able to transmit to user the flavour (the sensory experience?) and **emotion** that has lived in that place, creating a chain of memories that can hardly become part of the current process, that process is exhausting and closed in the disposable life cycle.

Despite the “good intentions” which refer to the recovery of cultural values, to territoriality and sustainability, this “doing” of the new creatives brings a limit that may not be less attentive to the showing due to the experimentation of self-producing, in its nature of fairly recent trend may not always be an in-depth study and a mere research on what may be the most appropriate materials and technologies to innovate the product and its production process. There is the risk, without realizing it, of creating a fleeting and falsely virtuous trend, unable to generate a real stage of advancement of the processes, with it being too careful to only certain dynamics of charm and emotion. The limits of self-produced objects is in the weakness to innovate due to the prevailing of the value of charm and emotion prevailing, thus excluding the contribution of technology and innovation. For example, many lamps built with scrapped pieces or elements neglect the contribution of the technical components in terms of sustainability, or the lack of an accurate verification in terms of technical performance of the individual elements as for the entire system.

1 **Serge Latouche** states: “The decrease is a virtuous circle that is divided into eight goals, in a process that we can call the eight “R”. The first two of which are certainly “Reassess” and “reconceptualize” and this involves a reversal of the way of thinking and apprehending reality. You need to decolonize the imaginary values of society’s growth, which are competition, the appropriation and commodification of the environment, speed, and find a way to live in harmony with nature, recovering the sense of limit. This leads obviously to changing the relations of

production: then "Restore" or adapt, as a function of changing values, the economic and productive structures, consumption patterns, social relationships, lifestyles. Changing the relations of distribution, then "Redistribute" fighting inequalities, ensuring that all the inhabitants of the planet have access to resources, access to natural resources, ensuring a satisfactory job and decent living conditions for all. You must then "relocalize" or consume local products, thereby supporting the local economy. Any decision of an economic nature should be taken locally, for local needs. "Reducing" the carbon footprint, waste, work schedules, drug addiction by fashion. "Reuse" overcoming obsession, functional to the consumer society, the continuous tension to the new, "Recycle", recovering all the waste are not decomposable arising from our activities. 17 eBay is a platform (marketplace) founded in 1995 (in Italy arrived in 2001) by Pierre Omidyar. The site offers its users the opportunity to sell and buy items both new and used, at any time, from anywhere on the Internet and in different ways, including sales at fixed and dynamic pricing, commonly referred to as "online auctions". There are several formats of sale (auction, buy it now, buy it now with the purchase order, direct contact). The sale consists principally in the supply of a good or service by professional sellers and not, buyers are bidding to win the goods (<http://it.wikipedia.org/wiki/EBay>); Etsy is a website dedicated to e-commerce (activated in 2005 by Robert Kalin Chris Maguire and Haim Schoppik, which was added later Jared Tarbell), within which members may sell crafts or vintage items. Founded in 2005, the site is described as a cross between Amazon.com and eBay (from <http://it.wikipedia.org/wiki/Etsy>); Blooming (activated in 2010) promises to make e-commerce "simple as blogging "and accessible to all. It offers comfortable and free online software that allows everyone, simply to open his own blog, manage comments, and insert various applications (surveys, calendars, tag clouds, etc.). Compared to e-Bay, Blooming changes the way in online sales generating an embed code from "share" on various social platforms like a link or a YouTube video <http://www.webnews.it/2010/05/24/blooming-la-promessa-di-un-e-commerce-facile-e-flessibile/?ref=post>

Visione sostenibile (Sustainable vision in the conservation of cultural heritage project)

Anna MAROTTA

Full Professor, Politecnico di Torino
Turin, Italy
anna.marotta@polito.it

Abstract

"Who less sees, thinks nothing" in four words Filippo Juvarra emphasizes the close link between visual culture and architecture theory and practices. In this perspective, what meaning can be attributed (by designers or users), to their "own" architecture and their "own" city? Considering the landscape as a heritage to be safeguarded (according to the Europe Council, the landscape is "perceived territory"), new plants for renewable energy "with environmentally sustainable technology" are sustainable also from the point of view of visual consistency, and therefore of the "sustainable vision"? We are all ecologists and believe in eco-sustainability, but we have to take into account also the "sustainable vision" issue, that is managed by formally coherent and congruent actions in the architecture and landscape between text and context in all scales?. The same inconsistencies can be detected for new integrations (or recovery projects) in the historical structure of the city, which is characterized by specific aspects concerning what we might legitimately define its "visual structure". Similar problems can be finally found when the same visual characters are not analyzed, studied, acknowledged and valued appropriately within restoration and-or conservation projects, both in architectural dimension as well as in the urban one. A careful analysis of these phenomena - disciplinary identified - will avoid that such inconsistencies may exacerbate the increasingly diffused "cultural loss". In support of this thesis will be mentioned, within a large series of case studies being analyzed, national and international examples, both positively and negatively.

Keywords: sustainability, architecture, landscape

1. Sustainability

Bio-architecture, "green architecture" or environmentally friendly, as well as renewable energy, can be considered variations of the same concept, from the common root "green" in order to contain resources and energy, according to the recalled – on an empirical basis – by Hastings S.R, Wines J., Woolley T. [11] [1] [2] [14] [15] [5].

An energy consumed (and all it contains) in the production of materials and components or in carrying out basic functions such as temperature control; or as the "intrinsic"; or in the distribution and transport of materials and components to the construction site ("gray" energy); or even in managing of machinery and systems building and its inhabitants ("operational" energy). Not be forgotten other requirements, such as the ease of recycling of materials and the amount of the same effectively used by building. Despite the considerable progress in the introduction of measures for energy saving, some processes have slowed and sometimes hindered this trend. The capital required to invest in new equipment and procedures with high energy efficiency is often not easily available; measures to reduce waste and pollution (which have a higher legislative value of regulations to encourage monitoring of energy use) sometimes imply (contradicting the theoretical premises) an increase in energy consumption. Such as in some areas with "refined" productions: glass, composite and curtain wall. [9] [24] [13] [8].

1.1 Visual parameters in sustainable project.

Considering the building in its entirety, as well as can be conceived, designed and managed to ensure maximum energy efficiency, including renewable sources, the term "passive" appears misleading. The house passive solar or bio-climatic, to cite one case, there isn't an inert set of materials and

components: in fact it must have, or at least imitate, the constituent parts of an organism, capable of constant adaptations. Saw that the building depends on the exploitation of positive climatic factors, must also be able to react to their mutations.

Basically, "regulate" adjust the casing means that about a quarter of the wall surface of the building must be opened and closed, a third party must be able to let in natural light without hindrance and a similar surface must allow the solar radiation to enter at certain times and screen in other time. In addition, the casing must be designed to do all this without interfering with the ability to look outside. The new importance given to the casing respect to its general structure provided additional stimuli to the architectural expression of the facade and the coverage, elements that were previously confused - respectively - by the indifference of the curtain wall and the necessity to fit under cover implants, triggering even innovative forces in the industrial strategies. The production (for example) of the glass with "sustainable" characteristics has reached results which allow not only the visibility, but also the thermal insulation, the solar control and the spontaneous regulation between different modes of dimming [20] [26] [23] [16]. Innovative topics related to sustainability, are confirmed in the graft on the more traditional relationship between architectural project and its context: Steven Holl in defining an "anchor" the dynamic relationship that is established between the built and the site, considers foundation of the "concept": the resolution of the respective functional aspects, views and opening visuals, the circulation and access are "necessary physical to the metaphysics of architecture" [4]. In La Jolla, California (for example) at the Salk Institute of Louis Kahn (1959-1965), at a time of day the sun reverberating in the ocean, merges with the light reflected into the water of the moat that separates the central courtyard, while the functional and physical requirements blend with the visual character of the place.

So, in general, among the broader aspects of objective and individual comfort, along with data and objective standards, should be considered as perceptual, variables in the course of the seasons, the day, the users. Outside of specialist and disciplinary treatments, a possible definition of comfort could be a "no hassle" without forgetting the psychological well-being. But in the parameters to measure such comfort, is also included the visual one, according to the theoretical (for example) from Maslow? We can therefore talk - within the architectural / environmental sustainable system - even "sustainable vision", a visual input (perceptual and cognitive) acceptable and congruent of new environmentally friendly technologies and methodologies respect to the context? And this can be achieved with their methodological approaches, disciplinary and specialist? Or these discrepancies (as in the case of wind turbines, or "coat" linings) are a price "aesthetic" to be paid in the name of an "healthier" ecosystem?

2. Sustainable color

Inside of the problems outlined above, the chromatic themes arise with particular force and complexity: from the middle of the last century the tendency to color reborn through a number of objectives: to conflict with or accommodate the architecture (local or not); enhance or camouflage material construction, enhance or manipulate the volumes, or to emphasize the characteristic features of the building, such as the Centre Pompidou in Paris in which the building by Renzo Piano and Richard Rogers is inserted as a single volume in the variety of "Grey Parisian" adopting the typical colors of the technological information systems.

In the design phase, the set of conditions relative to the levels of building system adequate to health and the conduct of activities of the users can be connected to the use of color to enhance the sustainability of buildings. In particular it will be the need for thermohygrometric comfort, combined with the recommendation of climatic resource utilization, one in which the color will better contribute to the improvement of performance through a careful choice of materials, but also the coloring of surfaces, systems and technical systems and its exposure to the sun. The reaction / reflection that follows must therefore take into account, in an area predominantly constructive and architectural, the role of the color of the buildings especially with regard to the choice of materials or decorations, keeping in mind the characteristics for a sustainable color of natural light and artificial which (with its different intensity and with that brought from the shadows) will cause effects on items particularly charismatic and determinants, such as to greatly exceed the level of the single formal and "objective" image. The choice of building materials is also another important factor where the color can even more help to improve the environmental sustainability, not only individually building but also in the areas of reference (UNI 0050) [12] [22] [3] [18]. Has been widely demonstrated that in the phenomenology of color the physical definition "objective" is to be combined with aspects perceptive and subjective: when an object or a material is in our daily surroundings, its color just does not seem to change if it is to illuminate the sunlight or the light of a candle. For example, observing the snow at night we would be ready to affirm that this is white in color, even if the light radiation that comes to our eye is not at all. In this case it is our brain that deceives us by making a sharp correction on physiological data. But this trick enables us to live with greater security and mastery the environment around us [28].

2.1 Sustainable vision of new material

Among the new generation products, there is (among many others) colored glass, to continue the tradition of those mass-coloured: thanks to a chromatic "interlayer" in PVB. The interlayer, an integrated component of laminated glass, featuring a new generation of films for the manufacture of laminated glass for building, decorative, high technology and which opens the door to a new way of interpreting and using color in internal and external design. The range of products of interlayers is the versatile response to the growing needs of design whit glass and to the market changing . The system is made up of eleven primary colors from which you can generate more than a thousand tones transparent, translucent and opaque. The maximum size of production is directed generally to the size of the autoclave for the production of laminated glass: 2.00 x 7.00 meters or 2.60 x 4,60 meters. Interlayers provide the benefits commonly associated to laminated glass, widely used in construction: sunscreen, it can absorb up to 99% of harmful UV rays, resistance and therefore safety, as well as significant reduction in the transmission of noise in indoor environments. Staining of the color interlayers is based on shades of red, yellow, blue, black and white and can be stacked offering a full range of colors, from neutral and relaxing white and browns to lively and gaudy violet and orange. It will therefore be the color of the glass that you want to obtain to determine which interlayer chromatic must be privileged. The reproducibility of the color of the intervals is directly related to the gradient obtained from the mixers and the light transmission of each same interlayer. To get a specific shade, many configurations require asymmetrical compositions of interlayers. The perceived color may be different depending on the mode of observation, especially when the colors were examined by reflection [21] [7] [6].

3. Positive and negative examples

With figures like Richard Rogers, Norman Foster and Renzo Piano, in recent years the most advanced hi-tech movement has joined both the "green manifest" that his architectural vocabulary: on this trail, there are many positive examples made in the field of sustainable: the first selected here is the asylum "Els Colors" in Barcelona [Fig.1 and Fig.2], follow the Kilometro Rosso by Jean Nouvel [Fig.3 and Fig.4], the Centropadane Bridge in Brescia enlightened by Philips [Fig .5] and the Water Tower near the Farini Bridge at Porta Garibaldi Rail Station, Milan [Fig.6] in the new redesign.

Among the negative examples, carriers of problems and issues at stake, you can cite instead the wind farm in the Natural Park of Adelasia in Liguria [Fig.7] or the example of the thermal analysis of the housing stock held in San Lorenzo di Greve , Florence [Fig.8].

3.1 The "Els Colors" Kindergarten [Figg. 1 e 2]

Reassuring entertaining and educational spaces of nurseries and pre-schools are affected by the configuration of objects and places, but also by the colors with which children are having to interact daily. Generally environments asylum, both external and internal, their furnishings and finishes, provide a quality range of colors, materials and light large enough to activate sensory stimuli of various kinds. In particular, the colors affect the learning and development of children: the pink glaze is definitely more suitable for creating a magical atmosphere, instilling safety as a family environment and leading to the discovery of the surrounding environment; the shades of tenuos lighth blue __, however, help the older children to internalize those experiences in early childhood, facilitating the assimilation of information and understanding of the same. The search for a combination of formal and perceptual quality and technological quality of the project seems to resolve himself in "Els Colors" kindergarten, designed by RCR Arquitectes in the outskirts of Barcelona [17] [27], in juxtaposition between the use of color as characterization spatial technique typical of school building and the creative use of color interlayers inside the laminated glass. The architecture of this nursery is characterized by the simplicity of the composition obtained from a planimetric structure of high linearity: two longitudinal buildings whit a marked horizontal development, house the classrooms, spaces for socializing and dining, connected to each other in transverse with a covered walkway, access in turn also to the inner courtyard; a higher volume is positioned above the main entrance and is used as a multifunctional space. The project has been developed thinking to the different perception of space that have children and the fact that their point of view originates lower than that of an adult. The extensive use of bright colors (with hot / cold contrasting), yellow-green, orange, red and blue, coatings and glass walls of the classrooms allows to enrich the perception of children and direct them to the knowledge of complex relationships, interpreting spatial and perceptual differences suggested and also induced by the transparency and opacity of materials. A shade of green unifies interior linoleum flooring and the external in synthetic carpet, proposing on the horizontal plane the same visual continuity that windows ensure vertically. From a technical point of view, appears to be fundamental the choice of safety glass, given the proximity of the children to the panels . The color interlayers leds to a varied coloring, providing an ideal level of safety for cases, due to the excellent adhesion to glass and high elasticity, which allows an effective absorption of the energy impact. From

the point of view of the sustainability of buildings, the use of solar control glass, or sunscreen, has allowed to obtain a considerable energy saving for the air conditioning improving the indoor comfort due to a greater control of the temperature and brightness [25].

3.2 The "Kilometro Rosso" [Figg. 3, 4 e 5]

"For me there are only three colors: black, theoric gray(which we call neutral) and white. Other colors are mere nuances ". [10] Black is the color of the secret and pain, which absorbs and returns every light, every reflection. It is often combined with gold, red and electric blue to create theatrical effects, which emphasize the taste of the performance of the architecture of Nouvel. Black, gloomy during the day, comes alive with color at night, through lights flickering that remind lighthouses, which become points of reference for the viewer that is situated to admire the built. The power of light today it has become almost an obsession for Jean Nouvel. According to him, those who love light, like also its opposite, that is, its shades and fade away into the darkness, through a path of shadows that transform the distances in illusions [19], while its production is similar to a complex optical machine, more important for effects it produces than for their physical substance. This philosophy can be found confirmed in the realization of the "Kilometro Rosso", the first Italian opera of the French architect: an installation in the lombard landscape , located between the municipalities of Bergamo and Stezzano. The project is intended to be, within the Science and Technology Park, a sustainable last generation building. The main objective is the creation of environmentally friendly architecture as a symbol of sustainable development, innovation and research, ie an active role in the development of the entire territorial system in the respect for the environment, for the best quality of life. Nouvel use the wall as a real wall system, which "hang" the new architectures that complete the equipment of the Park, a place that is home to companies, research centers, laboratories and activities of hi-tech production. As for color choices, "Daniel Thompson considers the synthesis of vermilion as the most important technological innovation in medieval painting: there is no scientific invention has had a vast and lasting impact on the practice of painting, since the invention of this color, as if the Middle Ages had not owned this bright red, could hardly develop its high standard of color, and there would be less need to find other bright colors that appear on the scene from the twelfth century onwards. Was certainly the medieval prince of red» [17].

The wall / barrier, who is also the very important role of filter between the A4 and the Park that extends to the back of the barrier, is coated in red extruded aluminum; _ is just one kilometer long and a height of ten meters. The imposing red backdrop born of the water, rises, takes thickness and is deflected. Almost as if something huge was leaking from the highway and struck him. Then, plastically, falls and continues to run, ending its stroke after a thousand meters. The attention of the passer is certainly affected, arousing a feeling of curiosity, but the deciphering of the product itself is not easy to grasp, unless it is to stop to observe, penetrating inside. The red color , recently "rediscovered" by the designer, symbolizes strength, dynamism borrowed from the coordinate image of the new Center for R & D Brembo (manufacturer of braking systems for Ferrari). The red acquires a symbolic value, due to the client company, as well as functional appeal to its target of attention, due to the specific characteristics of the color. The same meaning is conveyed from the wall: this in fact is always the first step that moves the architecture: is what defines a space, defends and locks him scoring an inside and an outside. The perception of the architectural complex also imposes as an icon for motorists who travel the highway that passes by; but at the same time, the "Kilometro Rosso" is a protective shell for activities that are located within the park that extends over its structure.

4. Conclusions

In the project and sustainable yard, to avoid the rigidity of formal technology solutions that are likely to be highly repetitive, monotonous and serial proves fundamental the research and formal experimentation, without excluding the utility of theories of color and the vision, applied to sustainable project. And the same is true for studies aimed at a "sustainable vision" in deepen and develop in symbolic values mentioned in one dimension genuinely multicultural and inclusive. Thus understood, visual culture is the consequent - more pragmatic - experience of phenomena and visual characters not only be antithetical technological and constructive approach, but it will be an indispensable completion.

Fig. 1: The interior elevation of asylum that overlooks on the courtyard, used as a recreation area for children. From a technical point of view appears to be _ fundamental the choice of safety glass, due to the proximity of the children to the panels . Colored PVB interlayers provide an ideal level of safety for cases, due to the excellent adhesion to glass and high elasticity, which allows for an effective energy-absorbing shock. (In AA.VV. *Asilo Els Colors*, The Plan, n. 15, luglio/agosto 2006, p. 63).

Fig. 2: Focus on the reflective properties of the glass used, typical of multilayer glass with PVB interlayer plastic. Through this reflection, the building is fully embedded into context, reflecting the conformation. The importance of color in the relationship between man and the environment becomes therefore essential for the construction of a psychological climate for the function that is in charge of the place itself. (In AA.VV. *Asilo Els Colors*, The Plan, n. 15, luglio/agosto 2006, p. 68).

Fig. 3: The Kilometro Rosso seen from the A4 highway. Despite the cars slide quickly down the stretch of road, _ perception of the building is guaranteed by its color. The Kilomero Rosso is the first Italian work of the French architect Jean Nouvel; the barrier, which acts as a filter between the highway and the park, is covered extruded aluminum and is just one kilometer long and has an height of 10 meters (da <http://www.kilometrorosso.com>).

Fig. 4: Night view of Kilometro Rosso from the A4 highway, with the illumination of red. At perceptual level the wall is imposed as an icon for drivers who travel that stretch of highway. The imposing red backdrop seems to be born of water, rise, take thickness and inflect (da <http://www.kilometrorosso.com>).

Fig. 5: Centropadane Bridge near Brescia. The lighting design of the bridge is made entirely with LED products, because this technology enables highly dynamic nature and the ability to configure different scenes in an elastic way (da http://www.lighting.philips.it/projects/italian_projects/ponte_centropadane.wpd).

Fig. 6: Water tower near the Farini Bridge at Porta Garibaldi Rail Station, Milan in the new restyling. Restored for the FIFA Football World Cup "Italia'90", the coating is composed by ceramic tiles. (Image from www.panoramio.com).

Abstract

Guidonia Montecelio (Rome) is characterized by huge travertine extraction fields, which over the centuries conditioned its territory becoming.

We intend to verify the recurrence of a typological and constructive model - “*casale* (house) + quarry” - and how the spreading of this model over a vast area produced a reticular framework of infrastructures related to the basic stone production needs, where each *casale* + quarry unit is a sensitive ganglion.

Littered with partly active and partly abandoned industrial plots, quarries and buildings for stone extraction and processing, this built environment today is largely illegible.

To give value to the place identity and to manage its current weaknesses and contradictions should be the aims of an urgent redevelopment project, that should make clear the network of physical and intangible relationships between buildings and quarries, from landscape to architecture and viceversa, with a retrospective as well projective point of view.

The site has lots of environmental and cultural layers that need to be investigated through multi-disciplinary and infra-scales approaches and tools: integrated survey, historical and iconographic analysis, maps of physical items and perceptive values.

Preservation, regeneration and innovation in the field of heritage, architecture, landscape, are the main themes of this study, taking as sample the Bernini house, checking its potential for recovery and for new uses in a specific landscape context like that of the leaving off quarry.

Key words: landscape, quarry, survey, map, laser-scanner, inventory

Introduction [1]

The landscape of Guidonia Montecelio, in the province of Rome, is characterized by the presence of a large extraction field of limestone – the Roman travertine - which over the centuries has conditioned local transformation and identity. Littered with industrial plants, small buildings and quarries related to the extraction and processing of stone, partly active and partly abandoned, it presents environmental and cultural layers that need to be investigated through multi-disciplinary approaches and inter-scalar tools.

From a morphological point of view, it is a large area slightly inclined towards the south, surrounded by the crown of Cornicolani and Tiburtini hills. The hydrographic network plays on this frame and is composed of natural tributaries of Aniene river and surface artificial drains clearly identified by their serial order, signs of ancient water reclaiming, which remains in the memory by many names of places referring to the once swampy nature of the area.

The settlement system of towns and mobility conforms with these local morphological characters, so being natural physiology and human actions not separable at all: architectures and infrastructures form a coherent and readable system because they are based on the systemic elements of the natural geography.

The geological structure has allowed the development of mining activities that have so long and strongly marked the place, till to be the main element of its geographical, economic and cultural identity. The exploitation of travertine has been made possible since ancient times due to the presence of mobility infrastructure, roads and especially the river; in turn, quarrying has contributed to the definition of new infrastructure directly related to further development of travertine industries, including the production of lime.

The mutual interrelationships between natural and man-made geography have a circular character: for example, the artificial lakes produced in the quarries when the action of scooping machines ceases are signs that add to the natural water system, featuring profoundly the landscape as well the environment.

Quarrying has also promoted the development of buildings closely linked to mining, till to the definition of the quarry-house system which is the specific subject of this study. The house (*Casale*) was a key device for the management of the quarries territory: place of control, supervision, decision-making, organization of human resources and equipment, it was at the same time insignia of economic, technical and political power of the quarry owners and an equipment inherently connected to the proper functioning of the production process. So, its architecture has been characterized by the adherence to the functional program and also by an iconic desire.

Several *Casale* dot the plateau now largely eroded by the quarries. From their origins, they are an infrastructure network related to the basic needs of stone production and together form a framework where each unit quarry-casale is a sensitive ganglion and that needs to have again evidence and readability.

1. Landscape as a palimpsest. Description, interpretation, recognition, representation.

We mean by landscape a body of tangible and intangible characters, that at a given time and in a given context is perceived as a semantic unit by one or more communities feeling involved in. It's a sum of values of great relevance from a cultural, economic and social point of view. Landscape is therefore that quality of a place where legal and techniques practices and ethical and aesthetic reasons come together in a synthesis recognizable as manifestation of a shared culture.

Landscape, so defined, is generated through continuous overwriting, which accumulate and deposite on top of each other. So it's therefore describable as a palimpsest of progressive layers of signs. As Sebastien Marot writes: "The art of the landscape consists, starting from the observation of a given territory, in deducing the laws of formation, then taking them to design tools. The landscape project could not be defined as the art of the imagination, but of reminiscence" (Marot, 1996).

Both imagination as well reminiscence require to take a double identity, in a sort of game of disguise that makes us wear time by time the role of two different characters, one to the other essential: the geographer and the explorer.

Fig. 1

1.1 The geographer's gaze: the cartographic deduction

To decipher the landscape as a palimpsest, it is helpful to take an analytical look, processing for progressive disassembly and allowing to distinguish and name the settled traces. It is an exercise in questioning and describing places according to categories of homogeneous elements, which belong to the interrelationships between artificial and natural patterns.

To investigate an area means, in fact, taking care of two equally important aspects: on the one hand, the natural invariant items (related to the physiology of the landscape); on the other, the signs produced by the actions of settled communities. It means, in other words, to deal with the natural geography and the artificial geography.

This exercise of disassembling re-cognition is map-based and structured through partial questions for items that match sets of morphological elements (forms of the territory), environmental elements (the

conditions for the development of biological forms) and settlement elements (the forms of living and producing in a place), which are the units that over time have been affected with historical, symbolic and aesthetic value. One-level maps correspond to each of the selected categories (including geomorphology, hydrography, vegetation, mobility infrastructure, building components). They, properly stacked, return the complexity of the landscape and give clearness to correspondences between signs and their reasons, referring to the deep structures of territory and society: in a certain society (in its cultural and economic aspects) there is a certain landscape that manifests itself through a certain type of signs. In the specific case of the quarries of Guidonia Montecelio, disassembling and re-aggregating of categories of natural and artificial geographical elements highlight their structuring value for the whole territory. The analytical-descriptive scanning is instrumental to master the main materials that form the structural matrix of the place and to acquire the interpretative criteria of their re-aggregating potential, giving evidence to the hierarchies of significant relationships among the playing elements. In other words, this step of cognitive disassembling already contains the codes for turning then to practice of re-composition that is at the root of the project.

1.2 The explorer's gaze: the revealing experience

To have awareness of large scale territorial phenomena can be difficult and elusive: it is difficult to see, measure, describe, understand and then decide. Deciphering signs of macro-geography is not enough to landscape understanding and designing, if it is not accompanied by a survey of the places through their direct experience and perception.

The semiotic reading of landscape therefore requires to complement the gaze of the geographer with the explorer's one. It requires to verify the correspondence between the macro-marks found on a map and the "true form" of sensitive landscapes physically crossed and exhausted. In other words, it means to associate mapping to detect by measuring and the revealing experiential perception, combining the gaze from outside and above with the gaze from inside, employing a bifocal lens.

Fig. 2

This means to reclaim the need for a sensitive relationship with the landscape, in which the representation becomes the synthesis of synesthetic perception that inevitably takes place in the direct experience of places.

The direction of the gaze of the explorer cannot in any case be neutral, diluting much of the rigor of objectivity that still we find in the geographer's one. Regardless of the technique used - photography, drawing, collage, just as examples - the centrality of the perceptual aspects will always require a choice, a selection. The eyes of those who explore is by its very nature leading, directed by a prejudice that contains within it the seeds of intention, which is the very reason for exploration.

We can proceed browsing horizons, playing in the vertical dimension the same tool of overlaying layers of the palimpsest landscape: at Guidonia, on the distant horizon of wavy-edged Cornicolani hills, the straight lines and assertive sides of the quarry overlap, on which stand the profiles of machinery and cranes, till to the nearest horizon, the one of the fences, which, almost everywhere, stop the look on the first floor.

Exploring the mutual relationships between figures and backgrounds, with roles variously interchangeable, is an organization of meaning from general to the most salient detail, with the same inter-scale procedure that characterizes the cartographic reading. We can easily verify that the most obvious characters are found both in the general views of orientation, as in the observation of detail.

We can work through collections, samples, or - we prefer - through *inventories*, a very interesting word because it's the marriage, only apparently contradictory, between cataloging and inventing. The inventory can organize materials, as well as textures or patterns, finding even at the scale of the micro-landscape - that of the block of travertine marked by the grain and porosity of limestone on which the regular pattern of linear cutting lays out - the overlapping of natural and artificial categories, here continually and everywhere confused or repelled.

Fig. 3:

1.3 The meta- project transmission of the acquired knowledge

Information and interpretations collected as geographers and explorers are expressed through forms of representation that are on the one hand descriptive and analytical, as means to make visible and therefore understood the faces of the landscape; on the other hand, are intimately connected to design: the diagnosis of mode of genesis and evolution of a landscape is already an anticipation of transformative thinking about it. Landscapes are composed of heterogeneous elements that do not evolve all at once.

The exercise of reading (both for layered mapping, both for perceptual report), occurred over time, provides insight into the processing steps of each of these elements - or systems of elements - and into the eventual far-reaching transformative strategies that take into account the singular becoming of each face and the interactions among them.

The area of the quarries of Guidonia requires a project for the restructuring of territorial network simultaneously in multiple scales, from the geographical, to understand and decipher the frames that are largely invariant and structuring systems, to the minute intervention of architecture - including the building components as well those relating to open spaces - which functions as a kind of prototype. The relationship between the two scales is twofold: the territorial scale supplies the frames on which the minute interventions are anchored; then, these last have specific geographical memory of territorial systems - which are an important feature of – and, at the same time, help to measure the extent realizing what Michel Desvigne called "désir de réalité et d'architecture" (Masbounji, 2011).

It's the equivalent to create a laboratory to test the relationships of meaning, space and environment sought and evoked at the large scale. We cannot have the claim to determine a unified framework for such a huge place and for so long time. Therefore, it is necessary to activate processes of changes, acting on sensitive areas which can then propagate their effects around, as in acupuncture. The quarries will not be deleted, their presence is welcomed as a significant sign of this landscape, but they'll change character, role and nature: "tout reste en place, mais tout change de nature", citing again Desvigne (Masbounji, 2011). We can prepare this territory to its future vocations, not working on forms, but on processes: conversion, new functions, new meanings, new nature, all included in transformation projects that are part of a long time ambition.

Fig. 4

2. The survey project in an inter-scale field: hypotheses and lines of development

The survey phase of the project, following the step of collecting historical material/documentary analysis and in situ reconnaissance - both in support of the survey itself - proceeds in the development of paths method and considerations that are presented in this paper. The methodological approach to the case sample wants to be an example of a method applicable to a wider territorial system, such as the North East of Rome, subjected to stone extraction and characterized by different entities (vegetation, archaeological, industrial, infrastructure, thermal systems) that contribute to the identity of the landscape between the Tiber and Aniene rivers.

2.1 Lines of investigation and instrumental management for the survey of the built environment

The case study presented in this conference offers the opportunity to act as a survey method of applied research in which speculation and experimentation discipline will contribute to the development of strategies to be implemented for recovering a specific built environment: that of travertine quarry - called Bernini in Guidonia Montecelio - and the connected *Casale* of historical relevance. The methodological and instrumental experimentation will operate on the sample, checking the concreteness and the real validity of the proposed objectives: knowledge of the system *Casale/quarry* and enhancement of environmental contexts with outstanding productivity and/or disposed of. In practice, the emphasis is placed on survey as a challenge, to renew its role as guarantor of interdisciplinarity through the neutral and polythematic reading of existing realm.

It pursues the task of revealing visible and invisible data, of knowing necessary permanent and temporary man-made transformations in the environment, of catching relationships of discontinuity/continuity among different configurations of space, matter and time. This is a survey that offers scientific and critique interpretation of reality.

Fig. 5

The built environment under investigation is a highly complex system, where a variety of information converge together. The inter-scale survey, through its various stages and methods, transfer the inter-scale approach into scientific terms: it will be managed both instrumentally, both in terms of processing and return of data. But we must now focus on a reflection.

Fig. 6.

Experience shows that the integrated survey provides a more comprehensive knowledge and all methods contribute, from time to time, according to the arising situations, to acquire information about the object/landscape as a whole. Laser scanner is the proper instrument for the detection of geographical areas such as quarries, in this case under the sky[2]. The use of this tool opens up fields of inquiry and theoretical issues. In general, the laser scanning involves the acquisition of a large amount of information - geometrically contained in the point clouds - above the usual level of predictability shared by other detection methods. In this study, it is assumed that the management of the data is expected to become a stimulus to the knowledge of the different landscape invariants - present but not noticeable - in order to broaden the scope of the design choices.

The discovery process should grasp the links between the different materiality in the area, surpassing the hierarchy or traditional divisions between survey and architecture, making choices of acquisition and return on multiple scales simultaneously. This approach can be made possible by the use of laser scanner: since neutral instrument, it is able to cover large distances with a coverage of 360° on the horizontal and 270° on the vertical and to detect - defining the resolution - from the existing general retail, providing data on the material consistency and color[3]. Reading and selecting data in the points cloud will return - according with different scales and themes - many aspects that arise, from the metric to the material, cracks etc.. The guiding idea is to return a model in which the relationships between architectural forms and landscape shapes - related to the extraction cycle and stratified in time - could be revealed tracking technological and cultural signs.

Fig. 7

2.2 Discretization and survey project The perceptual analysis performed on site shows that the Casale Bernini is located in the middle of three travertine quarries, with different activities conditions: one in full operation, a disposal one and a disposed of one. The quarry originally related to the Casale was placed in front of the building.

We will proceed to laser scans at multiple points of stations - even at very different levels - so to scan the item on time and the Casale/quarry unit in the first instance by ensuring knowledge of dimensional relationships, in linear, superficial and volume terms. From this information, however geo-referenced, we'll be able of course to extrapolate data to understand the directions of spatial development - both linear and volumetric - in comparison to the other Casale/quarry units in the area of Guidonia Montecelio, that in fact took part - with different functions - at the travertine production cycle.

Fig. 8

The identification of topological relationships between elements of different scale is among the objectives of the geometric models definition. This is useful for the interpretation of the spatial configurations that have sprung up in the interweaving of natural and man-made phenomena (geological layers, vegetation, hydrography, mining methods, settlement). Also it is assumed to perform taken data at successive times in order to detect the permanent and temporal entities: it can thus provide models of the steps of the manufacturing process, whose output will present images of the concretization of variability. We can think, for example, about the temporary accumulation of granules, the different position of the cut and then assembled blocks or subsequent signs of tracking cut on the quarry fronts. These data, returned in a scientific way, will then be subject to interpretation in the project, revealing the identity of the place and its memory.

In the light of these considerations of method, it is natural that the acquisition with laser scanner should be guided by careful design, otherwise we may not be able to use the large amount of data. The discretization of the landscape in terms of previsions prepares the data knowledge for the elaboration of the final intervention: the enhancement project. This condition, with interdisciplinary reflections, makes creative the definition of point stations, in terms of quantity and position and then the reading/processing phase, finalized to obtain appropriate models for the fixed purpose. In essence, we are creating an inventory of what is considered appropriate to be detected: an inventory of ideas, arguments, true or plausible, relevant to the project. In the first draft, we'll deal with the following characteristics: dimensions, referring to the limits of quarried, the volumetric size of the void (intended as survey of the immaterial), the house and the industrial buildings; the presence/consistency of the footprints on the ground given by the historical and current processes; matter, relating to the geological aspects of this limestone and the material quality of the settlements; the variables phenomena such as the presence of groundwater, vegetation, referring to the natural and planted flora.

Last but not least, the survey will provide the state of rules and laws about mining landscape to interpret and reconsider a regulatory framework currently very complex, through the development of a graphical language coded and implemented.

Fig. 9

Conclusion

What above exposed means to develop a model of the evolutionary dynamics of the territory and interactions with man-made actions. Consequently, we will have to identify data patterns that, interpolated and thematized, allow a simultaneous reading of all aspects of a built environment. The study of Casale Bernini and the appurtenance quarry is proposed as a model of knowledge applicable to qualify the network of quarries and buildings of that specific landscape, just because the investigation is polythematic and not fractionary: the topic is that of a historic Casale in relation to an under the sky quarry excavated in a plan, with fronts of mixed spatial configuration in an extreme landscape. The presence of artificial constraints - such as the road network to support the plants, settlement buildings, placed in apparent randomness in the system of extractive industry - and natural ones - such as the water system and the orographic system - must be related and decoded to reveal the presence of invariants items. Reading a wide spectrum, accompanied by detailed information, the aim is to reveal the essence of the place: a mining landscape, characterized by secular activities, of which only a part disposal, and architectural artifacts of historical value, not yet subject to protective restrictions by laws. The theoretical orientation is also to include the methodological approach to survey in a procedural framework closely related to the project to improve the built environment [4]. The comparison with a different epistemology of the project will reveal the historic potential connected with restoration project of cultural heritage, within a system still largely industrial, for valuation strategies that can resolve open issues and create new development opportunities.

Fig. 10

Fig. 1, page 2: Sequence of maps surveying mobility infrastructure and urban settlement. From left to right: mobility infrastructure pattern (see Fig. 2, page 3); the border of urban imprint; the character of urban imprint related to its evolutionary processing (see Fig. 3, page 4); the overlapping of infrastructure and built areas (see Fig. 4, page 5).

Fig. 2, page 3: Mobility infrastructure settlement. In yellow, the E45 motorway; in red, the main roads; in ochre, the secondary local roads. The dashed red area is the Guidonia airport. We can note the close coherence between the roads layout and the morphological items of this territory. The prevalent direction of main roads is

parallel to the river and follows the connection between the extractive area and Rome, originally the principal travertine business basin. We can also note the thick pattern of local road very close to the mining area.

Fig. 3, page 4: The built area. In dark gray, the processing urban settlement; in medium dark gray, the steady settlement; in light shade of gray, the historical urban realm. The red dots mark the presence of the unite *casale+quarry*, with a greater concentration in the traditional mining area.

Fig. 4, page 5: The map shows the overlapping of the previous ones: mobility infrastructure plus urban settlement. We can observe the huge interruption of the urban imprint corresponding to the extension of the mining area and also the minute grain of urban texture – we can gather by roads pattern - in the areas very close to quarries.

Fig. 5, page 6: The urban settlement and the mining area. In dark pink, the excavation areas; in violet, the storing areas and those one used for travertine manufacturing. We can well observe the so huge dimension of mining areas, compared with urban imprints and other geographical signs.

Fig. 6, page 7: Perspective sketch indicative of the relationship Casale /quarry. A first discretization of the environment relates to the identification of: superfetations, architectural elements for the recognition of settlement forms, spontaneous elements such as the presence of vegetation, access paths, topographical features. The view also shows the relationship between the development of the vacuum of the quarry and the vertical direction of the element punctual -house

Fig. 7, page 7: Eidotipo of longitudinal section of the quarry. The profile shows the relationship among the Casale and the quarry and the depth of excavation.

Fig. 8, page 8: Eidotipi in plan and sections of the system house / quarry. It 'clear that the house stands as punctual element, positioned in apparent randomness within a territorial transformation. The performance of the sections are indicative of procedures for the extraction of limestone. Also indicates the presence of groundwater, element variable trend.

Fig. 9, page 8: Sketch indicative of the relationship Casale /quarry, in a near quarry. The Casale/house is on the quarry face.

Fig. 10, page 9: Photography and sketch of a quarry face with annotation graphics and written for the recognition of stratigraphic sections of travertine quarry. This gives a first reading of the different porosity of the material, a feature that will impact on the acquisition and return data with the laser scanner. Also highlighted are the vegetation system and the presence of machinery to carry out the extraction cycle. These are among the elements of temporality and variability of the environment.

NOTES

[1] This paper regards a didactic research in progress at the Department of Architecture of Roma Tre University, starting from the master thesis in architecture of Silvia Rinalduzzi, who's the author of the drawings collected in these pages, under the direction of Laura Farroni, with Annalisa Metta e Francesca Romana Stabile.

[2] The use of laser scanner allows a high dimensional geometric control for framing in the environment and the environmental impact study. Specifically, the instrument offers a high flow rate of the shoot, the speed of acquisition, production of models DTM (Digital Terrein Model) and DEM (Digital Elevation Model), useful for the management of the quarry cultivation. Standardized operations are the calculation of the volumes (cut and fill also at different times to evaluate the areas of excavation) and surfaces, the extraction of the vectorized level curves of the area of quarry and the extraction of the sections of the quarry faces .

[3] To the digital returned model can be applied further information through the use of BIM.

[4] That sees the environment as a resource and not just tied to different constraints that may limit the development

Cultural landscapes in transition: Representation and relationship between shape and context

Serena ABELLO,¹ Chiara CANNAVICCI²

Department of Architecture and Design, Polytechnic of Turin, Italy

⁽¹⁾ serena.abello@polito.it; ⁽²⁾ chiara.cannavicci@polito.it

Abstract

The transition of the defense landscape understood as a variation, modification, of the image type, with different cultural backgrounds, communication objectives, completions of sense exists in parallel with the physical transitions, changes of use, changes in sense and meaning, as a real language. The fortifications draw the territory through a deep cultural stratification emerging interpretations of images with different and unique in shape and conservation condition have come down to us. Each historical period is characterized by methods and technologies available to designers: the representation is child of its time, from simple pencil sketches to "elevations" to the seventeenth-century prints perspective views to the current three-dimensional views. In order to better understand the nature of fortifications is essential to observe the changes of the project, from architecture "drawn on paper" to "drawn on the ground" from drawing to reality. The perfection of the geometric rule is applied on imperfect orography territory. Thus, the defense landscape lives and completes the transition "from war to peace", with its use of structures for different purposes, including through the process of "visual transition". They are fortresses, castles and fortifications born with functional and economic reasons that they cannot be reactivated today. However they can be modified and they can transit to the topicality by acquiring new meanings and values.

Keywords: representation, fortification, shape, context, drawing

1. Introduction

This paper continues the issues presented during the IX International Forum of Studies "Le Vie dei Mercanti" of 2011 (Aversa-Capri) focusing mainly on the relationship between form and context [18]. At this meeting, there were reported the first results of a research conducted by Serena Abello under the guidance of Professor Anna Marotta, concerning the cultural landscape in its conception from the material to the immaterial. Here, we propose further results of the research project that is to be completed as part of the PhD thesis in Cultural Heritage. Some themes still have to be further studied and deepened, as the thesis could only outline the main guidelines.

The themes here presented are to be placed in a wider territorial system that allows to observe and describe the anthology of European defensive types (preserved in treated), able to provide a new and different "network of learning and knowledge", as shown in various examples, from theoretical texts in the territory application.

The transition of the defense landscape understood as a variation, modification, of the image type, with different cultural backgrounds, communication objectives, completions of sense exists in parallel with the physical transitions, changes of use, changes in sense and meaning, as a real language.

Thus, the defense landscape lives and completes the transition "from war to peace", with its use of structures for different purposes, including through the process of "visual transition": from a real perception to a virtual vision, for a different and fully awareness of the landscape, understood as a disseminated and understood Cultural Heritage. In the written contribution for the XVI International Interdisciplinary Conference "The cultural landscape mosaic in transition" of 2011 (Udine), Anna Marotta and Serena Abello propose, through an summarized outline of the method, an approach for the defense' territory observation [19]. The study of the types of fortifications and the types of

representation were carried on through case studies taken as samples and gathered by categories with respect to typological and iconographic similarities.

The analyzed case studies are fortresses, castles and fortifications born for functional and economic reasons that cannot be reactivated today but that can turn and transit from the topicality by acquiring new meanings and values.

2. The context drawn: the defence territory

The fortifications draw the territory through a deep cultural stratification emerging interpretations of images with different and unique in form and conservation condition have come down to us [18] [19].

The perception of our cities is increasingly complex, and the observer becomes an insatiable researcher for new incentives and relationships. The definition of a specific territory, in particular the defense ones, requires the definition of landmarks thought as strong territorial signs with vast structures that characterize the urbanized areas. From their recognition it is possible to develop a restoration project, considering the existent as a mosaic of landscapes, that could be tangible or intangible. This constitute an integrated and consistent way to read the territory both in its complexity as in every single component.

The defense of the territory - with their "science and arts of war" constitutes, together with the food supplies, one of the human oldest activities. It can be considered one of the first human processes and therefore one of the first elements structuring of the landscape.

In particular we can notice how the symbolic value can be considered as an element able to support the cultural tourism – that is having an increasingly importance in the world economy – as well as social support if conceived as recognition of the population' identity.

The landscape, once became officially part of the Cultural Heritage, imply increasingly difficulties in decision-making because of the range of implicit meanings: the choice between the ideal image of the landscape – as proposed by Viollet-le-Duc – and the love for the ruin – as suggested by Ruskin – becomes complex. Von Humboldt, a member of the geographical and natural Mitteleuropean school, in 1846 defines landscape as "the entirety of an area features".

Among the key parameters for the analysis and observation of the territory, Anna Marotta [21] shows the relationship between two strong concepts like "geometry" and "architecture" that can be enhanced if they are correlated to each other, especially if the link between them is the word "construction". From the abstract form of the first of the first concept to the tangible physicality of the second one, the distance seems really short.

More in specific, Jacques Le Goff in his contribution (*Construction and destruction of the fortified city*) in the volume edited by Cesare De Seta [6], speaking about the city (in particular the city of foundation), shows that the urban phenomenon can be studied just starting from the concept of the "building": the city's history is articulated by alternating periods of construction, reparation, reconstruction with other periods of destruction and survival in the form of marks.

The research addresses the defense of the territory of the Alessandria area [Fig.1], as a vast anthology of fortifications types and military architecture. It has been inspired by the examples already studied by several authors – among them Anna Marotta, who has been crucial by her several contributions – trying to make a cultural connections within the Citadel of Alexandria [Fig.2] and others Citadel and City of foundation in a wider European context [7] [9] [12] [13] [14] [15]. This study determines a knowledge path and cognitive similarities and / or differences between the investigated types.

3. Representation and time

Each historical period is characterized by methods and technologies available to designers: the representation is daughter of its time, from simple pencil sketches to "stand up" to the seventeenth-century prints perspective views to the current three-dimensional views.

The representation has to be seen as an educated and critical knowledge operation that enables the communication and dissemination of a message. Of course, one of the first steps, to exploit the full potential of representation and visual communication at the same time, is the selection and definition of an adequate representation code. The collection of drawings in the Treatise of Wilhelm Dilich [1] make us understand, through the beginnings of the current representation codes, how the characteristics of fortified systems are described with embedded images, usually a floor plan and a front view. In the following pages there will be reported an example of fortification built on high ground [Fig.3] [Fig.4].

The representation of this specific structure can not be described exhaustively only by its planimetric view. Therefore it has to be associated with the design of the landscape in a three-dimensional view which is exactly halfway between the traditional statement of orthogonal projections and the axonometric and landscape definition.

In the eighteenth century the territory is mainly described in drawings of the "landscape" artists, how substantiate its entity through three-dimensional images, making the representation – this type of

representation – the best that allows the "visual possession" of the whole surrounding territory [Fig.5] [Fig.6]. These drawings were also performed works by survey operators – architects and engineers as well as artists-geographers – who, with few simple sketches, conveyed the thought and knowledge of the area to armies and leaders [20]. The landscapes also became the opportunity to represent the war describing the fortified structure at specific war event, as well as the attack and defense techniques at that time. Such representations, also if not metrically reliable, constitute a fundamental document for historical memory. The "views from above" representation, or axonometric and aerial perspectives have been constituted for a long time the element to convey the architecture and landscape knowledge. Moreover, in theory, the Treaties provide us the formal features of the fortifications, whereas the project drawings allow us to analyze the cultural context (investigating similarities and/or differences with the theoretical types).

At the same time the observation of the existent – with its graphic outcomes – allows us to verify the conservation state (including in relation to the original functions, modified or not) with the changes of the mutual relations between the defense project and territory, welded in a "defense landscape" in transition. The integration of various representation codes has been accompanying the iconography over time until, for example, the nineteenth-century celebrating drawings of the fortress of Bard by Francesco Antonio Olivero, that follow the established discipline of geometric design [Fig.7].

The assume is confirmed both for the traditional representation and the digitally expressions – in the geometrical thought as well as in the practice – it constitutes the fundament of the architectural formation and production. This is true both for the architectural and urban dimension: especially for defense architectures and cities of foundation.

4. Architecture "drawn on paper" and "drawn on ground": the shape

In order to better understand the nature of the fortifications is essential to observe the changes of the project, from architecture "drawn on paper" to "drawn on ground" from drawing to reality. The perfection of the geometric rule is applied on imperfect orography of territory [Fig.8].

In the implementation of the project from the intangible drawings to the materiality of realization often occurred that the perfection of the project had to fit the land conformation: the drawings were corrected during the execution phase and later depending on the peculiarities of the site.

In this case the representation can be seen as a tool for verification of the existent from the drawn project, in comparison with the archival documents, those belonging to the treatises (and iconography) and the physical reality. From research carried out on fortifications emerge that there are some case studies that allow the comparison of experiences very different each other. In this report, we want to give two examples of the relationship between architecture "drawn on paper" and "drawn on ground" and finally realized: the walls of Tortona and the Citadel of Alessandria.

Tortona is recognizable as a particular case in which architectural elements are "invisible" and no longer existing but where we can identify them through the knowledge of archival documents [Fig.9].

During her analysis phase on the Tortona Castel's shape, Anna Marotta [15] had to face with sources that mention how the original design was changed several times to adapt to the existing territorial situation.

The drawings show that from the "perfect geometry" with six bastions of the fortifications, the fortress had to adapt to the existing structures of the territory. The first version of the project is characterized by perfect geometric rules, then it has been transformed to meet the built environment. In this case, the project designed by the mathematician Campione has respected the position of the Convent of San Francesco that stood just outside the borders. The drawing also offers two variants for a section of the wall in which it was decided that *"Il colorito di Giallo pare meglio parere che fare la linea Rossa / e solo si fa una faccia in più"*. The design is considered an important document to understand the study and research of the best walls conformation in the existing territory.

The case study of the Citadel in Alexandria represent an example of fortification which, starting from the contemporary treatises indications, fits the physical conformation of the context in this specific case also geological [9].

Amelio Fara [5] describes the Bertola fortified hexagon, referring to the particular hexagonal shape and its deformation with the consequent loss of radial symmetry. In the specific case describes the generated shape as inscribed in an ellipse. Fortified hexagons take shape in the sixteenth century and are developed mainly in the seventeenth century, for example in the transformation of the hexagonal citadel in the castle of Milan, as well as the citadels of Perpignan and Casale, the Goletta Nuova, the hexagons of Vauban and Coehoorn.

Before dealing with the project for the Citadel of Alexandria, Ignazio Bertola has meditated on the theory of the fortified hexagon. His "Inventory of fortification" shows that he studied in particular in the treatises of Daniel Speckle (1589), Claude Flamand (first edition in 1597), Vincenzo Scamozzi (1615), Peter Sardi (1618) Pierre Mallet (1666), Donato Rossetti (1678), Du Fay (1681), Menno van Coehoorn (1685), De Cambray (1689), Doroteo Alimari (1692), Naudin (1695), Johann Friedrich Pfeffinger Junior (1698). Gabriello Busca, were defined as 'specialist of mountain fortresses' because he was able to

design observing the different levels of altitude that may affect the safety of a place controllable from above. In 1601 he wrote that "*la figura di sei lati fa il belouardo perfetto con la punta, se non retto, di pochissima cosa minore*" [9].

The shape of this peculiar fortress is coming from the need to allow the soldiers' wait as near as possible to the river, in order to take advantage of the best natural obstacle that you could have: the Tanaro river. Other factors that influenced his elliptical form, no longer evident, were related to hydrological issues: a large area in the south-west side of the fortress was (at that time) invaded by a branch, now deceased, of the Tanaro, with stationary and muddy water.

Furthermore, the chosen shape had also the purpose to avoid laying the foundations on areas prone to flooding. Bertola was able to design a form characterized by great harmony and rationality.

We can also compare in the literature different definitions of the shape of this fortified structure: "hexagon elliptical" and "hexagon oval" at the same time. Of course this dichotomy of terms can be evaluated only after a verification of the actual shape through an appropriate survey because, the geometry of the two geometrical figures can be obtained by different processes.

Finally, we can notice that the citadel was designed, and its location has been defined, mainly "on paper" and subsequently has been assessed the impact that this project would have: the complete destruction of an entire neighborhood with a major impact on urban conformation and its neighborhood as well as on its future opportunities for growth and expansion.

5. Conclusions

The architecture verification from the representation "on paper" and from the survey "on ground" can be the fundamental basis of a new representation which, also through digital technology, enable the revision, the study and the possibility of recovery in order to bring of the defense system from the past to the future, making itself an active part on this process.

The redesign of the built environment becomes a verification tool able to highlights the intrinsic value of the choice of an appropriate representation code. The drawing is then proposed as an explanation of the form as well as a tool for its comprehension and verification.

The representation codes – especially the axonometric one – have been crucial in the past for the checking of the fortified buildings. When the construction of physical models (*maquettes*) was too expensive, axonometric projections were the solutions for the calculation and verification of the range, for example, of the cannons. The great dissemination power of digital animations could act as a suitable tool to explain the geometry of fortified building that, starting from an hexagonal scheme as defined by treatises, could describe the really made conformation, as in the Alexandria Citadel case study (inscribed in an ellipse with major axis parallel to Tanaro river).

Moreover, the notion of shape can be extended from architecture sphere to the urban context. The value of the geometric construction of the territory is confirmed with great vividness in the fortified city, which was for centuries the urban prevalent model in the West world. This model is today presented to historians as a material structure at the same time, urban, social, political and, from the representation viewpoint, as an conscious and recognizable image. In particular, from what concern the urban form, the planimetric conformation of the current Citadel of Alexandria allows the reading of formal modifications which led to the tradition "from war to peace" up to the present. The urban form was substantially blocked in its expansion until more recent times, when the preservation of the fort territory has been forgotten leading to an incontrollable spread of buildings. But this is another topic ...

Sustainable Landesign for Archaeology

Ottavia GAMBARDELLA

Department of Architecture Federico II, Naples, Italy
ottaviagambardella@gmail.com

Abstract

The abstract proposes an illustration of a Research carried out during the Workshop "Archaeology and Architecture: Campi Flegrei"¹. The aim of the Workshop was to identify strategies of intervention to enhance the cultural and archaeological heritage of Campi Flegrei in Pozzuoli. My research is focused on the theme of landscape design and mobility at urban and territorial scale. The mobility infrastructure has a key role in the use of cultural heritage "establishing violent, though sometimes suggestive, relationships with the context" (B. Secchi, 2000). The mobility space is not only seen as a simple connection element but as real place for socializing and living outdoor. The design approach for the regeneration of the areas is characterized by the use of a complex and integrated system of sustainable mobility, which is a hybrid between the traditional public transport and alternative means of transportation. One of the aims is to change the approach of people to the mobility in the territory, promoting knowledge of the city and a perception of archaeological sites different from those given by the use of the car. The complex system of sustainable mobility and the redesign of the urban park proposed could represent strategic tools to improve the habitability of archaeological sites and the quality of life of citizens, in a new concept of city that is not only welcoming or supportive but that can reinterpret itself and interpret new forms of living, mobility and production.

Keywords: sustainability, mobility, Archaeology

1. The Analysis of the area

The Campi Flegrei is a large volcanic area situated in the north-west of the city of Naples. The area is characterized by a strong presence of volcanoes and archaeological finds that determine an enormous historical, environmental and territorial importance. During the Workshop "Archaeology and Architecture: Campi Flegrei" my research has been focused on the identification of strategies of intervention to enhance the cultural and archaeological heritage of Campi Flegrei in Pozzuoli through the regeneration of the areas and the creation of a complex systems of sustainable mobility. From the Plan it is possible to notice the landscape importance and the strong presence of archaeological sites in the area. The archaeological remains, due to their fragmentation and the absence of historical and urban contextualization, present a condition of incongruence with the territory. Both the remains visible for centuries, and the finds discovered or rediscovered recently are not or poorly integrated with the urban space. There is mostly a musealization to fulfill conservation purposes. There isn't a dialogue between the different times of the city, thus reducing the archeology passive object of a merely aesthetic contemplation. To avoid the embalming of archaeological remains - and its reduction to relic of memory - the architectural design should try to trigger new relationships between the finding of the past and the contemporary urban landscape.

¹ Workshop that took place in the University of Naples Federico II, Department of urban Design and Urban Planning, on June 2012, proposed by Professors F. Izzo, P. Miano, L. Pagano.

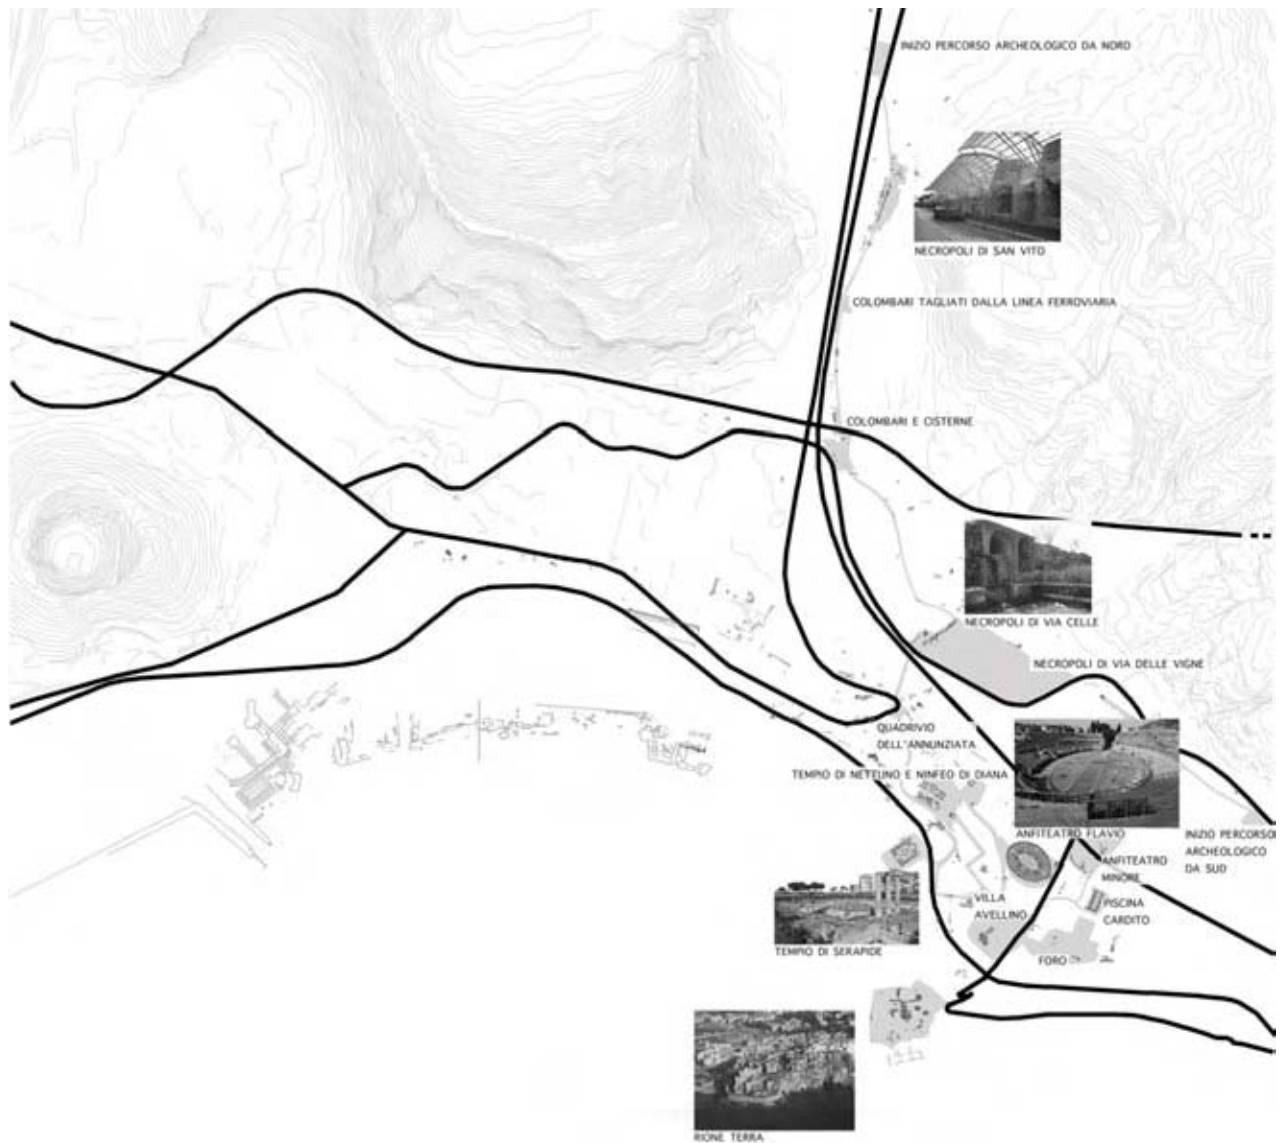

Fig. 1: Areas of interest.

Fig. 2: Morphology and Archaeological areas| Infrastructures.

The plan highlights and shows the archaeological sites of major interest in the study area considered during the Workshop, (the Rione Terra, the Temple of Serapis, the Flavian Amphitheater, the Necropolis of Via Celle, the Necropolis of San Vito, etc.) and it shows the idea of an archaeological trail to connect them together. Currently the area is characterized by a reduced or absent accessibility to archaeological sites, by a lack of integration with the context and with the existing infrastructure, by a strong traffic resulting in congestion of certain road networks. As it is possible to see from the plan the area has a relatively well-developed infrastructural facilities (rail, metro and roads). It is characterized, however, by a lack of sustainable mobility, lack of public spaces, green spaces and urban parks, overload of traffic, inadequate parking system, widespread presence of unused areas that are characterized by spontaneous vegetation and degradation, and the environmental and landscape quality of the context is not adequately valorized. But the same territory is also qualified by the presence of several factors interpretable as strengths that form the basis from which it is possible to define the strategies oriented towards a sustainable redevelopment. The availability of historical and archaeological heritage, the presence of a significant natural heritage and the good existing infrastructure networks, represent strategic factors exploitable in the view of a sustainable process of development to valorize and to enhance the cultural identification of the territory.

2. The Strategies

Fig. 3: Archaeological park.

It is essential a rethinking of public open spaces that should be reorganized through a unified design that enhances the archaeological areas, improving the management and use. The archaeological park proposed in the plan would have the function of connecting the various archaeological sites scattered across the territory, but also to regenerate unused or degraded areas, provide green spaces, create public spaces and meeting places, increasing the environmental quality of the area.

Fig. 4: Archaeological route.

Like the built environment, the space of mobility is not continuous as a fully connected network; you can read it instead, as an addition of separate layers that have different uses, in the complex urban “palinsesto” (A. Corboz 1985). It is necessary to analyze the infrastructure system to understand the role they have played and still have in creating the shape of the city. It is not seen only as a simple connection element but as real place for socializing and living outdoor. The design approach for the regeneration of the areas mentioned before is characterized by the use of a complex and integrated system of sustainable mobility, which is a hybrid between the traditional public transport (metro, electric bus) and alternative means of transportation (bicycle lanes, bike sharing, electric car sharing, cable car). This system could constitute a valid transport alternative to private vehicles with the result of a strong reduction of vehicular traffic. One of the aims is to change the approach of people to the mobility in the territory, promoting knowledge of the city and a perception of archaeological sites different from those given by the use of the car. The most appropriate strategy in this urban area could be a system of squares and pedestrian paths within the broad areas in the park. It seems of particular interest the study for the connection between the compact urban area (where the greater amphitheatre is located) and the hills to the north of the Via Campana, currently separated by the railway. It is important to note the crucial role of the urban mobility system, as part of the redevelopment of this area that has to deal with the concepts of environmental sustainability and the new social and cultural needs of the inhabitants. Strategic actions on mobility, as well as the reconfiguration of the entire system of public spaces, allow to redefine the structures hierarchies and to bring to fruition the collective abandoned places or the hidden high environmental qualities. Improving the system of

mobility in a sustainable way, through the introduction of alternative forms of transportation, the offering of innovative solutions for the context, the optimization of all the forms of transportation, the integration of different types of collective and individual transportation, and the introduction of pedestrian and cycle paths, together with the rationalization of traffic flows, is a necessary step to improve the quality of the environment and the lives of the inhabitants. Given the high natural and historical value of the interested areas, it has a considerable influence the enhancement of sustainable tourism, through the insertion of paths and tourist routes of large area, resulting in the development of new economic activities related to tourism oriented towards the discovery and the enhancement of historical and natural resources. Another important aspect of the project is the integration of research built with a green project, with the reconfiguration of spaces and the creation of new ecological connections and the improvement of environmental quality. In addition to improving the quality of life of citizens and the environmental quality, these actions could allow greater synergy between different economic sectors (culture, tourism, services, etc.), including through the organization of events capable of giving increased visibility to the territory and to its economic activities

Abstract

The energy saving has been labelled as "the first renewable energy source" and thus it can play an important role in the reduction of electrical energy use for artificial lighting. A way to achieve this consists in a conscious and careful use of daylight design, within the architectural design process, aimed to evaluate the natural lighting conditions inside a building and for studying the distribution of daylight across a space.

In this paper are presented the results of daylighting measurement performed inside an artificial sky of a "mirror box" type where a scale model of an industrial building was tested to acquire data on internal illuminance levels, daylight factor and luminance distribution of internal surfaces.

Data were then compared with those obtained by a computer simulation software to determine the potential savings due to daylight and to compare the physically accurate simulation results vs. videographic measurements.

Keywords: Scale model, artificial sky, daylight factor, Ecotect, Radiance

1. Introduction

Nowadays the daylighting impact on interior building requires particular attention with reference to the several steps of the design process, due to the "environmental issue", that claims for energy savings above all and for energy use reduction in the artificial lit environment. To this aim, the daylighting potential assessment can be exploited by means of several tool that offer to architects, the way to evaluate the daylighting performance during the several design choices. Many software are commercially available, and the daylighting calculation can be "physically correct" depending on the capacity of simulating all variables that occur during the process (sky luminance distribution, glazing characteristics, internal wall and furniture characteristics, etc...). On the other hand when the building shape becomes very complicate or it is essential for architects to personally appreciate the luminous environment of a space and to compare several solutions qualitatively, the use of scale models allows to evaluate the light behaviour under real sky or, using an artificial sky, to achieve repeatable data to compare the results for different design solution. The scale model utilization lead not only to an intuitive appreciation but can give, when properly constructed, the distribution of daylight within the model as exactly as in a full-size room with very accurate results. Especially for complex model, it is essential built it carefully to obtain accurate results. To reduce arising errors in the scale model construction and evaluation, several rules and tricks have been developed [1]. The use of scale models offers the opportunity to use real material and, if used under artificial sky, to simulate many tipe of sky condition. Since materials used to built scale models represent a fundamental aspect to get accurate data, it has been developed a tool to help architects and lighting designers to choose suitable materials to build scale models [2].

Daylighting models are used throughout the architectural design process to help make decisions about the natural lighting conditions inside a building and for studying, above all, distribution of daylight across a space, luminance evaluation and quantitative measurement of daylight levels in a space with

Fig. 1: The artificial sky realized at Department of Architecture and Industrial Design "Luigi Vanvitelli".

its potential lighting savings. Together with other prediction tools, like computer simulations, daylighting models have the advantages of seeing and evaluating the daylighting both qualitatively and quantitatively, modelling spaces with geometries too complex for computer simulation and finally, changing and optimizing for the best lighting conditions.

In this paper are presented the results of a research developed, involving, by several steps, the available "tools" for the assessment of daylighting contribution in a lighted environment.

2. Sky simulator facility

To offer to architects, lighting designers and students the possibility to evaluate lighting performance in buildings, at Department of Architecture and Industrial Design "Luigi Vanvitelli", an artificial mirror sky was realized. The figure 1 represents a reconstruction of the artificial sky realized, in which is possible to identify the position of mirrors, lights, scale model and the other components.

The artificial sky consists of a box (3 m x 3 m) whose walls were coated with mirrors and whose ceiling was realized by a bank of linear fluorescent lamp behind a plate of opal polycarbonate. It was realized and calibrated to simulate the CIE standard overcast sky distribution [3].

To allow the acquisition of data, artificial sky was equipped with illuminance sensors and a luminance measuring camera. When a scale model was tested inside the mirror sky, are acquired the internal illuminance levels, to calculate the related daylight factor (DF) and the luminance distribution of internal surface, to know the distribution of daylight within the model.

The daylight factor, so calculated for different points of scale model, were then compared with those obtained by a computer simulation software "Ecotect" and "Radiance" to determine, with its daylighting features, the potential savings due to daylight while, the luminance distribution, acquired using luminance measuring camera, was compared with those obtained by a computer simulation software "Radiance" to evaluate the physical accuracy of simulation results.

3. Methodology

This paper deals with process of the renewal and refurbishment of the fabric of an industrial building; in particular the building considered housed an old "Opificio". In figure 1 is reported an external view of the building analyzed. The research has been organized in four steps:

- The first step is to raise information about the state of the structure and the environment in which it was located, the geometry and the photometric characteristics of the material used to realize it.
- The second step is to realize a scale model for reproducing geometry of the real building and the property of materials characterized in the first step.
- The third step is to implement a geometric model of building in a simulation program.
- The fourth step is to compare experimental and simulation data [4] and to verify that the daylight is compliant with italian standard.

Fig. 2: An external view of the “Opificio”.

3.1 Site characterization

To obtain geometrical information about site, building dimension, form and orientation, internal division of space, position and dimension of windows, an on-site survey was realized.

In the same way, the surfaces were characterized by photometric point of view, using a spectrophotometer (Minolta CM – 2600d). The photometric characteristics of walls, ceilings and floors were measured and were archived through graphic data, about colour and reflectance property, and numerical tables, about colorimetric values and indices. The properties were evaluated considering the specular component included and excluded.

The site survey, showed that the building required major repair, especially for the stonework which has weathered or decayed to a structurally unsound or aesthetically displeasing condition.

3.2 Daylighting model and acquisition systems

The investigation target was the evaluation of daylight distribution inside the building and the proposal for an integration with the artificial light. To this aim a scale model was built-up with appropriate scale and materials. The materials photometric characteristics measuring in situ were used to define the property of scale model surfaces.

The model was realized using wood to ensure a very robust structure; to reproduce photometric measured values wood surface was coated with white paint. In this first analysis step, the windows were not considered. To limit the disturbance, that the presence of scale model brings to the artificial sky luminance distribution due to the limitation of the inter-reflexions, the size of model was limited to 0.3 m for height and to 1.0 m x 1.0 m for base.

To guarantee the accuracy of experimental measurements, it was not sufficient to realize with care the model and to choose its size to minimize the disturbance of the artificial sky luminance, but many attention were also placed into collocation of illuminance and luminance sensors. For this reason, several instrument have been employed for scale model experiments [5].

The model, so realized, was then tested under the artificial sky developed at the Department of Architecture and Industrial Design “Luigi Vanvitelli”.

To evaluate the distribution of daylight factor, the illuminance values, inside and outside the model, were acquired with miniaturized photometric sensors. The illuminance sensors were made by PRC Krochmann GmbH and have a small directional error (cosine correction). Similarly, to evaluate the luminance distribution on the inside surfaces of the model, some snapshots within the model were taken using a LMK 98 colour CFA CCD luminance-meter. In the figure 3 is reported a picture of the scale model.

3.3 Daylighting study

Simultaneously, a geometric model of the “Opificio” was implemented in two simulation programs, Ecotect and Radiance. In figure 4 is shown the model developed for simulation programs.

Fig. 3: Scale model of “Opificium” for acquisitions in the artificial sky.

ECOTECT uses the Building Research Establishment (BRE) Split-Flux method that is a widely recognised and very useful technique for calculating daylight factors in a preliminary study (it's defined as the ratio of the illuminance at a particular point inside a space to the simultaneous unobstructed outdoor illuminance under exactly sky conditions).

This method is based on the assumption that, ignoring direct sunlight, there are three separate components of natural light that reaches any point inside a building:

- Sky Component (SC) - Directly from the sky, through an opening such as a window;
- Externally Reflected Component (ERC) - Reflected off the ground, trees or other buildings;
- Internally Reflected Component (IRC) – The inter-reflection of surfaces within the room.

RADIANCE is a computer software package developed by the Lighting Systems Research group at Lawrence Berkeley Laboratory. It is a research tool for accurately calculating and predicting the visible radiation in a space by using a combination of raytracing and radiosity techniques (it takes into account specular, directional-diffuse reflection of materials). The program uses three dimensional (3D) geometric models imported by ECOTECT to generate spectral radiance values in the form of photo realistic images.

The simulation analysis for “Opificium”, distribution of illuminance and daylight factor, was firstly performed considering a simplified, but faster, approach, and later considering and evaluating the parameters that could affect the analysis to enhance the results obtained in the first simplified approach. To also evaluate the luminance distribution, the model was exported to Radiance Desktop to obtain illuminance distribution.

Fig. 4: Geometrical model of Opificium developed for simulation programs.

3.4 Comparison of experimental and simulation data

The experimental data, obtained for the scale model under a mirror sky, and the simulation data, implementing a geometrical model in a simulation program, were then compared to have an indication about the relationship between data acquired under artificial sky and output from simulation. The comparison was conducted in terms of daylight factor and luminance distribution. In particular, for luminance distribution it is interesting to notice the capability of simulation program to predict luminance distribution.

In addition, some pictures were taken within the scale model (illuminated by artificial sky) to evaluate the behaviour of inner light and compared it with light behaviour simulated by using Radiance.

4. Results

In figure 5 the sketch of scale model and the acquisition points are reported. The position of sensors were organized in four rows with seven points for row, with a total of 28 measurement points. The location of sensors were chosen in order to evaluate the illuminance values variation from windows to middle of building. The data was acquired with an external illuminance of 10000 lux. In figure 6 were reported the position of sensors for row #1 and row #3.

Fig. 5: Map of scale model with acquisition points.

Fig. 6: Photometric sensors placement in row #1 (left) and row #3 (right).

To compare the results of the analysis, both experimental and simulation data are reported in figure 7, where are plotted the values of daylight factor related to the investigation points. The values are showed considering selected rows and the associated measurement points.

From the reported graphs it can be inferred that both measured DF distribution and simulated DF distribution at different rows, show low percentage deviation with DF good uniformity; near the windows and at the back of the room, the deviation among different rows slightly increase. It can be noted that largest deviation occurs for calculation point # 4 on row # 4 for Ecotect simulation; this software simulation also evaluate higher DF values for row # 4 with respect to those evaluated by Radiance and measured.

As one can expect, all compared graphs show higher values near to the front wall aperture, a regular decreasing in the middle points and a very slight increase for the inner placements (points # 1).

Finally the main difference arise from direct comparison of DF values; the Ecotect results largely overestimate the measured DF, giving values that are 100% higher than those acquired. The comparison between Radiance and measured data shows a good agreement for points near aperture (# 7), with Radiance graph decreasing toward lower values (# 4).

The pictures in figure 8 shows the light diffusion in the internal space of scale model (left), and the light distribution simulated using Radiance (right); the comparison is done for two areas of building.

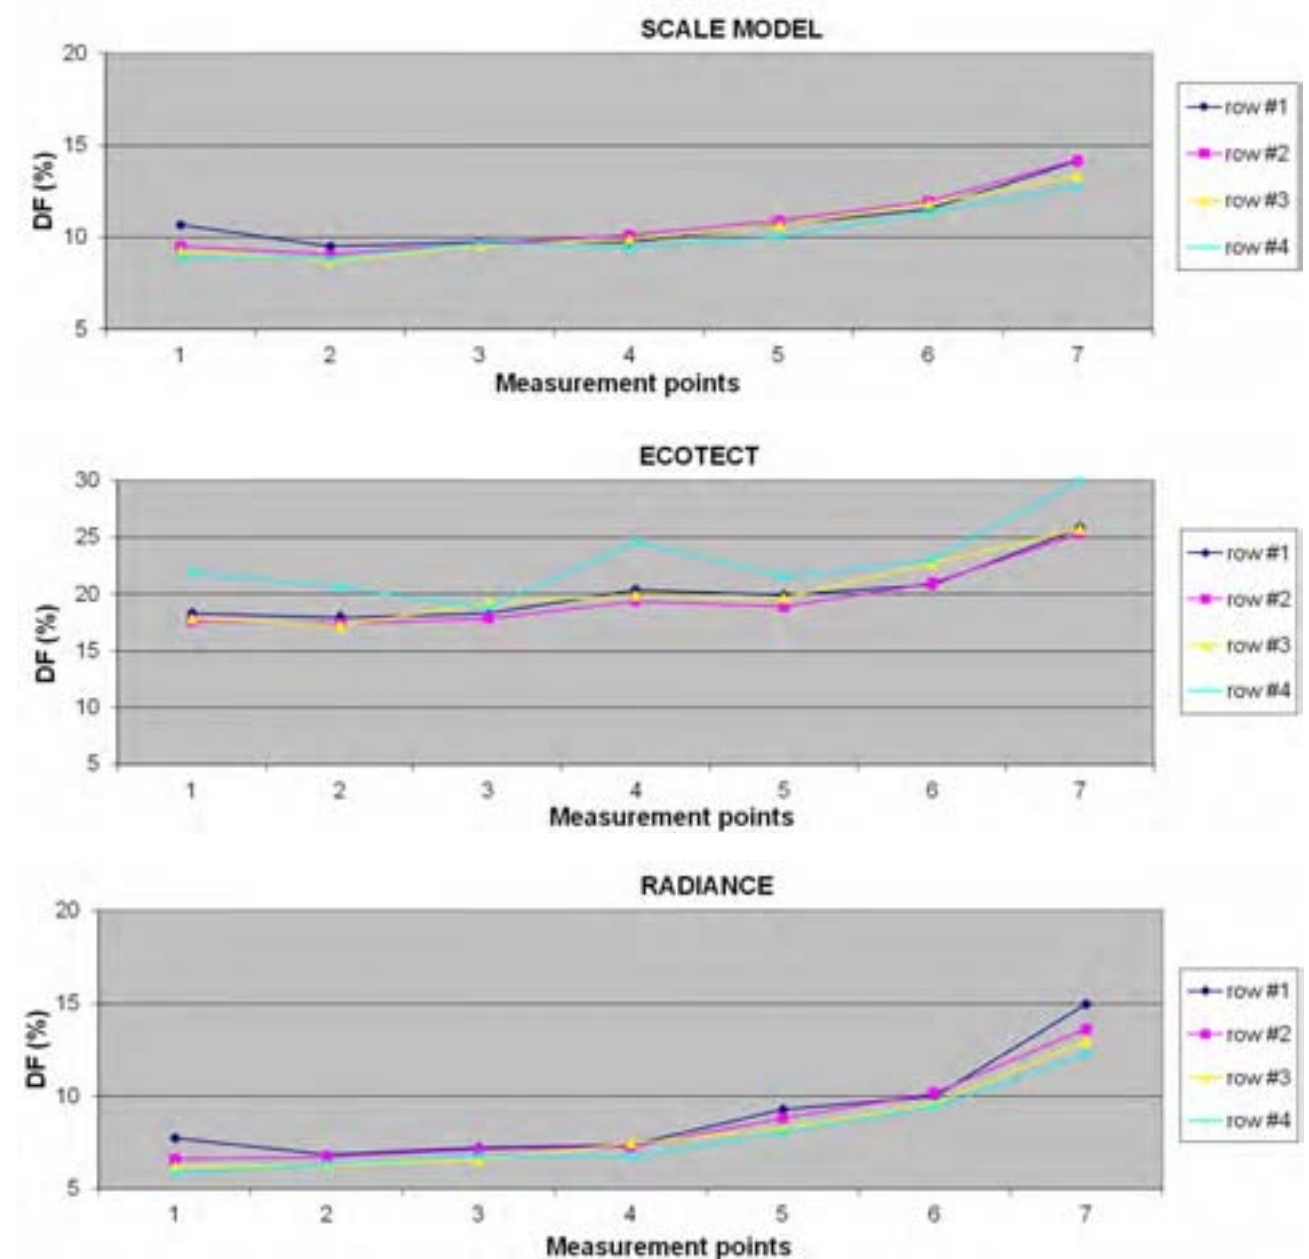

Fig. 7: Daylight factor comparison, obtained from scale model (first), Ecotect (second) and Radiance (third).

In figure 9 are showed the results obtained by the comparison of Radiance internal luminance mapping vs. luminance distribution measured with a CCD videoluminancemeter. The false-colour mapping highlights the influence of model reflexions onto internal mirror wherever the radiance simulation gives an uniform source on the aperture considering also the ground presence; furthermore the luminance value corresponding to the aperture (950 cd/m^2) is greater than that measured (806 cd/m^2).

At the bottom of the aperture the luminance values of software and acquisition appear very close, confirming the results of DF analysis, whereas the luminance values on the room vault by Radiance calculation seems to be significantly lower; this should lead to a minor influence of internal reflection and thus it could partly justify the discrepancy in the comparison with reference to the inner points.

Finally the Radiance mapping shows, above all, a greater homogeneity of luminance distribution patches.

Fig. 8: Internal light distribution comparison scale model (left) vs. Radiance (right), for two building area, a) and b).

5. Conclusion

In the study above are presented the results of a research on daylighting assessment in an industrial building fabric; the research was developed involving scale model DF measurement in a mirror sky box (under CIE standard overcast sky distribution) and its comparison with a computer simulation software "Ecotect" and Radiance; the last supplying the opportunity of evaluating and comparing the internal surface luminance distribution.

The utilization of scale model allows, even if computer simulations can give very accurate results in a reasonable time, the capability of appreciating internal environment and comparing several solutions. This requires the utilization of sky simulator (reproducing standard sky luminance distribution) and a properly constructed scale models that are built accurately and with respect to several rules to reduce the error sources.

Fig. 8: Luminance distribution comparison scale model (left) vs. Radiance (right), for two building area, a) and b).

The opportunity of measuring the internal surface reflective characteristics can help in reproducing the physically-based lighting calculation.

In our study both software simulation give, with an acceptable accuracy, a quite uniform shape of DF pattern on grid measurement, but Ecotect software greatly overestimates the DF values; this is in contrast with the Ecotect calculation method that use the BRE Daylight Factor method and so it doesn't consider multiple reflections.

The Radiance performances are instead quite close to model measurements both for illuminance calculation and luminance distribution; it seems to be related onto the opportunity to reproduce the theoretical Radiosity-based diffuse reflection calculations reducing the errors source.

The different approaches used to evaluate daylighting performance and the results obtained by their utilization suggest a suitable choice of the better "tool" to be used depending on specific application. A software capability of performing daylighting, solar exposure, insulation, thermal, acoustic, lighting analysis could be very interested in the initial step of design process because of it is able to provide important design decisions. On the other hand a more accurate daylighting evaluation approach (scale model/radiosity based software) has to be carry out for taking into account the variables involved in the complexity of the daylight distribution inside a space.

A DIRECT LINE TO THE RIVER SIMETO

The result of the third edition of the international workshop *simeto landscape* organized from the founding of order of A.P.P.C. of the district of Catania was the point to start some considerations, studies and investigations on the Etna area, crossed by the river of Simeto. As a pulsing artery of this area, the river pumps energy and provides to the conditions to develop different systems of settlement for size and morphology. Quiet and discreet, the river reaches a length of over 113 km, it is the main river of Sicily both for its hydrographical and anthropic size. In his path does not cross any major center, but it touches the countries of Bronte, Adrano, Paternò, Motta / Misterbianco to flow at the end in the bay of Catania. The river represents a line of conjunction both morphological and socio-cultural of this territory, but overall it represents the cohesion of all different landscapes of this area. Along the way he meets different landscapes, sometimes finds space between the walls of black volcanic rock, sometimes crawls on rough track of pebbles and red sand, other times creeps inside of thick green areas rich of vegetation, in this continuous change of level, of scenes, of colors and smell, are two the elements that never change, that are always the same at every season and at every hour of the day and the night, and that represent the aim and the power of this landscape: the Etna and Simeto.

Keywords: riverfront, valley, fortress.

1. The concept of landscape

The implementation policies of environmental sustainability to the term "landscape" has never been associated with a clear definition and agreed until the entry into force of the European Landscape Convention.

The Convention considers the landscape as a "certain part of the territory, as perceived by people, whose character is the result of the action of natural and / or human and their interrelations" is the "essential component of the living environment of the people, expression of the diversity of their shared cultural and natural heritage, and a foundation of their identity". The term "landscape" then defines a part of the territory which is recognized by the inhabitants of that place.

The link between population and territory is closely related to the spatial and temporal forms of that place, that are perceived by inhabitants and represent the identity of the same place. This character of the landscape is thus related to natural and cultural factors / human factors, it is necessary to clarify definitively that the concept of landscape is not defined only by the

environment but also the transformations, that people pour on their territories, delineate a combination that allows us to observe "the landscape" and recognize it as such. [1]

2. The river Simeto

The work of the third edition of the international workshop "Simeto landscape" organized by the order of the APPC of Catania was the starting point from which to do some thinking, studies and investigations on the Etna area crossed by the river Simeto. The river is a pulsing artery of this area, pump energy and provides the conditions for settlement systems with different size and morphology. Quiet and discreet, the river reaches a length of over 113 km, it is the main river of Sicily, both anthropic that hydrographic point of view. Born about 10 km north-west of Bronte almost touches Bronte, Adrano, Paternò, Motta / Misterbianco but his path does not cross any urban center. The whole course of the river is included in the district of Catania, while its basin extends in the district of Messina and Enna. The river is an element of union and conjunction, both topographical, that morphological and socio-cultural point of view. The regime of Simeto is typical of rivers of Sicily, extremely torrential floods in autumn and winter, and strong lean in summer. Only the mouth of the river at south of Catania, as well as the industrial area, is the most prone to flood risk (Fig.1) for the illegal buildings that cover indiscriminately this area, and which in 1951 resulted in a devastating flood. This is the area in which the river is close to the biggest town along the rest of its course, going back to the source, the river bed is plenty far away from population centers. For this reason it's important to think ideas for the redevelopment of riverfront, that is able to rehabilitate a direct relationship between the river and the city. An important point to start is the infrastructure system of the river. A series of bridges of different historical periods through it, but have lost their connection function between the river and the city, and represent metaphorically the bond apparently lost between man and the territory from which itself comes from.

2.1 The passage of Pietralunga

The passage of Pietralunga (Fig.2), which takes its name from the old Roman bridge, its remains are still visible, along with many others, has been included in the list of Sites of Community Interest SIC for the conservation of natural habitats and of wild fauna and flora and a territory which includes the municipalities of Biancavilla, Centuripe and Paternò. In this list we find lava walls of varying heights between 5 and 15 m, excavated by the river in the basalt formed as a result of lava flows from Mount Etna, the largest volcano is in fact very close, and the river touches almost throughout the western part of the base. From the ancient Roman bridge (which dates back to the Roman conquest of Sicily, and at the first Punic war, to tear Messina to the Carthaginians in 264 BC), today remains just a fragment practically abandoned and the name of the bridge was eventually assign to a another bridge more modern, in concrete and iron emblem of speculation of 70s. The new bridge of Pietralunga is an infrastructure disproportionate to the place and its function, it connects the main road n° 137 to countryside, and to private land today uncultivated , but that once housed farms and guestrooms. The bridge despite his total inadequacy in shape and size (Fig.3) in a country setting, unites and divides the two sides of the river, highlighting the differences between the two landscapes in contrast. So on one side of the bridge, we have an agricultural landscape planted with orange trees, well-kept with an irrigation system that takes advantage of the proximity of the river, from the other side instead an arid landscape, with sand's mountains deposited there by the river, dry thistles and indian fig . The bridge seems thrown there by mistake, it is the only element that expresses the relationship between the river and the city of Paternò which is located about 3 km in north. Across the orange groves, beyond the walls of lava's stone and other crops that spread along the valley, stands on a hill the symbol of Paternò city, the Norman tower clearly visible, even from the valley of Simeto.

2.2 The castle of Paternò

The Norman tower also known as the Castle of Paternò was the main tower of a fortress complex , of which today remains just a bastion facing east towards the valley of Simeto. The tower became the symbol of the city, it was part of a castle which was built in 1072 by Count Ruggero to ensure the protection of the valley of Simeto from the Islamic incursions. The castle was given to the daughter of Ruggero, Flandrina, wife of Aleramico Enrico of Lombardia. Around the castle and the

small village the population started to grow thanks to the numerous mercenaries of Norman conquerors and the arrival of settlers coming from Northern Italy attracted by the privileges granted to them. The first nucleus of the manor was soon expanded and original functions purely military were replaced in civilian use and became the seat of the County of Paternò that Henry VI of Swabia in 1195 gave to the noble Norman Bartholomew de Luci kinsman of the king Swabian . The Castle in the following years was the residence of kings and queens, including Frederick II, Queen Eleanor of Anjou and Queen Blanche of Navarre. The castle of Paternò and territories surrounding, in fact, were included in the so-called Camera Reginale which was founded by Frederick III of Aragon as a wedding gift to his wife Eleanor of Anjou and then was inherited from Queens that followed, until its abolition . After the 1431 belonged to the Special family and from 1456 until the end of feudalism was owned by the family of the vice-regal Moncada. Used as a prison in the eighteenth century began the process of decay and neglect, but by the end of the nineteenth century saw several campaigns of restoration that has returned the ancient majesty. The building has a rectangular plan on three levels and reaches a height of 34 m. Since the Swabian castle was crowned by Ghibelline battlement (as noted in the seventeenth-century Drawing of the view of Paternò) of which at present resist only some stumps. Particularly interesting and enjoyable the effect of bichromatism that is created between the dark color of the walls and frames of openings in white limestone. On the ground floor there are a number of service areas and the chapel of St. John decorated with very valuable frescoes of the thirteenth century. The first floor of the great hall of arms is illuminated by a series of windows. On the top floor there are four large rooms formerly used for the residence of the kings, these are separated by a space with the same size of the living room below, but placed transversely to it, closed on both sides by two large gothic windows, which allow to our eyes to enjoy of the view of Simeto valley and volcano Etna. A most recent restoration carried on by local government in the 80's makes more changes, some of which may be too invasive, as the reinforcement of the reinforced concrete structure in the upper part of the tower, to bear the large and heavy glass windows with its iron frames, which close the huge windows of the royal hall of the tower, which once were obviously open and allowed a good view on whole Simeto valley on one side and on the village from other side. Another restoration it's done on the walls, which were completely plastered and in some point have been created spaces with seats in bricks and mortar, an intervention maybe a little bit too arbitrary and artificial.

2.3 "City - river"

Paternò has a long history and complex, which is expressed clearly through its urban fabric, marked by a significant variety of styles and architectural orders. On the hill stand out sharply the Norman tower and the church of the cemetery, (Fig.4) from where starts a magnificent Baroque stairway that connects the upper part to the lower part of town (Fig.5). Paternò infact is divided into two parts, one consisting of oldest buildings, typical of country houses perched and linked to each other and then there are more modern buildings, without any kind of architectural quality that correspond to the new part of the country, the suburbs, arose under 70s. Behind the tower affords a completely different scenery, contaminated only in the very first part from the skeletons of the paper factories abandoned (Fig.6), and some mills too they no longer in use, the rest is a large land of fields of orange and olive groves, unto shore of river. The Norman castle therefore acts as a fulcrum between these two different systems. From the point of view of landscape was surprising to discover the power of Simeto valley to collect inside a wide variety of landscapes. This river is a "good river", has not very large, it is not full of water, did not cause much distress and have not been registered numerous floods, for this reason seems really possible recover the ancient connection between city and river, to return its true identity at this place. The objective of departure was to connect the two territories, the castle rock, symbol of the city of Paternò, and the downstream area of the river. The Simeto, layered palimpsest of landscapes far in the time, since antiquity was navigable and was the main means of communication between the parts of the urbanized area, has now become a subject of discussion and fulcrum of an hot debate to find an idea that values this place to give a new and stronger identity. The area identified poses a objective: the connection between the river the networks that crossing it and the city. Restore the relationship with the Riverfront identifies three main objective that the project have to connect : the fortress, the valley and the river.

Design a piece of a larger system, the river, where you have to take into account the difference in scale between the urban and the surrounding landscape, was the real challenge of this work. The place itself has suggested the solutions of a project to promote and protect a place of great cultural and scenic value, which must be promulgated and published and must be able to accommodate a larger number of tourists in order to create a new economic resource for the country, which has a great potential for cultural-tourism poorly understood and exploited.

2.4 The fortress

After a pleasant walk through the cultivated fields of Paternò i tried to capture some ideas, find solutions that marry well with the environment and the existent , ideas that the landscape itself could suggest. so I found myself admiring a solution of containment of the soil used by farmers widespread almost everywhere lent itself well to a reinterpretation to resolve the difference in level between the tower and the Simeto valley (Fig.7). This containment system uses the typical material of the area, and therefore readily available, the lavic stone. So i thought at a series of lavic stone walls retracing the old defensive walls of the ramparts at the base of the tower, to mark at same time a path which in some places opened by slits to the landscape and in others it becomes parapet of a viewpoint, from where you can catch with look at the beauty of a unique landscape, with the Etna on one side and the sea from other. At a certain level you can also arrive to the only remaining bastion that has an internal path, between the thickness of the two walls, where once stayed the guards who controlled the territory, o you can stay on the top of bastion at the level of another path. these two trails are linked to another zig zag path that winds up from the base to the top of hill. Along the trail it's possible to find several little spaces suitable to hospitality for tourists, simples viewpoints or a series of small "workshops" carved into the hill , with three walls underground and one open on the path, these places provide shelter from the sun, provide a space where you can stop and enjoy a picnic lunch or find a small restaurant.

2.5 The valley

From the parking lot at the base of the castle hill, in the side facing valley, the tourists, who arrive here by car or bus, can pick and choose if climb up to the castle or rent a bike or quad to reach the river. Along the road that leads to the bridge of the 137th Pietralunga, a series of shops may sell wine and food products of the place. Other shops placed also inside fields of orange and olive groves, with the consent of the owners could enhance the activity of direct collection of crops, particularly of blood oranges, typical of Paterno, whose production in some areas, it's unfortunately already been abandoned due to the crisis. More shops that they are simple containers made of wire mesh and stones wasted from working the fields, the trees instead provide shelter from the sun and exudes a intense smell of orange blossom. These activities are offered mainly to tourists but nobody forbids that the citizens can take advantage of these services during feast days and enjoy the wealth of a place and a landscape that belongs to themselves.

2.5 The river

The river is a truly identifier, from here you can enjoy a landscape even more surprising, the murmur of water, the wind in the trees the protected species of fauna and flora, that are and should remain the owners of this place. To have a successful project we know that it must emphasize and enhance the characteristics of the place itself. It certainly can't think of upsetting the space, it's important to capture strong point of place. Here the strength is unquestionably the direct relationship with nature, an uncontaminated nature that must be safeguarded. A minimal intervention, that allow a cohabitation more "comfortable" between the travelers or visitors and the river. Some rafts made by a wire mesh filled with lava stone,(fig.8) lying on the banks of the river could be a good solution for the use of this site. The rafts from the simple and pure form are very versatile and can be the solarium rather than staging points for refreshment, rather than points in which to read a book or to fish during a camping . Since Paternò is far from the sea but however exposed to the summer heat, a system of phytoremediation (fig.9) allows the purification of river water so in some places the people could make a refreshing bath. This would become a viable alternative for the residents of Paternò, who instead to make many miles to reach the Plaja of Catania, they could have the opportunity to live their river

Abstract

The “theory of permanence”, formulated by Aldo Rossi drawing on the thinking of French proto-urban planners Marcel Poète and Pierre Lavedan, has designated, in Italy as in the rest of the European continent, a period in which a founding value has been attributed to the concept of “persistence” and taken up as a essential axiom of western urbanist thinking.

In this contribution, the intention is to start off from the deep groove made by research into urban morphology, and set out the construction of a view on the city that from this highlights the multiplicity of the structures in evolution and the multiplication of the cycles of change. According to this different perspective, the value of transformation, gripped between the diverging demands for conservation and innovation, seems to take on a new allure, especially concerning urban renewal processes.

Rossi's theory, reassessed through the filter of the culture of the ephemeral and “non-conventional”, thus constitutes a matrix from which to reconsider the creative process of the architectonic and urban project, in relation to the dynamics of today's society and to the “*régimes sensibles*” pertaining to them.

The theme proposed in this contribution is part of a broader study and represents an extension of that work. The investigation was prompted by a series of reflections on the alternative practices of intervention in the delicate urban and the suburban *maillage*.

Keywords: Interdisciplinarity, Urban Design, Temporalities, Ephemeral, Transformation

1. Between analogy and permanence

“Le temps ne sort pas du présent, mais le présent ne cesse pas de se mouvoir, par bonds qui empiètent les uns sur les autres. Tel est le paradoxe du présent: constituer le temps, mais passer dans ce temps constitué.” Gilles Deleuze

The “theory of permanence” (*Teoria delle permanenze*), formulated by Aldo Rossi [1] drawing on the thinking of French proto-urban planners Marcel Poète and Pierre Lavedan, has designated, in Italy as in the rest of the European continent, a period in which a founding value has been attributed to the concept of “persistence” and taken up as a essential axiom of western urbanist thinking.

In this contribution, the intention is to start off from the deep groove made by research into urban morphology, and set out the construction of a view on the city that from this highlights the multiplicity of the structures in evolution and the multiplication of the cycles of change. According to this different perspective, the value of transformation, gripped between the diverging demands for conservation and innovation, seems to take on a new *allure*, especially concerning urban renewal processes.

In Rossi's theoretical evolution, the idea that the city is structured around “hinges”, understood as stable and predominant elements or as consolidated urban connections, underwent a change when the notion of analogy began to make headway. The concept of persistence still remains in some way in “*La città analoga*” (The Analogous City), the celebrated table - considered the emblematic critical

Fig. 1 Aldo Rossi, *La città analoga*, in *Lotus13*, 1976

body of *Tendenza* - that appears for the first time on occasion of the Venice Biennale of 1976. The monuments occupy in "*La città analoga*" the place assigned to them by etymology: memory and warning, but this is no longer the issue of a firmness that celebrates the main features of the urban fabric in permanence and repetition. Neither is it about nodes around which the city's articulation is perpetuated. The stability of the urban system, based on the inexorable traces of history, is visibly compromised by the intrusion of a random logic, that of a paratactic composition, where it is possible to identify an uncoupling between reason and imagination, a *clivage*, like a fracture line between a reasoned structure and invention. The table in question, in the form of urban collage, is the result of an additive composition, revealing a form of flexibility of the city not yet present in the "theory of permanence", where the urban fabric hinges between the persistences and pre-existences of the past. If "*La città analoga*" is understood as a "*trame agissante*" [2] this is because in Rossi's concept the city is a social fact and therefore it cannot be imagined as a simple repertoire of forms, but as an active "*série d'objets affectifs mobilisés par la mémoire lors de la conception du projet: comme une 'méditation des thèmes du passé'*" [3], and the fact that the monuments are no longer the guarantors of order and continuity Rossi himself expresses in the terms of "the division of things in order to be added up following different rules" [4].

The city idea thus continually moves further away from the image of an accumulation of traces, imprints, sediments and constructions, in a word of "persistences", which add up layer by layer, following both a linear as much as inexorable historical chronology, in order to approach, ever more

so, the allegory of a free co-existence of parallel dimensions [5], a concept to which Rossi returns, several times, in his correspondence with Ezio Bonfanti.

The city changes because everything is impermanent: "I think then that the additive procedure is linked to the knowledge of the city, to the buildings and the monuments, but conceive all of this as a series of fragments" [6]. In Rossi's reply to Bonfanti it is the use of the adversative adverb that provides a key to interpreting this urban collage, full of disjunctions, incoherencies, leaps of scale and type. In the same letter, a few lines later, he writes: "You see therefore the collage procedure also becomes a kind of warehouse of forms (...)"[7], where it is the forms that renounce every kind of "persistence" and open up to a multiplying of meanings.

It is certainly no chance that, a few years after the "adventure" of *"La città analoga"*, Rossi is the author of one of the most interesting temporary projects of the architecture of our times: the *Teatro del Mondo* (1980), the sublime floating ephemeral theater on the Venice lagoon.

This questioning the value of transformation is an attitude that we find again becoming more specific in current design practices. Can the contemporary city still be understood as "something that lasts beyond its transformations" [8]? The transition from a culture founded on objects and permanence to a culture hallmarked by flows and instabilities [9] seems to have definitively distorted the paradigm of spatial continuity, highlighted the values of adaptation and flexibility and, as in the Calvino's *Sophronia* [10], inverted the very statute of persistence. In this paradox, these would constitute the temporary and fragmentary part, the less autonomous and lively segment of the city.

Rossi's theory, reassessed through the filter of the culture of the ephemeral and "non-conventional" [11], thus constitutes a matrix from which to reconsider the creative process of the architectonic and urban project, in relation to the dynamics of today's society and to the "régimes sensibles" pertaining to them[12].

2. The impermanence of places

"Historicité non pas des représentations de l'espace, mais bien plus profondément de l'espace 'lui-même', qui ne peut plus être considéré comme une donnée pérenne mais qui se modifie en fonction de conditions proprement historiques. C'est là un des enseignements fondamentaux de l'anthropologie, de la sociologie de l'art, et de la phénoménologie (entre autres disciplines) : l'espace n'est pas simplement donné, il se constitue, se construit". C. Younès

In this study, the word "impermanence" has been considered in its wide-ranging semantic implications, allowing the various interconnected phenomena like the ephemeral, dislocation, deterritorialization, discontinuity, mutation, metamorphosis, transformation, destabilization, fracture, fragmentation, dehiscence, disjunction, and so on, to revolve around this concept. The list is inherently transient and could grow and be modified infinitely. This word, often denoted negatively, and represented as a *dessin en creux* reducing its meaning to the logic of absence or the dimension of loss, designates instead an outlook that is sensitive to the changing reality, beyond every Manichaeian determinism and every dual and opposing logic.

The theme proposed in this intervention is part of a wider study and is its continuation.[13] The theme, considered in a wider context, leads to the dissolution of the great principles that have guided design and planning in the modern age, and opens a reflection on the new orientations of urban research around the issues of the "uncertain margin" [14] and the temporary use of the territory.

The investigation is inspired by a series of reflections already under way on the alternative practices of intervention in the delicate *maillage* between the urban and the suburban. The uncertain, the temporary, the vague of the urban interstices or marginal areas, have recently lost the negative connotation that in the past had rendered these zones de facto en attente areas in conflict with the space of the habitat. Where the void and the absence of a coherent morphologic configuration dominate, the insisting of more 'places' in the same space (where space is intended as "*lieu pratiqué*", with the meaning given to this definition by Michel de Certeau [15]) becomes a planning exercise, a multidisciplinary intervention directed towards experimenting an alternative way of conceiving, planning, regenerating and building the city fabric.

But what are the principles guiding the transformations of the city today? Also the dialectic of the stabilizers, these "points or centres" that figure among the "*objets trouvés*" without time of the "urban collage" [16] of Colin Rowe and Fred Koetter has been re-evaluated by diverse spatial topologies, experimental fields in which to establish new types of relationships between the city elements.

To create unexplored bonds, activate unknown aggregations and retrace devices that may translate emotions and collective *desiderata* into forms, today means tending to structure the territory with modifiable models, identifying what Edward Lorenz [17] would have called "attractors", units towards which the dynamic systems evolve in a determined temporal arc.

Beginning with this realization, many issues unfold: would the city planned according to the criteria of a "light" (MVRDV 1997) or "weak" (Branzi, 2006) urbanization, through paths of transformation and

temporary interventions that challenge a determinist planning, be able to generate an evolutionary logic of growth?

And again, is the city conceived with changing scenarios, following waves of probabilities and fluctuating spatiality/temporality, micro-interventions, compatible with the new logic imposed by sustainable development?

3. Towards a culture of the “living project”

“(…) Créer une architecture et un urbanisme qui, par la forme construite, puissent rendre signifiants le changement, la croissance, le mouvement, la vitalité de la communauté” Alison et Peter Smithson

The discontinuity of the urban *recit*, the increasingly swift cycles of transformation, the variety of the rhythms, the irruption of the événementiel, the arbitrary obliteration of the traces – together with the weakening of the idea of transmission of memory that can be read in the urban lacework - are the several ways in which the city today exceeds itself, exhausts the figurative nature associated with the urban and provokes the breach of dominant schemes.

Already beginning from the 1950s, with the advent of anti-urban theories, and in the course of the 60s and 70s, through the vast utopian production, the very idea of the city had been challenged.

Ecological knowledge, the new alliance between organic and inorganic and the developments in biology that have introduced the concepts of self-organization and complexity, have contributed considerably to delineating and orienting new pathways.

At the beginning of the 70s, on the science front, new ideas came forward on concepts of adaptability and reversibility: in 1973 the ecology researcher Crawford Stanley Holling formulated the concept of ecological resilience, bound to the complex systems of adaptation and self-regulation, in terms of the capacity of an ecosystem to take on and model change. Besides, the prolific line of the *Nouvelle Ecologie*, already active during those years, was based on concepts derived from biology and genetics, highlighting cycles and biological rhythms.

The culture of the architectonic and urban project has for a long time been greatly influenced by these studies, as Gregory explains: “The new echo-scapes: projects generated in the search for a connection and deep convergence between the organizing principles of architecture and living systems, explored through differentiated pathways and strategies: here following dynamic and evolutionary conceptions of form, based on ecological-relational, co-evolutive and co-organizing properties; now developing within ever more sophisticated biological analogies the search for an ‘animated form’ through self-organising and auto-poietic morphogenetic processes; then again highlighting in the continuous evolution the interaction of the form with man and environment through artefacts capable of adaptation and change.” [18]

The concept of “Deep Planning” of Vab Berkel & Bos, for instance, is an important starting point for the planning theories based on the adaptability to the environment and self-organization. The “Principle of continuous difference” they postulated opens the world of architectonic planning to the notions of mutation and renewal, conceived according to self-regulating processes.

Following these new openings and mutual contaminations, in the past few years science has extended its field of interest to art, contributing to the improvement of the critical instruments to understand and represent an alternative way of producing and creating.

In contemporary art the deviation between the increasingly important value attributed to transformation and the fear of instability, together with the impasse of the liquid evolution of a society that is losing ever more, and even more rapidly, its points of reference, are by now recurrent issues. A growing number of interdisciplinary collectives are currently concerned with alternative interventions in city areas undergoing major transformation. These new tendencies reveal a different pulse with respect to those that even just recently were defined the ‘difficult zones’ of the city. « *Pourquoi ne pas vivre dans un chantier permanent ? Il ne faut pas imaginer que les choses sont finies* » [19] challenges provocatively the French artist Fabrice Hyber, stressing the need to invert certain negative logics that affect our way of creating and conceiving of the city.

4. A Case Study: Saint-Etienne, une ville en transformation

ATELIER S7|D1, Architectural Lab “*Dynamiques architecturales et urbaines*”, 2012|2013

Ecole Nationale Supérieure d’Architecture de Saint-Etienne. Director: Silvana Segapeli, Guest critic: Jean-François Pirson

<http://ensaseateliers7d12012.blogspot.fr/>

Students: Bekaert Natalie, Berger Elisa, Brodeur Laurence-Emilie, Delangre Arnaud, Garneau Lysanne, Hernandez Joris, Kolesnichenko Marina, Mastroianni Alexandre, Mailhet Sophie, Oams Charlotte, Raynaud Coralie, Rinchet Dimitri, Rodriguez Leon Isabel-Pilar

The terrain of study of this architectural laboratory is situated in Saint-Étienne; this is an industrial *friche* at the juncture between multiple kinds of urban fabric and the different histories that its landscape narrates. It is a void *en attente*, between a compact urban mesh, whose margin is made up of the archipelago of the former *Manufacture des Armes de France*, today *Cité du Design*, and the open weave of the diffused city, lacking a settlement framework and designated by large road infrastructures.

Moving from recent theoretical debate on the transformations of the post-industrial city and the new realities between the urban and periurban, the themes for consideration set out by the laboratory “*Dynamiques architecturales et urbaines*” involve a series of *techniques appliquées*: a long stage of observation of the area, of a sensitive reading of the landscape and sensory experimentation, through the practices of walking and “*transurbanza*” [20]. The objective is to succeed in ‘mapping’ the landscape in transformation and interpret its mutation cycles following the Close Reading technique.

From a projectual viewpoint, the greatest challenge lies in the attempt to ensure keeping the enzymatic nature of this *entre-deux* space lacking a stable image and with a fluctuating identity. Furthermore, it is hoped to go beyond the very concept of identity, understood as a crystallizing condition with respect to the study’s investigation field.

The renewal of the city space takes on the dimension of an emergency in this context. Starting off from the notion of reurbanisation of Oriol Bohigas, that considers the road as the place and the itinerary at the same time, the public square and the block as city matrices, the focus is directed to the field of connections to be established between built space and public space.

LANDESIGN “TRA AGNENA E REGI LAGNI”

Vincenzo POLLINI¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Italia
vincenzopollini@gmail.com

Abstract

The area of study, placed in the western part of the low flow of the river Volturno, identifies a way of real knowledge, not virtual, where pedology combines with architecture. It's situated between the inferior part of Savona-Agnena and Regi Lagni, where the Volturno flows from Capua to Castel Volturno, hence the title “*between agnena and regi lagni*”. The work has started from the studying of lands, exactly from their substratum, and to do it the whole symbology of the *geological paper*, produced by Campania Region-Defence of land area, has been reported. After analysing essential aspects as the land and the pedolandscape, I have passed to a careful analysis of the paper of geological unit reported from the plan of the authority of Liri-Garigliano-Volturno basin, and to the analysis of the climate of this area, to the one of imbalance, in addition to a careful analysis of flora and fauna, of respective biotic poles and an exact swot analysis. I've passed to the individualization of the first stop points called “posts”, in the communes of Castel Volturno, Cancellò ed Arnone, Santa Maria la Fossa and Carditello. This itinerary has been conceived like a ride along country paths and farm roads, also enjoyable by whom destiny has taken away some perceptive abilities, with two starting/arrival stations, the real hunting of Carditello and the hyppo kampos resort in Castel Volturno. The way develops through Variconi oasis and the areal of cow buffaloes between Cancellò ed Arnone and Santa Maria la Fossa.

Keywords: Landesign, the Volturno, learning and representing a landscape.

1) Learning and representing a Landscape “from the past traces to the reconstruction of DNA”

How many times we have said “What a wonderful landscape!”, in front of a little town laid down on a hill or in front of a tract of seaside. Probably, we have never asked ourselves what a landscape is really. It comes from the french paysage that in its turn comes from pays and it means the aspect of a place, the whole of its forms and of interaction among them.

Several thought schools discuss about the meaning of landscape but the official definitions are two: 1) European agreement of landscape “a certain part of the area defines it, so that it's perceived by people, whose character derives from the action of natural and human elements and from their interrelation”, 2) and the code of the arts of landscape “it's defined by a homogeneous part of area whose characters derive from nature, from human history or from their reciprocal interrelation”.

Landscape is the whole of typical and distinctive elements of an area. To know a “landscape” we shouldn't stop at appearance but consider a series of elements that cannot be set aside. As a matter of fact, today, every landscape appears in a complex way and so to create a course of knowledge and to represent it we shouldn't dwell upon the addition of several components that form it but it's essential to conduct a more in-depth study. The latter can start from the analysis of physical, biological (lakes, rivers, mountains, etc.) and anthropical (towns, houses, streets, etc.) characteristics and it can carry on with a study of theoretic, cultural, historical and town planning knowledge of the area, a registration and cataloguing of urban properties. It's also important the study of pedological processes that produce the different nature of grounds and landscapes and their different capabilities of use and abilities, conditioning forms and typologies of landscape. What is really pedology? It consists in

studying the land. Instead, the “pedolandscape” is an innovative and transversal concept: we could think of pedolandscape as an enrichment of the classical idea of landscape, like a “landscape whose lands that support it have been understood too”, or as “a dynamic combination between the exterior aspect of landscape and its inner roots”. Another basic passage is given from the study of aspects that have damaged its image, changes that have taken place in time and the ones that have changed environment thanks to natural and human factors, positively or negatively. Anyway, analysis of changes has got as logical essential antecedent the study of roots in order to explore territory and to look for some signs of its evolution and of its executive elements. As a matter of fact, past marks take on a value of statement that being in harmony with present changes draft the destiny of territory.

To know the geometric origin of the past (“signs of the past”), the way is to examine scraps of architecture, the reasons of its first form, technologies and materials, we have to look beyond the material sign to deduce concepts of that construction. With the succession of mutation of human needs, and sometimes with sudden catastrophic events, we live mutation about both natural and built environment, with consequence that these concepts risk of losing their identity.

My research-study is based on the method of reconstruction of dna of territory, moving from the simple geometric relief to the relief of all the elements that make up it: this is the exact objective of the multicriteria analysis. Therefore the main operation of this analysis is to ponder and recognize reality: if it is an object, an artifact, a part of city, an entire territory or more in the large an entire environmental system. Environment, as we know, is a complex and well-structured system, constituted by areas that are some spaces defined by legal-administrative spheres. For this reason the action of multicriteria analysis aims to a deeper knowledge of the examined object through the integral of competence to contribute to the deep knowledge of environment. The way to rebuild dna of territory is a cultural behaviour that allows the surveyor to understand generating signs both of the context and of the object to examine. Discretization of architecture, in its main parts and elements, constitutes the essential and methodological foundation of every case of construction.

The surveyor who works through multicriteria analysis, through the operation of measurement of territory, explains and discretizes event, it reconstructs the system of relations among the parts, between places and space, between territory and architecture, economy and plan, because the knowledge of signs of what has been already done enables us to plan the frontier of the future. Today, the surveyor, has at his disposal avant-garde technologies; among them, the gis (geographic information system or sit, italian acronym) has taken a particular importance and it's considered by many people as one of the most powerful instrument among all technologies of information, because it enables to integrate knowledge from multiple sources and to create a transversal environment of cooperation. Gis systems are basic instruments to value, analyze and represent every kind of spatial phenomenon; so it is a data processing system that can produce, manage and analyze spatial data associating one or more alphanumeric descriptions with every geographic and landscape element. Essentially, in a smaller time we can obtain bigger properties and results.

In a landscape, it's necessary to inquire into reality and reconstruct it, describing the infancy of area, places, objects, points of view of memory, every material and immaterial component, this represents an ecogeometric model of reality, a paradigmatic model of the environment and of what has been built.

Behind the progressive change of human needs there is a biological meaning of the plan: bioplan. It consists of an ecological geometry of reality, or the knowledge of what is and what will be, through the transformation of all the components that form reality. Drawing the knowledge of what is and what will be becomes the most fascinating part of architecture and especially of landscape architecture, because during our linear course we'll find that surprise, that deflection that will cause crisis amidst the ideas of our unreal journey.

The ways of the knowledge of architecture should be the model of the right approach for recovery and improvement of this complex system that, with different facets, from time to time we call environment, territory, landscape and that includes cultural and artistic heritage of man. Gradually, this research-study must teach how much human environment needs to reach an equilibrium with nature, regain possession of its times, its rate, of feelings that are peculiar to human sphere that produce a real and no more apparent wealth.

1.2 Study case “Landesign between agnena and regi lagni”

In the journey of my life i've deepened the importance of landscape, since they have labelled the land of Caserta, where i come from, like paradigm of deterioration of the environment, of camorra's abuse of power and of cultural vacuum. In particular if they refer to the low area of Volturno-Domizio coast, nothing can be more false and insulting both towards honest citizens and toward environmental, achitectural and historical goods, of which the land of Caserta is rich.

There are two solutions: or to suffer, abdicating to civilization and giving natural, cultural and physical property in the hands of speculators, or to rise up investing really in that property that we want to ignore, giving back it the removed and denied value and dignity. This analysis is a flexible method,

applicable to the different territorial and landscape areas. In the point of view of how much and how we can work to recover the territory, this project of landesign originates to identify a way of real knowledge, not virtual, where pedology combines with architecture, integrating the study and knowledge of territory in its geological, climatic, pedological, socioeconomic and historical elements. The analysis i've conducted signs a way in the land of work, from agnena to regi lagni, starting from the land to reconstruct the marks of our belonging to a place and a local, real community, preserving the extraordinary difference of it that is the biggest creative power. Landesign is drawing, taking part, doing, telling, communicating, popularizing the land. Land + design = drawing of land; lan + design = local area network design. Local, a project that dips its roots in the place, in the land of reference in, for and from which it takes out traces, signs and fragments for the project of things that become events; area, land as common property, limited not renewable, as defined surface, area as phisycal surface that it's seen, touched, listened, enjoyed, perceived; network as system of meeting, of real spurs for people who, all together, take part to a local project of regeneration that comes from the land.[1]

Landscape represents a document, an idea, an image, a word, but expecially an emotion. As a matter of fact it's the complex whole of pedogenetic factors and components that produces the different nature of grounds, of landscapes and their different abilities and aptitudes, conditioning forms and typologies of settlement and management, after all, the courses of social and artistic development.

The study area, set in the western part of the low course of the volturno, is situated between the inferior part of Savona-Agnena and regi lagni, where the river Volturno flows from Capua to Castel Volturno. From here the title "between agnena and regi ragni", that tells about the study conducted on this rectangular-shaped area marked by the agnena channel, by the territory in the east of Capua, by mediterranean sea in the ovest, and it extends for about 30.000 hectares. The division of territory doesn't represent a discontinuity of system but there is just a change, first of all territorial, because pedolandscape are different, because the geolitologycal substratum is different and because grounds on the top are different.[2]

The study started from the analysis of grounds, exactly from their substratum, and to do it i've related the whole symbology of geological paper produced by campania region-defense of land area. On the base of available data, for the study area under consideration, it's possible to sketch this statigraphic structure of the substratum from the top: [3]

- Sandy lands, dunes of seaside and silt-clayish sediments of interdune, that emerge in a 1-3 km belt, overlooking the sea;
- Silt-sandy sediments, marshy rivers associated with peaty sediments that emerge in most area under consideration and they reach the biggest depth near the flow of the Volturno;

Geomorphological events are typical of a ground. So the ground is a living body in continuous becoming, it's made up of inorganic particles, organic substance, air and water, where biogeochemical cycles carry out. These cycles are necessary to the support of organisms on the planet surface. It derives from complex and continuous events of interaction among aria (atmosphere), water (hydrosphere), geological substratum (lithosphere), living organisms (biosphere), human activities (antroposphere) and it represents the "membrane" through which exchanges of energy and matter with lithosphere and the other environmental sections happen.

"Pedolandscape" is an innovative and transversal concept: we could think of pedolandscape like an enrichment of the classical idea of landscape, as "a landscape whose support grounds we also understand", or even as "to the dynamic union between the exterior apsect of the landscape and its deep and pedogenetic roots". The pedolandscape function is the most prosperous and complex function the grounds carry out in ecosystem, going beyond the purposes of production or protection, to include the balance of environment in its complex, involving, moreover, cultural, sociological, naturalistic and historical aspects. It's the ground to define the use of ground, that in turn defines the development of civilization.

Fig. 1: LANDesign

Fig. 2: Analysis of the area

Fig. 3: Geology and soils

To understand better the links “ground-use of ground” i’ve realized some diagonal and longitudinal sections of the area that is the subject of the study, even to understand the elevation profile of area. The bends of level are low on all the area because of recovery on the right and on the left of the Volturno that has contributed to determine the pedologic and geomorphological state of grounds strongly. [4]

Fig. 4: Section

After analyzed the basic aspects, as the ground and the pedolandscape, i’ve have passed to a careful analysis of the paper of geological unit related from the plan of authority of Liri-Garigliano-Volturno basin. The area of my study is crossed by the Volturno that, with its 6342 km of surface, represents the sixth hydrographic basin in Italy. The plain of the Volturno represents a significant part of the prolific field, full of water, that has been called Felix Campania [5] since ancient time. From a partial swot analysis [6] of the area “ also known as swot matrix, it’s an instrument of energy planning used to consider strengths, weaknesses, opportunities and threats of a project or of an enterprize or of another situation where an organization or a person must make a decision to reach the purpose”, we can see how the most important strenghts of this area are characterized by the presence of an environmental, historical-landscape, natural and momentous heritage, the presence of local agricultural products as campania’s annurca apple, milk derivatives as buffalo mozzarella, to which, thanks to strict supervision of european union, has been given the dop wording, buffalo butter, ricotta and dop caciocavallo, that are exported products in all over the world and they give to these areas a big-relief image, another strenght of these places is an elevated presence of buffalo breeding factories. If on the one hand we have described strenghts on the other hand we have to put in some opportunities that have to be considered as the biggest sensitization of man to protect this huge wealth that our land offers us, trying to increase the value of watercourses, staking on the growth of these revies as dop and doc, increasing the value of tourism through initiative turned to point out

weaknesses of these lands as the strong presence of clayey grounds, high percentage of degraded areas that can lead to some threats as the neglect of traditional farms and the increase of pollution. Another strength of this area is the presence of a temperate hot climate that makes this area one of the most fertile of the whole region, constituting a habitat propitious to the presence of fauna and flora along all the low course of the Volturno. [7]

Fig. 5: Attractors biotic

Fig. 6: Swot Analysis

Fig. 7: The cards climatic

After analysing the general organization of this area i have passed to specification of the first stop points called “posts” [8], in the communes of Catsel Volturno, Cannello ed Arnone, Santa Maria la Fossa and of Carditello, every five analysed post differs from the other one for fauna, flora, music, attractor poles and typical products, besides for different structural and environmental characteristics. In these communes a further analysis has been developed, arteries, the use of agricultural land, hydrography, hydrogeological sensitivity, an analysis both of current ties and of description provided in town-planning schemes that are in force in the communes. Through diachronic cut i have done a research related to territorial development since 1951, through 1984, until 2004.[9] From here the course that bounds the river banks starts, with the aim of sensitizing fruition of these areas both for tourism and inhabitants of this place. The way of knowledge isn’t dedicated to the banal superficial tourism that still characterizes area of Caserta but to intelligent and sensitive traveller who is able to seize , preserve and transfer all the emotions he has observed and known during his physical and emotional way. Itinerary has been conceived like a ride along country paths and farm roads enjoyable also by those whom destiny has taken away some perceptive abilities, with two starting/arrival stations, the real hunting of Carditello and the hyppo kamos resort in Castel Volturno. The way develops through variconi oasis and the areal of cow buffaloes between Cannello ed Arnone and

Santa Maria la Fossa, involving all the traveller's senses , not only through brackish smells of lagoon , smells of soil, scents of vegetation, recalls of birds, change of pedolandscape and of perspectives. To sailor tradition and to baroque neapolitan culture will be dedicated dinners in the posts of Castel Volturno and Carditello, in the stops of the areal of cow buffaloes, recipes of the land of work and villanelle. [10] In the search of a concept, an idea, communicative metaphor that contains in itself the whole project, we have thought that from the traced way a tree could take shape. The trunk is rooted in San Lorenzo's orchard and from it three main ramifications start: one for every analysed post; from each of these three branches other secondary ramifications start, each of them regards one of five senses. Essentially the post is analysed through a sensory way that crosses sight, olfaction, hearing, touch and taste. So we have tried to carry out an in-depth study or branched from our territory that comprises also flavours, smells, and all the other peculiarities that characterize the culture, environment and traditions of this area. [11]

For a deeper knowledge of territory it has been created a masterplan that represents geological, climatic, pedological, socio economic and historical elements of territory. It wants to be a moment of knowledge, a sensorial journey, directed to exalt visitor's five senses. [12]

"Landesign project; ways of knowledge from pedology to architecture" wants to be the antithesis of paradigm of desolation, the model of correct approach for recovery and improvement of that complex system that, with different facets, from time to time we call environment, territory, landscape, and that includes man's cultural and artistic heritage. It's the indispensable method for the correct defense and management of natural and built lands, conscious that the theorem of ecocentric isolation of nature from its territorial context, with interdiction of matter and energy fluxes, is not only lacking in scientific foundations but itself is a source of depauperation as much of food chains and biodiversity as of wealth and culture.

THE PROJECT EXPRESSION OF AESTHETIC QUALITY IN THE CULTURE OF PHYSICAL TRANSFORMATION

ID 170 Arch. Paola Giannattasio ⁽¹⁾

⁽¹⁾ Department DSAT, University of Architecture of Reggio Calabria, Italia paolagia@alice.it

⁽²⁾ The project editing of Furore's PUC is still in progress with the collaboration of arch. Francesco Montella and Arch. Lycourgos Lambrinopoulos

Abstract

Cultural awareness of the right to a quality which is also aesthetic has re-emerged in the process of territorial transformation, in administrative organizations, in the collective desire, as well as in the challenge of territorial competitiveness and landscaping that requires that the 'places' need to attract, seduce and be agreeable. Some aesthetic and idealistic theories have influenced the understanding of 'quality', simplifying its content and identifying it only with its formal significance. In fact, "quality" can not just be reduced to the value of the territorial planning, of places or landscapes, assuming the architectural project as the sole holder of the 'quality' territorial integrity and of the ability to give meaning to spaces. In the belief that the development of the identity of a specific territory enhances individuality and the identity of places, strengthens the landscape, contributes to its uniqueness and its durable and steady peculiarities, the project characterizes as a new regulatory guide ordering element of physical changes. In this direction it establishes the basis for a planning (of rules) that underlies among the rules, the exception, the irregularity; that underlies among its permanent features the creation of novelty that evokes variations, among its previsions the strength to imagine unpredictable scenarios, that is, to think the reality as it is with its unreality that gives new prefigurations to the mind of the architect.

Therefore the project, refusing standard scopes, becomes itself a value producing complexity, capable to capitalize an aesthetic quality that does not adorn, but instead becomes a second nature to the needs of humanity.

Eco-museum - Aesthetic Quality - Cultural Landscape - Resource - Territory

1. New unexplored potential besides the crystallization of forms

We live in a time when the global commodification of land produces phenomena of standardization and trivialization of 'places', of their distinctive features and peculiarities.

Consolidated are those that Marc Augé has defined as non-places, serial landscapes which can be duplicated in all areas of the territory. The standardization and reproducibility of urban landscapes is a peculiar characteristic of this process, leading to the cancellation of local history, of the historical memory of a place, of a sense and a direction that is historically expressed by living in those places.

Unfortunately, this is a worldwide process with spatially different results depending on how a given territory responds to these dynamics. The global process of commodification has not the same standardization-trivialization effect on the relation between space and time in all places. In fact, if the pressure of the world market expands the rate of production, distribution and consumption of goods, to increasingly occupy not commodified spaces, to make more and more use of natural resources, local communities do not adapt in the same way to this process which increasingly drains two fundamental goods: Space and Time. An open space, enjoyable, that can be used collectively, and a time other than that arrhythmic one the time of the clock that, as Georgescu Roegen says, replaced the biological time, the time as distension of the soul, the individual time, unrepeatable, the time which marks all life. Any form of differentiation is generally tied to the strength of the history and of local identities. There are areas where alongside the process of 'modernization' there are forms of resistance and original solutions of the local / global relation. In these situations, local communities conserve and preserve the

common areas, the ethical / aesthetic dimension of living, the natural, historical, architectural and landscaping heritages. In the 'places', however, where there is no history sedimented in conscience nor in the territory, where there is a lack of stories and local identities, where local communities have internalized an inferiority complex and live in the myth of the great capitalist metropolis, the process of commodification affects the peculiarities and the fragmented, residual stories, together with the fragile and uncertain local identity. In these areas it activates a process of modernization-physical transformation that compromises their cultural aspects and creates only new forms unrelated to contexts, and that absolutely do not generate opportunities for development.

While agreeing that the changes are not only those we consider to be 'real', physical, visible, but also the cultural ones, related to the way in which we interpret the same phenomena, and indeed we can say that it is the interaction of these two dimensions to express and give shape to the 'change', this cultural process must be controlled, managed in accordance with the cultural geography of the places.

The global scale of the changes brought about by the actions of transformation and by the model of development inextricably linked, has generated new forms, threatening and compromising the identity of the landscapes. Actions that generate discomfort and demand a stronger and stronger control. The attention to the visible, to the images of forms, without understanding the causes of the ways of being of which every action is a physical expression, limits the understanding of the processes and affects the objectives, neglecting some conceptual categories such as aesthetics, environment, sustainability and compatible development. The cultural geography of an area, result of a process stratified in time, must be identified and recognized as a new space, a creative opportunity for new interpretations, as strategic direction to be taken for interventions of modification compatible with the system of resources made available by the history of the places and the new culture of competition.

To understand and exploit the new unexpressed energies and the potential of places, it is necessary to know and take the cultural armor of a territory, origin of its historical identity as renewed declination of its development by recognizing the project as the only means of enhancement and conservation of the local cultural system; it is only possible through the project to identify and interpret the historical identity, the local belonging which denotes relationships, the permanence that expresses the power, the exclusivity confirmed by the persistence of a local cultural system, categories that allow to preserve and enhance the territorial dimension of a landscape whose space, expression of new necessities, will be rethought in a relation of continuity, of memory. Functions, 'parts', and the objects of the territory to which then award a sign of recognition and appearance will be chosen according to parameters which aim to a 'wise use of land', a use that does not destroy the essential features, the physical structure, the form, function and beauty. It is necessary to explore the territories of the present to prepare to 'meet' what has not yet been mapped. It is necessary to methodologically take on new practices to capture and understand the new energies, the potential, the raw materials that await 'expression'. To explore these unexplored potential requires a reversal of the trend, to take interpretative analysis other than conventional: to overcome the panoramic and contemplative sight from the outdoor; that 'zenithal view of the forms' that precludes the understanding of the invisible meanings of changes. It is necessary to restart looking at the places from a reverse perspective, learn again to feel them leaving the contemplative attitude which prevented in the normal practice to understand and interpret the personality of existence. It is away from the rigidity of plans and pre-established order that it is possible bring out a widely spread creativity; it is in this dimension that new spaces, new centralities can take shape, new spaces fragmented in the conflict and contradiction of complex places. It is in these spaces that "(...) may arise unexpected forms of beauty, able to shine in new constellations." Planning is behind the representation of what is emerging in the territory. Each local project must begin with a 'map' of these fluidity that characterize the consolidated spatial structure. A cognitive map of this kind requires a practice of cognitive exploration across the space: from local to global (and vice versa), from solid to fluid, from necessary to indeterminate.

1.1 How the cultural project becomes a project of physical modification

The urban project is complex, born as a cultural project and finalized in its implementation as a territorial project, to relate the values of the program with the materiality of form. In defining the relationship between formal and programmatic values attention should be focused on enriching with the aesthetic quality of the environment built both the elements of complexity typical of general and cultural formulations, and the values expressed by social languages and literature. The transition from cultural project to territorial project must be built on the assumption that a plan, as a process of knowledge and organization of the territory, should be entrusted to a process of signification planning based on sustainable and qualified activities undertaken as new conceptual categories: an alternative operating model in which uncertainty, pluralism, disorder and contradiction are the new informative concepts, becoming a tool of complexity production. To accept and share this 'transition' from cultural to territorial project involves taking on two paradigms within the process of transformation, that are, nature and culture, as both unique and essential for the ability to organize and shape the territory starting from the environmental, cultural and natural resources we want to characterize an area, in

which the sedimented culture of places becomes the polar reference in redesigning the territory. When in spatial design the themes of belonging, local identity, and knowledge, which define the relationship between local and global, arise, the territorial project exceeds the sole purpose of spatial organization, becoming the central engine of a physical and cultural reorganization of economic and social resources. This means that the focus shifts on the whole territorial system, starts from the natural and cultural resources taken as characteristic features, measuring and expressing planning in the area through its forms of urban planning and architectural design. A territorial project is configured as the organization of a place, based on the relation among architectural, ecological, historical, cultural values, measured over the important denominators of the urban landscape and the natural environment. The intense encounter between naturalness and architecture is the general principle of transformation. Today there are many reasons if our territory includes marginal and degraded urban areas where spontaneity and aggressiveness of the educational process have weakened and contaminated the landscape: these are political, social, relating to the general history of the South, but also a great territorial reference has been lost, that is, aesthetic quality. Cultural awareness of the right to a quality which is also aesthetic has re-emerged in the collective desire, and has become an important parameter of appreciation, requiring that the 'places' need to attract, seduce and be agreeable. Aesthetic quality must be meant as the relation between morphology and function; therefore, it appears that only the project, intended as a comprehensive proposal of changes, is able to fully consider and reinsert the aesthetic quality as an essential requirement for sustainable urban and territorial planning. Quality then must be researched in the preparation and planning of spaces, whether empty or not, which are used to produce new models of relationship with nature and the external environment. A deep understanding it is needed of the character of the element on which we must work on in order to define links, interactions and effects which are not only physical and visual, but which also arise from the history, traditions and the whole background that forms indeed the broader concept of landscape.

2. Construction of the landscape

The most immediately visible result of history is the intense transformation of physical space, its widespread humanization, the capacity allocated to the immaterial to speak the language of culture, or better said cultures. Men are and represent the physical part of the landscape invisible horizon. The landscape is a complex intricate relation of elements, where everything is always connected in a constant osmosis of emotions, sensations, vibrations, and it is affected by any action or intervention undertaken, it can never be independent, it will have effect over time and space. The visual spectacle implied in contemplating the elements of a landscape, whether flowers, mountains, rocks, any human evidence, must be admired with serenity to enjoy it, so blend in its beauty, to understand the harmony among all its parts. Over the years, societies have built human landscapes, radically different from natural spectacles, which are nothing but the organization of the natural elements: sun, sea, rocks, beaches, rivers, elements that contain in their forms and matter an invisible and latent part, which only careful spectators can see, provoking strong emotions. According to Pierre Gentelle, human landscapes are the product of the transformation of nature by man, and they all contain a part of nature and a part of the culture, of the civilization, and are available in a wide diversity depending on the society. The metaphorical reading of the landscape as a theater, where nature and culture interact becoming a unique example of social expression, is the key that opens the reflection on the importance of environmental scenarios in which man moves and reflects. In this way the landscape performs the role of synthesis and verification of the actions that converge on it and overlap. The review of the paradigms research is dealing with facing aesthetic judgment compared with scientific one, the importance of formal-aesthetic assessment, incidental in the landscape culture, assumes the role of a moment of synthesis also containing subjects which could be more objectively classified in ecological, environmental, economic and historical perspectives. The construction of the landscape is based on the interpretation of places formed, on territorial identities built over time; the project comes from the recognition of the values of the place and from the social, cultural and technical energies that enable the transformation of memory into innovation. The idea that the landscape is culture, that is, a phenomenon of signification and communication, underlies the Resolution 53/97 of the European Council, which called it "a certain portion of land which is perceived by the man, whose appearance is the result of action of human and natural factors and their interrelations", pledging to "consecrate it by law as common good, foundation of the cultural and local identity of populations, an essential component of quality of life and an expression of the richness and diversity of cultural, ecological, social and economic heritage". In the construction of this complex meaning of the landscape, and its subsequent inclusion in the process of transformation and government of the territory, the scientific support of landscape ecology is considered fundamental, together with the consideration of aesthetic, semiotic, ethical, symbolic, historical and cultural values. The project "Landscape Convention", approved in 1998 by the European council, highlights the transition from the identification of single "cultural landscapes" to recognition of the "cultural value of the landscape". Landscape is seen as "an

essential part of people's life, contributing to the formation of local cultures and representing a key factor of European cultural and natural heritage". In addition to the meaning "culture" referred to landscape, there are two more assignments granted with this strategic shift: the explicit attribution of an economic value to the resource 'landscape' and the extent of landscape values to the whole European territory from "remarkable landscapes" to "ordinary landscapes". This consideration addresses the attention from simple protection problems more complex management problems, implying a deep review of policies and tools that relate to the landscape heritage. The assumption of the landscape as a reference for policies regarding the local development of the territory, urban planning, culture, environment led to an evolution of the protective activity, from mere obligation to strategic choice. Most of the strategies to be undertaken must be designed to consider and to affirm the 'landscape' as reference for efforts in favor of sustainability and protection of diversity as a richness to oppose to territorial standardization. The preservation of differences is presented as priority for actions involving the governance of the territory. Through an interpretive reading of the qualitative differences of the landscape, knowledge is the basis of the territorial project aimed at production and management of 'high' environmental quality in the process of territorialization.

2.1 Emotions of a landscape

Assuming the attention to diversity as a richness that creates and preserves the environment, this approach has been tested in a experience related to professional and research activities, by building a path aimed to reconstruct the bonds that tie man to territory, turning it into the landscape. The case study presented here is a synthesis of a scientific reflection and a professional experience, combined on the issue of territorial planning and the aesthetic quality of the landscape, to check both the scientific validity that the practicality, towards those activities and innovative planning processes that lie ahead. The territory of the municipality of Furore lies within the Amalfi Peninsula, an environment among the most fascinating of our country as a result of a well-balanced connection between natural shape of places and human intervention, which over the centuries has adapted to the geomorphological conditions of the area producing a wonderful synthesis environment. In addition to the inherent natural value of the places and the widespread consolidated human adjustment to the environment, the landscape has unique characteristics: the geological features, thanks to the presence of cliff edges, the waterways' pattern, bridges, springs, lush vegetation; although the land is very close to the sea, the mountain indeed has influenced the history and the landscape settlement. The interpretation of landscape as a social-historical expression leads the need for a broader debate that clarifies the importance of protecting the different types of 'diversity' that form the landscape. Therefore the conservation of the differences must be a priority for action involving territorial governance. The proposed strategies have been addressed in considering the landscape as a reference for sustainability and protecting elements diversity such as shape, connectivity and heterogeneity, indicators of ecological and human processes. The reading of the qualitative differences of the landscape provides the basis to re-establish a territorial project aimed at the creation of an high quality environment: proportional organization, as explicit expression of the space, is an interpretive requirement for a landscape knowledge. This has resulted in the possibility of representing the system in a combined framework of different units, at different scales, with a characteristic resolution of heterogeneity, which proportional domains correspond to the habitats of existing species and the processes inside cosystems.

The emphasis on the construction of a cognitive process bonded with the territory and the search for the involvement of local energies, turns this local urban project into a projects-park, from which tangible initiatives of landscape and cultural heritage recovery arise. The methodology developed in building the project gives it dual meaning, the whole work of research and analysis has an intrinsic value and an autonomy from the hypothesis of connection that it activates with the areas of the entire coastal district. The specific contents of the project concern the problem of conservation and restoration of rural buildings, the restoration and revitalization of the old town, the transformation of publicly owned spaces into accommodation, the production of equipment for pedestrian routes to be implemented on ancient routes.

In a particular attention to diversity as a resource that forms a landscape, one of the proposed and viable strategies was represented by the Eco-museum. Its idea was born as proposal of a new interpretative model of the coevolutionary action of man with nature.

The attention to the presence of human marks over the territorial plan, implies a conception of the museum which is more innovative than the traditional action of pure conservation linked to the transfer of objects from the past. The Eco-museum is a museum of knowledge, a cognitive, selective and interpretative tool of rural and urban evolution process, becoming over time 'home' of the appreciation of material and cultural heritage.

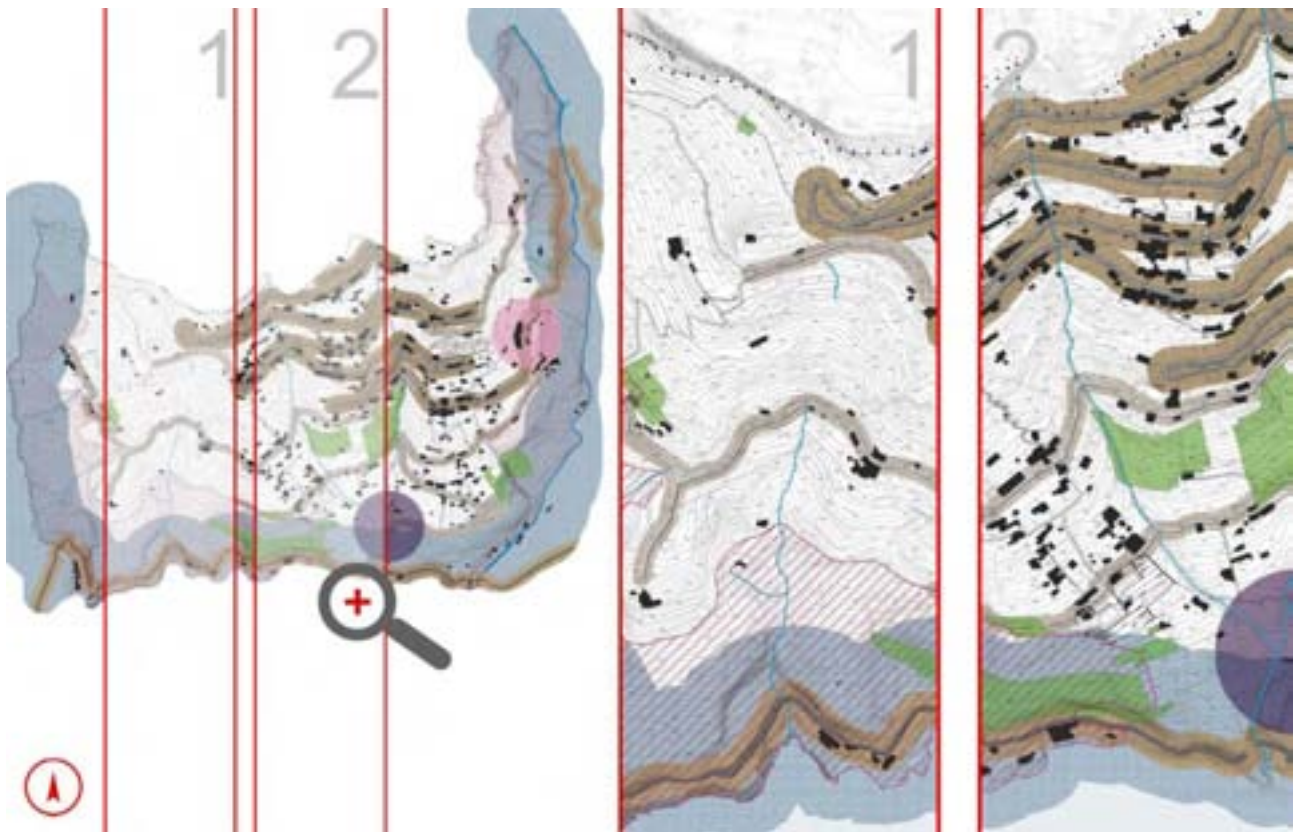

Fig 1 Table A5b: System of constraints operating on the territory

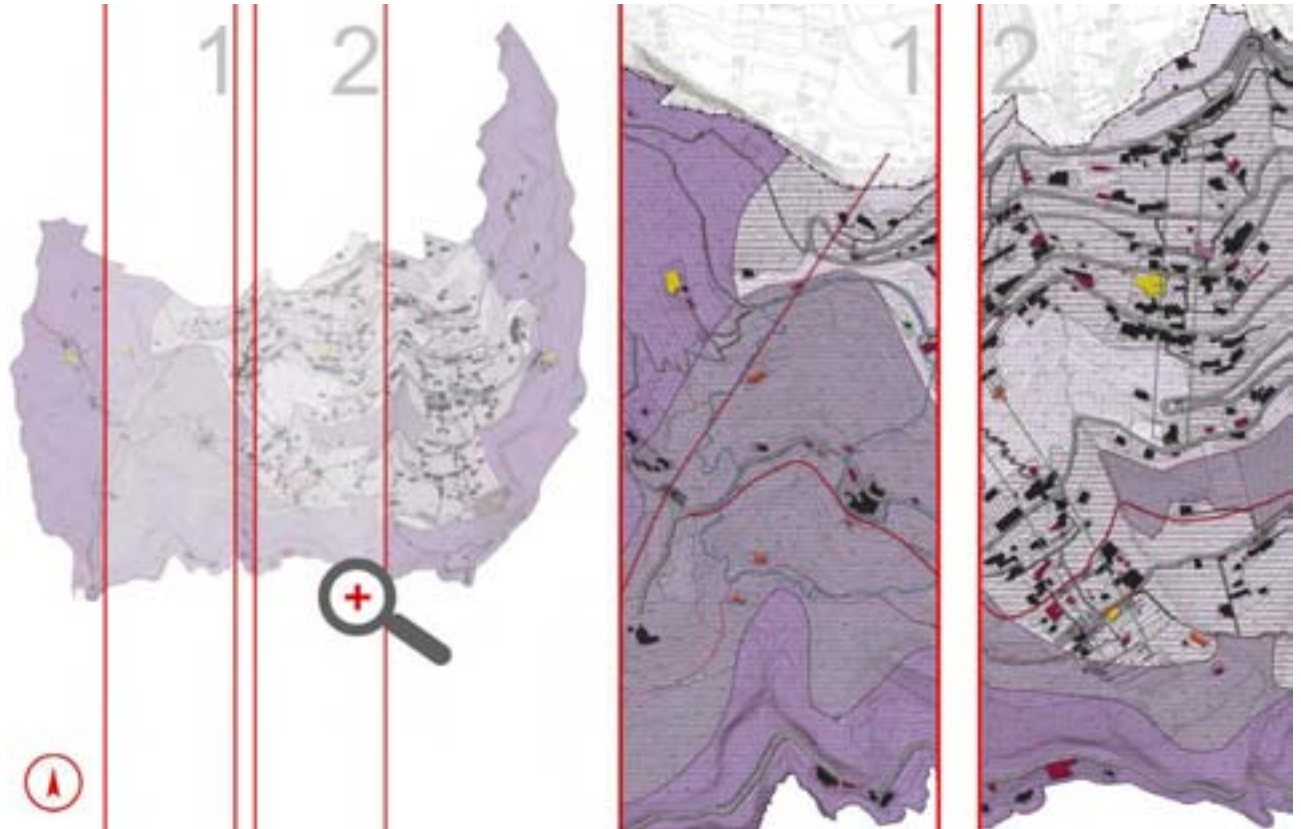

Fig 2 Table P1: Overall framework of urban design-guidance

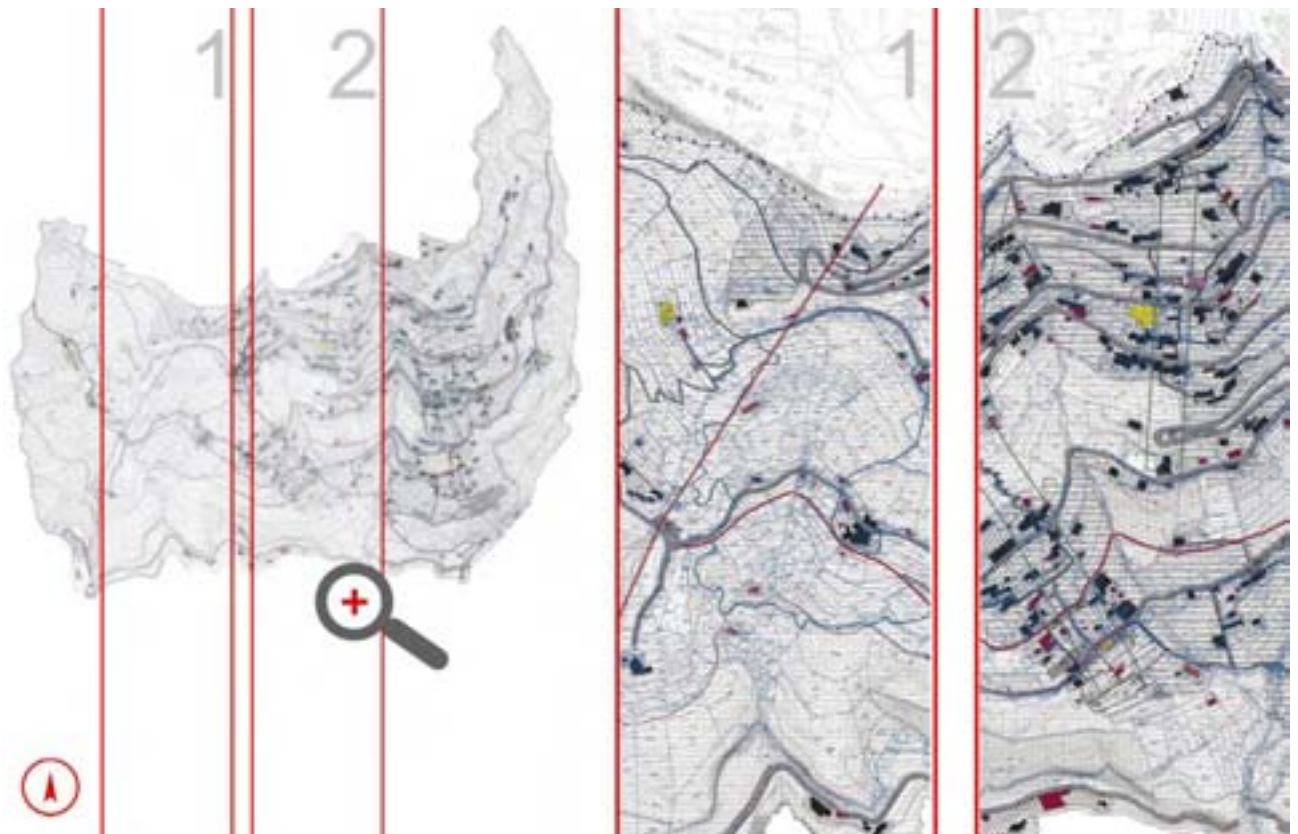

Fig 3 Table P4: Municipal area allocation

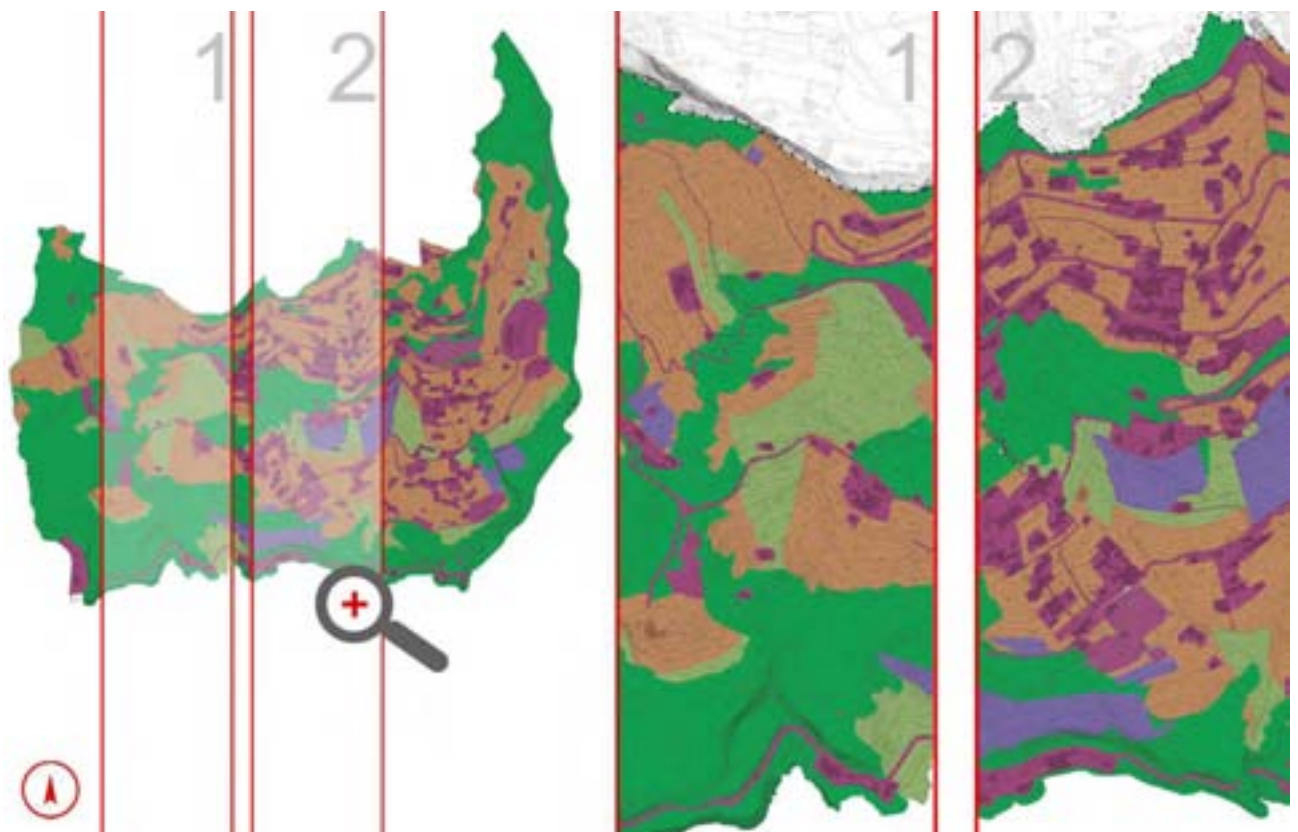

Fig.4 Table P7: Paper Unit Landscape

The Eco-museum is one of the most privileged places, both on a communicative and symbolic level, of a new belonging desire and of a social identity need, to reestablish the sense of man-land combination.

The museum becomes then a studio in which the knowledge of physical objects adds a new cognitive' function to indicate the compatibility of transformation processes regarding cultural-territorial heritage. The museum must be read in accordance with all the codes and categories that allow to understand signs men have used to communicate in history; it is not only about recovering and restoring 'old' values, as rather to understand if the values responsible for the contemporary spatial structure are still effective. The methodological action of tracing those elements which are essential to ensure a dialogue between the past and current values allows to: "reopen the dialogue with the hidden geometry of places, with the signs of local stories and geographies, with images of the collective memory in which occur opportunities and resources to reinvent, in the structure of the signs and of the existing settlements, new territorial identities which can make (or enhance) landscape".

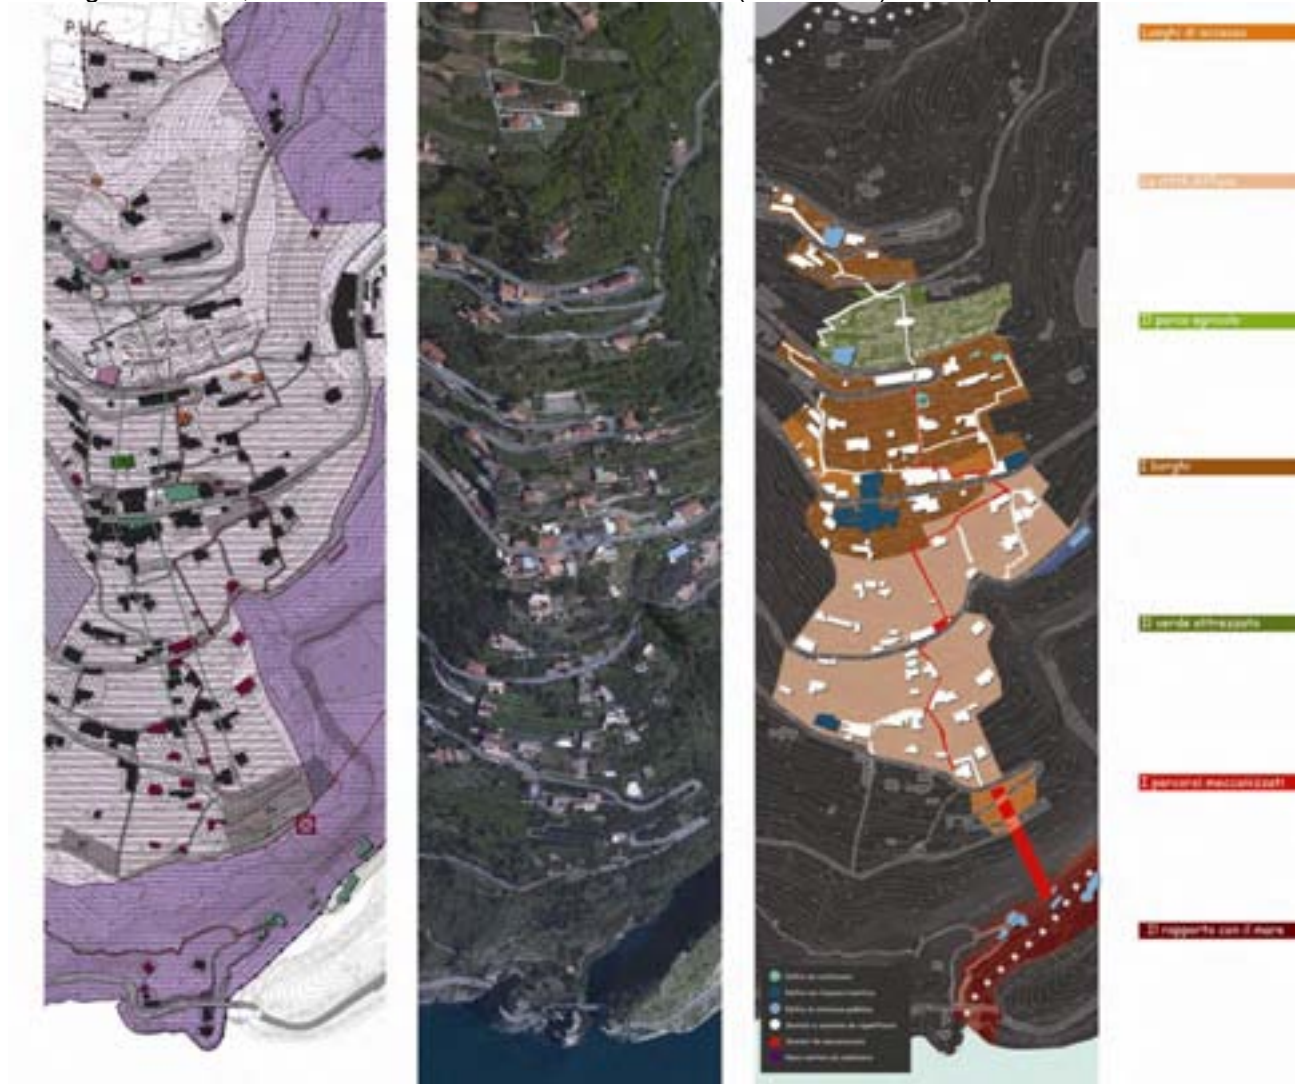

Fig.6 Table P1a3: tourism development axis - Route 3

3. The aesthetic quality

... we realized, in landscape cities and territories are a presence of history in nature : history as the time of which city is the spatial image, in nature as the time whose spatial image is landscape. The story begins in nature, as city arises in landscape; and nature has its epilogue; epilogue, also, of the historical city ... (Assunto, 1973, p.103) The beauty of the Italian landscape is today largely damaged, if not lost, in many places, where heavy speculation and lack of planning 'rules' have often diminished the historical memories and natural landscapes. The territorial system has been attacked, vexed in its topography, morphology and aesthetics; for long time planning policies have focused only on how to preserve, forgetting that quality today needs to be justified in order to be used. The failure of only conservative policies has not allowed an understanding of the reasons behind degradation nor to propose new conditions for this process to be changed. The project measured on landscape values represents the formal return of the transformations they happened. As formal synthesis of the places, in architecture and urban planning it can be the reference against which to measure subsequent changes required by social demand. Not only an element of cultural reference, but also an organizational and functional element fulfilling a specific task: bringing interventions back to places and measuring them in relation to their identity. At the same time, the local landscape is a cultural

factor: if each place is expression of the natural and artificial actions there produced, the interpretation of these expressions, their study, the assignment of value, are an expression of the culture that interprets and creates the place. These two cultures often do not match in the historical phase or for social and economical prominence; it is that the time when the history of the place lives in full this contradiction. Today, in our territorial readings, there is a clear history of fast overlapping, of replacement induced by behaviors and manners which often were not completely assimilated, by new entries that deeply shock the system of relations and the energy exchange, which test trough the mill the limits and the ecosystems carrying capacity. The social demand of reorganization, recovery and restoration of the environment is growing, and expresses a need for actions too often ignored. It is to combine the culture of urban planning with the holistic method to interpret reality and with the cultural attention to places that we take on landscape as a regulator, formal assumption for interventions and constraint for transformation processes' aesthetics and dynamics. If the landscape is the formal synthesis of changes and the project is a tool that allows its interpretation through the knowledge of the past of the area, the planning process can not be separated from the value of landscape as a historical-visual continuity, which can be culturally interpreted, of the transformation that took place and those that has been proposed. 'Project' does not only mean the autonomous intellectual and professional act of interpreting the social and institutional demand for transformation, but the transformation process of the activities of the places which has been socially requested organized. Until the emergence of modern city there was a full correspondence between social and economic process that constitutes the city and its organizational form: the form urbis corresponded to the structure that had generated it. The contemporary city does not only expand in space where it has been built but, in its consolidated form, there is a the prominence of the recovery actions and restoration against new constructions. The space in front of which we are standing is not material and it is only expressed in always visible forms, but it can also take much more subtle characters that need, in order to be investigated and shaped, manners capable of going beyond the sight. Territorial space is currently inhabited by qualitative multiplicity that are not only metric, which occupy it without counting, and which can be identified only walking on them. Therefore, the methodological path taken has been on experimental basis, a path that has not led to seek for regularities, but has rather discovered 'vague essences' and differences, strengths and intensity, energy and new individuality.

Fig. 7 Table P1b3-villages: tourism development axis - Route 3 - in-depth design project of the "villages" element - Restoring of pedestrian route

The ways of conceiving the (territorial) project are a key factor. In the first place, the sense of the project is mainly in the ability to activate constructive processes, production processes of 'meanings' and, in particular, to establish an interaction between the "instituting" dynamic of societies, and in these urban communities, and the tendency of institutions to self-preservation and self-reorganization. The project then becomes the place of collective imagination, mainly characterized by: Relational contexts within which the different interacting actors are themselves the planning subject; Contexts and situations that are able to involve these same subjects, from all points of view (emotional,

symbolic, imaginary); which are able to activate and maintain vital the motivations of 'designers', developing simultaneously empowerment and, on the other hand, accountability; Ability to develop critical knowledge together with the dynamics of interaction, that is, assuming a 'political' feature, which means above all the ability to develop and revise the inner meanings of "collective magma". The project, as an act of physical transformation, is unique in its reflection of freedom, man is then the actor who, in an ecological sense, transforms the environment, the landscape of life, marking it with the sign of its action, entrusting to his skills the feeling of power towards nature. Territories, cities, or fragments of cities, everything is landscape, and they become the means, the instrument to activate these processes, the object around which the motivations of individuals and their planning skills are kept alive, in a projection of usability and enjoyment of the rich architectural and natural heritage. It is a cultural experience that must be encouraged against any form of physical standardization, and that forms in the interaction between history and nature.

9. In ecological thinking, the 'difference' is the evolutionary foundation of life and through it we determine the relationships between living organisms; the term 'Eco-museum' was coined in the seventies by Huges de Varine, General Secretary of ICOM (International Council of Museums), as opposed to the traditional concept of "fortress museum". The addition of 'eco' to the root 'museum' reiterates its willingness to maintain a link between the material and cultural expression of man and the environment in which the production of this made sense. But this bond is inseparable from the early nineteenth century, when supporters of popular culture give the meaning of museum to humble, poorer artifacts; the 'museum of arts and popular traditions' were born, having dynamic and evolving characteristics, as an alternative to the static exposition of traditional museums.

Abstract

The crop circles, images in the grain that appear mysteriously during the night, in the country sides mostly British, from hundreds of years fascinate and intrigue scientists around the world. Their origin is unknown, although they declare an evident geometric matrix, which brings to mind an ancient symbolism, essential to every earthly worship.

Many are the theories in this regard, including the one that arouses most interest is that they are a symbolic forms explicitly registrants energy, i.e. that serve to represent and to tell the origin of all things: the energy that permeates the Earth.

Crossing the symbolism of numbers, considered as (but not only) "signs", the present work intends to investigate the possibility of an analytical link between the physical concept of mechanical energy, as it is understood in classical mechanics, so in the sense of work done by a system of forces for a system of displacements (dual of a system stress -strain), with the evocative images suggested by the mysterious signs in the grain, chosen basing on the most functional representative form, with the aim to re-find (or re-invent) a new representation of the energy.

Keywords: crop circles, signs, numbers, energy, physic

1. Introduction

It is known that from the point of view of Eastern philosophy, the cosmic energy is the source of all the living things, and it is the essence of the movement, processing and life. The primary energy is manifested in heaven (Yang) and in the earth (Yin). So the meeting of the cosmic energies with the nutrient energies of terrestrial, generates man and woman, mediator principle of Yin and Yang.

In Western philosophy, the word "energy" derives from the late Latin *energĭa*, in turn, from the Greek *ἐνέργεια* (*energeia*), a term used by Aristotle in the way of effective action, consisting of *en*, particle intensive, and *ergon*, capacity to act.

During the Renaissance, inspired by the thought of Aristotle, the term was associated with the idea of expressive power. But only in 1619 Kepler [1] used the term in the modern sense of energy, namely as the ability of a body or system to do work.

In classical physics, the energy is defined in various forms, each of which has its own energetic equation. The main forms of energy (each expressed through its own equation) are: mechanical energy, classically defined as the sum of potential energy and kinetic energy, chemical energy, biological energy, electricity, light or radiant energy, thermal energy, electromagnetic energy, nuclear energy.

Such forms of energy can be transformed one into another, but each time that such transformation occurs, a part of energy (more or less consistent) is inevitably transformed into thermal energy (that is, it produces heat); one speaks in this case of "dissipative effects".

At the beginning of the twentieth century, Max Planck [2] introduced a new theory, based on the fact that some quantities of certain physical systems, such as energy or angular momentum, can vary only of discrete values, also called "quanta". So, if energy in classical physics is a continue scalar property stored in a system, in quantum mechanics the energy is "quantized", i.e. it can take a number of

discrete values (or "energy levels"), all multiples of a quantum of energy, which represents the lowest amount of energy that can be stored in the system. These systems are called "linked", because the energy of the particle never exceeds the potential barriers.

2. Brief compendia of links between mathematic and signs

Only two things are infinite, the universe and the human stupidity, and I'm not sure about the former (Albert Einstein)

The infinite symbol ∞ was probably created by John Wallis, that used it in one of his first texts, *De Sectionibus Conicis* (1655), where it was called to express himself about the concept of "bent infinite", and then in *Arithmetica Infinitorum* (1656), when he ideated a simple infinite product able to find the π value

$$\frac{\pi}{2} = \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdot \frac{8}{7} \cdot \frac{8}{9} \cdots \quad (1)$$

Between the various hypotheses before his death, the most reliable is that his inspiration was founded on a very similar image used by the Etruscan to indicate the number thousand, often used to say "many".

Fig. 1: Etruscan system of numeration

But considering the various hypothesis, the most fascinating is the association of the infinite to the alchemic ancient symbol of $\sigma\rho\phi\sigma\rho\phi\sigma$, the snake that bites its own tail, from ever associated to the cyclical nature of all things, the neverending return, base of Gnosticism and Hermeticism [3].

The following picture shows a crop circle formation appeared Liddington Castle (Wiltshire) in June, 17 2001. It could represent the Uroboros around the Earth, and if we like to work with the imagination, we can see also the famous Lay Lines [4] that wrap around the earth.

The Lay lines (or "pathways of the dragon", according to the principles of Feng Shui [5]) are currents of vital energy that cross the Earth in the direction of the parallels and meridians.

In reality, the Ley Lines are alignments of a number of places of historical and geographical interest such as ancient monuments and megaliths, especially belonging to the British area, within which a large amount of energy is suspected or imagined that is given off. Flows of energy similar to rivers that intersect in a straight line on the Earth's surface, according to the Geobiology they have a variable width ranging from 3 to 30 or 40 meters, and an estimated length from 5 to 30 meters.

Fig. 2: Liddington Castle (Wiltshire), 2001.

One of the many theories on the causes of location of crop circles, is the one linked to the presence of Lay Lines just in that position.

In some pictures, the snake is shown half white and half black, recalling, in this way, the ancient oriental concept, pivotal of Tao philosophy, represented by Yin and Yang, that means the dualistic nature of all things, and above all the concept that the opposites aren't in conflict with each other, but their existence is necessary for the equilibrium of all creation, phenomenal and not.

It's interesting also emphasize that the notion of infinite, in the "rational" sense of the term, rooted its *raison d'être* only in 1400, as dichotomy of finite.

In fact, already from the Pythagoreans, the only concept that was taken into account was the idea of finite, as synonymous with perfection and completeness. So, extending this doctrine toward the numbers, only odd numbers were considered perfect, because their geometrical representation gives definite figures.

With Democritus (450 b. C.), in *Testimonies and Fragments*, the idea of infinite began to take a form in the philosophical thought, and an overcoming of the ancient archaic vision has been beginning, and the cosmos has not been considering anymore as a finite and limited reality.

But the real inclusion of the infinite notion as base of metaphysical philosophy will occur only in late Hellenistic period, of Neoplatonic tradition and culture, when the **metaphor** was used in religious matters with the aim to collimate the principles of faith and the rational human thinking.

This concept became more significant through the ideas of Nicola Cusano, who in *De Docta Ignorantia* (1440), tried a reconciliation between infinite and infinite, between man and God, stating with his theory of *coincidentia oppositorum* that it is possible to transform the infinite into an absolute dimension in which man will be able to increase his knowledge.

Naturally, man for his nature (finite), can be never fully understand the secrets and the knowledge of the absolute, but reasonably and potentially he will be able to have this perfection through the progression of one's spirit.

With Giordano Bruno (1548-1600) the metaphysical and mathematical developments of the infinite concept are significantly radicalized in the naturalistic and pantheistic sense.

In his famous *Cosmological Dialogues*, Bruno [6] processes his own idea, as infinite space and time. The Universe is not simply a finite region, but it extends itself without limits in all directions and in a-temporal manner.

His conception had a great extension: he arrived to conceive the existence of infinite worlds, infinite solar systems, infinite living species and intelligences.

These statements so daring for those times, caused many problems and theological debates. Already St. Augustine thought and stated that it was not possible to conceive that there was life on other planets, because if that were the case, we would have to accept the idea of a God willing to incarnate in other worlds, with a pietas and crucifixion repetitive in time, which would have declassified the idea of the divine in the service of men with the aim to redeem them from sin.

This concept of a God subservient to the cross and with the ability to incarnate whenever there had been a need, was inconceivable for the Church to such an extent as to define heretic anyone would embrace such assumptions.

It is true that even Cusano somehow came up at these theories, but he was a Cardinal, therefore equipped with a high power in the sphere of the Church, and this fact gave him the possibility to enjoy of some privilege.

For Giordano Bruno was not the same, and therefore the idea of infinite condemned him to the stake at the dawn of the 1600s, however leaving, despite death, his conception of parallel universe, that comes to be part of the Copernican theory which marked the birth of modern astronomy. A momentous time, if we consider that the concept of infinite abandons the philosophy for enter in science.

And in fact, in such a revolution, the thought of the philosopher Spinoza has been stating, who conceived the idea of infinite as an immanent attribute of reason, fulcrum on which he will argue the current of the German idealism, promoter of the great debate about the absolute, to which, in recent times, reflections of Auguste Blanqui and Borges will be joined.

And it is the latter, Borges, who in the *Metamorphosis of the turtle*, in *Otras Inquisiciones* (1952) writes about the concept of infinite from which was totally fascinated.

"... I'm speaking about Infinite. Sometimes I wished to fill its moving history. ... The great Hydra (swamp monster that is like a foreshadowing or emblem of geometric progressions) ... that should crown the sordid nightmares of Kafka, and his central chapters not ignore the guesswork of that remote German Cardinal Nikolaus Krebs (Nicola Cusano), who saw a polygon with an infinite number of angles in the circumference, and he wrote that an infinite line would be a straight line, it would be a triangle, it would be a circle, it would be a sphere... Five, seven years of apprenticeship metaphysical, theological, mathematical, could put me in a position to plan decently perhaps this book. Needless to say, life prohibits to me the above hope and also this adverb. ... "

But Borges did not disdain even the enumeration, that exercised a great interest over him, to the point that he wrote:

"Theoretically, the number of numeration systems has no limits. The more complex, in use to the gods and the angels would record an infinite number of symbols, one for each integer. The easier requires only two of these: zero is written 0, one 1, two 10, three 11, four 100, five 101, six 110, seven 111, eight in 1000 ... " (Leibniz's invention that apparently had been stimulated by the celestial hexagrams of I CHING).

It's impossible to enumerate all the logical-mathematical paradoxes about the infinite: we would like to remember the Paradox of Albertus de Saxonia (1316-1390), which speaks about beams of infinite length, typology often taken as pattern in the texts of Structural Mechanics [7] where, of course, there is no reference to the paradox. It is: *the volume of a beam of infinite length is equal to the volume of the whole Space*.

Undoubtedly related to the concept of infinity are both the representation of the number 8 and a particular algebraic curve in the shape of eight inverted, the Lemniscate of Bernoulli that is, as it is known, a particular case of the *oval of Cassini* (1680).

2.1 The enigma of the number eight

The graphic representation of the number eight (as well as the infinite symbol) is a curve that the human hand can repeat indefinitely, without ever disconnect the pencil out of the paper.

The cases in which the number eight achieves a particular importance (not only symbolically) are various and heterogeneous: from the Esoterism to the Metaphysical Sciences, to the Mathematic, to the Classic Physic etc. Some examples of what, are listed below, between science and no-science:

- 8 rotated 90 ° is the symbol of infinite
- the number 8 is universally regarded as the cosmic number
- 888 is the number of the portal toward the infinite, the eighth dimension!
- 8 Hertz is the Schuman's frequency, the heartbeat, or the pulsation of the Earth
- 8 hertz is the frequency of the mystics healers

Fig. 3: Evolution of the number 8 from the Indians to the Europeans [8].

Apparently, among other things, the symbol has taken inspiration from the shape of the Via Lactea, since in some ancient texts it was considered a huge serpent of light residing in the sky and that circled the Earth.

Then, it was widely used by mathematicians from all over Europe, but in a rather random. In fact, until the mid-nineteenth century, the dominant philosophical idea was derived from Aristotle, so that the actual concept of infinite, not only was not included, but there was neither in the empirical sciences, nor in those math. The sign of infinite was only designed to express a numerical continuity, endless, inaccessible and unattainable, function and domain of a single Almighty Creator.

Additionally, the use of rigorous symbols to express concepts, was equivalent to the alchemical invention of complex codes, through the which use it was possible to achieve solutions, decipherments that in a sense revealed the secrets of God.

2.2 The Lemniscate

In mathematic the Lemniscate is an algebraic curve approximately with the form of an 8 rotated of 90°. It has a node in the origin and two double nodal points in its cyclic parts [9].

In Cartesian coordinates it is described by a rational quadric

$$(x^2 + y^2)^2 = a^2(x^2 - y^2) \quad (2)$$

The graph of this function produces a curve similar to the infinite symbol, which, in turn, is often called just Lemniscate.

Fig. 4: Graphic representation. a) Lemniscate; b) Watt's system

A famous type of Lemniscate was described for the first time in 1694 by Jakob Bernoulli, as a modification of the ellipse, which is the locus of points for which the sum of the distances from two fixed points (called foci) is constant. A Lemniscate, vice versa, is the locus of points for which the product of these distances is constant. Bernoulli called it Lemniscus, which is the Latin equivalent of "pendant ribbon".

The Lemniscate can be drawn with the system devised by James Watt (1736-1819). The Watt's parallelogram is a mechanical connection, in which the movable central point of the system is forced to move approximately in a straight line.

It consists of a series of three bars, two longer and measurement equal between them, both connected to a smaller central bar. The outer ends of the long bars are pivoted in fixed positions between them, while the two joints between the three bars are free to rotate. Taking into account the fixed distance between the outer ends, the system is an example of a "connection to the four arms".

A strange formation of crop circle appeared the August 8, 2008 (8-8-8) in Wiltshire (U. K.), and naturally this fact interested very much all the Ufologists, that spoke about a mysterious signal came from the sky. They thought, perhaps, that the portal toward the infinite has been opening just that day [10].

Fig. 5: Formation of crop circle appeared the August 8, 2008 (8-8-8) in Wiltshire. a) Preliminary diagram; b) overview.

3. The spirals

An Archimedean spiral is a curve which can be described in polar coordinates (r, θ) by the following equation

$$r(\vartheta) = a + b\vartheta \quad (3)$$

with a and b real numbers, and b strictly positive. The change of the parameter a rotates the spiral, while b controls the distance between the arms.

The spiral of Archimedes [11] is distinguished from the logarithmic spiral for the fact that the subsequent arms have a fixed distance, while in a logarithmic spiral the distances follow a geometric progression.

Fig. 6: a) Spiral of Archimedes; b) Crop circle in the Wiltshire countryside.

A logarithmic spiral, equiangular spiral or growth spiral is a special type of spiral that is often found in nature. The logarithmic spiral was first described by Descartes (1596-1650) and later extensively investigated by Bernoulli, who called it *spira mirabilis*, "the marvelous spiral".

In the logarithmic spiral, the radius grows while it turns. As it approaches the pole, the curve "wrap itself" around this without ever reaching it.

In polar coordinates, the curve can be written as

$$\vartheta = \frac{1}{b} \ln\left(\frac{r}{a}\right) \quad (4)$$

Fig. 7: a) Logarithmic spiral; b) Stonehenge, July 7, 1996.

The problem of rectification of the circle, which cost much effort to the ancient surveyors, was also solved by Archimedes, with the introducing of a new curve, over than those that can be generated

using only a straightedge and a compass, that is his spiral. He was able to produce a result that, if one thinks of mathematical tools of the time, is incredible.

Consider the first circle of Archimedes (figure 8). Draw the line s normal to the radius of the first circle AH and passing through the origin of the spiral A . Consider, then, the straight line tangent to the spiral in H that intersects the line s in a point called F . Archimedes shows that the segment AF is the rectification of the circumference of the circle of radius AH . So doing, Archimedes moves the problem of rectification of the circumference to tracing the tangent to the spiral, which with the only use of a ruler and compass it's impossible [12].

Fig. 8: Archimedean construction

In geometry, a logarithmic spiral with factor of growth b and growth equal to φ , with

$$\varphi = \frac{1 + \sqrt{5}}{2} \approx 1,6180339887 \quad (5)$$

that is the golden section, is called "golden spiral" [13, 14]. The graphical representation of this spiral is based on a series of squares that can be insert inside the golden rectangle (Fig. 9 a). The realized construction can be related to the Fibonacci sequence, because the squares have, as sides, just the values of the series: 1, 1, 2, 3, 5, 8 ... See Figure 9 b

Fig. 9: a) The construction of the golden spiral; b) relation with the Fibonacci sequence

4. Conclusions

A researcher that approaches the study of the crop circle formations, will find a lot of arguments about the "energy". But in literature we cannot find anything that treats the question in really "scientific" terms.

In particular, the following figure had us intrigued (Fig. 10): it is clear that it is an expression of energy, but is it connected or not with the actual scientific knowledge about the matter? Or is it just a legend by esoteric culture?

So, we wanted to verify if a similarity, in terms of algorithmic expressions between crop circles and energy functions, really exists. And if we could found this similarity, perhaps we could transfer it to the stones of Stonehenge, which most probably represent in "up", what the crop circles represent on a bi-dimensional plan.

This aim was very ambitious, in fact the calculations that we have addressed while we have studying the question, have been very onerous [15].

Fig. 10: June, 17, 1996. Alton Barnes (Wiltshire)

Hitherto, a result has been achieved, because we found no algorithmic link between the formations and our studies about mechanics, but since doing research is also formulate hypotheses and then exclude themselves, the material collected there seemed enough to a conclusion.

At the time the studies are still in progress, and we cannot exclude that other researchers might find new objective a part from this work, or that ourselves may achieve more results about the argument, afterwards.

Moreover, in this paper we cannot formulate any hypothesis about the origin of crop circles, because this is not our aim, so in conclusion we can only emphasize that the link that from ever joins men and Universe, expresses itself by the Signs and tries to explain itself with the Mathematic.

These are the only two tools (apart from the mind that govern them, naturally) through the which the men can try to understand their provenience.

So beyond the algorithms, the Energy is contained in the effort of the humanity to express and to explain oneself.

Abstract

Modern society is a complex system, where the transformations of the urban environment are characterized by growing interdependence of parts.

This interdependence leads to the necessity in solving simultaneously a multitude of problems. These social, economic or political problems can't be understood using a classical approach, for example a sectorial approach is not capable to explain this kind of problems.

The space, where these problems are developed, is not static but it is dynamic. In this context, multi-criteria analysis constitutes a powerful tool to improve the procedural rationality, underlying complex decision problems, ensuring an integrated, multidisciplinary and transparent entire evaluation process.

The ANP in particular, thanks to its dynamic approach, is systematically capable to manage all types of dependence without the need to specify levels. The ANP approach results to be the most promising tool, available in the field of strategic decisions. It can be considered as a technique capable of grasping and properly reflecting not only the multi-dimensional profile of the problem of choice, but also the complexity inherent to real problems.

Multi-criteria analysis is a tool to support this integrated approach capable to insert different stakeholders' points of view. This tool is capable, in the development processes, to improve the procedural rationality in the context of assessments and decisions concerning complex systems; therefore playing a role of fundamental importance in the path towards sustainability.

Keywords: Enviromental, Decision making

1. The analytic network process

The Analytic Network Process is a multi-criteria technique of decision system designed by T. L. Saaty. This technique is well known as the implementation of the best-known Analysis of Hierarchy (AHP), in order to overcome the linear structure of traditional evaluation methods. These methods are unable to reflect the complexity of real problems, structuring and embracing a more dynamic one and better reflecting the complex interactions related in the various components of a system. Using the ANP approach, every decision problem is structured as a network of elements, arranged in groups, according to multiple relations of influence. This configuration allows to implement a structure capable of incorporating interdependencies and feedbacks, both within each group of elements and between various groups of elements. By considering the existence of feedback, in fact, not only the alternatives depend on the criteria, such as in a hierarchy, but also all the factors above taken into consideration.

The network structure is the base of an ANP model and it is defined as a set of components (cluster) and elements (nodes), linked together by a relationship network. Such interactions can occur between both elements belonging to different clusters, and by elements belonging to the same cluster. Furthermore such a

type of relationship makes possible the existence of feedback mechanisms (feedback) between network elements. Depending on the examined case, there are two different types of models: the "simple" structure and the "complex" one. The first consists of a network of relationships which develop between clusters and within the same cluster, with each cluster consisting of a number of specific elements and with a cluster reserved for alternatives of choice. The structure of "complex", presupposes the existence of a hierarchy of control that gives rise to sub-networks, each organized according to the "simple" structure. This structure contains groups, elements and alternatives.

2. ANP model definition

Due to the high complexity of the decision problem, the more suitable model to the development of Analytic Network Process, seems based on the complex structure. The decision problem has been split into 7 clusters (alternatives, environmental, economic, energy, logistic, social and urban, planning factors) organized into BOCR (Benefits, Opportunities, Costs, Risks) subnets.

Benefits and costs have been identified with known aspects, respectively positive and negative. These aspects are due to their transformation evaluated at present but looking at a medium-and long-term future forecasts, which has been developed in a quite detailed way. The opportunities and risks have been considered to be less in certain aspects. These aspects, positive and negative respectively, have been evaluated when the transformation has taken place and looking at an even further away future, for this reason it is more difficult to predict. The alternatives, whose analysis has focused on, are two: the "inertial" alternative and the "eco-museum" one. In both the cases the design options are related to the future. The first alternative is defined inertial because it represents the evolution of the current situation in the absence of the eco-museum and is therefore characterized by long periods and uncertainty. The second is based on the implementation of the eco-museum, a catalyst element characterized by transformations and at the same time an innovative urban symbol.

	Alternatives	
	Ecomuseum	Inertial
Tourist attraction and heritage	It multiplies the value of existing assets, we take into account new opportunities	We don't develop new projects, but we enrich existing ones
Transport and mobility	Strengthen the efficiency of transport networks through eco-friendly's works	Maintenance of existing transport networks with routine maintenance
Identity and local firm	The local community is more cohesive, conscious and vital	we don't seek new roles for the area as a potential producer of wealth

Fig. 1: Alternatives, inertial and ecomuseum

3. Cluster and elements of decision-making network

The most common case of complex model, based on control hierarchies, is the model called BOCR (Benefits-Opportunity-Cost-Risk). The multitude of factors that characterize this analysis can be simplified, every decision problem is characterized both by positive and negative aspects. Some of these factors are certain, others are less certain and are characterized by having a probability to be realize. Some favorable aspects can be considered as "benefits", instead the negative ones are considered as "costs." Also uncertain aspects of every decision can assume a positive connotation and therefore become "opportunity", or a negative and turn into "risk".

BOCR	CLUSTER	NODES
BENEFITS	Logistics	Effectiveness and efficiency
	Energetics	Renewable energy sources usage
		Power Consumption optimization
	Social	Degree of comfort in the attraction places
	Urban	Urban redevelopment
Economic	Enhancement of the best for a tourist	
OPPORTUNITY	Urbans	Sustainable networks creation
		New simbols and landmark creation
	Economics	Creation of attraction poles for the development of the area
		Environment enhancement
	Environmental	Long-term performance and functionality
Quality of degraded areas improvement		
COSTS	Logistic	Urban restructuring
	Energetic	Raw materials consumption
	Economics	Construction and maintenance
		Archaeological maintenance
	Environmental	Environmental impact
RISKS	Logistic	Malfunctions
	Social	Project support failure
	Urban	Lack of integration with the urban context
	Economic	High managment costs
	Environmental	New traffic flows

Fig. 2: Diagram of complex model called BOCR

Once the decision problem has been structured in clusters of elements, according to a more suitable scheme, it is necessary to connect every cluster or component with all the elements where is possible to establish some inter-relationship.

The definition of these links is a very important operation in order to perform a correct evaluation process. In fact, the setting of pair wise comparisons, through which can then express their preference judgment, solely and exclusively, have been defined as connections between various elements of the network.

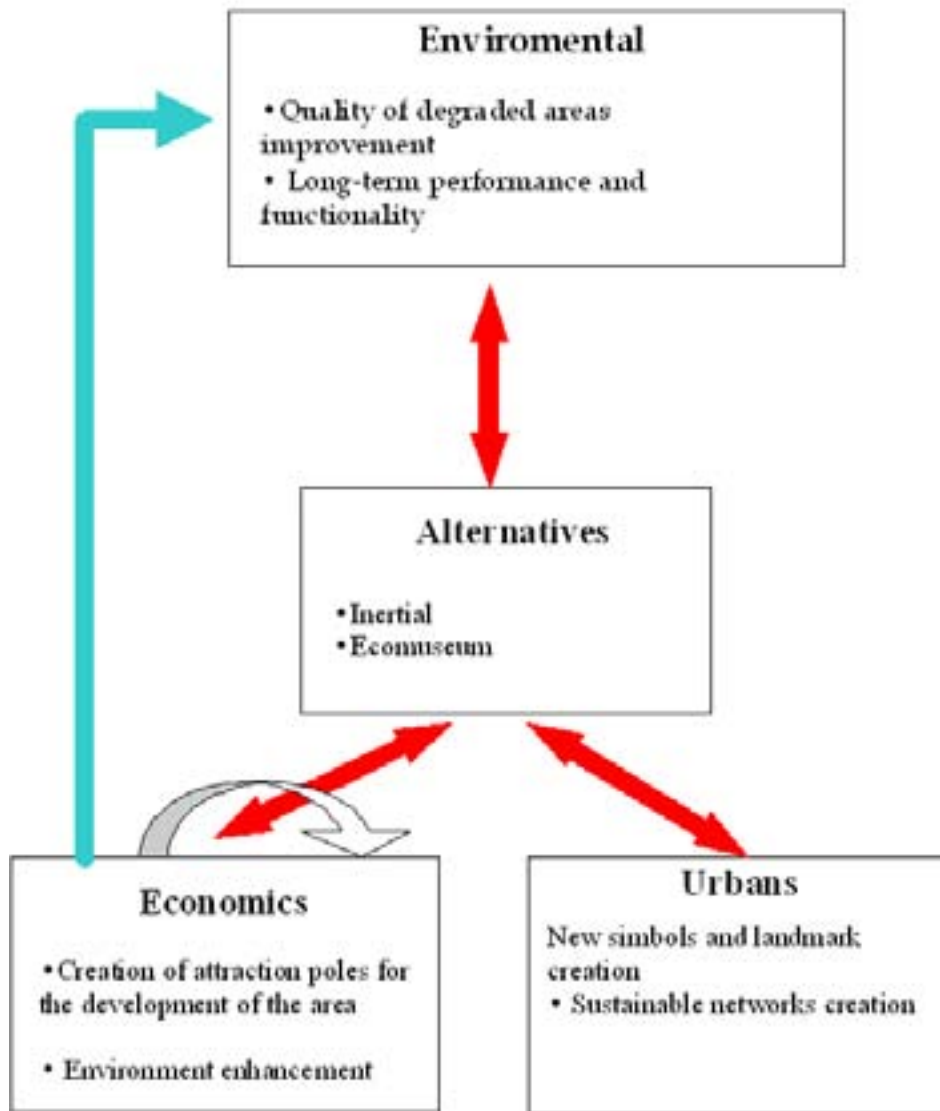

Fig. 3: Diagram of opportunities subnet

4. Analysis

Established the decision-making networks are necessary to compare them in pairs at the level of clusters. Considering the overall objective of the model as "Parent Node" the questions that must be answered for the compilation of pairwise comparison matrices are the ones depicted in the following. With reference to the identification for the best solution to creating an eco-museum in the Pompei area, the aspects depicted in the following aspects must be analyzed.

Urban	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	Enviromental
Enviromental	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	Economic
Economic	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	Urban

Fig. 4: Comparison between clusters

Evaluation results of the comparison between clusters have produced the values suitable to be included in columns of the matrix.

	Enviromental	Economic	Urban	Priority
Enviromental	1	4	1/4	0,223
Economic	1/4	1	1/8	0,070
Urban	4	8	1	0,707

Fig. 5: Comparison matrix between pairs cluster (opportunities subnet)

Once obtained the priorities of all the clusters, it is possible to build the so-called matrix weight. This matrix is constituted of priorities arrays extracted by every square matrix of pair wise comparison at this level.

	Alternatives	Enviromental	Economic	Transport
Alternatives	0	1	0,188	1
Enviromental	0,223	0	0,73	0
Economic	0,07	0	0,081	0
Transport	0,707	0	0	0

Fig. 6: Weight matrix

After the analysis of each subnet-model, clusters layer, it is necessary to deeply exam the results and consider various elements, concerning to the influence and interdependence relationship at the network nodes level.

Always with reference to the Opportunities subnet, in the following, is shown a comparison between nodes as parent node having the inertial alternative and as child nodes the elements of the cluster of environmental aspects connected to it in the assumed model.

This type of comparison is used to assess the influence of various elements on the considered alternatives. This topology of comparison is useful to evaluate the influence of various alternatives elements and represents the so-called available feed-backs generated by the ANP methodology.

The question which needs to be answered to is the following: With reference to inertial alternative will their weight more to improving the quality of degraded areas (A) or the long-term performance and functionality (B)? How much?

A	9	8	7	6	5	4	3	2	1	2	3	4	5	6	7	8	9	B
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Fig. 7: Comparison between alternatives

Once the comparison and evaluation phases are ended, it is possible to build three super-matrices for every subnet of sub-model.

	6	0,167	0,028	0	0	0	0	0	0

Fig. 9: Weighted super-matrix

Once obtained the weighted super-matrix, it is necessary to multiply it by itself a number of times versus to infinity in order to obtain the so-called limit super-matrix.

		ECOMUSEUM	INERTIAL	1	2	3	4	5	6
Alternatives	ECOMUSEUM	0,403	0,403	0,403	0,403	0,403	0,403	0,403	0,403
	INERTIAL	0,086	0,086	0,086	0,086	0,086	0,086	0,086	0,086
Urban	1	0,259	0,259	0,259	0,259	0,259	0,259	0,259	0,259
	2	0,088	0,088	0,088	0,088	0,088	0,088	0,088	0,088
Economic	3	0,024	0,024	0,024	0,024	0,024	0,024	0,024	0,024
	4	0,017	0,017	0,017	0,017	0,017	0,017	0,017	0,017
Enviromental	5	0,053	0,053	0,053	0,053	0,053	0,053	0,053	0,053
	6	0,070	0,070	0,070	0,070	0,070	0,070	0,070	0,070

Fig. 10: Limit super-matrix opportunity sub-net

The final priorities of the obtained alternatives from the limit super-matrix of each subnet are normalized by constituting the alternatives sorting.

A greater value of preferability in the sub-net Benefits and Opportunities list means that the alternative leads to higher benefits or opportunities and consequently is preferable. On the contrary a higher value in the list on the Costs and Risks subnets means that the alternative involves higher costs or risks and consequently is less desirable.

ALTERNATIVES	BENEFITS	OPPORTUNITIES	COSTS	RISKS
INERTIAL	0,18	0,176	0,36	0,2
ECOMUSEUM	0,82	0,824	0,64	0,8

Fig. 11: Final result

5. Conclusions

The application has showed a clear preference for the option in making an eco-museum in Pompeii area against the option in maintaining the nowadays structures. The aim of this work is to show the potentiality of the ANP methodology. This methodology is capable to solve cases of partial data availability with the presence of unknown factors using the decision-making process.

This methodology is capable to include dependencies, incorporate feedback in modeling, taking in count the uncertainties in the decision-making process. At last the proposed methodology is capable also to include consequences of a given action between the factors exerting an influence on a decisional process.

Abstract

Small children are a mere example of virtue in the matter of inventiveness: bear in mind that they are able to reuse and recycle any domestic object or accessory belonging to a more jointed system of technological as well as handmade things. With their unaware like extraordinary operations of “ready made”, they are able to create new extemporary habitats, thanks to their play world and play relationships, where “new objects” acquire a clear and precise identity through a series of unthinkable combinations between form and function, utilizations. In this way they can develop the knowledge of external world and self awareness and learn the importance of roles and rules through the play functions. To design an object, equally an architectural space, means a little to take away children’s innocence and ability of converting spaces and objects in order to create instruments of cognitive survey besides comfort. At the same time, on the one hand is essential to reaffirm once more the importance of the smart reuse as an ethic measure as well as a significant part of a responsible task that includes the respect for the life cycle product and the sustainable relations among production, environment and man.

Keywords: fun, irony, measure, memory, smart reuse.

1. Comic design. Memory between fun and benevolent irony

On the other hand, in a post global age how it is the present one, meeting the demand of a share of the market is also to say that the plan must be a way to design in full compliance with a new kind of needs like to take possession again of nature, to rediscover own identities, collective memories concerning peculiar places and customs, combining allusive cross - references and technology, possibly with nonchalance. In a similar context where doesn’t exist more an absolute reference point we can see a great share of designers, architects, artists - not only belonging to younger generation -, which express playfulness in their works, trying to reach a new manner of converting, mixing and de-contextualizing functions, shapes, materials, colours and finishes through a sense of funny - that belongs not only to the play or toy design planned for the children - united to a certain irony and self irony. Design for funny as well as the “comic opera of design”, mentioning the case of the Neapolitan artist - designer – architect Riccardo Dalisi, don’t come from a mere desire of debunking and desecrating, but represent a peculiar manner of meaning design an life and reveal a particular way of involving the user – consumer. Sometimes this concept, taken out of didactic and serious impositions, seems to be one of the most appropriate vehicle of information, knowledge and at least, it is a cause for reflection. Dalisi writes that “everything, even the most serious thing, has its moment of play, during which, it is transmuted and transformed. For design, this happens in the deadly serious design for children’s and adult’s games – and in others areas” ¹ He speaks about the comic design and the similarity with other fields, in particular the musical one: he alludes to Pergolesi, the father of comic opera and in this sense he affirms that his “comic opera of design” came into being quite spontaneously and that “from the intense lengthy research regarding very serious technical and experimental coffee-pots for Alessi emerged, at a certain stage, an ironic and playful vein” united to a

Fig. 1: R. Dalisi and “the Comic Opera of Design”: Neapolitan copper coffee - pots.

Fig. 2: *Domus* (Archive | Munari) 202, October 1944. MUNARI, Bruno, *A person comes back home tired having worked the whole day and finds an uncomfortable armchair*. This is an ironic provocation addressed to the he over productive design.

great passion for the Neapolitan coffee – pot. Through Dalisi this particular object conquers a proper life and seems to narrate the stories of heroes, real and / or imaginary, such as Pulcinella, Geppetto, “Totocchio” - a combination of Totò and Pinocchio - and so on. Through almost childhood sketches and very amusing artifacts, the Neapolitan artist underlines not only the value of memory and the importance of the discovery of the original functions, but also the object’s communicative possibilities, included the sense of tenderness and curiosity; at least, he carries out a sort of humanization process

Fig. 3: Down, on the right, Dalisi wrote me with fun irony: “Tu devi essere insoddisfatto per essere soddisfatto e non sfatto” that in English it should be something like that: “You must be always dissatisfied to be satisfied and not destroyed”. (1999)

of his objects, suspended between comic sense, fun and benevolent irony. To this end I remember a personal experience with Riccardo Dalisi – in the Neapolitan period of my Industrial Design courses: the theme of the project - exercise was the car, one of the most dear to him: down a my disengaged sketch, he wrote: “Tu devi essere insoddisfatto per essere soddisfatto e non sfatto” that in English it should be something like that: “You must be always dissatisfied to be satisfied and not destroyed”. Then I was rather young and just later I have understood deeply the sense of those words I remember even now.. In the past many designers have worked with intelligent and subtle spirit of irony: for example bear in mind Bruno Munari who designed, with subtle sense of healthy provocation, the chair that has to dissuade the unwelcome guests. This one underscores the question of the (un)comfortable seat, as well as the ancient matter of relation between esthetic and functionality, shape and use. In the forties, formerly Munari have affirmed that sometime it'd be better to perfecting some comfortable existing prototypes and models – often very economic too, such the classic and simple deck chair - instead of inventing new models to infinity; on the contrary, as in a perverse practical joke, designers keep designing thousands of seats, chairs, armchairs and every kind of poufs, that change shape and style continuously with the trend, but are often less and less careful to their final chief aims: functionality, duration, comfort, cost | price.

2. Irony & Ecology. It is not a matter of trend

Maybe it is not excessive to underline that generally irony diverges from laughter and comic sense: the first one is more subtle, a sort of “intellectual exercise” that doesn't let the rumbling laughter, but leads us to smile at the thought of man and life relativity that the designer desires to express through his artifacts. Through an “ironic” artifact he proclaims, clearly or implicitly, human inconsistency and incoherence in despite of feel of organizing and controlling everything, but without aggressiveness, provoking - as obvious consequence - a reflection that leads designers to realize (and metabolize) the consciousness of our inability of dictating (and communicating) any absolute truth. Some researchers define irony as the result of a kind of dialogue with “our and other people's intelligence”, that, finally,

bring us even to enjoy the sense of relativity. However to be or not to be ironic is a matter of natural attitude, not a forcing; to be ironic at all cost doesn't make sense. Even it appears contradictory, to be ironic means to have a certain dose of freshness, candor, openness. In other words to be ironic means not having the consciousness to be that. Unfortunately, on the other side, it is possible to perceive that in many cases the tendency of irony tout court has become just fashionable; it's a kind of manufactured pass to parade "simplicity" – but irony is not just simplicity -, that often, is none other than the result of a well structured economic plan that doesn't know anything other rule than the market's one. In other words irony becomes just a way, unnatural and deceiver, to impose one's artifact on consumers, maybe belonging to a more sophisticated target or to a more culturally refined group. Nowadays, there is a great confusion in social political and cultural fields, so even in the design world always more frequently the cheapness reigns and every kind of artifact, every time justified by different principles and theories, becomes a truth carrier example.

In despite of that, we have several examples of coherent design artifacts in which, furthermore, irony is adjoined to a very good dose of ecology, producing one of the most interesting binomial. Bear in mind Gehry's long chair named "Little Beaver" (designed in 1980, produced in 1987 by Vitra), exhibited at the Vitra Museum by Herzog and De Meuron: its irregular form of flat-cut blocks of corrugated cardboard underside with metal plaque, is the spark for a series of considerations about the innovative and smart way of using this material, its cheapness, besides all the questions pertaining to relationships between functionality and esthetic. We cannot remain speechless in front of the deep erudition lavished in the innovative treatment of material (the corrugated cardboard). Certainly Gehry's revolutionary sense of esthetic, in his design products reflects full well his continuous tension towards a limitless space vision as in his sculptured architectures projects, that, following on from some critics, represent a kind of landing place in a New Baroque Era. Certainly as is common knowledge, we are aware of the importance and the weight of the economic strategy plans existing in back of these kind of brand merchandise, but, at least, it is impossible to sit indifferent in front of artifacts like that have all the features of a product that is the result of a bright and fascinating working process that starting from complexity awareness reaches a fresh ironic synthesis, and joins with our individual (and collective) imagination presenting an entire satisfaction to our eyes, touch, and comfort. In substance we can perceive that very special feeling that only certain high - evolved design by some (not all) sensitive designers and architects can emanate. In the matter of irony (and practicality), in particular, as Prof. Volker Albus (teacher at the Hochschule für Gestaltung in Karlsruhe) writes: "The

Fig. 4: From the left. A Japanese restaurant; some interiors made by cardboard elements.

'Little Beaver' chair provokes *oohs* and *aahs*, but not when you first see it, and not even when you realize that the corrugated cardboard it is made out of is actually warm and comfortable, but when you realize that any stain, be it caused by Fido or visiting grandchildren, can be cut away: quite an advantage over other upholstered seating! To the profane however, the non-conventional essence of these objects remains incomprehensible. And not only. They are incapable of participating even minimally in their subversive quality or of understanding the complex creative process behind them. Because what we have before our eyes is not just a chair, a shelf or an armchair made out of unusual materials. No: thanks to their simple, even banal components, which are just as subtle and brilliant, these projects raise questions about our traditions of function, conformation and use of materials that are deeply rooted in our furniture culture. In other words: once you have seen the 'Little Beaver' chair,

Fig. 5: On the top. F. O. Gehry and his corrugate cardboard chaise longue and armchair “Little Beaver”. At the middle in time sense: different colour versions of “Little Beaver” with pouf; Gehry in his American atelier while makes some component prototypes of his “sculptured” architectural design; the “Easy Edges” in flat cardboard. Down from the left: the new Guggenheim Museum in the Cultural District of Saadiyat Island in Abu Dhabi United Arab Emirates (UAE); from the past an example of organic architecture by A. Gaudí, “Casa Milà”, Barcellona, Spain.

all you can do is crack a malicious smile at all those people dusting and cleaning the upholstered seating in their formal living room"². Gehry chose a different method, which gave birth to sturdy cardboard furniture like cardboard sculptures: "One day I look in my office at a pile of corrugated cardboard, the material I normally used to make architecture models, and I began to experiment with it, to stick it together and to cut it into shape with a hand saw and a penknife"³. After his "Easy Edges" from 1972, a series of cardboard furniture with flat surface, Gehry proceeded to use corrugated cardboard for making furniture and gave life to "Experimental Edges" a series of surprisingly comfortable chairs and easy armchair with an unrefined, raggedy - looking surface.

3. Sustainable design and green architecture. No paternalistic worldviews

Certainly, irony and fun apart, ecological design, sustainable design, green architecture are not recent discoveries. From time immemorial nature represents the most incisive living model for architects and artists besides poets, scientists, mathematicians, physicists. Be enough to remember the Ancient Greeks and their deep relationship with nature as a source of inspiration, a terms for comparison of which to emulate perfection and beauty. Be enough to give thought to Italian Renaissance that assimilated Greek aesthetic theories through Latins, in particular Vitruvio: in other words the ancient “designers” took the cue from nature and natural events to resolve the planning questions and to create balance between appearance and substance. In the twentieth century many architects and designers have theorized and exercised organic and “ecological” architecture; in the States, first among all, we remember Frank Lloyd Wright, founder of Taliesin, the School of Architecture (1932) such as the Italian Paolo Soleri, founder of “arcology” (architecture + ecology); in Europe, even before, Antoni Gaudí, and then Hans Poelzig, Hans Scharoun, Rudolf Steiner (architect and anthroposopher), the Finnish Alvar Aalto; successively Lucien Kroll, Makovecz Imre, Roger, the Italian organic architects and designers G. Michelucci, B. Zevi, C. Scarpa, G. De Luca, A. L. Rossi and many others. Unfortunately - even though in recent times, it is possible to notice a greater ecological awareness - in different circumstances designers show us just an illusory development in this direction: their solutions and proposals seem to be the result of an exterior examination well away from the essence of material requests, and reveal a paternalistic and restricted worldview that puts western man at the middle of universe, an universe chiefly based on technological and industrial values. In other words they neglect ecological questions from more complex and global perspectives, retracting, at the end, the final objective as well as leaving aside the ethic question. Nowadays it is indispensable to develop a genuine deep green consciousness that means to know that every choice has its own corresponding effects, often negative on other latitudes, for other communities: everything is strictly interconnected. We need to acquire a holistic worldview in which technology must not be invasive, it has to be respectful of nature and sustainable as much as possible to not impair any people on the globe.

Nowadays for designers to have an “ecological awareness” ought to mean more than ever to return to nature, to fight colored socio political economic supremacy and prejudices, to avoid unnecessary, aggressive and invasive technicality, to overcome arrogance that causes vain wishes of omnipotence. Furthermore, to stimulate a healthy environment of a geographical area it is necessary to keep away from summary survey methods of modern eco design movement that generally underestimates regional problems and tends to superimpose external, standardized global project solutions, exclusively on the strength of fashion wind and market trend; it is indispensable absolute knowledge of historical, geographical, physical, cultural, socio - economic territorial features, contextualizing solutions in local scenarios, above all not neglecting deep and detailed studies about regional standards, human problems, demands, requirements, needs, necessities, rights. Every context needs its appropriate plan choice and it is improper to adapt to an Italian town projects designed to an American metropolitan area exclusively on the base of prepackaged modular schemes or own personal practice.

Fig. 9: From the left. Ironic chairs and armchairs: John Krubsack (Wisconsin, U.S.A.), naturalistic chair grown by tree shaper, 1919; Achille & Pier Giacomo Castiglioni, “Sella”, Zanotta 1957 and “Mezzadro”, Zanotta 1971; Jonathan De Pas, Donato D’Urbino, Paolo Lomazzi, “Joe”, Poltronova 1971; Philippe Stark, “Gnomes”, Kartell 1993.

3. Toy design_Children and adults. Matters of ethic.

Returning to irony, and sense of funny, it’s important not to lose the taste of playing in any project aims to explore unconventional scenarios or materials. Sometimes in planning approach it is necessary to become like little children again finding to invert order of elements. Unfortunately this ability is always more rare in the toy design world, that instead of being oriented towards the child perception, always more frequently, is governed by a sort of incapability of respecting children’s world: every choice is governed by market oriented adults and “children are in background, a long way off, out of focus, as would be appropriate for minor parts in films”. In this way the author⁴ of a written published in the review *Modo* a few years ago, expresses his uncertainty, adding that toys, “to be useful, should be deconstructed and simple. They should not require assembly instructions. They should be intuitive, innovative. They should be published not on television, but in daily papers”. Perhaps, it is for these reasons - explains the author - that Bruno Munari, a great supporter of sustainable toy design, is neglected by the chief companies that are exclusively occupied in increasing sales.

Fig. 10: Eco toys made by wood, cornstarch, recycled plastic and other biodegradable materials.

Toy and game design are very important for children education and training opportunities. Play is a basic moment at root of intellectual and social child development. “Design can do a lot to help society change course, and it can do this by thinking about the importance of play, even before considering the toys as an object. Play should not be associated with just the period of infancy. Design can also foster reflection on age and time in a philosophical sense. Is there a thread that links the chapters of life, connecting infancy to adolescence and then to adulthood? Are these instruments for play suitable

for each of these ages, or is it possible to conceive toys that surpass these definition and bring people together regardless of age, educating and amusing at the same time?”⁵ The issue is very delicate and concerns deep studies about psycho – physical interaction on children growth, sustainable use of materials, their ambient impact, effects including the matter of packaging and the themes regarding the different ways of recycling waste materials.

4. Play and plan in urban scenarios. New research processes

The participation of people, included very young people and children in the architectural and design planning and activity is well understood by a significant number of academics and researchers in the world. They assert to corroborate and analyze in depth potential resolutions of problems, tied to real people needs and requirements, it's necessary to listen the user – consumers through a tangible strong emotional involvement. In this direction, the importance of play not only in domestic design, but also in architectural and urban one, has been explained and experimented by the Newcastle University (U.K.) researches that in 2012 have conceived an ideal “mini – city” erected by more than 110,000 blocks of Lego. Through the interactive exhibit called “The Great North Build” lodged in the New Castle’s North Museum (April, 14, 2012), the English researchers invited citizens, “architects, practitioners, old men, children, students to take part in the sets of problems related to the urban development of the city”⁶, and to contribute and find correct answers and appropriate solutions to questions such as urban expansion, demographic development, life quality, green areas, old town centres, hospitals, conversion and modification of industrial areas: in other words all possible elements necessary to improve the urban context on the bases of citizens’ requirements. Through a thought-provoking platform for discussion they wanted to look for answers to searching questions, such as how does a city plan for a growing population and how can urban design improve the environment. Although the great enjoyment that this event has assured to all aged participants, citizens have been challenged in work in progress and stimulated from time to time to study and purpose new solutions related to unexpected planning hypothesis and emergency ones. In conclusion, instead of usual planning means, the experts have chosen the game and the exhibition to corroborate new interesting studies and cognitive methodologies aimed to explore the impact on people’s everyday lives and to find key to society’s big questions to translate in urban sustainable plans..

Abstract

The paper seeks to offer some observations about the relationship between the complex connectivity of contemporary reality and communications strategies by seeking a field for reflecting on issues of the representation of the city within the general theme.

Representing the city has always meant 'presenting it' using visual systems that can capture its identity and transform it into an image. The state of the contemporary city makes this work more complex and suggests new forms of representation that take account of change and represent the complexity of experiencing a situation in constant flux. It is therefore crucial to abandon 'assertive' approaches towards viewing the city, and put forward new and multiple 'perspectives' which can create narrative schemes by weaving together individual stories, urban tactics, temporary uses and descriptions of places. Like modern-day *flâneurs*, these new perspectives should focus on experience rather than interpretation. They involve creating dynamic maps of a discontinuous present created through forms of listening and the production of communicative artifacts which are not always conventional but are capable of re-orienting the exploration of places and promoting strategies of signification and possible future uses.

Keywords: sense-making, social interaction design, narrative tactics

1. Representations change the landscape

This paper examines our relationship with the city and the urban landscape. The contemporary urban landscape is changing rapidly and these changes are forcing all of us to reflect on the thought structures that enable us to interact with its complex series of connections and on the need to redefine interpretative strategies and representative paradigms.

The theme will be examined from the viewpoint of an academic who is interested in 'representing' reality. 'Representation' is a discipline that is traditionally concerned with interpreting architectural and urban phenomena and transcribing them into images. However, representation is never neutral and not even just 'presentation'; much more often it is a complex action that leads to various possible scenarios. At times, it constructs these scenarios and produces collective imaginary worlds, creating reality and can therefore be regarded as a constructive rather than a descriptive action.

Fig. 01_ Armelle Caron, *Tout bien rangé*, 2009. Graphic anagrams of maps of the city

As Henri Lefebvre has persuasively argued, *"inhabiting a place is an anthropological fact consisting of objects that represent relations"* [1].

It therefore constitutes a starting point, in a certain sense, the assumption of these reflections, the abandonment of the notion of space – and, in particular, the space of the city – as a series of places corresponding to functions rather than people, and the adoption of a concept of space as a network of relations and thus in a broad sense as a 'space for living'. They configure the 'life space' of the city, which is a fascinating maze of signs, symbols, codes and metaphors of living. It is a complex system whose signals should be intercepted in order to understand the sense of individual or collective actions. These actions have the power to modify the physical structure and relational components of urban space through a process that often spontaneously activates behavioural strategies that give new possibilities of meaning to inhabiting space [2].

The focus will initially be on the alterations affecting forms of contemporary living and its own vocabulary, which are leading to a general rethink of the methods and strategies involved in the rigid paradigm concerning the representation of the city and its territory. The visual conventions of the representative processes of urban space have experienced an unstable and turbulent period for a considerable time. This is not principally due to the major innovations in digital representation systems, but rather due to the fragility they demonstrate in adequately expressing the accumulation of differences and contradictions that characterise the new forms of living and the new tactics of using urban places. New ways of interacting with the territory are emerging, in which the processes of signification of space multiply and overlap. Unprecedented temporalities regulate individual and collective experience. Interconnections are intensifying and the processes of globalisation are radically altering the relationship between space and time, leading to a new condition of an elsewhere that is simultaneously everywhere or nowhere.

Representing this complex polyphony is a crucial challenge for understanding contemporary life, but also for addressing its modifications with greater awareness. Representations have the power to construct meanings, to institute and shape forms of knowledge, and to transform the collective perception of reality. Galimberti is absolutely right when he argues that "men have never inhabited the world, but only the description that religion, philosophy and science have, in turn, given of the world" [3]. One inhabits representations of reality and these "founding tales or maps have the power to construct belonging and relations, stratifying images and common sense, embodying desires and the possibility of control"[4].

2. Tuning into the city: circumstantial perspectives

Within this context, which involves both 'representation' and 'self-representation', the contemporary city displays its most distinctive feature: it simultaneously belongs to multiple collectivities, involved in a constant state of flux where local affairs and global affairs, near and far, past and present all coexist. Plural cities encourage anyone who is interested to tune into their significance and to adopt new perspectives, considered to be the most suitable for portraying this ever-changing world.

There are people who place their trust in a wholly virtual approach. One such example is the research carried out by Carlo Ratti and his SENSEable city Lab, the multimedia laboratory of MIT in Boston which formulates strategies for representing urban reality. All the strategies are based on the possibility created by the space of the network (platforms, portals, virtual piazzas...) in order to portray the city as a series of 'information flows' in the form of interactive maps which can represent the vibrancy of life and activities in real time. Some believe that the multi-scale approach, with the infinite possibilities for gathering data provided by GIS (Geographic Information Systems), is an exhaustive and comprehensive solution.

However, others are firmly convinced of a 'lateral' approach that uses a perspective which, above all, perceives the distance between itself and observed reality and is careful to explore urban processes through multiple viewpoints (perceptive, sociological, anthropological...). All are equally useful for investigating reality and providing representational images that are highly subjective and unconventional: installations, cognitive maps, eclectic atlases, an occasionally surprising result of combining different levels of reality.

The project-installation entitled USE Uncertain states of Europe proposed by Stefano Boeri and his Multiplicity research team is an excellent example of this 'lateral' approach to depicting reality.

Lastly, there is an approach which could be defined as a 'nomadic' point of view which is far more capable of prompting a mobile view of a space that is in a constant state of becoming and manifests itself essentially as the space of relations and connections, a space of interferences. An approach that seems to be much more capable of understanding this dynamic, which refers simultaneously to 'representation' and 'self-representation', the contemporary city displays its clearest aspect: the state of belonging simultaneously to multiple collectivities, involved in a permanent flow in which there is a coexistence of local and global, near and far, past and present.

As can be seen, these approaches are not traditional and contradict the descriptive anxiety that has marked the recent analysis of urban processes which has used top-down morphology as an almost exclusive paradigm.

This latter paradigm essentially as the space of relations and connections, a space of interferences. The descriptive anxiety that has marked the analysis of urban processes in recent history has adopted a zenithal morphology as its almost exclusive paradigm. This paradigm attributes meaning only to the figures that express themselves in complete form within a two-dimensional surface. According to this paradigm, it is desirable to establish an observation point in an absolute position, remote from the observed object, almost as if the impersonal and synoptic gaze of the observer somehow guarantees the 'objectivity' of the process of investigating the city.

This kind of visual paradigm finds it hard to recognise that urban reality is not a simple overlap of levels of information, ascribable to flat two-dimensional representations, but rather a "collective way of conceiving space"[5]. In order to represent it, it is essential to combine different languages, adopt alternative forms of representation, alternative visual conventions and alternative investigative strategies.

Fig. 2.0_Off-center On-line , Koning Eizenberg, 2008 (in Uneternalcity, Urbanism beyond Rome, Section of the 11th International Exhibition of Architecture curated by A. Betsky)

Recognising the opaqueness of zenithal representation is the first step towards discussing the relationship between the map and the territory and the need to adopt a circumstantial approach to viewing, a sort of lateral approach to the observation point which makes it possible to create other maps. They are provisional maps which are at times incomplete but capable of expressing subjective points of view. "The map is not the territory" as Bateson reminds us [6], but merely a way of interpreting it and codifying it. From this perspective, mapping a city means "organising one's own spatial experience through highly subjective operations of selective representation"[7]. It is no mimetic seduction nor surrender to a passively descriptive approach, but rather a reinterpretation and transfiguration into image and narrative. From this perspective, maps and territory interface according to relations of sense rather than mimetic analogies. The adoption of an intentionally lateral and circumstantial view means choosing a self-reflexive and, in a certain sense, 'biased' condition of a representation that deliberately avoids adopting, as an operational category, the objectivity that "leads the observer to keep a distance from the territory and delude him or herself into employing the same impersonal and powerful perspective that he or she uses" [8]. However, this relational dimension should not be considered as conflicting with the physical dimension of urban reality. On the contrary, physical space and relational space should be explored in dialectical terms because both define the plot that connects humans to their surrounding environment. It is a scheme in which perceived space, conceived space and experienced space are intertwined [9]. Concerning this point, Soja's observations in his theory of 'third space' are particularly illuminating [10]: while the first space is the material space of spatial forms and the second one is the perceived space that derives from mental representations, the third one is the space of experience and practice, a conceptual category in which materiality, perceptions, imaginary worlds, desires and actions merge with each other. It is a space whose representation does not simply involve enriching previous paradigms with 'new images' but, instead, involves developing "a new spatial thought made up of interconnections, short circuits, fluidity and dynamic tension"[11]. This form of representation should be sensitive to processes of signification and focus on qualitative rather than quantitative methodologies, examining differences with far more interest than invariant features. What is therefore required is a truly pluralist form of representation.

3. Interaction and Sense-making. Towards hypermedial interaction

By abandoning the top-down perspective and entering the wrinkled folds of reality, it is necessary, to quote de Certeau, "to think the very plurality of the real and to make that way of thinking the plural effective". This implies employing multiple viewpoints in the field. Above all, it means considering the city as a 'social construct' rather than as a construction, a dimension where an important part is played by the flow of social practices, behaviour, relations and signifying. In this context, they take on the meaning of forms of discursive

and interactive knowledge, accounts and stories of life. These forms of self-representation constitute an extremely important element in the process of constructing the image of the city as a dense, stratified and changeable scenario. Giving people the chance to appear and represent themselves offers a precious opportunity for self-determination; it provides the project about the city with a formidable innovative significance that draws more on individual experience rather than a team of experts summoned to solve a problem.

Asserting the importance of narration in analytical and decision-making processes means acknowledging that social interaction de-structures the relationship between, knowledge, decision and action. It implies emphasising the relational aspects and interaction between players and implementing a complex process that can be defined as *sense-making*: in other words, a process of constructing meanings that acts as an ideal link between individual, subjective perception and collective symbolic norms. A similar approach could be applied to the world of objects, considered as relational devices that, in their own way, narrate stories about the spirit of places and their destiny. Narrative thought would thus enter the sphere of urban practice and narration could be transformed into planning. In representative terms, the biographical approach and qualitative research procedures have extraordinary allies in the potential of new audiovisual methods and the recent inclusion of new technologies which give an even more interactive quality to what is defined as the "rhetoric of scientific argumentation" (the way the results of research are communicated).

Audiovisual language offers interesting opportunities in the sphere of urban analysis. Multimedia devices provide an extraordinary tool for representation for the theme of relational research itself since they hybridise languages and create complex narratives which are hypertextual rather than linear or one-directional. Due to their open structure, these narratives create a field of multiple signification which is undoubtedly superior to any form of paper-based support, giving rise to narrative structures where multiple viewpoints find a clear form of expression.

The temporal dimension enters representation, showing the rhythm of urban life, documenting the process of becoming by focusing on the timescale of the elements in an account, the timescale of the story and the timescale of knowledge.

Fig. 3.0_ Sensitive City. Portatori di storie, Studio Azzurro.

Sensitive environment, Shanghai, Italian Pavilion EXPO 2012. "The idea of Sensitive City stems from the request for the Italian Pavilion at the Universal Expo in Shanghai 2010 and draws on the great tradition of imagined cities, from Tommaso Campanella's city of the sun to the invisible cities of Italo Calvino. Rather than remaining a suspended model or a literary invention, it is ideal merely because it still does not exist but potentially could. Siracusa, Matera, Lucca, Chioggia, Trieste... all differ from each other and it would be necessary to explore them all and travel round them repeatedly to have the chance of describing them. There is an increasing interest in using the idea of the anti-utopian city as an opportunity for offering ideas, stimulating points for discussion to create a vision of what a city in the near future might be like". www.studioazzurro.com

5. A case history_the area of Porta Nolana in Naples.

Representation and pluralist thought

Exploring the depths of urban reality and examining the variety of worlds and stories within it means, to use the words of de Certeau, "thinking of the pluralist nature of reality and making this pluralist thought effective"[12]. This is the spirit that lay behind the analysis of the 'urban experience' of 'Porta Nolana' and the definition of the narrative strategies and planning actions capable of capturing the spirit and profound link with the sense of place.

It is not completely obvious that an urban plot can generate a coherent narrative.

Fig. 04 _ Babelfish, image processing.

Spaces and people overlap in an alternation of uses and customs: 4.00 pm, via Sopramuro is empty, the shops are closing and while in the morning there is smell of fresh fish and the cries of fishmongers, in the evening the area is “taken over by foreigners”. There’s a person who says he is Sicilian to explain that women are not welcome where he is going; because it is time for prayers and he is going with other “Sicilians”, dressed in his thobe, felt hat and a western style men’s racket that is slightly too tight for him.

[Cf. Maria D’Uonno, *Babelfish*, degree dissertation, degree course in Fashion Design, SUN 2011/2012, supervisors A. Cirafici, C. C. Fiorentino]

In the case of Porta Nolana [13], which is a market area because it is a frontier zone, this has been clearly confirmed over the centuries. In a period of little more than a hundred years, the urban frontier has shifted considerably. The marshland to the east – flourishing areas dotted with mills – has witnessed the invasion of the industrial structures of modernity which were unrealistic and have already been dismantled in a squalid landscape. The eastern port has been handed over to Chinese containers. The new social fabric outside the gate is an area of commerce, much of which is of an unmentionable nature. However, the fish market is almost identical to how it was in the past and the activities of the people who crowd the area of Porta Nolana are, now as then, marked by precariousness. There is a sense of precariousness where everything is at the very limit. This is the state of frontiers, a feature of places where the distinction between power and freedom is blurred. There is a precarious balance between law and regulation, of something within bounds that goes beyond bounds. It is both a threshold and customs barrier. This function has been obsolete for a long time and yet it has left an imprint that still remains to this day. This genius loci is perceptible each time one passes through the gate because although one is aware that one is neither leaving nor entering, the imposing stones still reflect a sense of adventure and leave-taking. A gate is a gap in an enclosure, a break in a journey, routes that branch out, warehouses and display counters. The names speak for themselves: Via Sopramuro (‘above the wall’, linked to the larger defensive walls built by the Anjevins) and via Carriera (a street where carriages can pass); via Gabella della Farina (Tax on flour); vico Forno (Oven) e vico Molino (mill) e, poi vico Vetreria Vecchia (old glassworks), vico Ferze (cloth) e via Croce al Lavinaio. If there is one apparently significant alteration to the scene, then it regards the way spaces originally designed as a single urban structure, a busy place for ‘staying within the walls’, have been transformed into a series of places that are rapidly crossed in the chaotic and feverish flow of people.

The large historic market of Naples was located nearby. Piazza Mercato, a large square with the church of Madonna del Carmine, the famous bell tower on the side and the scaffold for executions or hangings in the centre, braziers to keep warm in winter and large tents or marquees to provide shade in summer. The Mediterranean city preserves many such sites: waterfronts and ancient gateways to the east. These cities have always been home to many different languages. Places for meeting, places with no clear membership

of a state, foyers for foreign travellers, free-trade areas, places for prostitution and places of excess for various social orders. They are uncertain and contradictory places, full of new anthropological features, linguistic crossovers with surprising accents. In these places, where there is considerably more than just colourful tradition, all references to identity should be tentative because they are places where the rapid acceleration of historical events has brought about change. They are places for experiencing the dynamics of mutual tolerance, getting an initial idea of others, of welcome and betrayal. With the persistence of the same activities and customs, the inhabitants and activities of the market represent a unique cultural heritage. However, this cultural heritage should not be sought in a single identity. This would only be possible if there were a coherent community which is certainly not the case today.

This is not all. The fish market at Porta Nolana in Naples is a place where fish is sold and where a market is held, not just during the period around Christmas Eve, something which is quite clear to every foreign passer-by or resident.

It is a market that has always thrived and functioned without the area where objects and people are situated being legally recognised by the appointed authorities as a market. This institutional vacuum has led to the use of a degree of discretion, as well as the possibility of blackmail, neglect and abandonment. The people who live here, or merely work here, are not protected by the legal authorities and are not free outside it [14].

The truth comes out is that today the area of Porta Nolana is a piece of heritage that simply deserves to exist in civic freedom and to be run independently [15].

The aim is to recount this multi-faceted situation and recognise the site's vocation. It is a situation that is chaotic and stationary, surreal and iconic, stratified and anarchic, conspiratorial and circumstantial, multi-ethnic and a linguistic melting pot, supportive and marginalising ... this existential space has been the subject of narratives in a context where individual 'stories' have taken on a special significance and the biographical approach [16] has become a consolidated method. The aim is not just to explore a context made up of fluid identities and emerging forms of citizenship, but also to ensure that life stories represent a form of dynamic and interactive knowledge where it is possible to trigger processes of sensemaking that can reveal unprecedented imaginary worlds and the potential for change. These micro-narratives are full of meaning and tell the story of people and their relations with the city's space.

Fig.5.0_ To lead Nolana Images processing.

The images represent the activities in the area of Porta Nolana over a 24 hour period and describe the alternation and overlapping between commercial activities, leisure activities and meetings, together with the "incursions" of tourists. The representation is part of the analysis conducted to design a blog about the inhabitants of Porta Nolana aimed at re-establishing coexistence between people.

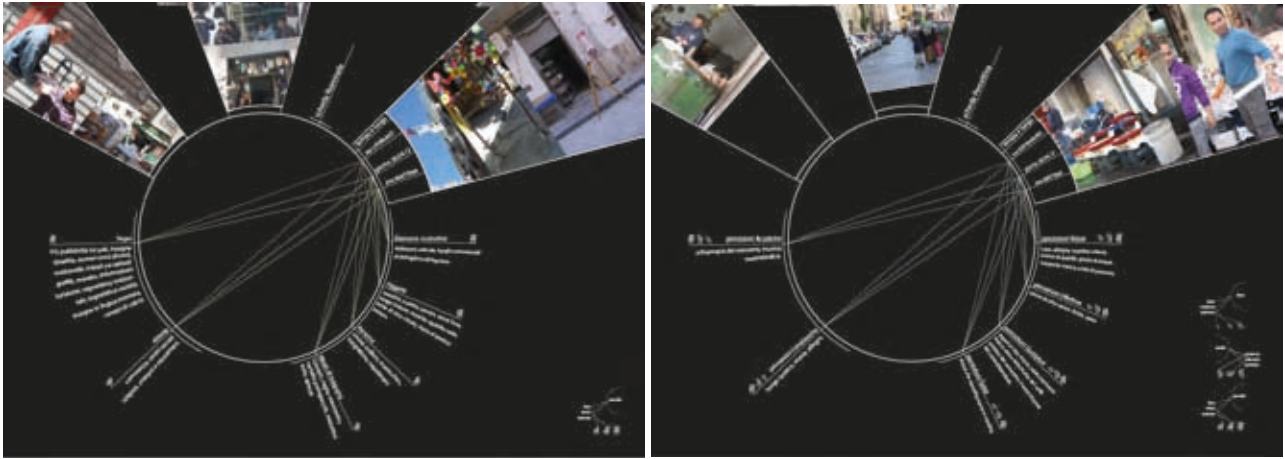

Fig. 6.0_ Babelfish, Maps of nominal and perceptual analysis

The map recounts the sensations experienced during surveys in the area of the Porta Nolana fish market. Before creating the map, files were prepared in which some of the data from the 'sensitive survey' [Cf. Marichela Sepe, *Il rilievo sensibile*, Franco Angeli Urbanistica, Milan 2007] contributed to defining the map of sensations. The map indicates the areas and itineraries of the market, together with objects that are present there and the sensations linked to their functional and 'expressive' use.

[Cf. Maria D'Uonno, *Babelfish*, degree dissertation, degree course in Fashion Design, SUN 2011/2012, supervisors A. Cirafici, C. C. Fiorentino]

Fig. 07_ Babelfish, the map of objects.

The map describes objects in the area of the Porta Nolana fish market as relational devices. The cataloguing of 58 everyday objects was carried out using individual files. Their functional and relational uses were then linked to the places of Porta Nolana in this map, from which it emerges that the practical uses and uses related to urban practices overlap and are repeated in different areas of the market. Indeed, besides its strictly functional use, the same object may be used to mark out a boundary, as a means of defence, or to indicate links.

[Cfr. Maria D'Uonno, *Babelfish* dissertation, Fashion Design degree course, SUN University 2011/2012, supervisors A. Cirafici, C. C. Fiorentino]

The awareness of being inside observers of a field that 'contains' and 'interacts' strongly with the observer - rather than external observers - has inspired a representative approach that is organised into cognitive maps, infographics and hypermedia products. The perceptive, nominal and biographical dimension is intertwined in a 'space with different perspectives', rattling off a pluralistic account of observed reality. It requires an investigation that is careful to recognise systems of objects, sensations, signs, symbols and traces that define identity. Besides creating an effective map of reality, the accurate association between places and objects, places and sensations, places and signs, and places and stories has given the observed data the significance of an 'informative piece of evidence'[17] which is somehow geolocated, from which precious clues can be detected in the process of interpreting the meaning of a place. The recurrence of disarming strategies of decontextualisation of use objects gathered in eclectic lists has inspired endogenous devices where the hypermedia aspect of interactive communication has become the medium for the discovery and translation of the authentic urban ready-mades that make up the experience of Porta Nolana. The tendency for self-production in the systems of informative or directional signs, the habit of symbolic as well as physical appropriation of collective space as highly 'personalised' space, the gesturing that becomes a ritualised part of the daily mounting of the urban set, have all been transformed into various categories of a 'collective form of conceiving urban space'. This approach regards self-production and adaptation as the inspiring feature and underlying idea of a militant design where sense-making and framing operations activate processes of attribution of meaning and define the transition from an analytical approach to an interactive, problem-solving approach.

Fig.8.0_ Urban type. System of local road signs self-produced for the market at Porta Nolana.

The graphic system that could be used autonomously by shopkeepers to create their own signs is that of stencils created on a punched mould and with the use of non-toxic water-based paints. This easy, rapid and amusing system does not conflict with the tradition of self-produced systems of local signs which is so widespread at Porta Nolana. (Cf. Ludovica Saccenti, dissertation, Fashion Design degree course, SUN University 2011/2012, supervisors A. Cirafici, C. C. Fiorentino]

The use of surprising and eye-catching strategies for de-contextualising everyday objects in eclectic lists has inspired endogenous devices where the hypermedial dimension of interactive communication has become a means for discovering and translating the urban 'ready-mades' that are an integral part of the experience of

Porta Nolana. (For the project strategies, see the same volume C.C. Fiorentino, A. Cirafici *Authenti-city. Un progetto di design militante*).

Fig. 09_ Babelfish, drawing of one of the possible configurations of the endogenous device.

Babelfish is a sort of “useless machine”, an accumulation of obsolete electronic “devices”, such as cathode ray televisions, old generation computers and inkjet printers. The project aims to orient the user towards the discovery and translation of the code linked to the functional and communication uses of the objects in a place. The information can be consulted, printed, downloaded or uploaded. Anyone can contribute to extending the know-how of installation through audio, video or text files that are added via bluetooth or USB ports. Babelfish is a device that consists of a computerised system comprising the following elements: video cards; electric generators, the Arduino open-source framework; a series of USB links; processors and a series of peripheral devices: monitors, or video output; loudspeakers or audio output; video cameras; Hello Little Printers (2012). These elements were supplemented by the software and the supports that consisted of materials and objects available in situ such as the following: fruit or vegetable crates, wine barrels, wooden planks, rubbish bags, tyres, chairs and old furniture, cardboard boxes; ...

[Cfr. Maria D’Uonno, Babelfish dissertation, Fashion Design degree course, SUN University 2011/2012, supervisors A. Cirafici, C. C. Fiorentino]

What emerges is the awareness that the rhetoric of representation is a crucial issue for strategies of urban projects. Once an exclusively deterministic perspective has been superseded, the experimental production of dialogue-based representation, designed to encourage interaction and dialogue between the producer and the target user, opens up new opportunities for the relationship between analysis and the project. The rhetoric of representation becomes a language in which complex languages, forests of signs and communicative metaphors refer to each other reciprocally. Through the use of techniques of editing, mixing, superimposition, spatial combination, temporality and the contamination of expressive languages, the new types of media accurately represent the multiplicity and connectivity of the contemporary city in multiple expressive narratives which can filter reality in a creative way.

The result is the transfiguration of the world into a narrative of ‘visual metaphors’ and communicative, relational ‘devices’ that encourage the development of social bonds through the exchange of knowledge. These forms of ‘semiotic engineering’, to use Pi  re Levy’s definition, make it possible to explore reality in ways that are not just discursive but also sensitive, using approaches and associations that are full of meaning where the aesthetic quality of the artifacts takes on an unexpected significance.

In order to create communicative spaces and encourage action, description is not sufficient. It is necessary to convey energy and give vibrancy to feelings. Emotions need to be stirred which explains why aesthetic pleasure is not an accessory but a crucial underlying element in any communicative process. This is the final thought I would like to leave you with. It is vital that we all rediscover the importance of aesthetic and poetic sensations in communicative processes as well as in those involved in the project.

After all, the sense of ‘wonder’ lies at the origin of knowledge!

- [13] The area of 'Porta Nolana' is a fragment of the urban fabric of the historic centre of Naples, situated near to the infrastructural junction of the central railway station and the old piazza del Carmine. The area is clearly bounded to the east by the presence of the gate, the traditional access point to the city, and the remaining part of the Aragonese defensive wall system of which the gate was a part, and is closed off to the west by the irregular layout of the road network of Lavinaio – which can be clearly distinguished from the right-angled layout of the late fifteenth century urban fabric. The Lavinaio was an old water course that flowed close to the old Angevin walls and collected the rainwater from the hills of Capodimonte, taking it to the nearby sea. Over time the area has maintained its ancient nature as a 'market area', in particular a fish market. However, it is now crossed by flows of migrants and is marked by distinct alterations in the relational systems between different social and cultural contexts. New interpretations of the sense of places move restlessly in an urban context which, each day, invents and stages strategies and devices for individual and collective survival. This area represented the opportunity to examine the above-mentioned cultural assumptions and pre-conditions and rethink the forms of a 'view' of the city that can interpret its vocation and encourage collective actions.
- [14] This calls to mind the film *A day without a Mexican* [13] in which the xenophobic desire on the part of many US inhabitants to free themselves of Hispanic immigrants – both illegal and legal – is transformed into the complete paralysis of the state of California. The region is forced to declare a state of emergency due to the lack of drivers, plumbers, home helps, painters and decorators, gardeners, babysitters, singers and musicians, husbands and wives, farmers, nursery and primary school teachers, supermarket assistants, journalists, weather forecasters, communications technicians, rubbish collectors, fast-food sellers, cooks, parking attendants, waiters, researchers, tattooists, athletes and actors: in a nutshell, a third of the population of California.
- What would happen if the law was enforced and the market of Porta Nolana disappeared? It is very likely that no one would die due to the bite of a rattlesnake, as happens in Sergio Arau's film, but it would nevertheless be interesting to see the consequences of conforming to the law, a law which has not come to terms with reality.

Abstract

The paper describes the state of progress of the work presented at X Forum. It aims to identify the general indications for the militant design project which will be carried out in the market area of Porta Nolana in Naples. The theoretical basis of the project owes much to the ideas of Denis de Rougemont and the work of other personalists. It is also influenced by a series of case studies that refer to the practices of so-called spontaneous urban planning and, above all, to self-design as defined and practised by Enzo Mari in the 1970s. The design proposal is known as AuthentiCity, in which the notion of authenticity refers to its original etymological roots, namely being in control of oneself and thus responsible for one's own actions. In this context, the Greek etymology is interesting because the word 'authenticity' derives from αὐθεντης, i.e. author, the person who acts by him or herself and has authority over him/herself. Further references in the text underline the importance of multiple stories linked to the search for the spirit of places, such as the importance of objects - defined as relational devices - and as a contrast to official history which requires the carelessness of the interlocutor at least as much as the global market requires ignorance. The proposal related to the market area of Porta Nolana therefore involves a series of actions regarding both socio-economic management and the production of endogenous objects, through participatory workshops where knowledge-sharing is free.

Keywords: militant design, social interaction design, self-made design

1. The importance of multiple stories

While explaining how she found a way of expressing a voice that was culturally appropriate to her own personal needs and to the narration of stories that were truly expressive of her cultural background, Chimamanda Ngozi Adichie warns us of the risk of a *single story* [1]. She highlights the damage caused by adopting a single viewpoint, whether institutionally rooted and/or widely shared, especially when linked to the practice and contents of storytelling.

Her suggestions, if applied to the narration of the spirit of places [2], help to define the relationship between the analysis, reading and interpretation of urban contexts and systems of reference. They help to outline the steps of a method of investigating urban contexts with a view to practical intervention, where the bias of multiple stories taken together and the simultaneous rejection of a single story imply a type of analysis that does not lead to standardisation. Urban areas will therefore not have their boundaries marked, circumscribed and closed in fixed, stable perimeters.

Chimamanda Adichie began to write and illustrate stories at the age of seven. Born and raised in Nigeria until the age of 19, she lived within a university campus and her education, as a precocious reader, brought her into contact with the dominant culture of the Nigerian middle classes, so that she has an Anglo-Saxon cultural background. The main characters of her early stories had pale skin and blue eyes; they used to eat apples and play in the snow and talked about a day of sunshine as though it were something to be treasured. However, most people ate mangoes in the environment where she grew up as a girl. There was no need for remarks about the weather and no one knew how to describe the flavour of ginger beer. Chimamanda's stories are very revealing about the way reality is interpreted and how narratives and representations are, inevitably, always intentional. They show how the bias of each narrative is its distinctive feature as well as its own limitation. Above all, the words of the young author indicate how this limit is likely to lead to misunderstandings, especially when the interlocutor is

not particularly wary. Indeed, the writer describes a meeting with a poor family of a young man who used to help her parents with household chores: Chimamanda had only heard stories about the difficulties of these people linked to the lack of money and opportunities. When she had the chance to meet this family, who lived in a rural zone of Nigeria, she saw the handcrafted objects that they made and discovered that stories had conditioned her views. The stories had not enabled her to imagine these people as producers of anything because their poverty was the only story that she knew about them. Likewise, her first room-mate in college in the United States initially took pity on her before getting to know her since she only knew one (hi)story of the African continent and Africans. Her room-mate was astonished when she discovered that what was generally discovered as authentic - in other words, intimately linked to a place - was the result of operations designed to simplify complexity when not intentionally widespread for manipulative purposes influenced by interests.

Hence the sense of embarrassment and surprise about the extent to which the bias of stories creates prejudices and reduces the capacity for understanding. It also led to the awareness that stories and representations are a crucial vehicle that can compensate for the impossibility of gaining the varied personal experience that is necessary for knowledge. These reflections become even more pertinent when reading and interpreting either an urban or local context which, by their very nature, consist of complex data and are in a constant state of transformation. Due to its intrinsic nature, the *spirit of places* is generated by previous readings and interpretations; it is intimately linked to the lives of people from the past and the present who acted or continue to act in these places and who have modified both the real and perceived image of these places. If the aim is to interpret the spirit of places, the distance between official history and multiple (hi)stories becomes even more striking. Therefore, for urban narratives, especially if they serve as the basis for shared transformation projects, the personal responsibility of the author is inescapable. The author highlights several aspects of reality, or rather his or her interpretation of reality, in having to add incredibly explicit methodological notes, even in the description of how limited, as well as complex, the process has been. Although the “stones” and their official history already represent precious and eloquent materials for narrating/interpreting an urban environment, another potentially rich and untapped resource consists of the lives and works of those who, prior to a new story, have remained the “silent” protagonists.

The perspective from which Chimamanda writes can also be linked to another author, Neil MacGregor and his text *History of the World in 100 objects* [3]. These stories are based on objects of different provenance and date, ranging from two million years ago to our own era. The book stems from the author's work with Mark Damazer, the director of Radio4, and is the result of a series of radio programmes broadcast in 2010.

MacGregor's book begins from the assumption that the museum's role is to *recount history* through the objects on display and that a historical account inevitably involves interpretation and translation.

Both MacGregor and Damazer are aware of the fact that history consists of stories and that, far too often, official history does not consider all aspects, since it is the history of the rich and the powerful, written by the victors, because the history of monuments is the version put forward by those in power.

MacGregor's book has the merit of telling stories through objects. These stories help to shed light on controversial and hidden aspects of official history. It is also a work with many authors. During the radio programmes, experts with different backgrounds and skills were asked to comment on the objects. Another point is that the 100 objects were only visible in the British Museum prior to the publication of the book. However, the authors ensure that although it was not possible to show the objects on the radio, the narrative skills and the imagination of radio listeners contributed to the success of the programme. The authors emphasise this point, attaching great importance to the aspects linked to the imagination and oral narratives, because a story linked to objects - an unwritten story - is intimately linked to the narrative capacity of the broadcaster and also because writing (let alone printing) is a recent accomplishment of humanity; by contrast, many of the objects featured in the book are extremely ancient and come from worlds where oral storytelling was crucial, even for the objects' own existence. In order to explain the difference between written history and “speaking objects”, it is worth mentioning one of the objects in the book: an aboriginal wooden shield from Australia whose “discovery” dates to 1770. The main character in the story is the wooden shield while the “co-stars” are Captain James Cook – British explorer, cartographer and navigator – and the aborigines of southern Australia (which corresponds roughly to modern-day Sydney). Captain Cook arrived on the Australian coast on April 29 1770. On landing, he was greeted by a group of native people. Rather startled, he fired a shot to intimidate them while the aborigines threw stones to dissuade them from coming ashore. The aborigines fled, leaving the wooden shield on the ground.

This is a brief summary of the entry in the Captain's log and therefore part of official history. However, these facts are just the beginning of something much more complicated: on his return to Britain, Cook suggested using Australia as a Penal Colony, and this marked the start of a long process of transformation of Australia which damaged aboriginal culture and led to the destruction of many communities. Some regard Cook as the founding father while others consider him a usurper.

Only in the 1960s and 1970s did Australian aborigines, the survivors of the events that took place in the areas they had originally lived in, begin to fight for their rights and force a debate to be opened about aboriginal culture. Today this shield provides precise information about this story: the object is made of red mangrove wood, about a metre high and about thirty centimetres across at the widest point; it has an elliptical shape and a handle, also made of mangrove but of a more flexible species which comes from another region. This object has been crafted by skillful hands and has distinctive marks (the shape and residual traces of colour) which identify its provenance and the people to whom it belonged. It demonstrates that the people who made it were travellers who were ready to exchange objects since the wood comes 300 kilometres from the bay that Captain Cook named Botany Bay, in honour of Joseph Banks, the botanist who took part in the expedition.

The shield bears witness to the encounter/clash between two civilisations where nothing particularly civilised took place and which had enormous consequences; 'listening' to what the shield has to tell us gives us a better understanding of the culture of Australian aborigines who were initially crushed by gunpowder, which they had never seen nor even heard explode, and then by British colonialisation.

With other 99 stories, MacGregor's book is an invitation to look at the "biography" of objects and re-establish the relational role so that new light is shed on the events of official history. Moreover, if objects are considered as relational devices, the interpretation of objects – placing them within their socio-cultural context and their historicisation - helps to reassess issues which have been taken for granted, to dispel misunderstandings and preconceived ideas, or at least cast doubt on the notion of a single (hi)story.

The very nature of the relational device involves the capacity to shift attention from traditional viewpoints and, in this sense, it is also worth consulting the work of Daniele Pario Perra [4] and Vladimir Archipov [5], in which self-produced objects tell the story of cultures which are seemingly or actually marginalised.

The need for a single (hi)story is always linked to wielding power and the repetition of a single, simple concept is one of the practices exercised by power structures as a means of persuasion and seduction. The similarity with advertising practices is both immediate and disquieting and this sense of unease grows when looking at studies of local or urban marketing. Indeed, advertising and brand design strategies tend to reduce complexity in favour of clichés, emphasising uniqueness and tradition which, even when avoiding folklore, is of little help in defining the spirit of a place or identifying its vocation. The issue of the authenticity of urban places is a thorny question because it involves investigating the relations between borders and contexts. In other words, circumscribing research is essential for the analysis of urban contexts, although reading and interpretative practice makes it necessary to move beyond physical and temporal boundaries. The search for the spirit of places is therefore an operation which, when identifying an object of investigation, offers as many links as possible, depending on the nature of the object and the expertise of the researcher. This implies the need for systems of reference which are appropriate to the reading of spaces, such as the interpretative possibilities aimed at transformational actions and the desired participation in a dialogue between local analysis and the readings that connect single works and/or urban contexts to wider places or cultural environments until they are put forward in the interpretative phase as design proposals. Two points emerge from this: one is rather futile but suitably discriminating since it is linked solely to the capacities and skills of the operator while the other may be of wider interest since it is closer to more general methodological questions. The ambiguity of the objectives linked to the definition of a cluster poses risks when searching for the spirit of places. The customary use of association by proceeding according to systems of similarities is not particularly fruitful unless the similarity of certain urban spaces is not part of their original vocation as places; in other words, the definition of homogeneous areas and clusters is part of a method that restricts a priori the chances of a real understanding and rational transformation of urban spaces. The same is true of people: circumscribing people into homogeneous groups is a practice that belongs to cultural segregation whereas one of the possible solutions is to focus on multiple stories and possible affinities which make a system recognisable, provided the system is treated as the expression of different answers, both in terms of form and function, to a single question. This idea goes back to solutions proposed by Jamie Lerner and Marco Casagrande [6], and those who follow tactical urbanism or so-called spontaneous intervention [7], as examples of opposition to the construction of standardised clusters and single dominant histories.

Fig. 01 _ Examples of spontaneous Intervention.

Design actions for the common good, at the U.S. Pavilion, 13th International Venice Architecture Biennale, 2012.

2. The area of Porta Nolana in Naples

It is not completely obvious that an urban fabric can create a coherent account.

In the case of Porta Nolana, a market area since it is a frontier zone, this has been clearly confirmed over the centuries. In just over a hundred years, the urban frontier has shifted. The marshland to the east – fertile areas dotted with mills – has witnessed the invasion of the industrial structures of modernity although they have proved to be unrealistic and have been largely dismantled, leaving relics and squalid skylines. The port to the east has been taken over by Chinese containers and the new society outside the city gates consists of traffic of a frequently unmentionable nature. Nevertheless, the fish market is almost identical to how it used to be and the actions and activities of people who frequent the Porta Nolana area are still marked by precariousness.

This precariousness has ancient origins. Everything here takes place on the edge. One aspect of this condition as a border area is part of the history of the area, the walled edge of the eastern area facing the sea. On this subject, it is worth looking at the studies regarding the analysis and interpretation of the context of Piazza Mercato and Porta Nolana [8], which only mention the fact that an understanding of the area is linked to the coastal system. However, while neglecting the hermeneutic process carried out in the study of *La Piazza d'Acqua*, it may be interesting to recall the account written by Bartolomeo Capasso [9] about the life of Masaniello, the true protagonist of piazza del Mercato who lived “in the first houses after vico Rotto”, in other words the northern corner of the eastern sector. It is here that he is described by Capasso in the scene portrayed by Gargiulo [10], as he harangued his followers from a wooden platform placed there by a company of acrobats and tumblers who often appeared alongside the fisherman from Amalfi and leader of the tragic revolt (6-16 July 1647). Ultimately it was Capasso who conveyed the true image of the square as an area of craft activities and humble dwellings of the common people: an image that is rooted in houses and shops with public use located in the residual space for the punitive displays of power to which the rebels themselves were forced to conform. On the night between 7 and 8 July, in the most depressed areas of the city - Mercato, Lavinaio, Conceria and San Giovanni - the “pueblo inferior”, divided into corporations and the poorest inhabitants of the area, revolted against the excises under the leadership of Masaniello. The women from Lavinaio also protested and attacked the bell tower of San Lorenzo and set fire to the house of the governor of the pawnbroker's, although the main scene of the revolt remained piazza Mercato, the “reggia dei popolari” (palace of the common people), where Masaniello played the leading role and also met his end. Even in the days of his so-called madness – actually a lucid moment of self-awareness - Masaniello stirred the piazza as the symbolic place of the revolt: “The signs and ‘plans’ of madness are countless: the knife hurled into the crowd, the great rides on horseback, the nocturnal swims in the sea; and, as if this were not enough, the fisherman wanted to create the port within the market and a bridge stretching from Naples to Spain” [11]. Masaniello's vision of the *square as a bridge* is precisely one of the possible interpretations of the spirit of the place which, as a frontier site, possesses the features of those indistinct spaces between power and liberty, between rights and regulations, a place where one constantly oversteps the boundary between inside and outside, where the walls and its passageways are threshold places and customs gates where something of value is cleared through customs: this function has been obsolete for a long time and yet its imprint still remains today. This *genus loci* can be perceived each time one passes through the arch because, even though one is aware that one is not leaving the modern city, the imposing masonry, like its remains, still testify to a sense of adventure and leave-taking, a passage towards a space that is not controllable. Although its function as a transitional place and gateway no longer exists, one is aware that the transit in the two directions does not have the same significance: the exterior does not offer a way in or a means of interpreting the places that exists in the area within the walls. A gate represents a break in an enclosure, an interruption in an itinerary, routes that branch off, warehouses and display counters. Within the walls, the names are evocative: Via Soprammuro (‘above the wall’, linked to the larger defensive walls built by the Angevins) and via Carriera (a street where carriages can pass), as well as via Nolana along the same axis; via Gabella della Farina (Tax on flour); vico Forno (Oven) and

vico Molino (mill) and via Croce al Lavinaio. The large historic market of Naples, the setting for Masaniello's actions, was located nearby. Piazza Mercato, a large square with the church of Madonna del Carmine, the famous bell tower on the side and the scaffold for executions or hangings in the centre, braziers to keep warm in winter and large tents or marquees to provide shade in summer; Piazza Nolana, outside the city gates, with the church of SS. Cosmo e Damiano, provides access to Borgo di Loreto, which was already not urban although it was part of Naples. The spaces convey the identity of the Mediterranean city which preserves many such sites, waterfronts, bridgeheads, seafronts of various sizes and ancient eastern gates; in these cities the spirit of places speaks many languages, in places for meeting and with no clear membership of a state, halls for foreign travellers, free trade areas, places for prostitution, the worst examples of capitalism, arenas for shows, extreme places for different social groups. These are uncertain, contradictory places, full of new anthropological features and linguistic crossovers with surprising accents, where there is considerably more than just colourful tradition. Considerable care is required when talking about identity because these are places which have witnessed the acceleration of historical events, the promise of change, and the risk of a search together with random attempts. They are places with dynamics of mutual tolerance, getting an initial idea of others, of welcome and betrayal.

With the persistence of customs and traditions, the people and activities of the market represent a culture although it would be pointless to seek a single identity because this would be the result of a coherent identity which is not currently the case.

It is important to avoid confusion between coherence and homogeneity.

The market at Porta Nolana is renowned in other districts. Trips are arranged to go and buy fish or to eat it in informal eateries nearby. Its function is not dissimilar to the role still played by the Vucciria market in Palermo, even though Porta Nolana is situated between walls, masonry and structures that have played a part in the history of Naples, together with others which, in the same area, have devastated and damaged the city in the name of urban planning over the last 150 years. The authentic parts are hidden by the superficial lovers of folklore and, in particular, have been broken up and threatened by urban planning schemes. This town planning policy led to the construction of the eyesore that is the Circumvesuviana light railway station [12], designed without due reflection. Similarly brutal mutilations had previously been carried out as a result of the *Risanamento* (Redevelopment) scheme, an example of class speculation and plunder perpetrated by the influential middle classes at the time of Umberto I.

The fish market at Porta Nolana is renowned in Naples as a place for buying fish, not just in the evenings prior to Christmas Eve. This is clear to every foreign passer-by or resident.

It is a market that has always thrived and functioned despite the fact that the area where objects and people are situated has not been legally recognised as a market by the authorities.

This institutional vacuum has led to the use of a degree of discretion, as well as the possibility of blackmail, neglect and abandonment. The people who live here, or merely work here, are not protected by the legal authorities and are not free outside it. This calls to mind the film *A day without a Mexican* [13] in which the xenophobic desire on the part of many US inhabitants to free themselves of Hispanic immigrants – both illegal and legal – is transformed into the complete paralysis of the state of California. The region is forced to declare a state of emergency due to the lack of drivers, plumbers, home helps, painters and decorators, gardeners, babysitters, singers and musicians, husbands and wives, farmers, nursery and primary school teachers, supermarket assistants, journalists, weather forecasters, communications technicians, rubbish collectors, fast-food sellers, cooks, parking attendants, waiters, researchers, tattooists, athletes and actors: in a nutshell, a third of the population of California.

What would happen if the law was enforced and the market of Porta Nolana disappeared? It is very likely that no one would die due to the bite of a rattlesnake, as happens in Sergio Arau's film, but it would nevertheless be interesting to see the consequences of conforming to the law, a law which has not come to terms with reality.

3. Partaking and taking apart

"The only real questions are those posed by existence, certainly not those that we posed to avoid responding to the present", Denis de Rougemont, *Journal d'un intellectuel en chômage*, Albin Michel, Paris 1937. Italian translation.: *Diario di un intellettuale disoccupato*, Fazi Editore, Roma 1997, p. 114.

Is it acceptable that a monumental part of the historic centre of Naples, which has already been violated on several occasions by official history, is left to the mercy of town planning policies which are extraneous and derive from elsewhere? Is it fair that, rather than compensating for the damage done over more than a century and providing opportunities for civil coexistence in an environment guaranteed by hygiene and social effectiveness, an attempt is made to present a facade that contains nothing authentic except for a misrepresentation of its own origins in favour of a marketing exercise?

Today Porta Nolana is a piece of heritage that simply deserves to exist in civic freedom and to be run independently. There is a middle way between taking part and taking apart which presents a precious opportunity to conduct an intervention in the Porta Nolana area.

It would be advisable to take part in the spirit of the place and discard a false notion of identity.

Porta Nolana is partly Neapolitan and partly not (*Partenopea e parte no*), a place where individual stories should be listened to, told and shared in an atmosphere of lively coexistence among people who come from different places and cultural backgrounds. Rather than referring to intercultural exchange, it is far more important here to focus on people and the consequence of this ethical approach leads to collective action and the possibility of *thinking with one's hands* [14].

The text by Denis de Rougemont was written in 1936. It stems from a precise question: what is culture?

While attributing decay to a separation between *hand* and *intellect*, the author expresses his personalist stance. In the process he defines the elements for a culture that is antithetical to the dominant belief whereby the common good does not come before the specific good because the "purpose of society is the person" [15]. Together with the work of Jaques Maritain, Alexandre Marc and Emmanuel Mounier [16], these ideas underlie personalist culture which reveals the contrast between the individual and the person and between society and community. Within this ethical and theoretical framework, *thinking with your hands* is described in its best version and in its worst which consists in *frenzied action that merely brushes the surface of things*: "If only thinkers had large hard hands! Hands made for carrying and weighing, Hands that possess know-how, that achieve and sculpt: hands that can create" because "frenzied hands scarcely leave a mark on the surface, where you can recognise the thief, the person who goes around touching everything and touching other people's property. Because someone who touches an object without leaving a profound imprint and without making it his or her own can only touch the property of others. What he has not taken can never be his: it is outside the power of being able to take possession of it. Scholar and those who use quotes take advantage of great achievements on which they are unable to leave a trace but merely leave them tarnished with their imprint" [17].

With regard to the people who live, work and hang around in the market area of Porta Nolana, the desire to talk about people who have their own origins and history but more importantly a name and personal identity is neither an intellectual whim nor an attempt at political correctness but a chance to avoid stereotyping. It is an alternative to referring to people who inhabit the Porta Nolana area as Neapolitans, Chinese or Arabs, which immediately conjures up a jokey atmosphere. The French-Turkish writer Elif Shafak describes the term multicultural, with the benefit of personal insight, as a political fiction [18]. Indeed, the point is not to conceal the identity of a person's background but to understand that multiculturalism did not originate from the combination of individuals from different societies but from the coexistence of people which takes place here and now, in a specific place and time. Their needs and satisfactions depend much more on current circumstances rather than those linked to their native countries. An understanding of multiculturalism passes through an idea of identity as an entity that is not formed once and for all but is in a constant state of change. The seductive appeal of a stereotype is extremely powerful, primarily because stereotypes contain elements of truth. They simplify both the questions and answers related to transformation. However, it should not be forgotten that behind the power of a cliché, which leads to the definition of an identity, lies a distorted concept of the term 'identity' which is regarded as immobile and clearly defined rather than as it really is, namely elusive and changeable. The real problem of stereotypes is that they are incomplete and ensure that stories are obscured and flattened by a single story and that people are demeaned. "The consequence of the single story is this: it robs people of their dignity", explains Chimamanda Ngozi Adichie.

De Rougemont points out an uncomfortable truth which challenges systems of power and is difficult to follow even for those with an ethical sense: "thinking with your hands is thinking about the potential for action, it means thinking during the action where the spirit is actually involved, like someone who is ordered to judge, choose and transform the conditions he is provided with, and who refuses. Thinking with your hands means conceiving of ideas in actions, and this goes against the rationalist notion of a thought that is no more than a tardy comment on the actions of others. Lastly, thinking with your hands is not the exact equivalent of acting through one's own thoughts. This is because it is not the action that is of prime interest – with thought merely considered as its assistant – but quite the opposite; if I want to think through actions, then the thought only seems right and perfect in the moment when the action testifies to it and endows it with seriousness. There is no real action without thought and the formula implies the primacy of thought in every action, as well as the necessity of this action for thought" [19].

These ideas constitute the premise for the proposal for the market area of Porta Nolana. The proposal considers elusiveness and changeability as precious concepts that underlie any possibility for innovative transformation. They should be preserved and supported as interpretative categories for the definition of design proposals. In this sense, the importance of single stories, the awareness of objects as relational devices, the deceptive nature of the much-praised concept of multiculturalism all help to formulate an ethical and operational approach whose foundations are to be found in the ideas of Denis de Rougemont and which finds the space and perspectives for operating within personalism and the needs of the community.

4. Authenti-city. A project of militant design.

Something is clearly missing: for the inhabitants, for those who chose the Porta Nolana market area as a place for work or for passing through, and for the users of the market; for all these people, the place lacks something. Elusiveness and changeability are assured, both in terms of the code that accompanies the use of objects, the activities linked to the market and what remains, or can still be perceived, of the past.

The design proposals involve creating a reconnection, on a larger scale, between this area and the coastal system. They seek to look beyond the eastern area of the city, considering the possibility of reconstructing a map of memory where pride of place is occupied by the traces of the walls, the different types of fabric together with individual architectural structures, in the light of an idea represented by Piazza D'Acqua. The proposals are therefore aimed at providing various solutions which the single stories of the frontier spaces of Naples offer to those who know how to interpret them. Besides this, there is also the possibility of more precise forms of intervention which, in theory, could be carried out more rapidly. This type of intervention takes account of the needs of smaller spaces and, despite involving a reduction of the physical area of intervention, displays equal awareness of the complexity of the urban fabric and the relations that exist with the coastal system.

Once the scale is reduced, the design proposal for the market area of Porta Nolana is based on two elements, one of which is related to management while the other is more immediately linked to design practices. In terms of the first point, the general idea is to give official recognition to the market at Porta Nolana and to entrust the organisational and economic management of it to the people who are directly involved in its existence: the proposal is therefore designed to give priority to the inhabitants, the shopkeepers and those who would no longer be illegally occupying public space: transport workers, suppliers and even the users of the market. They would be part of a community with responsibility for running the market area.

In terms of ideas for the practical side of the project, the solution is simpler and refers to Enzo Mari's writings and activities in the 1970s regarding *self-design* [20]. Based on the elusive and changeable aspects of the market area, a restricted area of intervention will be chosen in order to try out the contents of Enzo Mari's proposal. The objective is to assess the feasibility of setting up permanent workshops for designing and making objects with the participation of the newly established community and those who wish to, and can, share their know-how with the aim of *thinking with your hands* and therefore attributing the right significance to things. "History has much to say about the power of things. It forgets that there is no action except through the action of humans, through the use of people's hands; thought never acts upon an era but rather on people who think with their hands, or on some of them" [21].

The self-design of the elements required for the Porta Nolana market area could be the appropriate design solution to avoid the risk of standardisation whereby a successful design could be repeated in a different context. Mari's manifesto, drawn up in 1974, aimed to raise people's awareness of the possibility of creating objects by following, modifying and improving his 19 self-design projects according to new needs. It contains the explicit need for the actual construction of the work which harks back to *thinking with your hands*, and the pressing need therefore of acting in an *unflustered* way, passing from model to model. It is in this sense that the models, or rather the sequence of models, play(s) a part in a dialectic process in which "knowledge is achieved through hard work", while merely producing sketches and drawings makes you "slaves to the economic system" [22].

As well as Mari's work, there are various experiences and case studies [23], all of which have the merit of having tested out a series of new possibilities related to the participation of inhabitants in transforming urban contexts. They have all reflected on the definition of urban space and the sense of community and membership in search of shared knowledge which is opposed to the ignorance necessary for the global market [24], and the carelessness required for writing official history. These references constitute the basis for formulating an intervention proposal which undoubtedly requires more time than that used by a designer to work out a final design in a studio. Workshops could be set up involving people from different backgrounds and with different skills and could lead to designs and objects that are suitable for the needs of the place and are the product of the activity of designers and, in particular, of 'prosumers'.

Fig. 03 _ Enzo Mari making a chair in collaboration with ArteK, 2010. [25]

These are the general contents of AuthentiCity, a project that seeks to bring about change based on authenticity and thinking with one's hands. The notion of authenticity refers to its original etymological roots, namely being in control of oneself and thus responsible for one's own actions. In this context, the Greek etymology is interesting because the word 'authenticity' derives from αὐθεντης, i.e. author, the person who acts by him or herself and has authority over him/herself.

In this sense, the proposal involves a project that uses the narrative of many different stories which make the Porta Nolana market what it is. The aim is to modify the area through the criteria of self-design and militant design by forming a community.

We conclude with a brief note about a project that seeks to create an endogenous device to be created close to Porta Nolana. As a useless machine [26], made up of a group of obsolete electronic "devices" (such as cathode ray televisions, old generation computers and inkjet printers), the device translates the expressive code linked to the different uses that the same object can have in the market area of Porta Nolana. This project, named *Babelfish* [27], is one of the possible narratives that can contribute to the definition of AuthentiCity. It is aimed at orienting the user towards the construction, discovery and translation of the code linked to the functional and communication uses of the objects in a place. The information provided by Babelfish about the objects in the area is the result – albeit temporary and in a state of constant evolution – of surveys, sensorial maps [28] and interviews and can be consulted, printed out, downloaded or uploaded. Indeed, anyone can contribute to increasing the know-how of the installation by adding information in the form of audio, video or text files that are added through Bluetooth or USB ports.

[10] Cf. the famous painting by Domenico Gargiulo (Micco Spadaro) portraying *The revolt of Masaniello* (1647). The painter depicts the scene from the perspective of the church of S. Eligio to include Vesuvius in the background but also from a mid point in the square which offers close-up views of the two rows of buildings. The lack of a row of buildings on the left, which constitutes the upper edge of the square (for those looking from the side close to the sea), is a device to gain an enlarged image of space. In the front row it is worth noting the arrangement of blocks of houses lying alongside each other on the short side and therefore belonging to horizontal plots of land. To the right, continuing from the bell tower of the Church of S.Maria del Carmine, the façades of the quadrangular blocks of houses are visible. The portrayal corresponds perfectly to the architectural forms recorded in drawings dating to the mid eighteenth century. Similar views, enriched with the presence of row of buildings on the left, can be seen in two paintings by Carlo Coppola, *The surrender of Naples to Don John of Austria in 1648* and *Piazza Mercato at the time of the plague in 1656*. The limits of the square also feature the upper row of buildings with blocks of detached houses, as they were destined to remain, and the Porta del Carmine, to the left of the church, a fixed point in the design by Securo for the proportioning of the row of houses and shops.

[23] e.g.: In 2011 during a lecture entitled *Proposta per una Autoprogettazione (Proposal for Self-Design)*, Enzo Mari took part in the activities of the ATTICA project - Archaeologies for self-management, promoted by NABA within the framework of the European project *The Art of Urban Intervention. The Art of Urban Intervention* is a European research project that involved various institutions from 2009 to 2011, Naba – Nuova Accademia di Belle Arti, Milan; ICA – Sofia Institute for Contemporary Art; The Blue House, organization, Netherlands; Rotor, organization, Austria; UJEP, organization, Czech Republic, BLOK_ Local Base for Cultur Refreshment, organisation, Croatia; DelVe _ Institute for Duration, Location and Variables, Croatia. Other references are to be found in the definition of *Design Libre* by Cristophe André: Design Libre is a practice that seeks to apply the free production model to the manufacture of material objects. Its aim is to describe the transition from the role of the consumer to that of the prosumer (producer and consumer), a person who takes part in the production process of objects in order to regain possession of techniques and know-how, and it is a practice for the free sharing of knowledge. See also the Download Design project by the Droog Design team dating to 2011.

[24] Interview given at the Triennale in Milan as part of the public meeting: "Enzo Mari, il lavoro del design" with Enzo Mari, Vanni Pasca and Vincenzo Basile. The interview was conducted by "B-Students TV", a multimedia channel created by the students of Bocconi University, Milan.

[25] 35 years later, in 2010, Artek asked Enzo Mari to "produce" the design for the chair that can be seen in the photographs. Besides the bewilderment that may stem from the fact that the design only became a product after 35 years, and that the price is far in excess of the cost of the materials, it is possible to dismiss this aspect as a necessary evil caused by sadly changing times. Perhaps we can continue to believe that, despite the compromises required, the popularisation of an idea linked to the concept of self-production still remains valid today. It can offer space to streets and places where the experimental work can take place, in the name of renewed attention placed on people and the community, and recalling that Mari himself has written that the last thirty years have been a period marked by an *increase in decay*, MARI, Enzo, *25 modi per piantare un chiodo*, Milan: Mondadori, 2011.

[26] Cf. MUNARI, Bruno, *macchine inutili*, 1930-1933; Bruno Munari's 'useless machines' are portable devices with only an aesthetic function; in this sense, the quotation regarding the endogenous device is intentionally imprecise and refers to precariousness, the combination of already existing elements, which have therefore been adapted and not designed for the purpose. It also alludes to the mobility of Munari's machines which, being built of lightweight materials, could move with minimal windpower, so the name also refers to the powerful influence that the context exerts over the device and its potential for modification.

[27] *Babelfish* is the title of the project of the degree dissertation by Maria D'Uonno. Cf. D'UONNO, Maria, *Babelfish*, degree dissertation, Fashion Design degree course, SUN University 2011/2012, supervisors Alessandra Cirafici, Caterina Cristina Fiorentino.

Cf. Web: www.arduino.cc

Babelfish is a device that consists of a computerised system comprising the following elements: video boards; electric generators, the Arduino open-source framework; a series of USB links; processors and a series of peripheral devices: monitors, or video output; loudspeakers or audio output; video cameras; Hello Little Printers (2012). These elements were supplemented by the software and the supports that consist of materials and objects available in situ such as the following: fruit or vegetable crates, wine barrels, wooden planks, rubbish bins, tyres, chairs and old furniture, cardboard boxes, ... the Arduino open-source framework, for the Babelfish device, makes it possible to manoeuvre the televisions and control the touch screen displays, as well as connecting to the project software. Original designers: Massimo Banzi; David Cuartiles; Tom Igoe; Gianluca Martino; David Mellis. The project began in 2005, with the aim of providing a control device for interactive design projects which was cheap and free from the laws of market forces. Arduino consists of a hardware platform for the physical computing developed at the Interaction Design Institute in Ivrea, set up by Olivetti - Telecom. The name of the board derives from the name of a bar in Ivrea attended by the founder members of the project which, in its turn, recalled the name of King Arduin of Ivrea. The board is based on a printed circuit which combines a microcontroller with a PIN connected to the I/O ports, a voltage regulator and, when necessary, a USB interface. The Arduino hardware platform is available in a pre-assembled version and can be purchased online or at specialist stores. The hardware is supported by an Integrated Development Environment (IDE) which is multiplatform (Linux, Apple Macintosh, Windows). This software also makes it possible, even for beginners, to write programs with a language derived from C and C++ called Wiring, which can be downloaded and modified. Arduino makes it possible to create prototypes rapidly as well as enabling rapid learning of the basics of electronics and programming. It can be used to develop stand-alone interactive objects but can also interact with software programs installed on computers such as Adobe Flash Player, Processing, max/MSP, Pure Data, Super Collider etc. The unusual aspect of the project is that both the information about the hardware and the projects developed over time are available to all, since Arduino is an open-source hardware distributed under the terms of the Creative Commons Attribution- Share Alike 2.5 licence. In this way, it is possible to reconstruct a clone of Arduino or create a modified version by downloading, free of charge, the electric board and the list of necessary electronic components. This opportunity has made it possible for Arduino-compatible products to be developed by small and medium-sized firms or by individual designers worldwide. It is now possible to choose from a wide range of Arduino-compatible boards. The common feature of these products, based on experimental electronics and development, is the source code and the resident library which are available according to the legal terms of a free GPLv2 licence. Due to the shared software, an Arduino community has been established which has developed programs to connect hardware to electronic objects, computers and sensors of various kinds. After years of experimentation, it is possible to make use of a vast database.

[28] The maps recount the sensations experienced during the surveys in the area of the Porta Nolana fish market. Before creating the map, files were prepared in which some of the data from the 'sensitive survey' [Cf. Marichela Sepe, *Il rilievo sensibile*, Franco Angeli Urbanistica, Milan 2007] contributed to defining the map of sensations. The map indicates the areas and itineraries of the market, together with objects that are present there and the sensations linked to their functional and 'expressive' use. Other maps also form part of the analyses carried out to plan the project, such as one that describes the objects in the area of the Porta Nolana fish market as relational devices. The cataloguing of 58 everyday objects was first carried out using individual files. Their functional and relational uses were then linked to the places of Porta Nolana in this map, from which it emerges that the practical uses and uses related to urban practices overlap and are repeated in different areas of the market. Indeed, besides its strictly functional use, the same object may be used to mark out a boundary, as a means of defence, or to indicate links.

The video, made using Adobe After Effects and Movie Maker software, is an audiovisual prototype of the information provided by Babelfish. The various displays capture the different "ready-mades", which consist of objects in the fish market area of Porta Nolana, showing their different uses through the superimposition of images in order to describe the contents of the expressive code linked to the various communicative functions or the use of individual objects. The video therefore appears as a document of the surveys carried out and can be continuously updated by users. The software makes it possible to isolate certain frames in order to print them, or to send them via email or download them using USB ports and Bluetooth in order to store both the images and the information related to the denomination, collocation, materials and uses of individual objects.

Hyperspectral and thermal airborne surveying for the characterization and the monitoring of natural and anthropized environment

Abstract

This paper presents the results of the research work conducted by a team of researchers and teachers of the Department of Architecture and Industrial Design "L. Vanvitelli" of the Second University of Naples (SUN), and by the staff of Gruppo Esplorazione Aeromarittima (GEA-GdiF) of Guardia di Finanza, on the airborne surveying activity aimed at the characterization of natural and anthropized environment, through the visible, thermal and hyperspectral analysis.

Airborne sensors used in aerial exploration - which are part of a broader technological assets owned by the university department - are installed on military aircrafts of GEA-GdiF as part of a supporting and technological transfer to Public Administration made by University.

Those technological professional and scientific synergies, between the University and GEA-GdiF, are outlining an experimental definition of a technical-operational Protocol on multi-dimensional Territory knowledge as an essential instrument for a deeper economic-financial investigation and its relation to the socio-urban fabric to achieve fiscal equity and social justice.

The first scientific validation of these procedures took place during of the aerial exploration of the Italian and Albanian territory (2012, July) as part of the Italy-Albania Operational Protocol.

The airborne surveying activity on territories mentioned above - aimed for the discrimination of large areas intended for the illicit cultivation of cannabis - has been a dual-purpose success: it has allowed GEA-GdiF to reassert itself as an essential institutional instrument for economic and financial governative investigations that can the underlying economic fabric and its dynamics in international settings too; and it has also allowed University to write, test and verify the technical and operational protocol, object of this paper, which enables researchers to form a digital knowledge 3D atlas of the Albanian territory where deeply analyse hyperspectral and thermal data.

Keywords: Airborne Remote Sensing, Multidimensional Analysis, Hyperspectral survey, Thermal survey

1. From methodological approach to Scientific and Technical Protocol (C. Gambardella)

This paper represents the first official occasion of reading to Academia, and to Public, the multiannual team work, conducted in collaboration between the Department of Architecture and Industrial Design "Luigi Vanvitelli," and the GEA - Guardia di Finanza, on the concrete actions prevention of the degradation of the landscape, the city and Territory, tangible manifestation of a deeper social decay.

Thanks to the synergy between Knowledge and Laboratories of the University and the great institution of Guardia di Finanza - in which men of unimpeachable moral and high professional profile work every day - was further possible to realize the scientific and methodological innovation of Knowledge Factory, which is anchored on Eco-Geometry's intuition. In particular, it has been possible to realize concrete actions for the community in the re-establishment of the Heritage crossed from Knowledge, and available for the Public Administration to undertake the development and promotion of Environment, Land and City, with a appropriate interventions' hierarchy, no longer random.

Naples, Caserta's Province, Pompei, Molise, and recently Taranto, are emblematic cases where the absence of a synergy between institutions (Academy and Research, Public Administration, the

Business Community and State Institutions) produced a short circuit that has degraded not only the landscape but also created an unbearable squandering of public money. This research is based on the belief that, nowadays, any action to protect and enhance places cannot be separated by preparatory activities of multidimensional knowledge based on discretization and measurement of the heritage. The currently available knowledge tools come from modern information technology, which expands the traditional notions of geometry and measurement, enabling a multidimensional representation, in which every element, tangible and intangible, has a represented dimension. The methodological support to this cognitive action comes from Eco-geometry, intended as a technological echo of reality, a model in which it is possible to measure all the components and relationships between the tangible and intangible assets, with the territory resulting as a constantly evolving, dynamic entity.

The Eco-Geometric approach therefore makes it possible to “measure the whole”, i.e. to recognise the basic characteristics of local identity through the reading of the long-term signs that relate to the environmental systems, ecological networks, watersheds, coastal systems, historic landscapes, settlement and production types, agricultural fabrics, socio-cultural models, and so on. In other words, all the features whose loss or degradation could undermine the sustainability of development, which must be based on the assumption of these assets as resources, declined as a profit and loss account. The multidimensional representation is, at the same time a project of what has already been made and what is to be made, in the sense that it includes all the dimensions of the knowledge of an object already contained in the prediction of possible changes, proposing future scenarios. It is therefore the most effective means not only to analyse a territory, but also to plan its management by defining a hierarchy of interventions for sustainable development.

Fig. 3: The Ministers Mr. Francesco Profumo (Ministry of University and Scientific Research) and Mr. Renato Balduzzi (Ministry of Health) visit the stand of Benecon/Guardia di Finanza, during the “Forum della Pubblica Amministrazione” (Roma 2012).

This research and the Scientific and Technical Protocol proposed (still in testing phase and verification) want to be a stem cell that, just because coming from the integrated knowledge of the genetic heritage and identity of places, can modify and create development, through working with Art and restoring quality of life to citizens.

The first scientific validation of these procedures took place during of the aerial exploration of the Italian and Albanian territory (2012, July), as part of the Italy-Albania Operational Protocol.

In particular, the aerial exploration over Albanian territory - aimed at discrimination of large areas intended for illicit cultivation of cannabis - was anchored on two fundamental values: the first is human, that is, the establishment of a surveying team involving university researchers along with military Officers and NCOs; and the second is technology, an innovative platform that is composed of hyperspectral and thermal sensors (Itres CASI-1500 and TABI-320), on GEA's aircraft; and GNSS permanent stations by TOPCON, positioned on the roof of our Laboratory in Tirana.

While the working group was immediately characterized by common passions and precise objectives; the research has been directed first to the identification of appropriate technologies - the aforementioned sensors - particularly interesting, because they allow you to discretize the characteristics of natural and artificial materials on the ground, from high-altitude flight.

In this research, therefore, the discretization of the spectral signature assumes centrality, as reflectivity characteristic of each material (natural or artificial), in function of incident radiation wavelength, in comparable environmental conditions. Being able to isolate the spectral signature of a material means, in other words, to know his fingerprint, an element that clearly identify it. Being able to isolate the spectral signature of a material means, in other words, know your fingerprint and then identify it with scientific objectivity. Just as was done for Albanian and Italian plantations and for polluted materials in various Italian scenarios.

Scientific research in these topics continues inexorably towards of continuous verification of scientific protocol proposed, and the realization of desirable multitasking aircraft of GdIF-Benecon that will fit out Lidar, photogrammetric, hyperspectral, thermal and SAR sensors.

Fig. 4: Processing of the spectral signature of cannabis. (C.Gambardella 2012).

2. Geo-intelligence as new frontier for an effective economic and financial police activity (S. Bastoni, G. Casbarra, F. Tessitore)

On the 19th July 2007, in the city of Tirana was signed an agreement between the Italian Government and the Albanian Government in order to strength the cooperation between these two countries against racket and especially against international drug trafficking and illegal immigration.

On May 16th 2012, in Tirana again, was signed an Operational Protocol between The Public Security Department of the Italian Home Office and the Central Department of the National Police of Albania.

Among all the activities considered in the protocol, particular importance is attributed to the opposition to the massive production of cannabis and the racket connected with it. The production cycle of the Balkan marijuana starts with the cultivation of the plantations and ends with the marketing of this drug in Italy and in Europe through our ports and coasts.

Fig. 1: Piaggio P180, Piaggio P166/DP1, ATR 42MP.

Before starting the operation the Headquarter of Guardia di Finanza – Centre of Operation with Operation Department of Criminal Police of the Home Office-International Cooperation Police Service, examined all the aspects connected to the kind of support they could give to the Albanian authorities, considering all the risks and the best operative approach.

Previous experiences in checking the Albanian territory made by helicopters have given safety problems, some shots of Kalashnikov were fired against them from the ground. Luckily they failed their targets but these incidents created a particular attention on the “ risk factor” in flying low over the Balkan territory.

In 2012, there was a big novelty in the Operative Protocol, the use of the airplane with airborne remote sensing in order to research and identify cannabis plantations. It quickly demonstrated its efficacy on the Albanian territory : both for safety in research operations and for the innovative scientific results it gave.

When the new operative Protocol was signed, the Operative (Air and Sea) Aeronavale Headquarter of Guardia di Finanza and its planes were directly involved, in particular the airplanes of the Gruppo Esplorazione Aeromarittima, with their equipment of hyper-spectral sensors CASI 1500 and thermic sensors TABI320. All this was possible thanks to the installation on Guardia di Finanza planes of the university devices for remote sensing. The cooperation of two different and quite distant organizations gave unexpected results. Guardia di Finanza and the Centro Regionale di Competenza BENECON S.C.aR.L. established in the Second University of Naples (SUN), signed together the Operative Protocol with the Albanian, on the 21st May 2011.

The operative-scientific partnership between Guardia di Finanza and the research centre Benecom allows to create high resolution thematic geo referred cartography, very useful in the research of cannabis plantations.

Fig. 2: Four preliminary phases to the first flight of remote sensing: the electromagnetic test in an anechoic room, 3D point cloud model of the aircraft, the sensors calibration, the improvement of the installation components.

In 2012 a mixed team of members of Guardia di Finanza and scientific researchers of Benecom started working together in Albania. The operative target of this international mission was to focus on the research of the wide, hidden and often unreachable cannabis plantations whose massive production represents a big threat for the European social and economic order.

Cannabis is the most popular drug in the world : genetic studies have produced easy-fitting seeds for every latitude. They give strong plants and abundant harvest. A U.N. survey states that 1/3 of the terrestrial surface is suitable to the cannabis production: a plant grown outdoor in good conditions can guarantee to the producer about 700 or 1000 grams of drugs. So it is easy to understand the reasons why criminal organizations have started a very thick net made of thousands of small growers regularly involved with the supply of their crops.

According to the annual report of the United Nations Office on Drugs and Crime (UNODC) of 2008 the production and the consumption of cannabis , which is grown in 172 of the 198 countries and territories for which the UNODC obtained information, attracted close to 160 million customers annually. The cultivation of cannabis herb is still concentrated in North America and Africa but nowadays something is changing and the Balkan area, Albania specifically, is among the 5 biggest areas of production in the world.

The mission in Albania took place in July 2012 with the support of Interpol and Guardia di Finanza with the researchers of the CRDC Benecom. The Ambassador of Italy in Tirana, Massimo Gaiani, really appreciated this experiment of international cooperation and the synergy between the university and the public institutions. In this mission there were pilots, technicians, flight engineers and university researchers working in Tirana, in a lab made on purpose where all the data collected by the sensors, placed on the plane, were processed, decoded and evaluated.

The activity of airborne survey was addressed to those areas of the Albanian territory particularly suitable to the illicit plantations of cannabis. These areas are usually far from towns and villages and they are hubs of criminal organizations. In particular the prefectures of Shkoder, Gjirokaster and Vlore were scanned.

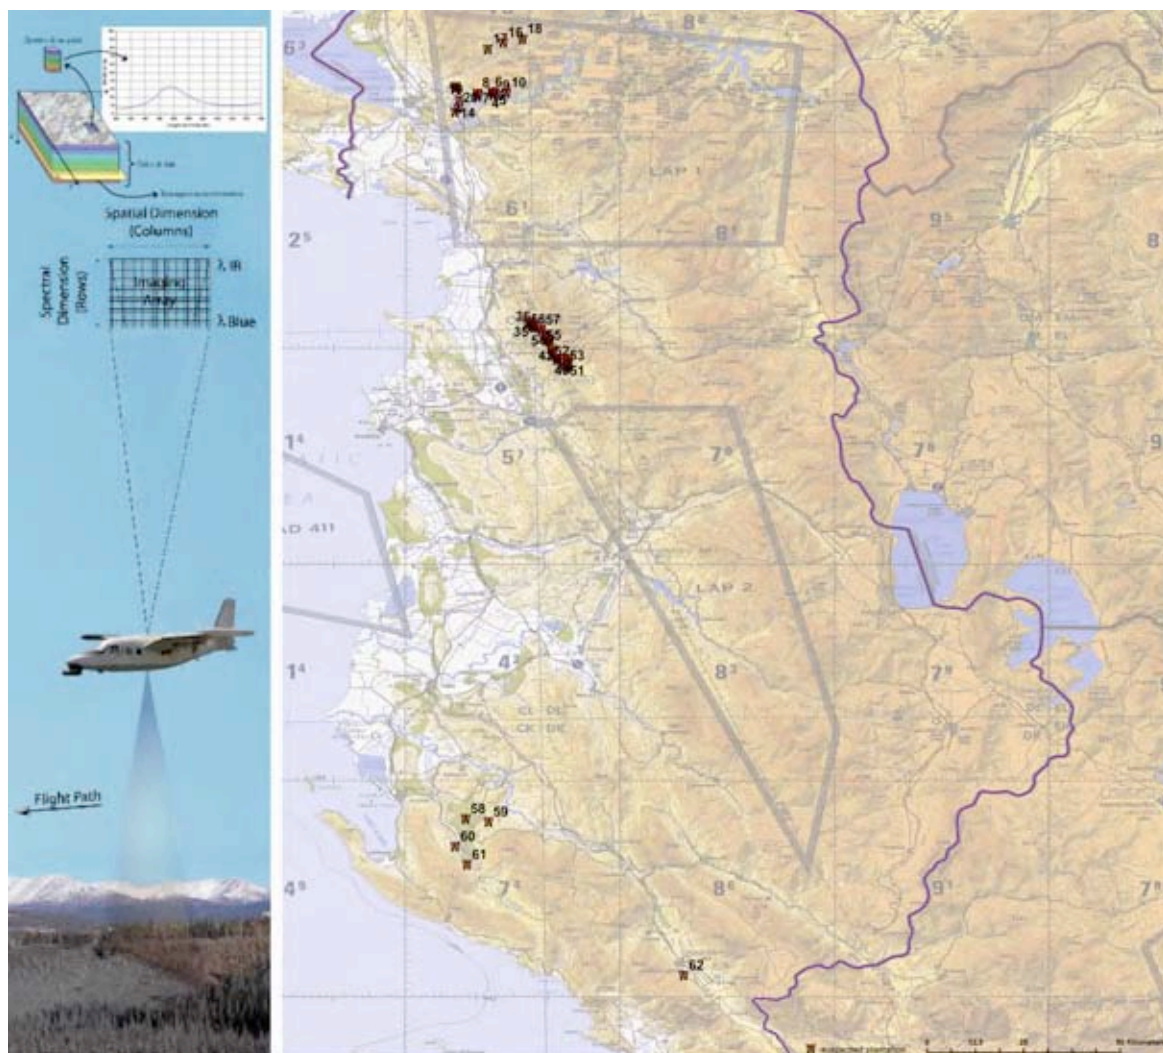

Fig. 3-4: Example graphic of hyperspectral scanning; cartography of cannabis plantations.

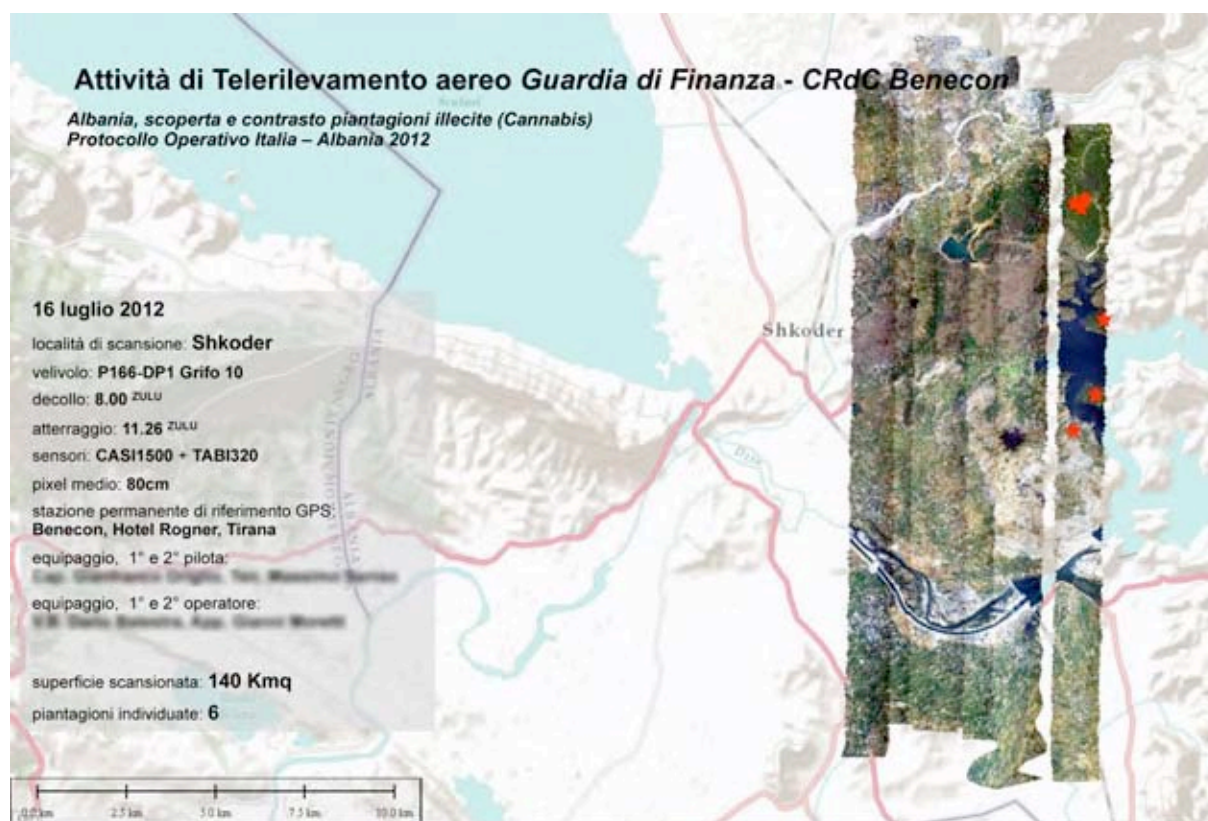

Fig. 4: Summary graph of a remote sensing flight, and mapping of cannabis plantations (red stars).

The aircraft P166 DP1 flew 16 missions and with the post processing of its data it was possible to locate 62 plantations for more than 403.530 square meters. The CRdC Benecon kept processing data in its labs in Italy and it identified other 193 areas of possible cannabis plantations. At the end of the mission 255 plantations were been identified for about 403.530 square meters.

This experience was totally new, there weren't other previous experiments of this kind. For this reason it can be considered immediately a "best practice".

Planning was of relevant importance. Everything was new and needed to be organized, studied, considered and evaluated. Our aim was, above all, to create a technical-scientific protocol reusable in other operative missions.

Great difficulties came from the huge amount of data collected by the sensors on which it was necessary to operate a regular post processing work. All these analysis were something absolutely new for a team made of university researchers and Guardia di Finanza members involved in an international partnership of police activity.

After the conclusion of the Albanian mission, on July 20th 2012, the local police made a raid with their special units, called Delta Forces. It was widely successful. They could go directly to the target finding in the pointed out sites plantations of about one thousand plants taller than 2.00 meters ready to be harvested. Albanian mass media gave important relevance to the monitoring activity made by the Italian group of work of Guardia di Finanza and University researchers. Above all they appreciated the usage of the aircraft both for safety and for effectiveness.

The Albanian kept using our data in the schedule of their activities and from their reports the success of our work is clearly confirmed. The percentage of cannabis in the pointed out areas was almost equal to 100%.

This important operative result shows the high quality of the level of competences that Guardia di Finanza has achieved in the rather new field of air remote sensing, becoming an international benchmark against drug trafficking and crimes against the worldwide community.

Airborne survey missions in Albania were excellent examples of effective synergies of different and complex abilities and skills of public authorities and national and international headquarters.

This experience enhanced the added value of the union of different skills and abilities. In only 17 days we got results far more effective than we could hope and it gave us the possibility to learn and improve our knowledge about airborne remote sensing.

In the late years the remote sensing, above all in the scientific research, is using satellites. Satellite remote sensing, however, has some limits when you need very deep, precise and geo-referred scans useful immediately in gathering evidences before criminal trials.

Airborne remote sensing, in the thermal or hyper-spectral field, on the other hand, can produce more precise data and the activity of sensing itself is more adaptable to the different requests and needs of detective work against any kind of illegal activities.

The hyper-spectral technique is the real novelty of the activity of geo-information: the creation of a specific algorithm associable to a specific material or plant, such as the asbestos or the cannabis would be the best result in the scientific and investigative field, giving the possibility of locating and analyzing data in real time.

CRdC BENECON gave to Guardia di Finanza, for the first experience in Albania, a hyper-spectral sensor CASI 1500 and a thermal sensor TABI 320. Now they have added other two sensors :laser scanner ALS50II e the aero photogrammetric digital camera ADS 40.

The installment of these other two devices has been processing by the technicians and it will give the possibility of scanning the territory in 3 D, opening new horizons of police actions against unlawful building and illegal activities in general.

Nowadays the Airborne Remote Sensing represents for Guardia di Finanza the opportunity of widening its operative context, going beyond drug trafficking and clandestine immigration research

The usage of the geo intelligence can become the source and the preferential means for a systematic opposition to unlawful building and ghost buildings.

Scanning the urban territories will be a means of fundamental contrast against the criminal organizations and on their strong control on the territory as an alternative to the state power.

This systematic and precise scanning of the National areas will create a territorial data base useful for the investigation activity of Guardia di Finanza.

The creation of the 3D thematic cartography is the starting point for the improvement of an information data base, essential for the daily investigative activities of Guardia di Finanza and of all the other police Organizations.

We are sure that the key words for the future of the techniques of national and international investigations are: geo referred cartographic data base. With these information the geo-intelligence will open new frontiers for an effective economic and financial police activity.

In 2013 the operative protocol with the Albanian Republic has been renewed .Guardia di Finanza with the aircrafts of the Gruppo di Esplorazione Aeromarittima equipped with the Benecon sensors is going back to Albania to continue his work for legality.

Fig. 5: A cannabis plantation, hidden by the surrounding vegetation, but clearly visible from above.

3. The hyperspectral and thermal survey of the territory: from three-dimensional representation to the multidimensional modelling. (A. Avella)

Aerial exploration aimed at the acquisition data to be used for the visible, thermal and hyperspectral representation of the territory is planned in relation to the object of the survey as well as the morphological and connotative characteristics of the area under study.

An airborne hyperspectral and thermal survey of the selected territory, carried out by means of the Itres CASI 1500 (Compact Airborne Spectrographic Imager) and of the Itres TABI 320 (Thermal Airborne Broadband Imager) sensors, capable of recording the electromagnetic response of the naturalistic and anthropomorphized environment, produces data that, after having been appropriately processed, contribute to the implementation of a technological platform, the results of all analyses carried out in the area under study are integrated in. This geo-referenced information system, capable of organically handling the multidimensionality of the environment, is an open and dynamic system of knowledge of the 'land patrimony' under study.

In the planning phase of the process of airborne surveying the first action is to find and systematise the numerical maps or in raster form (to be digitally edited), official orthophotos and three-dimensional models as well as of every certified geodetic reference of the territory under investigation, in order to "structure" the geographical data base upon which to articulate the planned airborne acquisitions and subsequently analyse, diachronically, the recorded data. The anthropogenic and natural processes that are layered progressively over a territory can be rebuilt and documented through the integration of data from direct investigations as well as the subsequent critical comparison with the cartographic material acquired and examined. The diachronic reading of the cartographic sources found, custodians of a precious archive of signs, therefore makes it possible to reconstruct the history of these places, interpret the territory that is modelled over time as well as understand the evolutionary processes that give the area studied a particular aspect.

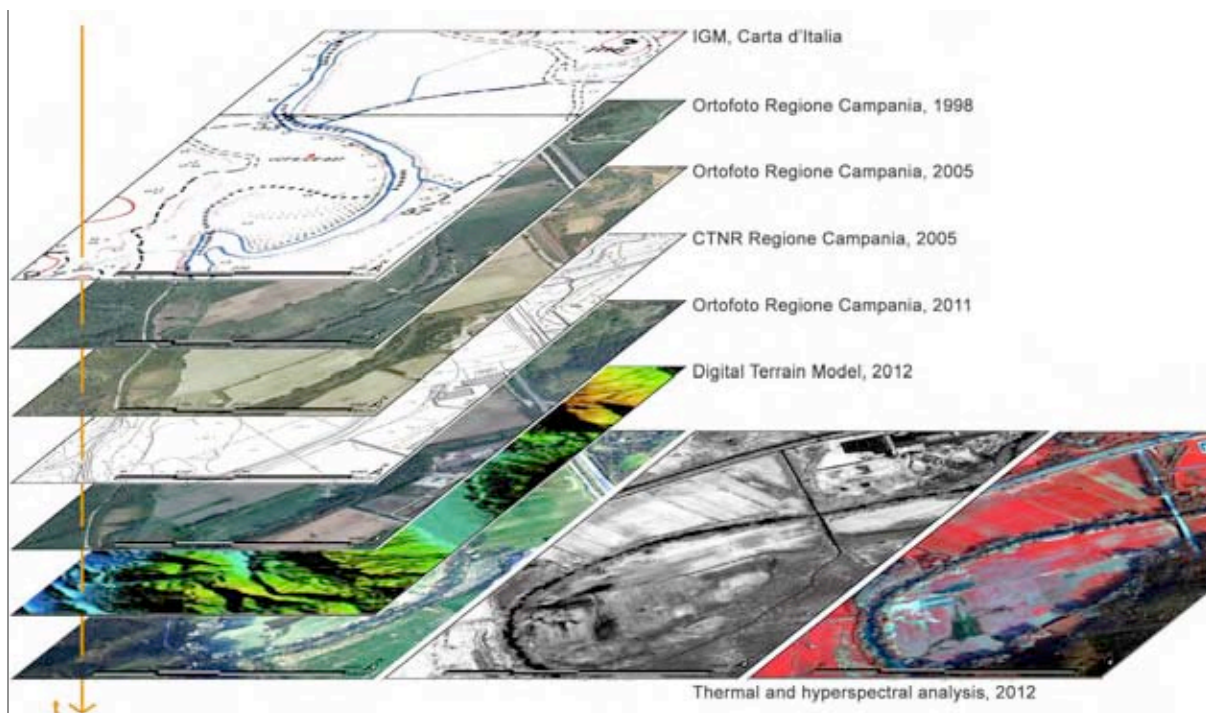

Fig. 1: Diachronic reading of the cartographic documents retrieved and thematic maps produced as a result of the hyperspectral and thermal scanning (A. Avella, 2013).

Official digital maps and models – useful in documenting a flown over area which falls in Italian territory – are published by the Military Geographic Institute, the Land Registry and the Navy Hydrographic Institute, that, since 1960, carry out the functions of cartographic organizations of the State. Even the Regions, Provinces and Municipalities are highly active in the production of cartography, especially at large scales (very detailed scales). Official numerical maps or rasters are available throughout the country at different scales, providing a representation of the territory adapted to different types of investigation.

For remote-sensing activities, carried out in order to guide the planning, management and monitoring of the national territory in question, as part of the wide range of cartographic material available – maps

at a scale of 1:25000 were acquired, produced by IGM as well as numerical and orthophoto versions at a scale of 1:5000 from the National Technical Map, which efficiently represent the forms the ground. For a proper planning of airborne surveying activity, it is essential to have in addition to the digital cartographic documentation described above, archived according to mapping plane element coordinates in UTM-ED50 in relation to the area, also a digital terrain model (DTM or also called DEM, Digital Elevation Model) or LIDAR data.

The experience gained on national and international territories by a survey team which includes university researchers, as well as the author, along with military officers and pilots, on board operators and technicians of the GdiF, highlight the need to systematise the digital maps and three-dimensional models in order to build the cartographic base of a Geographical Information System, structured 'ad hoc' to accommodate the survey data to be integrated and compared with those of the archives. In fact, the GIS is the technological platform which contains the thematic maps produced as a result of the interpretation critical of the surveys performed with hyperspectral and heat sensors, making them easy to read and highlight the spatial interrelations of the *n* themes elaborated with others phenomena mapped on the geographic database, including aerial and/or satellite images.

It should therefore be noted that the airborne sensor platforms, tested by the scientific-technical survey team mentioned above, does not replace the satellite sensors but increases the definition of the resolution of the ground images, and through the particular configuration designed, multiply the combination of data by providing precise information for the study of the evolution of the building work, unauthorized too, as well as for the study of the phenomena of degradation and pollution of the land, landfills, rivers and coastlines. Satellite images (which are transmitted on the Earth in raster form), or aerial photographs, scanned and entered into a geographic database, are corrected with an orthoprojection of the image, placing, in addition to information on the shooting mode (altitude, focal, or orbit, etc.), the digital terrain model that gives three-dimensionality to the GIS and makes it possible to correct those planimetric displacements that are due to the surveying. In addition to the contour lines and the digital model of a square matrix (DTM or DSM) of the area under study, other digital models may be useful to process the data acquired. One of the most popular models is the triangular mesh models (TIN, Triangulated Irregular Network) that are semi-automatically obtained with digital restitutions.

The copious official cartographic sources available on the Italian territory have made it possible to structure a geographic database of "support" to the activities of airborne hyperspectral and thermal surveying carried out on national territory by the University in collaboration with the GdiF aimed at monitoring the environment. The air mission in Albanian territory (July 2012) was a lot less fortunate. Carried out as part of the Operational Protocol Italy - Albania, between the Department of Public Security of the Ministry of Internal Affairs of the Italian Republic and the Directorate General of the State Police of the Republic of Albania, it aimed to discover large areas intended for the illicit cultivation of cannabis. During the planned hyperspectral and thermal remote sensing of the Albanian territory, it was possible to validate the scientific procedures of the technical-scientific protocol that is the subject of this paper, with it being necessary to deal with the difficulty of finding and systematising of digital maps and models of the territory flown over through traditional institutional and private channels. These difficulties were resolved thanks to the acquisition of cartographic material provided by the CIGA (Aeronautical Geotopographic Information Centre) of the Italian Air Force, listed in the table below.

Map Reference	Year of publication	Representation scale	Resolution
National Geospatial-Intelligence Agency, CADRG Coverage of ONCTPC05	Marzo 2010	1:500000	1 metro
Italian Air Force - Centro Informazioni Geotopografiche Aeronautiche, CADRG Coverage of 5NINM3134	Aprile 2012	1:500000	1 metro
National Imagery and Mapping Agency, CADRG Coverage of the Balkans (TLM-50s)	Novembre 2002	1:50000	5 metri
National Imagery and Mapping Agency, CIB (Controlled Image Base)_Albania	Luglio 1998	1:5000	1 metro
National Geospatial-Intelligence Agency Digital Aeronautical Flight Information File	Maggio 2012	1:5000	1 metro
National Geospatial-Intelligence Agency, SRTM DTED Balkans	2012	-	1 metro

Fig. 2: Cartographic database organized for the aerial exploration in Albanian territory, July 2012.

In addition, the comparison with the military authorities of the IGM and the CIGA, as well as the Albanians, highlighted that the geodetic network IGMGPS95 on the Albanian territory - materialized by the Italian Institute – has not been working for some time, and that the acquired mapping archive

produced only for the main urban centre of the territory, has such little reliable specificity (insufficient scale of representation, partial coverage, etc...) as to exclude the possibility of taking it into consideration when structuring the geographic database to support the investigations carried out.

The definition of the geographic database, specially structured in order to carry out the air missions both on the Italian and Albanian territories, followed by the location on the military maps of the areas of greatest interest for the purpose of the inquiry and the identification of the Permanent GNSS Station (Global Navigation Satellite System) next to the study area, or, in the absence of a Permanent Station, the materialization of an 'ad hoc' Station.

It should be noted that the registration of the GPS data during remote sensing flights is fundamental and indispensable for the success of the missions, equal to the efficiency of the aircraft and the aerial, geometrical-inertial and photographic, sensors.

In the case of the missions carried out on the Italian territory, it was possible to geo-reference the surveys by acquiring the differential corrections from the nearest GNSS Permanent Station to the area flown over with a recording per second from the satellite navigation data from the takeoff to landing of the aircraft.

In the case of the mission on Albanian territory, however, in the absence of a network of GNSS permanent stations, either working or next to areas flown over, two GPS stations were set up so as to record the satellite navigation data synchronously to the remote sensing activities. The Benecon researchers, on a mission in Tirana, continuously checked the GPS Base Station installed for this purpose and materialized with a pair of Trimble R5700 antennas/receivers.

The inertial (IMU) and GPS antenna unit, which combined, recorded in real time the structure and location of the aircraft during the remote sensing flight provided data that properly processed returned the route taken by the plane and its geo-referenced disposition so that the thermal and hyperspectral images could be corrected automatically and geometrically related to the area surveyed.

When the variations in terrain height is considerable, to perform the geometric correction of the thermal and hyperspectral image data is equally necessary the digital terrain model (DTM) in appropriate representation scale. Ultimately, the positional accuracy of a geocoded or orthorectified CASI and TABI dataset is dependent on the following factors: the quality and precision of the attitude data, the quality and precision of the position data (X, Y, Z coordinates), the quality and scale of the DEM, the ruggedness of the terrain, the use of a bundle adjustment procedure to correct for linear and angular misalignments in the installed sensors (IMU, GPS, and CASI/TABI sensor head).

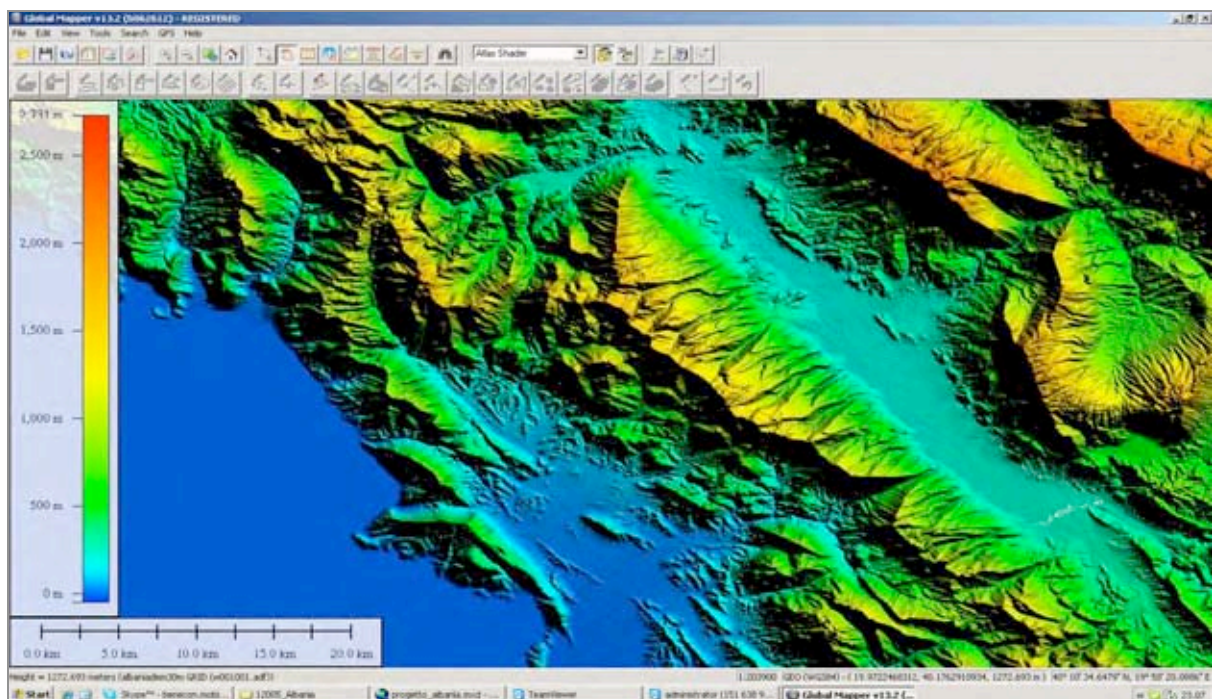

Fig. 3: Digital Terrain Model (National Imagery and Mapping Agency, 2002), Albania.

Using data from the POS-AVTM IMU, dual frequency GPS (differentially corrected), a good quality DEM, and performing a bundle adjustment in the orthocorrection of CASI and TABI image data, is possible to operationally attain output positional accuracies on the order of 1 pixel RMS (to 1 sigma) for 1 m resolution CASI and TABI data acquired.

It should be noted that the GPS antenna, establishing the geospatial position of data recorded during the airborne surveying activity, and the inertial system (IMU, Inertial Measurement Unit) for controlling the attitude of the aircraft, installed on board the military aircraft 'Grifo 10 P166-DP1' of GdiF in occasion of aerial exploration mentioned above, have a geometric configuration that is rigid and integral not only to the aircraft on which they are installed, but also in relation to the hyperspectral and thermal sensors that make up the platform. In particular, the GPS antenna is installed in the cabin of the aircraft so as to perform a reading of the satellite navigation data without interruption, even in case of not completely horizontal attitude assumed by the aircraft during the scanning phase and / or during phase alignment to 'runline' scan calculated and designed on the map. The IMU, also installed on the aircraft, describe any change in orientation of the aircraft with respect to the planned flight line in terms of the following three quantities (Euler angles): roll, pitch and yaw. When a precision geocorrection system such as the POS-AVTM is used, small physical offsets (both linear and angular) are present between the installed location of the CASI sensor head, TABI sensor head, GPS antenna, and IMU. The result is that each of these devices (each providing one of the data streams necessary for geocorrection) senses its environment from slightly different positions in 3D space. These small differences can lead to increased positional errors when blended together. To measure these offsets, a photogrammetric bundle adjustment procedure is run after each new instrument installation. In this regard, it is worth noting that the geometric configuration of the sensors on board the platform components - GPS, IMU, CASI, TABI – prior to being installed must be subjected to specific protocols in order to achieve military aircraft certification.

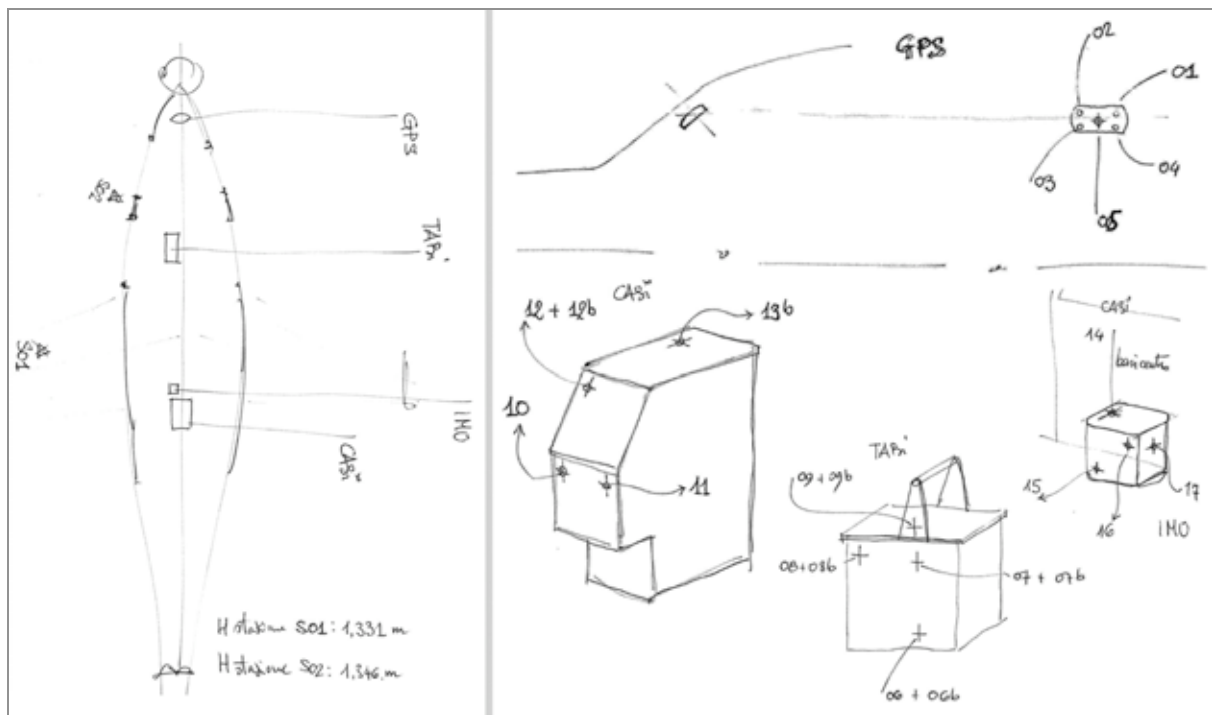

Fig. 4: Geometric configuration of the sensors (GPS, IMU, CASI and TABI sensors) installed on board the military aircraft 'Grifo 10 P166-DP1' of the GdiF, sketch (A. Avella 2012).

To measure the relative distance (offset) between the digital sensors installed on the 'Grifo 10 P166-DP1' and apply the bundle adjustment procedures, the researchers carried out the surveying with a Total Station type Trimble VX. During the data acquisition, the researchers had to face real time difficulties. On the one hand, the specific technical characteristics of the Total Station used that prevented the sensor from measuring distances less than 1.5 m, while, on the other, the difficulties linked to the limited spatial dimensions of the cabin of the aircraft in which the sensors are allocated. The introduction of a topographical Station on board the aircraft was solved by acquiring the points to be measured – according to standard procedures with readings conjugated places back and forth with respect to the reference station point - fixing two stations outside of the aircraft, planning and realizing in real-time in conjunction with the aeronautical technicians of the GdiF, a supporting the head of the topographic sensor, thus replacing the traditional tripod, ensuring high stability and at the same time reducing the space needed to operate within the aircraft.

Fig. 5: Topographic survey by Total Station type Trimble VX in order to measure physical offsets between the sensors installed on board the aircraft.
Support of the Total Station VX designed by university researchers and built by aeronautical engineers of GdIF.

A three-dimensional model of the spatial arrangement of the on board sensors was obtained from the topographic data, making it possible to carry out high-precision calculations of the relative distances between the sensors installed and re-enter the offset into the software.

Fig. 6: Three-dimensional model of the spatial arrangement of the sensors on board the aircraft. Measurement of the offsets between the sensors installed on board the aircraft, sketch (A. Avella, 2012).

In the preparing of the hyperspectral and thermal remote sensing, the planning of the flight over the area under study takes into account the orography, the average altitude and exposure of the soil under investigation. These parameters are functional to the correct definition of the digital hyperspectral and thermal scanning images. In particular, for the determination of the spectral bands of acquisition and the writing of the configuration file, it is necessary to emphasize that the hyperspectral sensor Itres CASI1500 passively records the radiation emitted by the land below in specific segments of the light spectrum (hyperspectral with 288 channel, ranging from the visible to the infrared), while the thermal sensor Itres TABI 320 records the radiation emitted by the area below the thermal infrared spectrum (surface temperatures in a range from -20°C to 60°C).

Fig. 7: CASI1500 and TABI320 sensors, diagram of the spectral resolution (see: The CASI1500 Instrument Manual)

During CASI 1500 operation, all 1474 light-sensitive spatial columns and 288 spectral rows of the CCD imaging area collect spatial and spectral information about the scene. However, it takes a lot of processing power to read out and record all this data. Longer processing times result in longer integration times, which are not always desirable. To manage this data volume, three modes are used: Spatial Mode (operational use), Spectral Mode (operational use) or Full-frame Mode.

Each mode is used to optimize the acquisition of the data in a particular manner. The mode that is chosen is dependent on the project data requirements. Spatial mode is typically chosen when high spatial pixel resolution data or spectral programmability is desired. Because a smaller spectral subset is acquired (though at full spatial resolution), integration times in spatial mode are typically shorter than in spectral mode.

The hyperspectral configuration (Spectral mode) of the CASI is useful when detailed spectra is needed, and reduced across-track spatial coverage is acceptable. In particular, spectral mode is well suited to identifying the spectral signature of a target that is not well quantified.

The flight planning also requires the calculation of the medium resolution of the scan, the speed of the aircraft in acquisition, the flight altitude and the areal coverage of the scans. These parameters can be determined by the relationships between them. For example, the along-track spatial resolution of the acquired data is dependent on both integration time (IT) and aircraft speed. The integration time is clearly dependent on the instrument's configuration. The more spectral and/or spatial information that the system must readout during a given integration time, the longer this interval must be.

Therefore, the selected the capture mode and established, as a result, the integration time is possible to calculate the other parameters of flight. The pixel size (which determines the spatial resolution of the data) refers to the projected spatial extent of an individual pixel on the ground; in other words, its ground 'footprint'. The chosen resolution is usually dictated by the requirements of the project. For instance, if ground features are to be differentiated on the basis of their spectral characteristics alone, this may dictate that a finer spatial resolution is used (meaning that the ground 'footprint' of a single pixel is smaller, resulting in less spectral mixing). Spatial resolution is measured in two dimensions (along-track and across-track), both which are measured with reference to the aircraft's flight direction. Both dimensions are independent of one another, and may differ based on such factors as the chosen flying speed, integration time, and lens field of view. In fact, the along-track resolution of an image pixel is a function of the aircraft (or other platform) ground speed (S) and the chosen integration time (IT). The variable 'S' (typically a value between ~80 and 180 knots) will depend on the chosen aircraft. In this regard it should be noted that the aircraft 'Grifo 10 P166-DP1' of GdIF, on which sensors are installed, on the occasion of aerial exploration on Italian and Albanian territory has had a steady flight speed of about 110 knots.

The across-track pixel resolution, however, can be easily calculated using simple trigonometry, because this value is a function of the field of view (FOV) of the instrument lens (of 0.028° along-track and a maximum of 40.4° across-track) and the flying height above ground level (AGL).

For the thermal acquisition, the range of the chosen aircraft is important. It influences not only the time required for the data collection, but also the ferry to and from the target region and between acquisition targets. To calculate the flight parameters is necessary to remember that the pixel size (which determines the spatial resolution of the data) refers to the projected spatial extent of an individual pixel on the ground; Spatial resolution is measured in two dimensions (along-track and across-track), both which are measured with reference to the aircraft's flight direction. Both dimensions are independent of one another, and may differ based on such factors as the chosen flying speed, integration time, and lens field of view. The IT is fixed for the TABI-320 at 17 ms. This value can not be changed.

The ground resolutions achievable with the TABI-320 are based on the FOV and sensor specifications. For example, in Albania to achieve 1 meter square pixels the data should be collected at 115 knots at an altitude of 1200 feet above ground. Note that once the flying height is known, this value must be added to the average height of the terrain (measured ASL - Above Sea Level) to determine the altitude that the aircraft must fly at (ASL) to achieve the specified resolution.

After the definition of the flight parameters it follows the drawing on the map of the scan runline, that is a series of "leg" to cover along the flight according to a relative 30% overlap that depends on the orography of the site. For this, sections of the landscape are executed for each scan runline.

These have a direction as much as possible parallel to the land orography in such a way that it is possible to evaluate the flight height on each "leg" as far as the land height changes. The runline, designed to cover all the flight area, are extended for a mile so the aircraft can easily align itself in the direction reported and it can keep the speed fixed for the scan.

The flight plan ends with the draft of a timetable of the acquisition campaign, which depends on the characteristics of the sensors installed on the aircraft.

Fig. 8: Flight plan, Albania 2012 (A. Avella, 2012).

In fact, the operative flights with the hyperspectral sensor, to be efficient, need the presence of the lighting source (Sun) at the time of its maximum radiation, that is at the solar midday in which the spectral distribution of the light is close to the "White".

On the other side, for the operative flights with the thermal sensor, the presence of the lighting and thermal source (Sun) can introduce an error connected to the reflected radiation component. For this it is better to use the sensor at the sunrise and sunset time; in such time the solar radiation is negligible respect to the infrared radiation emitted by objects.

For these peculiarities, and also for reasons connected to ground resolution, it is impossible the acquisition at the same time with the two sensors and as a consequence, for each investigation area it is necessary to plan a double acquisition campaign.

The data input (geographic coordinates and spectral configuration of the system on board) phase is followed by a phase in which hyperspectral and thermal scan is conducted and the data processing is done.

The adoption of technical-scientific protocol makes possible to handle a complex flux of data during the process from the flight for the hyperspectral and thermal acquisition to the draft data elaboration to the build up of multidimensional model.

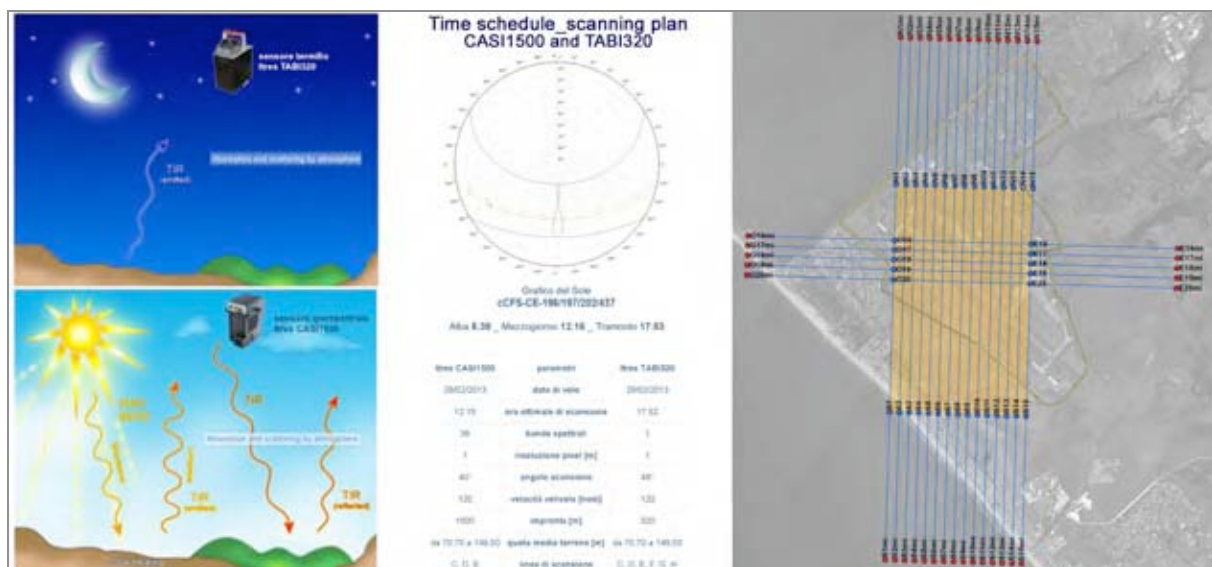

Fig. 9: Timetable of the thermal and hyperspectral acquisition campaign (A. Avella, 2012).

In conclusion, the elaborated multidimensional model is composed by several spectral layers which, classified in according to the type of survey to execute, give back thematic maps useful to handle planning and strategic monitoring actions and that are connected to the natural and anthropic investigated situation.

Fig. 10: Hyperspectral surveying in albanian territory (P. Argenziano and A. Avella, 2012).

4. Multidimensional mapping of the territory by hyperspectral and thermal scanning. (P. Argenziano)

In any direct or instrumental survey, analogical or digital, planning, acquisition and processing should have a role in mutual equilibrium. In other words, the strengths of the first step can propagate a positive effect on subsequent phases; and conversely, the weak points of each action can disrupt the entire process.

Airborne remote sensing's process, object of this paper, was not a simple juxtaposition of standardized actions, relating to the correct use of various sensors. It was based mainly on the establishment of a surveying team involving university researchers (including the writer) along with military Officers and NCOs (pilots, airborne operators and aeronautical technicians).

A motley crew blended by common passions, precise objectives and companion human relationship. The crew had a pivotal role in the articulate process, ensuring the balance of the trinomial planning-acquisition-processing.

If the planning phase, collaboration between pilot and researcher, to organize flight plans, may seem obvious (but it is not), the central role of the crew is exalted during the flight data acquisition.

During this phase must align a long series of procedures that involve ground staff and the on board one, as protagonist of remote sensing.

Fig. 1: Time line of key acquisitions for the remote sensing flight. (sketch by P.Argenziano 2013).

Fig. 2: GNSS permanent station coverage during a remote sensing flight. (drawn by P.Argenziano 2013).

Fig. 3: Two instants of hyperspectral acquisition phases on board.

The airplane must be in perfect working order, guaranteed by aeronautical technicians and tested by pilots. The airspace (above the study area) must be optimal for proper execution of the mission, as well as scheduled during the survey planning and guaranteed by the inspection airspace Office. The weather conditions must be appropriate to flighting, to sensors' functional characteristics and to overall aims of remote sensing mission. GNSS permanent stations, next to the airport and the area of study, must be functioning and operating in a time line that includes the remote sensing flight.

Before takeoff, the staff on board controls all sensors' functionality, ensuring that GNSS on board antenna and Inertial Motion Unit are active in a time line longer than flighting but smaller than GNSS permanent stations acquisition.

Remote sensing supervision is assigned to the operators on board (non-pilots), a military and a university researcher, as well as programmed in the navigation files, and in hyperspectral and thermal setting files. The operators are also required to perform effectively hyperspectral and thermal scans - operating on dedicated computers - when the plane flies over the study area, according to planned runlines. Each flight and acquisition phase is recorded automatically in log files of each sensor; while this effect shall be made on special forms by the two operators, for verification.

Fig. 4: Summary table of basic data of a remote sensing flight, required for processing.

Generally, during direct or instrumental survey, each acquisition phase is complex and presents some variables sometimes unpredictable. Specifically, a remote sensing flight presents difficulties and variables, such that two operators have to maintain high concentration and are ready to remodel the main acquisition parameters, where the circumstances make it necessary.

The quality estimation of airborne remote sensing starts, therefore, in the preliminary phases and continues during flight: all planning parameters and all mission basic actions must be met; all boundary conditions must be provided and solvable. To meet a high standard of remote sensing, at the end of flight, operators shall ensure the goodness of the recorded data, through a sample pre-processing, and provide the same data archiving; finally, they draw up an analytic report of flight that will serve as index to the next processing phase.

In a schematic way, processing is based on the integration of four data groups: the hyperspectral or thermal images; aircraft inertial and position data; GNSS permanent stations data; DSM or DTM models of the territory, object of study. Processing is conducted by university researchers through three software processes, distinct and sequential: calculation of aircraft position and attitude every second; radiometric correction of hyperspectral or thermal images; geometric correction of the latter.

Processing result is an multilayer orthophoto paper in which each layer corresponds to a wavelength reflected by the ground objects scanned and recorded by airborne sensors. The classification of various selective layer allows drawing thematic maps, as interpretation of case study.

Position and attitude processing runs through the integration of GNSS permanent stations data (static acquisition) with inertial and GNSS on board sensors data (dynamic acquisition). As is known, the first ones record the satellite coverage of the wide zone, including the airport and the study area; the second ones are a combination between position and attitude data (roll, pitch, yaw), registered every second during the flight, from takeoff to landing. The integrated processing of all these data reproduces the geo-referenced flight path, so that all thermal and hyperspectral images can be automatically referred to scanned area.

The experiences, gained through national and international missions, show that data quality (described above) is directly proportional to piloting actions. Id est pilots - as remote sensing protagonists as any other crew component - apply special flight techniques: the turns between sequential runline are very large and with a minimum angle, the flight speed is constant along runlines, also in the presence of adverse wind.

This underlines once again that remote sensing is unanimous action comparable to a symphony concert in which the perfect execution can only be achieved if each orchestra conductor knows the potential of his instrument and plays the musical score to the best of its ability.

Image processing is developed through two consecutive software procedures: radiometric correction is technically different for CASI sensor (Compact Airborne Spectrographic Imager) and TABI one (Thermal Airborne Broadband Imager); geometric correction is the same for the two types of images acquired.

Fig. 5: Comparison of radiometrically (A) and geometrically (B) corrected images and 3D model (C) highlighting the geographic coordinates and spectral ones. (created and drawn by P.Argenziano 2013)

During radiometric correction of CASI images, the raw digitized pixel intensities are converted into units of spectral radiance, thus estimating the true brightness of the target. Conversion of CASI data to units of reflectance requires that ground spectral measurements be collected coincident to the airborne image data. While, during the radiometrical correction of TABI images, the raw digitized pixel intensities are converted into units of Celsius degrees ($^{\circ}\text{C}$), thus estimating the relative temperatures of the imaged target. Processing of TABI data to absolute measures of temperature requires that some form of thermal calibration targets are flown at the time of data collection.

Estimate by scientific objectivity the radiometric value of each image pixel is very important in the remote sensing aimed at territorial policing or monitoring. So the opportunity to correct the radiometry of the images, acquired in real time during the flight, becomes strategic. This hardware configuration is currently being studied for multitasking aircraft of GdIF-Benecon who will fit out Lidar, photogrammetric, hyperspectral, thermal and SAR sensors.

During geometric correction, the image (radiometrically corrected) is aligned to position and attitude

data. At this stage, any across-line image, acquired in a known flight time is redrawn and shown in an orthographic XY plotter (by a chosen DATUM) thanks to a software integration with territorial DEM model. The comparison pictures show the difference between radiometric image and geometrical correct one; the third picture is a 3D model of the last one made by DEM used for the ortho-projection. The remote sensing activity ends with plotting of multilayer digital orthophoto maps of the territory. A particular type of digital image whose representation in real colors (hyperspectral scanning) or in gray-scale (thermal scan) - similar to the traditional orthophotos - is one of the possible spectral classifications. As anticipated, orthographic image of the territory scanned contains a specific spectral 'depth', in proportion to the spectral bands were selected during planning or related to sensor used. The CASI-1500 measures the spectrum for each location on the ground for each VNIR spectral band chosen by the operator. These light intensities may be recorded for up to 288 separate spectral bands. The bands may be placed anywhere within a ~680 nm spectral range, which itself may be placed anywhere between ~380 and 1050 nm. The CASI is thus sensitive to wavelengths in the Visible part of the electromagnetic spectrum, as well as in the Near Infrared. This means, about an hyperspectral orthographic image, 288 spectral layer may be added to XY dimensions, at most. Instead, thermal orthographic image (acquired with Itres TABI-320) are 'simply' three-dimensional, because the temperature recorded at each image pixel can be added to XY dimensions. The nominal temperature range of the TABI-320 is -20 through 110 °C (in low resolution mode, up to 1000 °C) and it is capable of resolving temperature differences of 0.1°C. Every pixel on the sensor contains both spatial information about the scene and thermal information from the 8- 12 micron region, processed in Celsius degrees. As the specificities of these spectral sensors, orthographic images have intrinsic features more relatable to satellite ones rather than topographic maps or traditional aerial images.

Fig. 6: Comparison of six spectral signature, recorded in hyperspectral image. (created and drawn by P.Argenziano 2013)

An hyperspectral (or thermal) orthographic image is processed according to a **mapping DATUM**, chosen for two-dimensional representation (for Albania WGS84-UTM34N); it has its own **geometric resolution**, which corresponds to pixel size projected to the ground; continuing, it has its own **spectral resolution**, about the number (or size) of electromagnetic bands that have been stored in its digital frame; and again, it has its own **radiometric resolution**, about sensitivity of airborne sensor to detect the difference in the radiant flux that propagates from ground to flying aircraft. If you wish to approach multi-temporal analysis of a specific territory, comparative reading of airborne data must be performed both in relation to the critical spectral region and in relation to these variation in the time "t" (**time resolution**).

Each pixel that makes up the orthophotos, records within itself wide range of information about the object present on the ground, of which that particular pixel is the corresponding hyperspectral and/or thermal discretization. The critical analysis, that results, is aimed to investigate the data recorded in the various pixels, in different ranges of wavelength, characterizing each pixel compared to those next, and by extracting the spectral signature (p) for each of them.

Fig. 6-7: Two spectral diagrams of cannabis, registered in Benecon Laboratory (A.Buondonno, and G. Serroni 2012)

Fig. 8: 'RedVeg' classification from hyperspectral image (P.Argenziano 2012)

The spectral signature - as known from scientific literature - is the reflectivity characteristic of each material (natural or artificial), in function of incident radiation wavelength, in comparable environmental conditions. Being able to isolate the spectral signature of a material means, in other words, to know his fingerprint, an element that clearly identify it.

A critical analysis, so based, has a preventive approach already in remote sensing planning phase, because it must be clear what is the project goal, and especially what are the factors to be analyzed on the ground. Or, in the case of a water course, to evaluate the presence, identity and the distribution of pollutants, algae, this is different from the study applicable to a forest, assessing the individual location, species identity, size, and health of trees. And yet, for agricultural soils, assessing the spatial distribution, species identity, maturity, and health of crops; identifying the types, wetness, and salinity of soils is different from assessing the impact of cattle grazing on vegetation, or is different from assessing the surface scattered land mines and unexploded ordnance in the military.

Referring to the experiences developed in the national and international scenarios - about plant species identification and weeds mapping - it should be noted that the reflectance curve (spectral signature) may change its geometry, depending on many factors among which the most relevant are:

plant type, leaf density, leaf structure, seasonal phenological phase, moisture content. This question is crucial in the study of vegetation cover, which have a specific phenological cycle throughout the seasons. For example, wheat can be distinguished from corn, because the two cultures have different phenological cycles. In contrast, the discretization of wheat from barley is difficult, because their cycle differs only a few days. Continuing, the spectral curves of the corn and soybeans are very similar because they have almost identical cycles throughout the period of greatest vegetative growth, although, the different morphology of the two crops can be a discriminating factor.

In scientific literature, it is known the relationship between the reflectance curve (characteristic of vegetation in different segments of electromagnetic spectrum) and leaves pigments (visible spectrum), as well as in comparison with cellular structure (near infrared spectrum) and water content (mid-infrared spectrum, not registered by CASI).

About plant elements of medium height and average leaf density, soil influences the overall electromagnetic reflection, recorded by the sensor, because within the same pixel leaves reflections are added soil ones, which can be seen through the same leaves sparse.

Fig. 9: 'True Color' classification from hyperspectral image (P.Argenziano 2012).

Spectral element of soil varies in function of its nature, of its coverage density (linked to the phenological stage), of vegetation type present, of water conditions, of growing techniques. The spectral curve of plant species differs, also, in relation to plant structure and its leaves. The algebraic combinations (Vegetation Index) of reflectance measurements in two or more spectral segments, near infrared and in the red, provide information on the amount of plant biomass present, allowing the continuous monitoring. All vegetation indices exploit the marked difference between the low reflectance in the visible range, and the high response in near infrared one.

Vegetation indices, therefore, are very related to health and productivity parameters of crops, as well as to density and green biomass, to Index of Chlorophyll, to Leaf Area Index (LAI), to Normalized Difference Vegetation Index (NDVI), to PVI (Perpendicular Vegetation Index) and to WDV (Weighted Difference Vegetation Index); mentioning only the most significant ones in relation to the experiences carried out.

For the discretization of cannabis sativa cultivation, the analysis of scanned data was inductive type, given the overall extension of hyperspectral and thermal scans of more than 778 sq km.

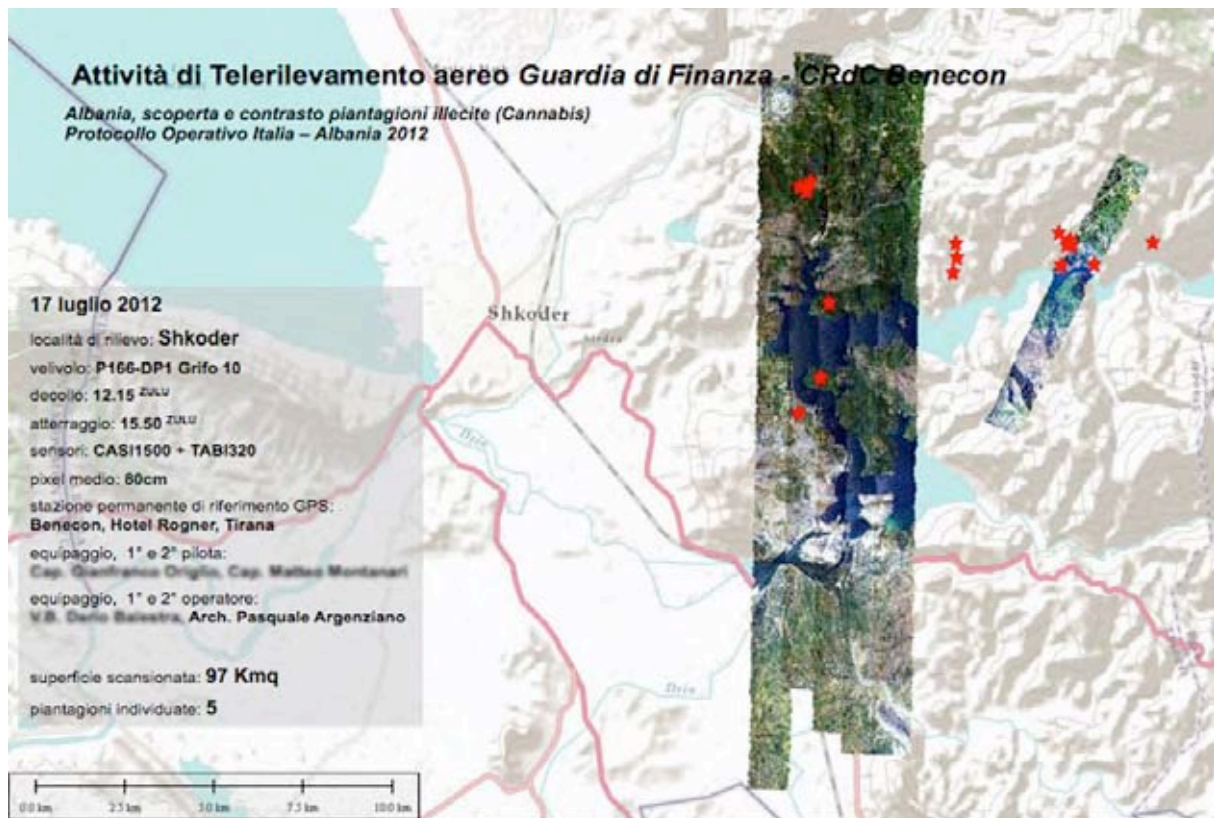

Fig. 10: Summary graph of a remote sensing flight, and mapping of cannabis plantations (red stars).

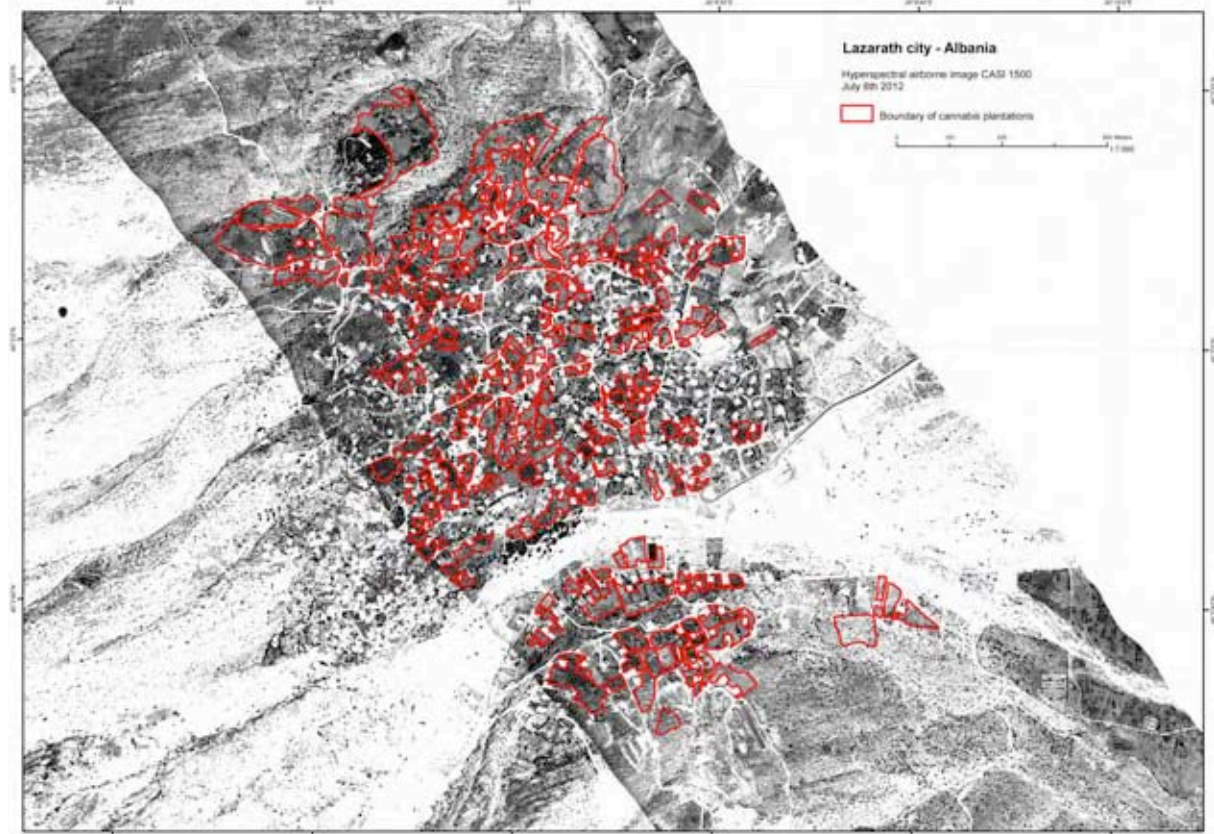

Fig. 11: Cannabis plantations in Lazarath city (map by P.Argenziano 2012).

Starting from orthographic images, by 3D software procedures, large favorable to the cultivation areas have been limited according to the exposure of the slopes and to the average altitude above sea level. On each macro-area identified, a combination of variable indices (described above) has been applied according to experimental procedures, in order to carry out the classification compared to cannabis spectral signature. The cannabis spectral signature has been previously analyzed from freshly cut plant specimens, in Benecon Laboratory. The discretization of cannabis cultivation was also

experienced through the application of a morphological filter, chosen according to cultivation techniques, and to the integration with thermal data for highlighting drains.

Selective application of Vegetation Indices to hyperspectral and thermal images, applied to architectural heritage, can promote new researches, and especially can solve problems about building maintenance and heritage preservation. The classification of density and green biomass, through critical comparison with NDVI can be the first step for weeds discretization on pitched or flat roofs - difficult to inspect - or on summits of ancient walls in archaeological areas, which cause a slow and inexorable decline. This approach can be done a territorial scale, through thematic images of large archaeological areas or large urbanized ones, ensuring sub-meter pixel resolution.

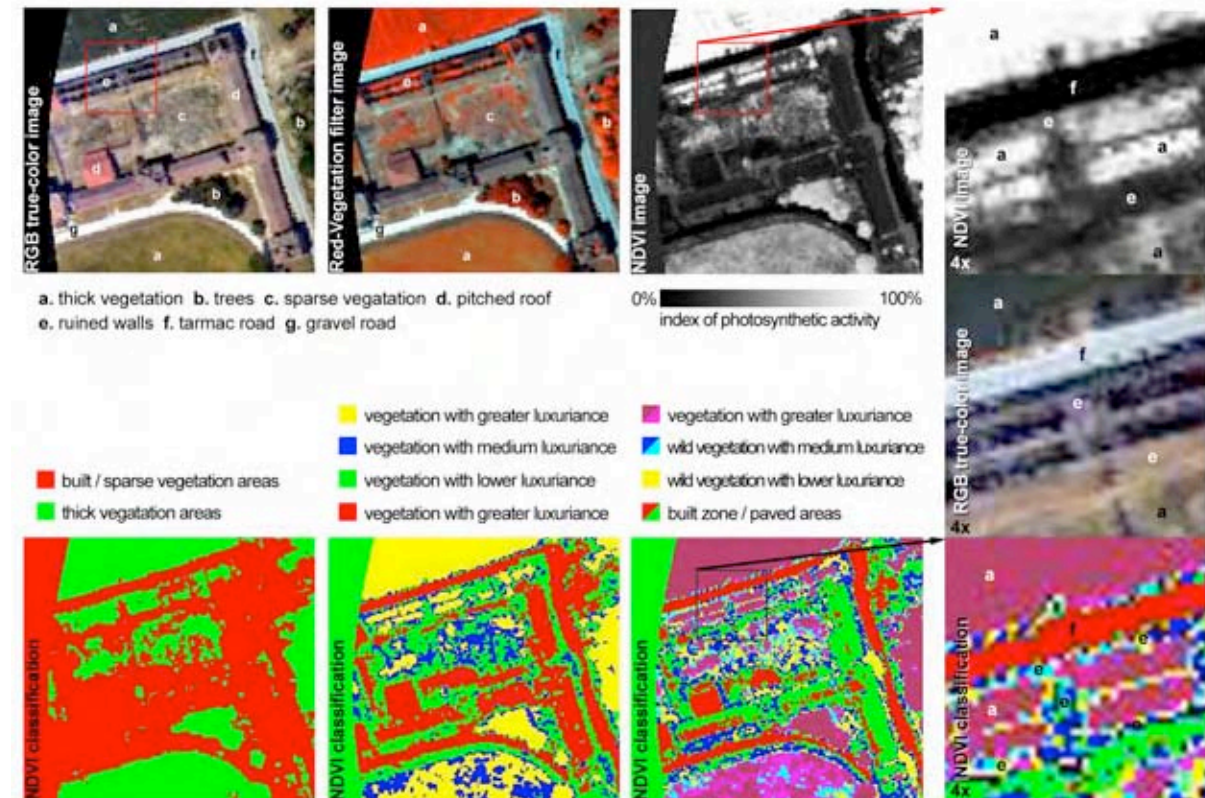

Fig. 12: First draft of the procedure for identification of weeds in the abandoned architectural heritage. The application case concerns some parts of the Royal Palace of Carditello, XVIII century (created and developed by P.Argenziano, 2013)

With reference to the table, in upper images, from left to right, the hyperspectral data were classified into real colors (RGB), into vegetal range colors, and according to NDVI algorithm. In particular, this index - integrated to the ground temperature data - can be classified by successive approximations to highlight the weeds, who lives on top of walls' ruins, or on pitched roofs not being maintained. The three NDVI images show the sequential classification of chlorophyll index, from two classes (red/green: vegetation areas or not), to seven classes that allow the identification of minimal presence of weeds. From the images' comparative reading, it was possible to highlight the weeds on walls' summits and on pitched roofs, in application to an emblematic case of Italian architectural heritage, now in neglect and decay state. By generalizing, the airborne hyperspectral and thermal sensors, and their integrated processing data, can also be applied to weeds' mapping at urban scale, thanks to a high spectral resolution and submeter accuracy.

Abstract

I would like to report the appearance of a design culture with sensitivity and attention that is able to step into existing landscapes in order to enhance the quality as well as propose a new way of reading them. This culture makes it possible to perceive the identity and beauty of the area, while stimulating the building of a better society, environmental, historical heritage but also devoted to promoting solidarity networks. The search for a solution not only on face value of the environmental problem calls for a different approach to the transformation project of the territories. It is not possible to solve problems if the way of thinking that created them is not abandoned: hence a "strategy of caring", which not only stems from the awareness and sense of belonging, but also refers to the principle of responsibility, anticipated by Hans Jonas in 1990. It is fundamental to an "architecture of the earth". It allows us to rethink this discipline and its historical identity at the service of society. An architecture modeled on nature and location can help humanity in its slow realization. An architecture that, even before being built, represents a new way of reinterpreting the deep sense of living.

"It is in us that the landscapes have landscape. So if I imagine them I create them, if I create them there, if I see them there."

Fernando Pessoa

"Works of art require interpretation because to be interpreted is their essence."

Arthur C. Danto

Landscape refers to the particular expression of an area determined by the physical, human, biological and ethnic, and - as noted Pessoa - it is essential to who observes and then the way it is perceived and experienced. As claimed by Claudio Magris¹, "... the landscape where what is in front of you catches you, it identifies and calls for a reply, your recognition. It is the double evocation between the viewer and the scene. "

According to some sources, the term originates from the French *paysage*, for others from Italian, which in turn comes from the Latin *pagensis* or *countryside*, territory, while its meaning appears in painting with references to the realism of some views and in literature, with the description of places.

One of the most representative images of a landscape painting is that of *The Wanderer Above the Sea of Fog* (Der Wanderer über dem Nebelmeer, 1818), symbolic painting by Caspar David Friedrich, one of the greatest German landscape artists. There is a man, seen

from behind, in a solemn loneliness, standing on a rock, the abyss that extends in front and misty peaks that emerge from the blanket. He looks absorbed in the sublime natural spectacle that unfolds before his eyes. He is trying to grasp something that is beyond human comprehension. The theme of the wanderer reflects the restless wandering and poignant metaphor for human existence, to something unattainable and the inevitable stop of those who, suspended between the finite and the infinite, in a precarious balance between being and non-being, has reached the limit of the earthly experience, aware of the unbridgeable gap between man and nature, but at the same time also their deep union.

The European Convention on the landscape has introduced a new way of thinking of the landscape dimension of the area, characterized by having attached to it the status of an autonomous concept which is an essential element of individual and social welfare, and its preservation, management and planning entail rights and responsibilities for each individual. There is therefore a right to the landscape.

Caspar David Friedrich, Der Wanderer über dem Nebelmeer, 1818

The landscape configures the shape of the country, created by the conscious and systematic human community that has settled in it, so intensive or extensive, either in the city or in the countryside, which acts on land and produces the signs of its culture, which then lives in this landscape. It is no longer the semantic equivalent of “natural beauty” which placed a

narrowing of the scope of the protection to the areas of landscape value, similar to the things of historical and artistic interest, belonging to the goods of public interest.

The landscape is, however, one of the components of the environment that is affecting large portions of the national territory, thus the landscape is an asset that must be recognized and legally protected. Its protection becomes the primary constitutional value, which must submit any inherent interest, and should be paid to conserve and maintain the significant or characteristic features, in terms of its heritage value derived from its natural configuration and human intervention. In the present time, there is a design culture that, starting from landscapes, with great sensitivity and attention is able to immerse into the existing ones so as to enhance their quality and propose a new way of both reading them and enjoying their beauty. We have selected a series of interventions that are able to witness this, or a new way of understanding the landscape, not only to read and understand it but starting from its virtuality that plays with its consciousness.

I think, a useful lesson can be learnt for architecture tour court.

We have put together examples of how small the extraordinary gaming experience, a cheerful invitation to play and have fun due to the fertile ingenuity of the study of designers pay particular attention to the landscape: ANNABAU in Wiesbaden. They have invented a spatial sculpture, to be explored, inviting you to climb on the curved steel pipes, painted green, to cling to the rope net that stands beside it. It is an endless game, an invitation to live a new experience outdoors and in touch with nature and the trees, watched from various different points of view. Or the hotel on the shaft, which aims “to get the most with the least”ⁱⁱ, or with minimal resource consumption, minimal environmental impact, minimal waste production, to represent a sort of oasis for the mind. However, the project constructed in Xian, China, from Topotek 1, which represents the implementation of the unconscious dream of crossing the entire globe, starting from Berlin to land on the opposite side.

ANNABAU in Wiesbaden

There are projects that have created a new landscape as the one for the sea front of Benidorm, the most paradigmatic example of the city intended for holidays, tourism, fun and sea. Carlos Ferrater has developed an intervention that assumes its own specificity and size through a series of fabrics that are intertwined with each other and have few geometrical standards, thanks to the input initial resulted from the image of a braid of hair that follows the outline of the coast. Then, there is the new port of Tel Aviv in 1965, which was abandoned as a docking port and suffered a continuing deterioration until a new project which restored it back to life. Surprisingly, despite the fact that urban planning was dominated by market forces, for the immense popularity of the proposal that we present in the audience, the project was able to circumvent the development programs intended for the area of five hectares creating a precedent for an urban transformation not propelled by building rights but by a unique strategy that has renewed the existing buildings and invested in the regeneration of public space.

We could go on to cite a number of projects that have shown us how we can intervene in particular areas with sensitivity and commitment, with the understanding that: "The forms of cultural expression construct their own public when it induces a desire to acquire the tools that

Carlos Ferrater, Sea front of Benidorm

are necessary to give meaning to the experience itself: when that happens, the experiences continue to produce value and meaning. In contrast, when the cultural experiences that are not trivially replicate the skills and expectations of the public they serve, while producing immediate feedback, they lose interest very quickly and become obsolete, almost at the same time as their productionⁱⁱⁱ."

Abstract

The Solar Eco-efficient Envelope Model is an innovative research of three research unities, TECN.AV Srl, BENECON scarl, Seconda Università degli Studi di Napoli (Dipartimento di Restauro e Costruzione dell'architettura e dell'ambiente, Dipartimento di Ingegneria Aerospaziale e Meccanica), with funds of Italian Ministry of Environment. SEEM is a research focused on an experimental model for analyzing the effect of heat flux on heat transfer and flow of air into a chimney, in relation to air temperature and velocity, also in order to use the results with the objective of an adequate energetic refurbishment. With strict relation to the emerging data of variable fields and the profiles of air temperature and velocity are analyzed. Simulations onto the plane of perceptive experience consider mutable prevailing conditions of air movement which, with its dynamic movement, connotes morphological aggregation.

Keywords: solar chimney, energy, bioclimatic architecture, experimental model

1. Introduction

The increase in world population and the improvement of living standards have led to a growing demand for electricity. The limited availability of fossil fuels and environmental pollution caused by them, push the development of new technologies for the production of electricity from renewable energy sources. With a view to sustainable development, therefore, the energy future must have as protagonists renewable sources (solar, geothermal, wind, etc.), which are not exhausted and have no environmental impact because they do not produce greenhouse gases.

Buildings as big energy-consuming systems require large amount of energy to operate. Globally, buildings are responsible for approximately 40% of total world annual energy consumption. Sustainable design and construction are gaining significant momentum in the construction industry. Designers and owners are learning that with smart design, buildings can save energy and have a decreased impact on the environment. Sustainable buildings with renewable energy systems are trying to operate independently without consumption of conventional resources. This reduces impact on the environment throughout buildings' lifecycle. Renewable energy is a significant approach to reduce resource consumption in sustainable building [1] and integrated solar chimney systems could represent a possible solution [2].

A solar chimney is essentially divided into two parts, one – the solar air heater (collector) and second – the chimney. Two configurations of solar chimney are usually used: vertical solar chimney with vertical absorber geometry, and roof solar chimney [3]. For vertical solar chimney, vertical glass is used to gain solar heat. Temperature difference between vertical glass duct and interior room produces a pressure difference. An interior air will go out through inlet because of this pressure difference. The temperature difference is a determining factor of performance of solar chimney [4].

Designing a solar chimney includes height, width and depth of cavity, type of glazing, type of absorber, and inclusion of insulation or thermal mass. Besides these system parameters, other factors such as the location, climate, and orientation can also affect its performance [5-7].

The solar chimney power plant uses solar radiation to raise the temperature of the air and the buoyancy of warm air to accelerate the air stream flowing through the system. This is an energy conversion system from solar to mechanical. A component, such as a turbine, set in the path of the air current, converts the kinetic energy of the flowing air into electricity.

Schlaich [8] in the late 1970s was the first to propose the solar chimney concept. Less than 4 years after he presented his ideas at a conference, construction on a pilot plant began in Manzanares, Spain, as a result of a joint venture between the German government and a Spanish utility. A 36 kW pilot plant was built, which produced electricity for 7 years, thus proving the efficiency and reliability of this novel technology. The chimney tower was 194.6 m high, and the collector had a radius of 122 m. Haaf [9] reported fundamental investigations, design criteria, and cost analysis for the Spanish system. Bernardes [10] presented a theoretical analysis of a solar chimney, operating on natural laminar convection in steady state. Von Backström and Fluri [11] investigated analytically the validity and applicability of the assumption that, for maximum fluid power. Von Backström and Gannon [12] were interested mainly in a one-dimensional compressible flow for the thermodynamic variable as dependence on chimney height, wall friction, additional losses, internal drag and area exchange. Pretorius and Kröger [13] evaluated the influence of a developed convective heat transfer equation, more accurate turbine inlet loss coefficient, quality collector roof glass and various types of soil on the performance of a large scale solar chimney power plant. Ming et al. [14] presented a mathematical model to evaluate the relative static pressure and driving force of the solar chimney power plant system and verified the model with numerical simulations. Maia et al. [15] presented a theoretical analysis of a turbulent flow inside a solar chimney. They showed that the most important physical elements in a solar chimney system are the tower dimensions as they cause the most significant variation in the flow behavior. Tahar and Mahfoud [16] presented a numerical simulation of natural convection in a solar chimney. They examined the effect of the system geometry on the natural convection phenomenon in the solar chimney.

In this paper a numerical investigation on a prototypal solar chimney system integrated in a south facade of a building is presented. The analysis is carried out on a three-dimensional model in air flow and the governing equations are given in terms of k - ϵ turbulence model. The problem is solved by means of the commercial code Ansys-Fluent and the results are performed for a uniform wall heat flux on the vertical wall is equal to 300 and 600 W/m². Results are given in terms of wall temperature distributions, air velocity and temperature fields and transversal profiles in order to evaluate the differences between the two base configurations and thermal and fluid dynamic behaviors. Further, the ground effect on thermal performances is also examined. The present study considers steady, turbulent, three-dimensional natural convection flow in a solar chimney as shown in Fig. 1.

Figure 1. Geometry.

All the thermophysical fluid properties are assumed to be invariant except for the density in the buoyancy force term which can be adequately modeled by the Boussinesq approximation. The compression work, viscous dissipation and radiative transport are assumed to be negligibly small.

The geometrical model and the step of preprocessing were realized with the software Gambit.

The boundary conditions imposed at the solid walls are mainly the no-slip and impermeability boundary conditions in addition to the specified wall heat flux. The conditions assumed at the inlet and outlet sections are those of ambient conditions (ambient pressure and temperature).

The governing equations given represent a set of coupled, non-linear, elliptic partial differential equations. In the present study, the numerical solutions of these were carried out using the commercial code FLUENT 6.3[18].

The operating temperature was set equal to 300 K; the acceleration of gravity was considered, and its value was set equal to 9.81 m/s². All the non-heated surfaces were considered adiabatic whereas in the first analysis an uniform heat flux of 300 W/m² and 600 W/m² on the heated surface was considered.

1.1 Results and discussion

Our objective was to analyze the effect of heat flux on heat transfer and flow of air into the chimney. For this reason, we presented the fields and the profiles of air temperature and velocity.

Figure 2a shows the field of temperature of vertical surface in case of heat flux equal to 300 W/m². The wall temperature increases from the bottom upwards due to the progressive heating of the air in the channel. Furthermore, it can be seen also that the temperature assumes an uniform value, about 350K downstream the middle of channel height.

Fig 2. Temperature field vertical surface.

Increasing the heat flux from 300 W/m² to 600 W/m² the wall temperature fields are very similar, but in this case the values found are more higher than before.

Fig 3. Air Temperature profile in the channel spacing, at the mid-channel section ($Z=0.75$ m) and several heights.

The air velocity fields, Figs. 4a and 4b, show an increase of it from the bottom upward to the progressive heating of the air in the solar chimney, and analyzing the velocity profile, Figs. 5a and 5b. for three different values of Y , it is noted that the maximum is reached in the outlet section in proximity of the vertical wall. The maximum air velocity is equal to 0.92 m/s for $q=300$ W/m² and 1.18 m/s $q=600$ W/m². Another important parameter evaluated in this study is the mass flow rate of air in the outlet section, it is equal to 227 g/s for $q=300$ W/m² and 289 g/s $q=600$ W/m².

Fig 4. Velocity magnitude field, at the mid-channel section ($Z=0.75$ m).

Fig 5. Velocity magnitude profile in the channel spacing, at the mid-channel section ($Z=0.75$ m) and several heights

From the comparison of the results, it is noticed that doubling the heat flux assigned on the vertical surface, there is an increase of all parameters. In particular there is an increase of almost 30% of the mass flow rate in the outlet section of the duct; an increase of almost 30% of the maximum speed of the fluid, and by about 10% of the maximum temperature of the wall.

2. Architectonical considerations about the SEEM System

2.1 Architecture and Chimneys: consideration at the territorial scale

SEEM is firstly considered in relation to the environment in which the technological system and the adjacent building envelope. The building represents an important central element of the environmental network on the territorial scale, seen as an integration among the infrastructural, and the ecological and landscape networks. So a transposition of such a concept has been made on the scale of the building in order to be able to make an accurate study of the energy-environmental quality of the local networks and to allow that the proposed system can be part of an environmental network on a scale of the building. This has oriented particularly the initial phase of the analysis made using the survey of the "territorial audit". Such an analysis aims at studying, from a methodological point of view, the environmental compatibility of the intervention proposed, above all, as it regards the relationships between the building and the system of the networks, with which it is related.

The design of the solar-wind chimney SEEM, representing the testing of so-called Solar Tower at the scale of building, raises the question of the compatibility between the modular element and the wall with which it must interface. Therefore, it is necessary, a data acquisition phase aimed at identifying the main features regarding both the environmental surrounding and the building envelope. The required data are not exhaustive of eco-technological analysis but it is closely relevant to the objectives of the project, and refer to three different issues: the first relating to how the external factors of the building can interact, positively or negatively, with the behavior of the new energy system; the second regards the energy performances of the existing building envelope; the third concerning the relationship building - infrastructure networks.

2.2 Architecture and Chimneys: considerations at the building scale

Speaking of "architecture" and "air", different mutable prevailing conditions are given by the nature itself of air, which is dynamic into aggregation. We must remember that often historic net of architecture with a net of patios and open arias, with up-and-down composition of areas and interconnections, is what reminds this sensation of thermal wellness, due to air movements.

As an alternative to mechanical ventilation, various technologies are today investigated. We know that indoor air is heavier than outdoor one, so we can drive air movements through a chimney; the movements, based on the temperature difference among the various air levels, with air going upward from a higher pressure to a lower one and finally towards the open air, are connected to the architectonic shape of the air conduct. The data to be considered are both the height, and the section dimensions, in order to let the air moving from the bottom to the top. Sometimes in the past a different strategy was used and an alternative strategy let air moving into architecture from top. So we can say that the air movement had different typologies: ascending, descending or partly ascending and partly descending.

Innovative systems, differently from the past, can be predictably exactly and air movements are predictable all the way through dynamic thermal models with variable performance evaluations, considering the alternatives among section choices and eventually individualizing the first-rate designs in order to promote air movement inside a chimney.

Differently from a "traditional" approach to design that interprets the question of integration of plant design in an organic vision of the relationship between environment/area/shape, in the case of the project SEEM, the architectural theme is that of identifying formal solutions, energetically performing, that, in the comparison and in the need for integration with pre-existing buildings, can achieve the dual objective of improving energy performance and presents itself as an opportunity for redevelopment of the urban habitat.

It is, therefore, to interpret a "plant" beyond its technical content, assuming the character of formal autonomy as an element able to communicate with the building called to host it. The definition of the basic geometries of the prototype represents a real experimental work in progress which involves, actively, multidisciplinary skills and that is started from the first formulation of a concrete case study that focused on the south side facade of the Laboratory Benecon-Ars in Frignano

2.3 Meta-design: Requirements for glasses of solar-eolic chimney at detail scale

Technological research engaged in the production of components for the transparent envelope is based on the study of performance improvement, correlating needs of the system and offer of energy (solar radiation) at different wavelengths to capture or to screen. The wavelengths in the visible range are designed to control the component light and the wavelengths in the infrared range are more directly related to the thermal behavior. This study is conducted in the second phase of the Project SEEM (Solar Eco-efficient Envelope Model) and it analyze the best glass components to guarantee performances demanded by system.

In order to make a comparison and thus a weighted evaluation about the products meeting the premises needs, it is appropriate to establish what the criteria for the selection of the companies were wide spread on the domestic market, vast offer productive, clarity of information and technical performance, availability of contact and certified performance.

The analyzed and compared glasses are produced by the most famous companies (Saint Gobain, Pilkington, Guardian, Isolac Glas; AGC and Finstral) and the technological solutions adopted for the comparison take into consideration common double-glazing (low-emission and solar control), ignoring the more sophisticated components still being tested.

The SEEM system, designed to be positioned adjacent to the opaque envelope of new or existing buildings, requires specific performance to maximize the heat flow and the resulting increase in temperature of the air inside the chimney's channel.

Therefore, the needs of the external transparent component are :

- Maximum input transmission of infrared radiation toward the air channel
- Reduced output transmission of infrared radiation toward the external environment
- Self-supporting structure
- Minimum adherence conditions (in ventilated cavity) in order to reduce the turbulent flow inside the solar chimney,

and the needs of the internal component (in adherence to the building) are:

- Reduced solar output transmission (thermal radiation) toward building
- Self-supporting structure (structural glass).

Therefore, the requirements of the external transparent component are high Solar Factor g ($> 70\%$) and high Direct Transmission ($> 60-70\%$) in order to gain solar heat. At the same time, since the temperature is a

determining factor of performance of the SEEM system, the heat in the channel must to be conserved. So, regarding to needs identified, the glass should have neutral colors (high internal transmission and low external reflection).and it should be with pyrolytic coating (economic and workable low emissivity film) on the inner pane. Considering the normal emissivity of the classic glass is equal to 0.837 (UNI 10345), the low-emissivity glass SEEM can reach 0.03.

The requirements of the internal transparent/opaque component follow a different select logic. The heat accumulated in the channel must not be transmitted to the building where the SEEM system is integrated. Therefore, this component must to be characterized by low thermal transmittance ($< 1\text{W/m}^2\text{K}$), low thermal absorption and high Reflection Coefficient that maximizes the thermal conservation in the canal.

Regina Viarum, Appia Antica

Gilda EMANUELE

Department of Architecture and Industrial Design "L. Vanvitelli"
gilda.emanuele@gmail.com

Abstract

The construction of the Regina Viarum represented in ancient times an event of extraordinary importance. The historical implications of its construction involved more than half of the population of the Mediterranean for over a millennium.

"He dug the hills, valleys and chasms, drew terraces with wonderful minds; spent all the state revenue, but he left himself in the immortal memory for having been ambitious in the "public interest". Diodorus of Sicily with these extraordinarily encomiastic words celebrates the virtues of the censor Appius Claudius Centemanno the Blind, recognized as the architect of the Via Appia: An infrastructure that not only constituted the first major road linking Rome and the Greeks, as well as the excellence of construction techniques adopted, but also represented a masterpiece of road engineering that for a long time was unsurpassed.

The Regina Viarum was built in several stages: the first stretch from Rome to Capua around 312 BC, the second around 268 BC extended to Benevento, while the third section was built around 191 BC., reaching Brindisi.

In particular, in the stretch of the Province of Caserta, the Via Appia knows situations of degradation, a fundamental action for the regeneration of one of the first objectives would be to restore its main function which is to link vehicular, pedestrian and cycle traffic and recreate Via Appia parking areas, typical of the Regina Viarum for the refreshment of new travellers.

Regina Viarum

Via Appia Antica

The construction of the Regina Viarum represented in ancient times an event of extraordinary importance. The historical implications of its construction involved more than half of the population of the Mediterranean for over a millennium.

"He dug the hills, valleys and chasms, drew terraces with wonderful minds; spent all the state revenue, but he left himself in the immortal memory for having been ambitious in the "public interest". Diodorus of Sicily with these extraordinarily encomiastic words celebrates the virtues of the censor Appius Claudius Caecus, recognized as the architect of the Via Appia: An infrastructure that not only constituted the first major road linking Rome and the Greeks, as well as the excellence of construction techniques adopted, but also represented a masterpiece of road engineering that for a long time was unsurpassed. [1]

The Regina Viarum was built in several stages: the first stretch from Rome to Capua around 312 BC, the second around 268 BC extended to Benevento, while the third section was built around 191 BC., reaching Brindisi.

The Via Appia, being strongly linked to the process of Romanization of southern Italy, was prolonged as the Empire conquered southern Italy: first to Benevento, shortly after 268 BC, then through the Apennines to Venosa and onto Taranto. Finally, in the second century BC, it reached Brindisi, the main port for ships bound for Greece and the East. Over the years, the original course from Benevento to Brindisi was gradually replaced by a shorter, easier through the region of Puglia until, in the early second century AD, the Emperor Trajan turned it into an alternative route and gave it his

name. The new Via Appia Traiana allowed travellers to go from Rome to Brindisi in 13-14 days for a total of 365 miles, a little less than 540 km.

For the first 90 km, the Via connects Rome and Terracina with a straight road. After Terracina, the road heads towards Fondi, through towering gorges of Itri and then down to Formia, Minturno and Sinuessa (today Mondragone), from there straight back to Casilinum (now Capua), on the Volturno River and then to the ancient city of Capua (today Santa Maria Capua Vetere).

The construction of the first section was in the middle of the Second Samnite War and the Roman expansion in Campania. Its creation represented a significant political act of the Roman settlement process in Campania. Appius Claudius, in fact, intended to reach as quickly as possible Capua, goal of military operations, providing an alternative to the path traced by the Via Latina (i.e., approximately the current Casilina). The Via Latina, like all the roads at that time, was not formed by a path but had developed spontaneously from the connection between the centre and the contiguous centre, so as to be in the end a long and tortuous route.

The maritime side was however, until then, almost impassable, being barred from the Pontine Marshes, the mountains Lepini, Muzoni ed Aurunci, the marshes and estuaries of major rivers such as the Garigliano and Volturno. The Via Appia, being realized through these territories, immediately formed a completely new model in the context of communications. It was designed as a main highway, through a geographical area that was so difficult, not only from an environmental perspective, but also that time showed supra. This road was an extraordinary technological and engineering achievement, with the emergence of a rational design even at the cost of extreme sacrifices, above adversity, which however was not disarmed by wanting to carry out the construction.

It can be compared conceptually to modern motorways, with the major cities encountered along the route being connected by means of secondary roads. Brindisi was seen as the ultimate goal of a long distance. The course was led to this on a perfect straight line, pointing and passing the steps required by the geography of the local landscapes, not worrying about the technical difficulties that may be encountered during its implementation in order to make quick path.

The fate of this original stretch of the Via Appia was related to the hydrogeological nature of the vast alluvial area. The particular clayey nature of the soil and the trend of the plain to be periodically flooded by the river that passed through, had induced the Roman builders to remove it from the wetlands. This led to a lengthening of the path and away from the straight path (preferred by the Romans), leading to a gradual bend in order to reach Capua.

Since Roman times the main road was the Via Appia that crosses the plain below while staying parallel to the river Volturno.

The last short section that is located in Capua reaches an area of lowlands, formed by alluvial sediments, consisting mainly of clayey – lime soil, strongly influenced by the rivers Volturno (south) and Agnena (north). These with their floods have made the inhospitable wetlands, so that the work carried out over the centuries mainly focused on recuperating it.

The Via, near the Roman bridge of Capua on the Volturno, joins the Via Latina that descends from the north and connects the plains to the mountains.

Currently, while the route of the Via Latina is retraced in part by State Route 7, one part of the Via Appia is retraced by the main road Capua-Brezza which still constitutes an important artery of the territory along this road between Capua (more populated centre) and Brezza (a small hamlet consisting of a few houses, but with consistent Roman traces, known by the name of Villa Bretiae), where the houses are mostly distributed according to the Fascist land division plan, which also fill the areas near the road branches off to the north and south.

The lowland area between the two towns has always aroused the curiosity of many scholars who have interested in identifying the route of the Via Appia, since the eighteenth century. In particular, the most interesting findings of this stretch of the Via Appia are from G. Novi, who in the nineteenth century, during the excavation for the construction of the road Brezza - Capua, recognized several remains of the pavement of the ancient Via Appia, finally clarifying this part of its course.

Currently, scientific interest has increased, expanding from Roman times to the protohistoric period, thanks to important archaeological discoveries in response to other excavations carried out prior to construction of the Italian Aerospace Research Centre (CIRA) and the high-speed railway line (TAV).

Another stretch near Casilinum (ancient Latin name of the river port of Capua, where the Civitas capuana found refuge following the incursions of the Saracens) was reported by G. Novi. In fact, in 1858, in Poliorama Pittoresco G. Novi writes, "the new road from Capua leads to Brezza, it has laid bare a beautiful stretch of the Via Appia, so that in constructing the ditches of this new road, about three feet below ground level of the campaign (so about 1.20 am) magnificent remains of the Regina Viarum appeared. The new track of the ancient road axis, coinciding only for about half a mile along the defenses of Nunziatella and Frascale. "

Currently, the route of the Via Appia is traced by the main road Capua-Brezza, which is still the main artery of the area.

The most interesting findings on the Via Appia are due to G. Novi, who in the nineteenth century, during the excavation for the construction of the road Brezza-Capua, acknowledged that below it there were some remains of the paving of the Regina Viarum, clarifying definitely part of its course.

On the west side of the Via Appia, Casilinum consists of two straight paths, which meet near Masseria Bosco. The two sections are along the route of the nineteenth-century modern road Brezza – Capua, below which were found paving remains. The news reported by G. Novi about this discovery is very clear: “The track is composed of a layer of strong rubble laid by hand with great art ... the cover is a layer of rubble thicker than half a palm (12.5 cm), which combined with the aforementioned framework, presents a consolidated thickness of an inch and a half (37.5 cm). The road is crowned by both sides from the edge of travertine of the width of two feet. Towards the Brezza valley, there are big tufa stones.”

According to reports from the nineteenth century and the recovery of the paving remains, it is assumed that the path of the road Capua - Brezza largely coincides with the ancient Via Appia.

This hypothesis is confirmed in the study of cartographic data and the archaeological discoveries that prove the presence of perpendicular streets with Appia and the function of decumani.

Despite the Via Appia appearing to have been the scene of historical movements of particular importance: road for the Roman troops bound for Constantinople, a transit route for the merchants who came from the East to the Ionian cities, vital artery crossed by pilgrims in the Holy Land and Christians during the Crusades and today, it sees its archaeological, historical, monumental and landscape completely obliterated.

There is therefore a real need for a regeneration that leads to the never silenced roots, re-giving it the dignity of Regina Viarum.

For the regeneration of one of the first objectives, its main function should be to restored, that of carrying vehicular, pedestrian and cycle traffic and restoring ancient stop off areas, typical of the Via Appia, for the refreshment of new travellers.

Along the Regina Viarum, places for parking and admission of travelers and media have been recognized. The best preserved is located just downstream of the fort of St. Andrew, made from a hollow rectangular area on the uphill side of the road, while the downstream side is supported by a powerful wall in rectangular blocks taken from the same quarry and strengthened with concrete. The area is about fifty metres long and about fifty-two wide. This is not the only one along the Via Appia.

It could also serve to create a break in the traffic in case of overcrowding of the sanctuary of Apollo just above, with the road blocked by ceremonies of worship.

There are other laybys at regular intervals.

Despite the lack of maintenance even in 540, during the Gothic wars, the road was used daily and with no problems, and Procopius had words of admiration for the perfect state of basalt, saying: “Of all the roads, it is the most wonderful. The stones are joined so firmly as to give the viewer the impression of not being connected to each other, but to form a whole. Over the years, many have passed over them, day after day, cars and all kinds of people – however their structure has remained unchanged and not even one of the stones has split or torn, and they have not even lost their luster”.

Many changes were made on the Via Appia in 1500, most of which concern mainly the stretch from Rome to Capua. [2]

The stretch of the Via Appia between the Garigliano and Volturno is constituted by a series of tracks, almost shreds, which have nothing of the suggestiveness and monumentality of the road. They are, however, important fragments as elements for the reconstruction of route in Campania, that had yet to be finally drawn to this area where until a few years ago, when there was had occurred on rare occasions investigations particularly in the areas traversed by that road.

In the stretch of the Province of Caserta, the Via Appia knows both situations of extreme deterioration in the sense that it is entirely obliterated and its path is realized only by the presence of funerary monuments and situations of possible enhancement, since, in addition to neighbouring monuments, if they do not retain only the path but the complete paving of sidewalks, as is in the case of Sessa Aurunca and Mondragone.

The funerary monument that marks the path along the Via Appia Antica near Ancient Capua (today Santa Maria Capua Vetere) is the mausoleum of the Distaff, or simply the Distaff. The monument consists of three layers. The lowest, which contains the burial chamber, has a simple structure that supports another square body with rounded edges to form four columns at the sides and concave walls, in each of which there are formed a central niche with gabled roofs and two smaller side with arched vault. The upper drum, is divided equally in half-columns protruding and niches. Inside the base, a square-shaped burial chamber is of the type columbarium. Made from a single row that runs along the walls are eleven niches designed to accommodate the jars or urns containing the ashes of the deceased.

The long route of the Via could be structured with the inclusion of laybys for relaxation of travellers and small green areas to brighten the pedestrian promenade.

Small elements with educational and informative information on the historical route of the Via Appia could also be introduced. Thus, the journey becomes a journey aware thanks to multimedia videos that trace the Via Appia Antica.

The above described could be part of a larger project, which also includes areas, for the regeneration of the traveller, dedicated to physical well-being based on the judgement of fundamental importance for the Romans, from a line in Juvenalis (Sat. X, 356): *Orandum est ut sit mens sana in corpore sano*.

Abstract

The paper aims at discussing the issues of the integration between planning, landscape and sustainability. These themes are nowadays very much debated internationally.

By now the cities' progress cannot be considered regardless of the territorial planning and Landscape design, dealing with different aspects such as sustainability, preservation, valorization of local specific features and attractions and the urban and territorial development.

These matters are considered in two recent debates: on one hand the Proposals concerning the desirability of a standard-setting Instrument on historic urban landscapes, General Conference, 36th Session, Paris 2011 and on the other hand the Sustainable Development Goal (SDGs) and the following updates from the United Nation Conference on Environment and Development (UNCED) in 1992 - also known as the Rio Summit - the last of which is the United Nations Conference on Sustainable Development held in 2012 - commonly called Rio+20. These statements are only an exemplification of a major debate that has originated the trend of including in the planning practices different themes. It should include technological solutions, social aspects, use of the new Information Communication Technologies (ICTs) to preserve and promote the local specific features and attractions as drivers for the growth and the territorial competitiveness.

Following the previous considerations it is necessary to move from the concept of '*smart City*' to extend the point of view in a territorial scale, disregarding political boundaries, considering elements of identity as well as historical, geomorphological and territorial features. The latter have characterized the territory and its development and these are potential elements for the definition of compact, connected and competitive areas: the '*smart Lands*'.

Subsequently to this initial stage of knowledge, a planning phase should follow as well as a communication strategy in the last stage. All these steps have to exploit the potentialities of the communication and information tools available, after having established a proper oversight interdisciplinary team. This working group should be able to supervise the integration among agriculture, food, cultural landscape planning, environmental preservation, sustainable regeneration and local development in order to guarantee an enduring growth. The suggestions outlined would allow a development both in the social and economic sphere that should not run out in the short period, in opposition with the unscrupulous logic that has dried out the territory, the landscape, the cultural heritage and has led to a loss of identity of the places, justified by a misleading economic profit.

Keywords: landscape, enhancement, sustainable development, smart Land.

1. Introduction

Being aware of the necessity to orientate into the same direction Landscape Design, Urban Development and Economic Planning, the paper will provide some different case studies to show how these leanings could be developed in practice.

First of all we will present the set of problems of sites in danger, which have been affected by catastrophic events as earthquakes, conflicts and wars. Following the analysis of different examples we will try to outline possible suggestions to develop 'best practices' exploiting these tragic events as opportunities, quoting the philosopher Gian Battista Vico¹: "*Paiono traversie ma sono opportunità*". Indeed it is important to exploit these tragic episodes changing them into possible drivers of a new territorial development through an innovative reconstruction. Features of innovation are represented by the integration of different aspects, as the environmental and sustainability issues, the social integration, the smart infrastructures and the promotion of the material and immaterial heritage. The second part will focus on the reuse of urban and territorial areas, offering two different examples of how a territorial development guided by the recovery of the spirit of the places could have positive effects in terms of growth and employment.

2. Sites affected by tragic events: reconstruction and innovation

The first case study is the UNESCO site of the city of Kotor² and surrounding territory. This natural harbour on the Adriatic coast in Montenegro was an important artistic and commercial centre with its own famous schools of masonry and iconography during the Middle Ages, it was seriously damaged by the 1979 earthquake but the town has been restored, largely with UNESCO's help.

Fig. 1: The city of Kotor within its natural harbor, strongly damaged by the earthquake of 1979.

After the tragic event of the 15 April 1979 the city was evacuated. Most of Kotor's palaces and houses, many b churches, all of Dobrota's palaces and Perast's main buildings have all suffered because of the earthquake and some of them have been partly destroyed. An intensive restoration and reconstruction programme has now been completed and the city is flourishing again. This operation has been successful because of the general aim of preserving the cultural features for a new birth. Another similar case is the city of Bam³ and its Cultural Landscape, situated in a desert environment on the southern edge of the Iranian

¹ Giovan Battista Vico (1668–1744) was an Italian political philosopher, rhetorician, historian, and jurist.

² Throughout the centuries, many empires battled to control of the city. In the 10th century, it was an autonomous city of the Byzantine Empire. From 1186 to 1371, it was a free city of medieval Serbia. It was under Venetian and Hungarian control for brief periods, an independent republic from 1395 to 1420, and then returned to Venetian control once again. French occupation from 1807 to 1914 was followed by Austrian rule until 1918, when Kotor finally became part of Yugoslavia.

³ The origins of Bam can be traced back to the Achaemenid period (6th to 4th centuries BC). Its heyday was from the 7th to 11th centuries, being at the crossroads of important trade routes and known for the production of silk and cotton garments. The existence of

high plateau, inscribed in the World Heritage List (WHL) in 2004. Following 2003 earthquake, a team of experts coordinated by UNESCO Tehran Cluster Office, Iranian Cultural Heritage, Handicraft Tourism Organization (ICHHTO) and the main management authority prepared a Comprehensive Management Plan, 2008-2017, which covers the World Heritage property and was developed through a process involving local authorities of the County, the five Districts and the municipalities of Bam and Baravat.

Fig. 2: The Site of Bam, before and after the reconstruction.

Conservation and management actions in the sites need to guarantee the preservation and communication of all key characteristics of the Citadel and the other architectural remains in the inscribed Site. The re-establishment of some of the pre-earthquake conditions will need to follow international conventions and charters to ensure that the conditions of authenticity and integrity continue to be met. At the same time, conservation and protection of the World Heritage Site requires a balanced approach in order to confer it its own place in the living culture.

The most emblematic Italian case of reconstruction, still in progress, is taking place in the city of Aquila. The first steps towards the ‘smart reconstruction’ after the devastating earthquake that affected the city in 2009 have been taken, introducing an innovative and updated urban system to optimize the management of water, energy, public and private space, time, traffic, green spaces and general services.

life in the oasis was based on the underground irrigation canals, the *qanāts*, of which Bam has preserved some of the earliest evidence in Iran. Arg-e Bam is the most representative example of a fortified medieval town built in vernacular technique using mud layers (*Chineh*). Bam and its Cultural Landscape represents an outstanding example of an ancient fortified settlement that developed around the Iranian central plateau and is an exceptional testimony to the development of a trading settlement in the desert environment of the Central Asian region. This impressive construction undoubtedly represents the climax and is the most important achievement of its type not only in the area of Bam but also in a much wider cultural region of Western Asia. Bam is located in an oasis area, the existence of which has been based on the use of underground water canals, *qanāts*, and has preserved evidence of the technological development in the building and maintenance of the *qanāts* over more than two millennia. For centuries, Bam had a strategic location on the Silk Roads connecting it to Central Asia in the east, the Persian Gulf in the south, as well as Egypt in the west and it is an example of the interaction of the various influences. The cultural landscape of Bam is an important representation of the interaction between man and nature and retains a rich resource of ancient canalizations, settlements and forts as landmarks and as a tangible evidence of the evolution of the area.

3. Urban and territorial reuse: identity and development

Other interesting experiences are those related to the reconversion of urban and territorial areas through culture and landscape, intended also in their productive meaning, as drivers for growth and development. The city of Matera, a small size provincial capital in the region of Basilicata in the southern part of Italy, is an example of these transformations. It is quite known for its UNESCO site⁵ - the old town of the so-called Sassi, literally "rocks" - which has been the first World Heritage Site recognized according to the category of cultural landscape. This recognition is due to the outstanding value of the historic town development and its relationship with the natural environment. After having been used for centuries to host inhabitants, animals and activities, the development of a new urban center and later of rural neighborhoods and suburban districts started the process of marginalization and the rise of dramatic living conditions within the historical Site. The Sassi suffered a complete decay until the recent rehabilitation projects where started, converting them into cultural and touristic venues. Meanwhile, Matera settlement was completely transformed, following the economical booming and the belief in the industrialization of southern Italy's former agricultural centers. Recently (January 2013) through the Piano Nazionale Città the municipality of Matera obtained by the government funds to regenerate urban areas⁶. A combination of "soft" projects working together could start giving the city visibility in the touristic circuits. The main orientations should be addressed to reconnect the urban fabric with the countryside, working on the peripheral belt and, at the same time, to prevent the urban sprawl, supporting the renovation of the inner city, also reusing and reactivating the large number of empty spaces and buildings, not just in the Sassi, but also in the more recent districts.

3.1 The metropolitan areas: local identities and networking against the de-growth

One of the reforms adopted to face the current economic crisis by the Italian government under Mario Monti this year is the bill 35/2012 converted to law 135, also referred to as the final part of the spending review. This law decrees the abolition of 64 provinces⁷ and from 1st January 2014 the suppression of the provinces of Roma, Torino, Milano, Venezia, Genova, Bologna, Firenze, Bari, Napoli and Reggio Calabria, and their conversion into counties (città metropolitane). This is part of process aimed at increasing economic competitiveness on an international level. Indeed nowadays in the worldwide geography of development, the territorial system of growth around large urban realities has gained importance as a global economy factor. An example of application of these processes can be the metropolitan area of Turin, where the change of its status from provincial administration to county would bring about a simplification of the procedures of intervention and an improvement of the coordination - for example - at the level of common infrastructures, networks, planning, economic development and transportation policies. In the metropolitan area of Turin it would be interesting to consider how to re-shape the new infrastructure network (by re-using where possible the already existing tracks) to connect the sprawl of the urban monuments to the clusters in regeneration. For instance the network of the 'Residenze Sabaude'⁸, consisting of sixteen Castles located in the metropolitan area of Turin, thanks to the county authority could have the possibility of improve their value within their clusters and enhance their promotion through the creation of new infrastructures to connect (in a more efficient way) between themselves and with Turin.

⁵ The UNESCO protected site includes the old town and the Parco Naturale della Murgia Materana, a natural park facing the Sassi and extended along the Gravina, the river and the canyon it created in the millennia.

⁶ For a total amount of 17 millions Euros.

⁷ With less than 350,000 inhabitants, or an area smaller than 250 km².

⁸ Residences of the Royal House of Savoy in and around Turin represent a comprehensive overview of European monumental architecture in the 17th and 18th centuries, using style, dimensions, and space to illustrate - in an exceptional way - the prevailing doctrine of absolute monarchy in material terms.

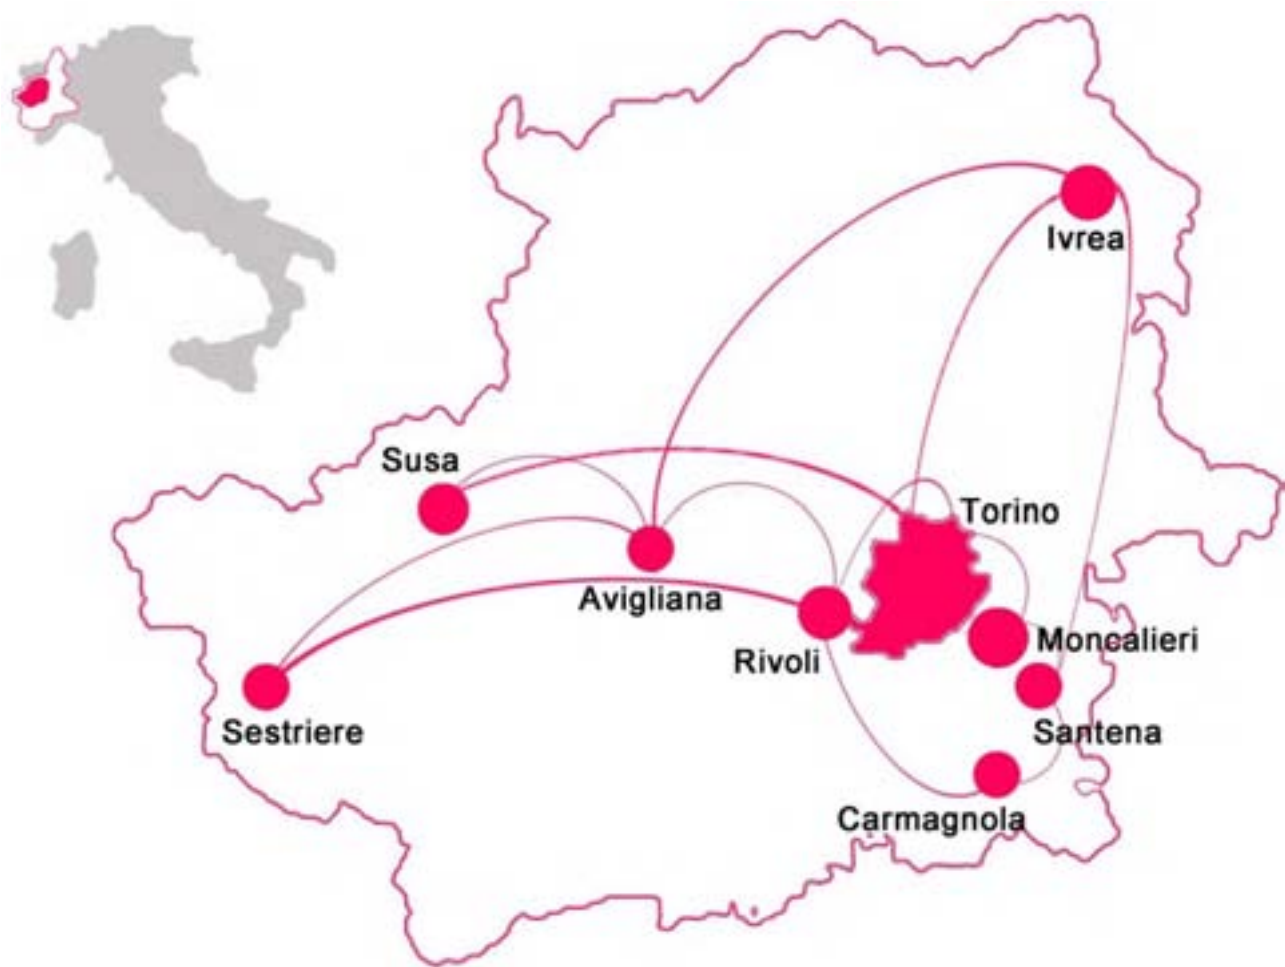

Fig. 5: Net of the Residences of the Royal House of Savoy in the Turin metropolitan area.

This could be feasible because of the new competences of the county in territorial planning, the creation of system of coordinated management of public service and organization of public services of general interest for the urban area. In addition this cultural net could interconnect other clusters with a territorial value, strongly linked with the local inhabitants i.e. ex industrial-productive areas. For instance in Turin the old 'Manifattura Tabacchi' is an example of district developed totally in dependence of this big factory, specialized in the production of cigars. After the closedown of the fabric, in 1996, the area was affected by a big depression. The following years witnessed some initiatives aimed at reusing this area by starting to rent it to private enterprise (Rete7 S.p.A.) or to public institution (Università di Torino, UNITO). Despite this, wide sectors of the area are still abandoned. New initiatives carried forward by partnership public-private, could give efficient solution in reusing the spaces and could bring new life to the area, having as central engine of this action the Manifattura Tabacchi, a building still strongly felt by the local population as an element of aggregation. Furthermore the building is located on the foundation of the 'Castello del Viboccione', a castle of the Savoia dynasty⁹, part of the original project of the 'Corona di Delizie'¹⁰, fact that makes stronger and more interesting an interconnection with the other 'Residenze sabaude' by creating new infrastructure to connect the cluster rethought and concentrated around them as elements of aggregation, and by reusing and re-establishing the existing ones when possible. This could be an example of how in a framework of contraction and re-thinking of the urban space, within the statement of the new county authorities, it is possible to integrate different clusters that, despite different identities, can be connected in some way between them with mutual benefit. The cluster regeneration in this framework is the goal to reach by

⁹ Destroyed in 1706 by the French army during the siege of Turin.

¹⁰ Term introduced by Amedeo di Castellamonte to define the system of the Royal Residences within his book "La Venaria" 1674.

engaging with the inhabitants through a conscious territorial analysis, including all its aspects (social, economic, cultural, etc.) for a new physical arrangement and new social opportunities at the same time. In this way it would be possible to face the de-growth, not with previsions and models of an improbable future new growth but within a conscious de-growth framework, rethinking the territorial entities starting from their history and distinctive elements.

4. Conclusions

The setting of proposals presented is oriented to explore the issues related to sustainable regeneration, to the exploitation of local resources, offering some examples of intervention in different contexts. We do not need cities showing off big works, buildings and infrastructures of questionable utility, but territories capable to take advantage from their own local features, using them as points of strength in order to renovate themselves. In conclusion it is necessary to define innovative participative models for the reconstruction, reuse and development of urban areas within their territorial context, using the cultural heritage as drivers for social and economic growth.
